- **Change** refers to requirements for growth and the need for continuous evaluation components built into the game curriculum. As students demonstrate understanding of certain components, the game should provide more advanced curricula. Hyperlinks within the slides can allow for previous responses to guide future ones. It could also provide different ways of addressing the same construct if the student fails to grasp it correctly on the first try. ADHD students may not respond correctly because of how the information is presented rather than from a lack of knowledge about the information.
- **Management** includes the player's degree of control over time, characters, and pace. As previously stated, the opportunity for the students to select their character increases the modeling effect. Given the characteristics of the "game generation," the management of the game is critical to its success. Providing

choice in characters can enhance the observational learning opportunities (making the behaviors of the characters more identifiable with the players).

- **Technology** relates to the compatibility with systems and suitability within the educational environment. Due to budgetary issues, schools face difficulties remaining apace with the most current technological advances. For students to be able to access programs, the programs should be compatible with the technology utilized by the preponderance of schools.
- **Use** refers to the actual implementation of the game. One limitation of this model is a lack of research support for how individuals with challenges in self-regulation (i.e., attention, hyperactivity, or impulsivity) respond to games designed using this model.

Though the FIDGE model was developed for designers of computer games, educators can benefit from understanding its unique instructional design components. Since the thoughts of the game generation and the ADHD learners jump from idea to idea, they require flexibility in approaching their curricula in the same mode. The FIDGE model can serve as a guide for educators as they prepare their digitally-based instructional materials.

CHOOSING INSTRUCTIONAL GAMES AND DEVELOPING LESSON PLANS FOR THE ADHD LEARNER

Gagné's "Nine Events of Instruction" theory of design development for instructional games (1985) is based on learning and instructional principles. The areas included in the theory are: (a) gaining attention (reception), (b) informing learners of the objective (expectancy), (c) stimulating recall of prior learning (retrieval), (d) presenting the stimulus (selective perception), (e) providing

learning guidance (semantic encoding), (f) eliciting performance (responding), (g) providing feedback (reinforcement), (h) assessing performance (retrieval), and (i) enhancing retention and transfer (generalization). The FIDGE model addresses the components developed, whereas the “Nine Events of Instruction” assess how interesting and functional the program will be to its users.

The ADHD learner has difficulty maintaining attention, remaining still and focused, or both. These children can make impulsive decisions, and require additional attention from teachers, staff, and peers. When making choices about ways to present a concept, teachers are trained to consider the needs of the learners. Gagné’s Nine Events of Instruction can support teachers’ efforts to evaluate these needs when the presentation of material is technology-based. Specific to the ADHD learner, these nine events can target how material should be presented to engage and motivate the student, and assess the mastery of the information:

Event 1: Gain Attention

With any task, gaining the attention of the ADHD learner is critical to the success of the instructional medium. Since inattention is a major challenge for most individuals with ADHD, gaining their attention can be difficult. Gagné suggests adding color or sound to the material that highlights specific information and does not overshadow that which must be learned (Gagné, Briggs, & Wager, 1992). Shaw and Lewis (2005) found children with ADHD demonstrated more on-task behaviors when animated stimuli were presented rather than simple text. Computerized animation can provide a wealth of options for stimulating the attention of these learners.

Event 2: Inform Learners of the Objectives

This event addresses the need to provide a learning map of the material. Ogle (1986) developed

the K-W-L instructional design to help learners identify what they already **Know** about the subject, what they **Want** to learn about the subject, and what they actually **Learn** as they study the material. The development of a graphic organizer helps the learner chart this information. Computer-mediated instruction offers learners a playground where they can attach websites, pictures, sounds, video, and more to their knowledge base about the topic. Titles and topic headings can be presented using *Flash* technology so they stand out to the reader. Informing learners of the objectives can be more interactive, thereby stimulating the interest of individuals with ADHD.

Event 3: Stimulate Recall of Prerequisite Learning

Individuals with ADHD can have difficulty retaining information. According to Barkley (1997), deficits that would impair an individual with ADHD from retrieving previously learned material to solve new problems include those involved in executive functioning. Working memory, activation, arousal, and effort, and complex problem solving are critical to processing new information. Skowronek, Leichtman, and Pillemer (2008) found individuals with ADHD demonstrate strengths in long-term episodic memory. This means when they have to retrieve information based on personal experiences they perform better than average. Attaching meaning to information could enhance the learning for individuals with ADHD. Animated computer education games can allow users to choose a character that represents them. The events can be organized in such a way so they simulate real life experiences, thus improving the chance they will be retained. Zentall, Cassady, and Javorsky (2001) suggest using voice-overs to ask users to recount previous social situations relevant to the material to help improve problem-solving strategies. This strategy capitalizes on the use of sound to maintain attention and episodic memory to enhance retention and recall.

Event 4: Presenting the Content

The presentation of content should vary according to the learning style and age of the user. Learning should be focused on showing the learner how to organize the information in the correct sequence. According to Kataria, Hall, Wong, and Keys (1992), the use of rehearsal, mnemonics, imagery, and organizational strategies can improve retention. The developmental stage of the learner would influence the sophistication of the mnemonics and the detail involved in the imagery. Mayer (1987) suggests that younger children may require support to create the image since they have fewer experiences on which to draw.

Event 5: Providing Learning Guidance

Learning guidance can be provided for the ADHD learner through clearly labeled navigational tools, verbal instructions are repeated throughout the activity, and interactive help menus. The appealing nature of videogames is the technology-driven emphasis rather than staff-driven. More students receive one-on-one learning guidance without requiring more teachers or paraprofessionals to be present. ADHD learners respond to one-on-one instruction where the material introduces the use of multiple senses, the breakdown of material into smaller pieces, provision of immediate feedback, and the limitation of unnecessary, distracting features (DuPaul & Weyandt, 2006). An example of learning guidance that meets these criteria is the use of interactive case studies where users must experience a scenario familiar to them, problem-solve responses to the scenario, and receive feedback as to their accuracy at the end of the presentation.

Event 6: Eliciting the Performance

Inattention can increase response time. The goal is to get a response to the material so the learner

can practice the skill. Teachers may struggle with motivating ADHD learners to start tasks, let alone getting them to complete the tasks. However, we have learned when individuals with ADHD are interested in the material, they are more likely to elicit a response. Opportunities for active learning will increase the likelihood of a response.

Event 7: Providing Feedback

As stated previously, immediate feedback can improve the task performance of ADHD learners (DuPaul & Weyandt, 2006). Furthermore, Codding, Lewandowski, and Eckert (2005) found feedback increased performance when the students actually set their own performance goals. Videogames and other computer education games can allow users to set realistic goals and receive immediate feedback on their performance.

Event 8: Assessing Performance

Any lesson plan should include methods for assessing learning. For ADHD learners these methods should occur frequently and not only assess learning of material, but also assess on-task behavior. Computer education games are capable of tracking responses of the user and adjusting the presentation of material to accommodate the user's specific needs.

Event 9: Enhancing Retention and Transfer

When individuals can take what they have learned and apply it to new situations, learning has taken place. The skills learned during videogame play (planning, organization, problem-solving, adaptability, and processing speed) can easily transfer to other tasks. Since many ADHD learners have deficits in many of these prefrontal activities, it is encouraging that a medium of task presentation can generate skill growth in these areas. A bonus may

be lowered levels of hyperactivity and impulsive responding, and increased on-task behavior.

By using Gagné's Nine Event of Instruction, educators can choose computer games that offer the best chance for success in teaching the material to the ADHD learner. They also guide educators in lesson plan development by dividing the lesson into measureable goals; i.e., from preparing the student for learning to generalizing the skills to new material.

FUTURE RESEARCH DIRECTIONS

Animated computer education games developed using the criteria discussed in the FIDGE model is essential. Data suggest a non-linear approach to developing "game-like environments" will suit the specific needs of the ADHD learner. However, the model has not been previously discussed in this context and no research exists to support its use. Instructional games are being developed commercially and by educators for use in their classrooms. Yet, there are no empirical studies that demonstrate whether the games meet the needs of the ADHD learner. Additionally, research to evaluate existing educational games to see if they meet Gagné's criteria for an appropriate instructional tool for ADHD learners is needed. Lesson plan development could also be evaluated to see if learning occurs when the Nine Events of Instruction are followed compared to traditional lesson plan development.

CONCLUSION

This chapter has provided a theoretical framework for understanding the ADHD learner and the importance of using instructional design models to guide educators through the development of appropriate animated computer education curricula for them. Computer gaming technology offers significant promise for the education of individuals

with ADHD. The unique challenges of the learner and educators to create a fertile and stimulating environment that individualizes the learning needs of those with ADHD and limits the distractions for non-ADHD students can be daunting. Animated, dynamic elements of computer education games are ripe for meeting those demands. Educators willing to improve their technological skill-sets and integrate computer games into the instructional environment in a purposeful way offer the best chance for the ADHD learner to succeed.

Chapter 5.7

Barriers to and Strategies for Faculty Integration of IT

Thomas M. Brinthaupt

Barbara J. Draude

Middle Tennessee State University, USA

INTRODUCTION

At most institutions of higher education, faculty members wear many “hats.” Among other responsibilities, they are expected to teach, conduct research, and participate in institutional and public service. Within the teaching realm, faculty members have always had multiple responsibilities. For example, in addition to being content experts, they may need to become course design, assessment, communication, community or interaction experts. Instructors can be described as architects, consultants, resources, reviewers, and role models (Oblinger & Hawkins, 2006). It is primarily (though not exclusively) in the teaching realm where instructional technology (IT) is relevant. The more that faculty utilize IT, the more the non-content aspects of teaching become salient.

Depending on level of faculty expertise, asking them to increase the time and effort they put into their teaching might reduce the time and effort they can devote to research, service, and other institutional requirements and responsibilities. Why should they, especially if there is very little acknowledgment or tenure/promotion credit given for incorporating IT into their teaching? This is, in part, why many faculty members may have to be dragged “kicking and screaming” into using these technologies.

BACKGROUND

To address the predicament faced by faculty, it would be helpful to provide some guidelines on how to balance multiple roles (and the time and effort required). However, there do not appear to be any models that deal with this challenge. One

DOI: 10.4018/978-1-60960-503-2.ch507

way to help understand the process of IT adoption is to consider the different roles or positions of individual faculty members. For example, non-users of IT face a much steeper learning curve than do instructors who have partially or fully integrated IT into their teaching. Learning to use IT might, therefore, be thought of as a socialization process.

In their model of socialization to groups, psychologists Moreland and Levine (2000) highlight the importance of the processes of evaluation, commitment, and role transition. In particular, in order to acquire a new identity as a group member, an individual must pass from being a prospective member to a new member to a full member. This passage is a function of how both the group and individual evaluate each other, their respective levels of commitment to each other, and the eventual transition in roles as the individual passes into and through the group.

For purposes of this chapter, we assume that higher education faculty go through a similar socialization process with IT integration. In particular, they must first evaluate the IT options available to them and determine if using those options is feasible. If their commitment to integrating IT into their teaching is high enough, they may begin learning about those options, depending on the support and resources of their institution. This learning process might shift the instructor's role from a prospective user to a new user and eventually to a full user of IT. The barriers to IT integration vary depending on the user roles that faculty play in this socialization process, how they evaluate IT, their own and their institution's levels of commitment to its use, and their IT learning

curve. Table 1 presents a developmental model of faculty integration of IT loosely based on Moreland and Levine's (2000) group socialization model.

Both non-users and prospective users of IT may not adopt it for several reasons. They may negatively evaluate the use of IT, lack the time and effort necessary to commit to its use, or fear the steep learning curve that awaits their efforts to integrate IT into their teaching. New IT users are more likely to evaluate its use favorably and to have more commitment to using it, yet will still have a steep learning curve. Of course, if new users' initial experiences are negative, they will be less likely to increase their commitment to and use of IT. Experienced users will typically show positive evaluations, high levels of commitment, and less steep learning curves. However, with each of these roles, there are potential barriers that limit the initial or continued integration of IT into faculty members' teaching.

PERCEIVED BARRIERS

Even assuming adequate levels of training, support, and access, there are many barriers to faculty members' adoption and integration of instructional technologies. Table 2 lists some of the major technology-related and academic-related barriers to IT use in higher education.

Prospective IT users may have the misconception that they should learn about and use IT because it makes teaching and learning more convenient. This may be true to some extent, but it is no more true than the claim that instructors use a textbook

Table 1. Developmental model of faculty integration of IT

Role	Evaluation	Commitment	Learning Curve
Non-user	Negative or neutral	Low	Very Steep
Prospective user	Negative, neutral, or positive	Low to medium	Very Steep
New user	Negative, neutral, or positive	Medium to high	Steep
Experienced user	Positive	High	Moderately steep

Table 2. Major barriers to IT integration in higher education

	Tenure & Promotion
	Job Security

for convenience. In this sense, there is nothing special about new instructional technologies. Whether one is talking about a pencil, a textbook, a whiteboard, or a 21st Century classroom, these are all tools along a continuum. Even if faculty members do not see it this way, their Net Generation students increasingly look at many of these new technologies as “pencils” (Oblinger & Oblinger, 2005), and those students use the technologies for multiple purposes (Donlevy, 2005). However, for faculty, this is one of the most obvious barriers when facing emerging technologies—the ever increasing, wide range of options. Even when they evaluate the use of IT favorably and are committed to integrating it into their teaching, they quickly become alarmed at how many different pencils they need to sharpen! The fear of failing to master these applications is also quite real (Beggs, 2000). Even for instructors who are experienced IT users, learning to use additional existing or new technologies can be a formidable challenge.

The content realm is probably valued most highly by the majority of faculty members. However, when new technologies are added to the changing characteristics of students, non-content aspects of teaching become more important, and attention is diverted from the content focus. Faculty might accept the fact that proper IT integration ideally results in a shift from faculty-centered instruction (passive learning) to constructivist or

student-centered learning environments (active learning) (Duhaney, 2005; Groves & Zemel, 2000). However, the dual role required of them has proven daunting for many. Exactly what is the faculty’s role—IT or content expert? There is no clear definition of the roles required to teach a course that takes the emerging technologies into account. Important questions to consider include to what extent and how often a faculty member revises and re-designs a course and who helps with those processes. This potential role conflict or role ambiguity may inhibit non-users from transitioning to prospective IT users. New IT users will need to negotiate their new roles actively. On the other hand, most experienced users have probably resolved the conflict or ambiguity associated with the new roles required by the integration of IT.

Closely related to these issues is the constantly changing nature of IT. With technology changing often and quickly, why should faculty spend time and effort learning something that may be radically changed or even obsolete in a few years? For example, an institution may be moving from individually created faculty course web pages to the adoption of a common learning management system (LMS) platform. Alternatively, there may be a conversion to a different LMS platform or to a new version of the existing one. Finding the time to stay current in their discipline, to bring in new material, or to update to a new text is made more difficult when time must also be devoted to staying current with instructional technologies (Beggs, 2000). Recognizing the need to adjust to IT improvements and innovations might decrease the likelihood that prospective users will increase their evaluation of and commitment to using IT. This barrier is also an issue for experienced users who may need to learn to use revisions of the IT that they have already mastered.

In addition to these technology-based barriers, there are several faculty-related barriers to integrating IT. Investment of time and effort pose one such barrier (Beggs, 2000). In fact, this expenditure is at least implied within all the barriers

ers we discuss. From training, to decision-making about which IT options are applicable to a specific discipline, to actual implementation, becoming proficient enough to use IT effectively calls for a significant commitment. “Why,” ask faculty, “should I make this investment?” Even the most committed new and experienced IT users, who know the answer centers around improvements in learning, are aware of the heavy costs in time and effort. This barrier probably has the strongest negative effect on the evaluation and commitment of non-users and prospective users.

Some faculty also worry about the academic quality of courses that integrate IT (Davis, 2005; Duhaney 2005), with suspicions of bells and whistles being used for their sake alone. Barone (2005) suggests that “Some traditional academics feel that the habits of the Net Generation result in a superficial grasp of their discipline and do not embody the gravitas of an ‘educated’ person” (§ 9). Duhaney (2005) points out that even more careful planning is required for a course that integrates technologies than for a traditional course. In addition, most higher-education faculty are not specialists in course design. They are teaching because of their content expertise. In many disciplines, it is uncommon for faculty to receive pedagogical training while they are graduate students. Determining how to integrate IT forces faculty to examine curricular design, something that they are often not used to doing. Because of this state of affairs, non-users may resist integrating IT because it also requires that they specify learning objectives and outcomes of their courses.

Another important barrier to faculty’s willingness to embrace IT integration is the perceived lack of substantive incentives and compensation. While release time, grants, and awards (if available) are a good start towards helping faculty get started and feeling that their efforts are recognized and respected, they are often not sufficient to offset the necessary amount of time and effort invested in training and implementation. Sometimes, even when such incentives are offered, prospective

users may be unable to take advantage of those opportunities due to teaching load, departmental, or other university demands. Additionally, when materials using IT are created, issues of intellectual property and uncertainty created by loosely defined copyright policies (Duhaney, 2005) present yet another issue for faculty.

All these barriers culminate in concerns over the tenure and promotion (T/P) process, an issue of utmost importance for faculty. It is widely held that efforts in IT integration, although undeniably linked to teaching, do not fit into the traditional teaching, research, and service categories of the T/P process (Davis, 2005; Hagner & Schneebeck, 2001; Seminoff & Wepner, 1997; Young, 2002). Many faculty are waiting for tangible recognition for the substantial time and effort investment required for IT integration, and it can come in no other way than by “having a positive impact on tenure, promotion, and salary decisions” (Hagner & Schneebeck, 2001, p. 4).

Closely related to the T/P issue, and equally important, is faculty concern over job security. Many higher education institutions have moved towards the creation or development of master courses by ranking, qualified faculty. These courses are then taught in multiple sections by individuals with or without tenure, often receiving lower salaries and no benefits. Some faculty feel that this trend heralds the erosion of the academic profession as faculty currently know it. It could also be viewed as a challenge to the traditional notion of faculty autonomy, a privilege faculty will be very reluctant to give up (Hagner & Schneebeck, 2001). As Beggs (2000) puts it, “devaluation of their profession and the possible elimination of their job” (§ 9) constitute a serious suspicion about and obstacle to faculty involvement with IT.

OVERCOMING BARRIERS

What can be done to overcome these many barriers and to encourage faculty to participate in

the “new academy” (Barone, 2005)? As Mitterer (2006) notes, the explosion of digital technologies represents “a veritable Trojan horse of pedagogy” (p. 60) for higher education. Non-users and prospective users need to be convinced of the wisdom and necessity of incorporating IT into their courses. As the list of barriers indicates, this is a very challenging task. Table 3 presents an overview of key strategies to attain greater faculty engagement with and use of IT.

First, IT is not a single thing that can be used in the convincing process. Different faculty will be interested in different kinds of technologies (Beggs, 2000). Thus, one strategy might be to provide faculty with very general overviews of the different technologies and what can be done with them, especially within their disciplines. Faculty who are exposed to this information might convince themselves of its worth and pursue more-specific training on those technologies that

are most relevant to their interests, expertise, or discipline. If the general overviews could be delivered by experienced faculty users within the department (or if there were an IT support person familiar with the discipline), new users may more readily see how technology fits into their and their discipline’s values. Because they are often not familiar with a faculty member’s discipline, IT trainers and consultants may have a more difficult job when they lack the credibility of a faculty member’s peers.

To reduce the learning curve for and time needed with the new technologies, faculty who are inexperienced with IT could be encouraged to simply use those tools. Trying to integrate them into their course more fully could be something that occurs later. By taking “baby steps,” these faculty might not get as frustrated or overwhelmed by the time and effort demands, yet they still might begin to see some advantages and opportunities that those

Table 3. Strategies for overcoming the major barriers to IT integration in higher education

	Barriers	Strategies
Technology-Related	Wide range of IT Options	Provide General Overviews of Options
		Encourage Small Steps
		Support for basic as well as advanced technologies
	Role Conflict	Foster Support & Training from Peers
		Departmental Roundtables
	Pace of IT Improvements & Innovations	Emphasize Student Need & Demand
Academic-Related	Time & Effort	University & Departmental & Course-Specific LMS Templates
		Departmental Standards & Requirements
	Academic Quality of Courses	Greater Emphasis on Pedagogy
		Emphasis on Course Design & Redesign Using IT
		Peer Review of Courses Using IT
	Incentives & Compensation	Increased Reward Structure for IT Integration
	Tenure & Promotion	Increased Guideline Definitions & Clarity
		Greater Emphasis on Quality Control
	Job Security	Greater Value, support, & reward for collaboration

technologies offer (Villano, 2006; Beggs, 2000). At the same time, IT support staff could calibrate their efforts to teach the basic technologies to new users and the more advanced technologies and integration possibilities to experienced users. Working around faculty members' schedules (rather than having set times for training) would also increase receptivity to learning about new technologies.

With regard to the potential role conflicts that can inhibit the integration of IT, experienced users can assist in clarifying the roles that new technologies enable or require. One strategy to combat role conflicts might be to hold regular roundtable discussions within departments to help faculty identify and articulate discipline-specific ways to achieve academic and IT integration. Another option is to create intra-departmental training programs that rely on experienced IT users helping prospective or new users (Clayton, 2005; Efaw, 2005). These approaches might show faculty how they can gain knowledge or expertise without taking on a new teaching role. It is also possible that experienced faculty members within departments will assume specific technology-related roles. These departmental experts can be an important source of support and training for both new and experienced users.

Because so many faculty members consider themselves to be instructional technology novices, efforts to increase IT integration must focus on encouraging and nurturing the non-users and prospective users. Efaw (2005) described a 3-phase approach to facilitating faculty integration of technology. The phases include learning about and becoming more favorable towards available technologies, practicing with and receiving feedback on those technologies, and continuing to develop expertise through workshops, discussions, and mentorships. In each phase, this approach relies heavily on the experiences, modeling, and feedback of veteran technology users in the socialization of new users.

To some extent, students are the force of change for faculty members (Donlevy, 2005). As more instructors utilize IT in their courses, students will come to depend on those technologies and might also complain about it when instructors do not include them. Thus, as more faculty and students rely on IT, the demand for incorporating IT into courses escalates. Faculty will increasingly find that they must begin incorporating these technologies, or they will figuratively, or literally, lose their students. A good strategy might be to recruit students to increase faculty use of IT. For example, survey data (e.g., Kvavik & Caruso, 2005) can be used to show faculty what students like or expect. Students should be encouraged to be more proactive regarding their education, at least in terms of how their instructors integrate technology into courses, by requesting specific technologies or applications from their instructors (Hagner & Schneebeck, 2001), particularly those that prepare them for the workplace (Beggs, 2000). They could also participate in IT roundtables and serve on IT-related committees at their institutions.

When turning to the more academic-related barriers, ways of overcoming the issue of time and effort becomes a prominent question. One simple solution is the development of departmental and course-specific templates within the institution's LMS platform (Clayton, 2005). Such templates allow less-experienced faculty members to minimize their learning curve with the LMS. They would also allow student access to standardized resources and materials for multiple sections of a course.

Another possible route to overcoming the time and effort barrier is the development of university and departmental standards or requirements (Seminoff & Wepner, 1997). For instance, some institutions have begun to identify the minimal technology tools that all faculty members need to have. It may be that faculty members do not need to become technology experts. Some could argue, for example, that because the IT support staff are the experts, instructors do not need to learn the new technologies. However, if faculty

will be using these technologies, there most likely needs to be some minimal level of understanding in order to troubleshoot and use them effectively. It is very likely that faculty will need to develop at least some level of expertise with the tools they use. Institutions might, for example, require a Web-presence for all their courses. At minimum, all faculty could present their syllabi and instructor contact information online, preferably through an LMS. Institutions may also want to mandate the use of an LMS. Although institutions have begun to address these questions, few consistent standards or recommendations have yet to emerge. This is a critical need.

To overcome concerns about academic quality, institutions will need to demonstrate the ways that IT improves the quality of courses that integrate IT. This effort must parallel institutional attention to accreditation standards, the development of learning outcomes, assessments and benchmarks, and course design and redesign efforts. Non-users and institutional decision-makers must be educated about the pedagogically-sound ways that courses can implement and integrate IT (Seminoff & Wepner, 1997). One strategy is to set up centers focused on learning and teaching like the Learning, Teaching, and Innovative Technologies Center at Middle Tennessee State University or the Technology Assisted Curriculum Center at the University of Utah. These Centers provide faculty with resources, training, and expertise on the use of IT. They strive to move faculty toward thinking about sound pedagogical IT integration by helping “faculty members gain a better understanding of technology and incorporate it into their lesson plans . . . [to] meet their education objectives . . .” (Villano, 2006, p. 32).

Another strategy is to incorporate peer reviews of courses using IT, not only to help to improve the quality of those courses, but also to clarify the criteria that constitute best practices (Bombardieri, 2006). When they receive peer reviews, new IT users are provided with developmental guidance and feedback. By conducting such reviews,

experienced users improve their pedagogical expertise. Thus, developing a peer review process is an excellent way to improve academic quality for users with different levels of experience. All of these strategies (as well as the ones we have listed in previous sections) can foster an institution’s education about and exposure to IT. As this process increases in frequency, concerns over academic quality should be ameliorated.

As we mentioned earlier in this chapter, even if incentives and compensation are available to help faculty learn about and integrate IT, time and effort demands must still be addressed. Increasing the size of these “carrots” might encourage some faculty members to become new IT users (Seminoff & Wepner, 1997). However, efforts must also be directed to increasing the perceived value and necessity of incorporating IT into teaching. Not only must faculty members be convinced, but department chairs, deans, and chief academic officers must also be brought on board.

As long as faculty members get little or no “credit” for re-assessing their pedagogy through course design and redesign efforts that incorporate new instructional technologies, they will continue to be resistant to changing their tried-and-true teaching methods (Beggs, 2000). Thus, another way to increase the perceived value of IT is for institutions to increase the credit given to IT users by promotion and tenure committees (Bombardieri, 2006; Hagner & Schneebeck, 2001; Seminoff & Wepner, 1997; Young, 2002). Young (2002) points to the seldom heard phrase, “‘Teach well or perish’”! (§ 57). Unless more value is placed on these endeavors, some faculty may feel it is more advantageous to wait until they have been tenured to learn about and to incorporate the new instructional technologies. The efforts to ensure greater academic quality discussed earlier can help T/P committees to develop appropriate guidelines that reflect best practices. Hagner and Schneebeck (2001) recommend that clear articulation of the parameters for scholarship and activity in the area of IT, which can lead to T/P, be presented

to faculty in writing. Failure to articulate those parameters will keep non-users from transitioning to prospective IT users and prospective users from transitioning to new users.

Finally, to ease concerns over job security in regards to the impact of technology-related issues, open dialogues between faculty and administration offer a good beginning. Faculty need a forum, be it special sessions of a faculty senate or an even more open venue, where they can voice their concerns. They need to be made to feel their input matters, and administrators need the opportunity to address and ease those concerns. Open discussions about this and all other barriers is a key element to promote IT integration (Hagner & Schneebeck, 2001) and to improve the socialization process. Negotiating to a level of comfort for both groups would do much for the future of higher education and its move towards increasing IT integration to promote student learning—after all, improving student learning is common ground for both groups.

CONCLUSION

Increasing faculty integration of IT in higher education has proven to be a complicated and difficult process. Faculty members encounter numerous barriers that negatively affect their evaluation of IT and adversely affect their commitment to implementing new technologies. They frequently need to change roles within the teaching domain (often without clear direction, encouragement, or acknowledgement), adding to the difficulties for prospective or new users of IT. The pace of IT improvements and innovations means that even experienced IT users cannot rest. Barriers aside, there are many ways that higher education faculty members and institutions can increase their commitment to and integration of IT. Despite the challenges, clear progress has been and will continue to be made.

KEY TERMS AND DEFINITIONS

Advanced Instructional Technologies: Cutting-edge technologies that have not been widely used in educational settings.

Basic Instructional Technologies: Technologies such as email and web pages that are considered standard tools of IT.

Instructional Technology: Applications of technology aimed at instructional objectives.

Learning Management System (LMS): Platform: Applications that collect the most frequently used IT tools into a combined application that can be integrated into a University's enterprise systems.

Net Generation: Persons born in the 1980's or later; members of the Net Generation have never known life without the Internet.

New Academy: "Acknowledges the changes manifested in the Net Generation; uses the power of technology to enable deeper learning; demonstrates the interplay of interaction of culture and technology; and changes the nature of interaction among members" (Barone, 2005, p. 14.1).

Student-Centered Instruction (Constructivism): Current approach to education based on active engagement with content.

Teacher-Centered Instruction: Traditional approach to education based on information dissemination, and passive learning.

Chapter 5.8

Social Psychology and Instructional Technology

Robert A. Bartsch

University of Houston - Clear Lake, USA

ABSTRACT

This chapter examines how principles in social psychology can be applied to instructional technology. Two areas are discussed to explain why individuals would have a positive attitude towards instructional technology but not engage in consistent behaviors. Social psychological research demonstrates attitudes do not necessarily correlate with behaviors. Factors that moderate this relationship include attitude extremity, attitude importance, attitude accessibility, direct experience, attitude specificity, habits, and social norms. Additionally, if individuals cannot comprehend messages, they cannot develop their knowledge of instructional technology even if they wanted. To comprehend messages, individuals have to have the ability (i.e., both knowledge and time) to

thoroughly process them. Examples are provided illustrating each of these concepts. The author hopes by examining the field of social psychology, new ideas, new understanding, and new areas of research can emerge in the field of instructional technology.

INTRODUCTION

It is often useful for outsiders to examine another discipline and suggest ways their field can apply. Therefore, as a social psychologist, I would like to glance at instructional technology and attempt to illustrate how research from social psychology can help instructional and other educational technologists better understand their domain. I will give a brief definition of social psychology along with its contribution of the idea of situationism. Then I will give an example of how

DOI: 10.4018/978-1-60960-503-2.ch508

social psychology can be applied to a perplexing question in instructional technology, why people who like and support instructional technology do not maximize their knowledge of or efficient use of their instructional technology systems. I will demonstrate that social psychological research on attitude-behavior consistency and the theoretical idea that people are motivated tacticians help explain this counterintuitive behavior.

BACKGROUND

Social psychology is defined as “the scientific attempt to understand and explain how the thoughts, feelings, and behaviors of individuals are influenced by the actual, imagined, or implied presence of other human beings” (Fiske, 2004, p. 4). A typical social psychology textbook includes chapters on social cognition, person perception, self, attitudes, prejudice, social influence, relationships, helping, and aggression. Issues relating to gender and culture are examined in each chapter. Theories and research from social psychology have helped create and expand the areas of industrial/organizational psychology, health psychology, forensic psychology, and political psychology.

Given that a main theoretical perspective in social psychology is sociocultural (Taylor, 1998), the theoretical paradigm in instructional technology that social psychology would most closely relate to is situated learning theory (Reiser & Dempsey, 2002). In addition, along with the rest of psychology, social psychology underwent a cognitive revolution in the 1970s with social cognition emerging as a main theoretical perspective (Taylor, 1998). Therefore, social psychology may also have applications to instructional technology that have its roots in information processing.

As the definition and the main topics illustrate, social psychology examines how people interact with other people. However, information technology often examines how individuals will interact with objects, and there are differences in how

individuals relate to people versus objects (Fiske & Taylor, 1991). As an individual perceives and interacts with others, others perceive, judge, and respond in return. Although objects may interact with people and respond to their actions, objects do not richly interact, are less likely to change, and are not perceived as causal agents. Nevertheless, there are several areas of psychology, especially ones focusing on intra-individual processes such as social cognition and attitudes that would be most relevant to instructional technology.

A key component of social psychology that relates to many issues in instructional technology is the idea of situationism. Situationism (Ross & Nisbett, 1991) is the perspective that a major cause of social behavior is the situation. Although many types of psychology relate to the importance of the individual, Lewin (1951), often considered the father of modern social psychology, theorized behavior is a function of both personality and environment. Social psychologists recognize the importance of the person, but they also recognize the importance of the situation and are familiar with research that demonstrates how many people underestimate the strength the situation has on people’s behaviors (Jones, 1990).

This idea of situationism has allowed social psychologists to explain why people often behave counterintuitively such as being willing to give electric shocks in near lethal doses to individuals (Milgram, 1974), deliberately changing their answer just to go along with a group (Asch, 1956), and not helping a person who clearly needs assistance (Darley & Latané, 1968). In each case, the situation was powerful enough to override how the individual personality would be prone to behave.

To demonstrate how social psychology could relate to instructional technology, this chapter explores two examples of why people may not maximize their knowledge and efficient use of their instructional technology system. Specifically, the chapter examines why a college instructor would not have a Web site for their course, and why people do not use many of the available shortcuts

on their computer. For example, in Microsoft Office, CTRL-S can be used to save a document; however, many people exclusively use the mouse to save. Although this keystroke saves time, many people do not use it.

There are many reasons why somebody would not be interested in instructional technology. Not surprisingly, people who are not interested in new technology or people who are afraid of new technology would likely not be motivated to maximize their knowledge and efficiency of their system. Rather, they would avoid using the technology altogether. This behavior would be intuitive although perhaps not productive. Therefore, to examine how social psychology can explain *counterintuitive* behavior, these examples will assume the person is interested in instructional technology and wants to learn and develop their skills and be a more effective teacher. Therefore, the examples used in this chapter concern a college instructor who wants to develop a course Web site but does not and a person who wants to learn Microsoft Office shortcuts but does not. To illustrate how people who have positive attitudes about instructional technology may not behave in ways congruent with that attitude, the following sections discuss research on attitude-behavior consistency and the theoretical idea of people as motivated tacticians.

ATTITUDE-BEHAVIOR CONSISTENCY

Attitudes are the “overall evaluation of persons (including oneself), objects, and issues” (Petty & Wegener, 1998, p. 323), and behavior is the action related towards the person, object, or issue. Early social psychological research LaPiere (1934) indicated people’s attitudes do not always match their behavior. In fact, an early review of the literature demonstrated typically small correlations, usually less than .30, between attitudes and behavior (Wicker, 1969). Later research has

indicated when attitudes are more likely to predict behavior. Factors that have been shown, through this research, to moderate the relationship between attitudes and behaviors include attitude strength, attitude specificity, habits, and social norms.

Several properties relate to the strength of an attitude (Krosnick, Boninger, Chaung, Berent, & Carnot, 1993). One might believe strength in attitudes relates only to the extremity of the attitude (Prislin, 1996). That is, a strong positive attitude towards instructional technology means the person is extremely in favor of it. However, stronger attitudes can also be strong because they are more important, accessible, or based on direct experience. Importance is defined as how deeply the individual cares about the attitude object. Accessibility relates to whether the attitude is routinely salient (i.e., prominent) in a person’s mind. For example, in a national election, people’s political attitudes will likely be more accessible. Direct experience means people have had encounters with the object themselves as opposed to getting information about the object from a secondary source. For instance, a person may have a stronger attitude about a specific brand of car if they have driven the car themselves rather than listening to a friend about his or her driving experience.

Based on the ideas of attitude strength there are many situations in which a person has a positive attitude about instructional technology, but does not act like it. Obviously, if an instructor only has a slightly positive (i.e., very low on extremity) attitude towards creating a course Web site, then there will be little motivation to complete that task. As another example, although a person may believe they should use the Microsoft Word shortcut, they perceive the consequences as being minimal and not affecting their values. Therefore, the attitude has low importance. Also, if their attitude about educational technology is not accessible during an important planning period, possibly because other topics are competing for attention, then behavior may not be predicted from a positive

attitude. Finally, if the person who has a positive attitude about course Web sites does not have any direct experience with them, then their attitude may be weaker than if they have previously had a course Web site.

Based on this analysis, there are several methods to increase positive behaviors toward instructional technology. (1) Increase the extremity of the attitude. Probably the most permanent way of changing an attitude would be to create quality arguments in favor of the instructional technology and give them repeatedly to the audience (Cacioppo & Petty, 1985; Petty, Haugtvedt, & Smith, 1995). (2) Emphasize the importance of the attitude. For example, a person does not likely care about wasting 2 seconds using a mouse instead of a shortcut. However, pointing out how many shortcuts exist and how much time could be saved over an extended period may increase the attitude's importance. (3) Create an environment such that people will recall their attitude at a crucial time. For example, instructors could be presented with information about course Web sites and reminded of their attitude right before they begin planning the next semester. (4) Finally, provide direct experience. Providing resources to instructors to allow them to create a course Web site, could increase the likelihood they would, in the future, create another course Web site on their own. However, care needs to be taken to make sure creating a course Web site does not make the instructor begin to have a negative attitude about course Web sites.

Another reason why attitudes do not necessarily predict behaviors is that the measured attitude is too general to predict a specific behavior (Kim & Hunter, 1993). For example, a person may have a positive attitude about the United Way but not make any yearly donation. Measuring the person's attitude towards, not the United Way as a whole, but rather towards making donations to the United Way will give a better indication of whether the person will make a donation to the United Way. Likewise, many people have a positive attitude

about instructional technology; however that attitude may be too general to predict the person's behaviors related to instructional technology. For example, an instructor may have a positive attitude towards instructional technology, but that attitude would likely not predict whether the person would create a course Web site. Rather, measuring a matching attitude about creating course Web sites would better predict behavior. Although this insight does not provide recommendations for getting individuals to use instructional technology more effectively, it does provide insight into how to measure attitudes about instructional technology that better predict a desired behavior.

Attitudes may not relate to behaviors due to habits. For instance, a person may have a negative attitude about biting one's fingernails, but continues to bite them out of habit. Research indicates habits are automatically activated based on a goal (Aarts & Dijksterhuis, 2000). For example, a person may have a habit of using the computer mouse that is activated by the goal of saving the Microsoft Office document. Because there is no controlled processing, the attitude of using instructional technology efficiently is not accessed. This factor could be quite problematic in the realm of instructional technology because adapting to new instructional technologies likely means discarding old habits.

A final reason why attitudes may not predict behavior has to do with social norms. Social norms are cultural rules about how to behave and not behave. Social norms are often powerful enough to affect behavior. For example, a salesperson may have a negative attitude about a customer, but it is unlikely the salesperson will behave in a way that lets the customer know their dislike. A teenager may only smoke because it is the social norm of their peer group. Social norms can easily prevent a person from adopting positive behaviors relating to instructional technology even if they have a positive attitude. If people do not receive approval from important others, or in fact receive disapproval from these important others, then

even a positive attitude will unlikely produce a congruent behavior. These important others can be peers, upper administration, students, and so forth. For positive attitudes about course Web sites to relate to behavior, the administration would have to make sure the social norms approve of course Web sites.

PEOPLE AS MOTIVATED TACTICIANS

The social psychological idea that people are motivated tacticians also illustrates why individuals may have a positive attitude towards instructional technology but not have matching behaviors. However, instead of directly examining behavior, this idea focuses on whether a person can become more knowledgeable about a topic. With the cognitive revolution in psychology and social psychology, researchers initially theorized people were cognitive misers (Fiske & Taylor, 1984). That is, people would only process the minimal amount of information needed about a concept and would naturally conserve their cognitive resources. Being a cognitive miser is oftentimes beneficial. With all the stimuli and decisions people are presented with everyday, people must have processing shortcuts to be able to successfully relate to the world around them. However, if people were consistently cognitive misers, it would be very difficult for them to learn new instructional technologies. People would rely on tricks used with previous systems and would be less likely to adapt to new technology or even new versions of existing technology. Rather, cognitive resources would be saved for other uses.

Social psychological theorists realized people do not always act as cognitive misers. Rather, they pick and choose when to expend significant cognitive energy and when to be cognitive misers. In other words, researchers theorized individuals are what are called motivated tacticians (Fiske & Taylor, 1991). For example, a person would

likely not spend much cognitive energy choosing which groceries to purchase. Rather, various shortcuts would be used such as what has been bought in the past, what is on sale, what is very convenient to get, and so forth. However, when a person purchases a car, they often spend much more time and energy determining if it is a good purchase. Although they may still use shortcuts (e.g., whether their friend likes the car or not), it is difficult to imagine a person being more cavalier choosing a car than choosing cereal.

Evidence indicates people process information thoroughly when they have both motivation and ability to expend cognitive energy (Petty & Cacioppo, 1986). Motivation to improve one's knowledge about instructional technology would likely be present if one has a positive attitude about instructional technology. However, if a person does not have the ability, that person will be forced to process information heuristically (i.e., using shortcuts). Ability includes both knowledge and time. If a person does not understand instructional technology, they will likely not be able to make good decisions concerning its use. For example, if the person does not have enough experience with the technology to understand the help documentation, then when they encounter a problem, that person will not be able to think carefully or easily expand their knowledge. Similarly, if a person does not have enough experience with a type of technology, instruction could easily be "over their head" and not useful. Likewise, if a person does not have enough time to think carefully about a topic, they will likely not be able to learn more about it. All of these problems can occur even if they are interested in learning about the technology. An instructor who wants to create a course Web site without enough ability would likely not be able to develop the knowledge necessary to facilitate the creation of a quality Web site. Consequently, for an instructor to be able to create an effective course Web site, they must have the time and enough knowledge to proceed.

FUTURE TRENDS

Although it is important to become familiar with one's own discipline, oftentimes other disciplines can shed light on important topics. Clearly instructional technology applies to many different fields from the military to business and from higher education to health care (Reiser & Dempsey, 2002). Undoubtedly, as instructional technology becomes more and more relevant, the frequency of potential applications will only increase. Hopefully, at the same time instructional technology will continue to incorporate research into their discipline from other fields. In this chapter I have suggested social psychology be at the forefront of disciplines that can be useful for instructional technologists to explore so they may better understand their own discipline. I would like to mention another benefit of examining social psychology. Although the examples used in this chapter assumed individuals would be positively motivated to develop their knowledge concerning instructional technology, that assumption is often not realistic. Research and theories from social psychology can also show how to persuade people to believe they need to gain a greater appreciation of instructional technology. This deep body of knowledge has already been applied to other situations in which a person is often not motivated, such as helping health psychologists study how doctors can get patients to obey instructions (Sadava, 1997).

CONCLUSION

Research and theories from social psychology demonstrate how individuals may have a positive attitude about instructional technology but not have a corresponding behavior. The factors this chapter has examined can be broken down into person factors and situational (i.e., environmental) factors. Person factors include attitude extremity, attitude importance, attitude accessibility, direct experience, habits, and knowledge. Environmental

factors include social norms. Although there are a greater number of person than situation factors, personality is not necessarily more relevant than the situation in determining how individuals will behave. Rather, the environment of the group (e.g., organization, classroom) can greatly affect not only situational factors but also many of the person variables. An organization can provide time and encourage direct experience. Likewise, an organization through its culture can increase attitude accessibility and the importance of certain attitudes. As indicated by research in social psychology, the situation is more important than most people realize.

KEY TERMS AND DEFINITIONS

Ability: Ability is having the resources (e.g., knowledge, time) to accomplish a task.

Attitude Strength: Attitude strength is the stability of an attitude and the impact the attitude has on information processing and behavior.

Attitude-Behavior Consistency:

Attitude/behavior consistency is whether an attitude (i.e., overall evaluation) does or does not correspond with behavior (i.e., action).

Cognitive Miser: Cognitive miser is the idea that people minimize the use of their cognitive resources.

Motivated Tactician: Motivated tactician is the idea that people choose when to minimize

the use of their cognitive resources and when to engage in effortful processing of information.

Situationism: Situationism is the theory that situations are a major determinant of individual behavior.

Social Psychology: Social psychology is the scientific study of how individuals relate with and are influenced by other people.

ABSTRACT

Emotions are attracting growing attention within the instructional design research community. However, clarification is still required as to how exactly to address emotions within the field of e-learning. The aim of this chapter is twofold. Firstly, we will focus on the reasons for including emotions within the instructional technology domain, and in particular, on the relevance of emotions to computer-based learning. The need for specific theory in this regard is heightened by the current drive to design instructional de-

vices that interact with learners in a motivating, engaging, and helpful way. Secondly, within the of the framework affective computing paradigm, the different modalities for detecting emotions in instructional technology contexts will be systematically reviewed, and the strengths and limits of each will be discussed on the basis of the most up-to-date research outcomes. Finally, a tentative architecture for emotion recognition in computer-based learning will be proposed, focusing on the adoption of a multimodal approach to emotion recognition, in order to overcome the limitations and the difficulties associated with individual modalities.

INTRODUCTION

The Role of Emotions in Learning

There is growing recognition that emotions and affect play an important role in learning. The learning process is influenced by factors connected to the person, the task, and the context as well as the learner's own on-going evaluation of the process itself. Situational characteristics and individual appraisals can trigger emotions (Efklides & Volet, 2005). In turn, as stated by Barrett and Salovey (2002), affect in learning facilitates the development of persistence and interest in a topic. Emotions can also influence learning through information processing activity and organization of recall (Pekrun, Goetz, Titz, & Perry, 2002). Furthermore, emotions can provide information about the learner's own evaluation of the learning process, since they are linked to control- and value-related appraisals within a learning environment (Gläser-Zikuda & Mayring, 2003). For instance, positive emotions generally indicate that successful task control and interest have been experienced. Our learning, therefore, is heavily dependent on the emotional state we are in (LeDoux, 1998), and on the dynamic pattern of positive and negative emotions occurring in a given time period within a learning context (Sansone & Thoman, 2005).

The role of emotions can be relatively easily recognized and managed within face-to-face learning, where they have been shown to be significantly related to student motivation, learning strategies, cognitive resources, and achievement (Pekrun et al., 2002). What is worth considering is the role of emotions when students are remote from their teacher—even when computer-based education can be supported by a human tutor, the latter is likely to have a lesser awareness of the emotional state of students, and may thus more easily fail to provide a responsible teaching presence and appropriate leadership and direction (Wosnitza & Volet, 2005). Despite general awareness of

the need to consider emotions in e-learning environments, it seems that, with the exception of computer anxiety, the emotions experienced during computer-based learning have not yet been analyzed in depth (Pekrun, 2005). Thus, there is a great need for e-learning projects to take the role of emotions in learning into account and to integrate this understanding into their pedagogical approach.

Affect and Emotions in E-Learning Design

Very often, e-learning implies the presentation of information and material on a very rational basis, overlooking the role of emotions. Yet, computer-based learning can be affected by a range of emotions, including some which do not occur within face-to-face learning, such as emotions directed at technology. Nowadays almost all Web-based training platforms allow computer-mediated communication, where e-learning can take place within either solo or social situations. In solo learning, self-directed, task-directed, and technology-directed emotions have been identified. In social online learning, further emotions have been observed, such as emotions directed at another learner, at the group the learner belongs to, or at another group of learners that his/her group is interacting with (Wosnitza & Volet, 2005).

Moreover, as O'Regan (2003) has pointed out, there has been little exploration to date of the extent, nature, and significance of affect and emotions in e-learning design. If emotions are essential to human thinking and learning processes, virtual platforms and learning environments need to cater to the emotional factor in order to be successful. In particular, the computer graphical interface should not treat humans like information processing machines, but should take their emotions into account. Therefore, it is critical that system designers consider the range of possible affective states that users may experience while interacting with the system.

The key problematic issue remains how to address emotions in human-computer interaction: This topic is currently the focus of a specific research field defined as affective computing (Picard, 1997). All studies with the aim of including emotions within information technology design can be ascribed to this domain, which deals specifically with three different levels of emotion integration: the detection of user emotions, the expression of emotions by computers, and ultimately, the possibility for a computer to “have” emotions. All three levels of emotion integration can greatly enhance the interaction of users with computer programs. Thus, software can nowadays be provided with a kind of emotional intelligence, conceived of as one of the most critical characteristics for successful human interaction (Salovey & Mayer, 1990). The current chapter will mainly focus on the issue of detection.

With specific reference to educational research, according to Picard et al. (2004), new technologies can play a double role: On the one hand, they can help provide new types of research data on the role of affect in learning, laying the bases for new approaches to education, and on the other, can provide enhanced computer-based learning environments to support the user more effectively through his/her learning process.

This chapter introduces the preliminary questions needing to be addressed in order to carry out emotion assessment within learning environments. Such questions highlight the need for wider use of recognition instruments. Subsequently, after reviewing a number of possible channels of emotion detection in e-learning applications, a multimodal approach is recommended in order to increase reliability of recognition outcomes. On the basis of this multimodal approach, a tentative architecture for automatic emotion recognition is outlined. Inclusion of a cognitive component is suggested, in order to integrate the outcomes from different channels, as well as the registration of meaningful events experienced by the user during the learning experience.

DETECTING EMOTIONS WITHIN INSTRUCTIONAL TECHNOLOGY DOMAIN

The first step towards the integration of emotional intelligence is the ability to detect users’ emotions. Two main emotion detection approaches can be identified within e-learning environments—that carried out by a human tutor, or teacher, participating in the learning environment, and that carried out by the e-learning system itself, termed *automatic*. The first is largely similar to the emotion recognition taking place in traditional learning environments and may also be used in computer supported learning, although the human tutor may have reduced access to emotional information. The second demands a more defined and specific basis and is more suitable for autonomous e-learning systems.

When addressing automatic emotion recognition, researchers must answer two main questions: First, when in the course of the learning interaction the system should be emotionally aware, and second, how it should recognize emotions, that is, based on which signals.

With regard to the timing issue, emotion recognition processes may be activated in three different periods vis-à-vis the learning path: (1) measurement immediately before and/or after the learning process, (2) measurement during the learning process, and (3) stimulated recall measurement of emotions after the learning process (Wosnitza & Volet, 2005).

Measuring emotions just before or after the learning process, on the one hand does not interrupt the learning experience but, on the other, requires specific pre-scripted moments to be integrated that may irritate the user and may lose efficacy due to the delay between the emotional experience and the emotional assessment. The delay factor also impairs the effectiveness of the “emotional coping” that the system should ideally carry out. Similar, but amplified, drawbacks apply to stimulated recall measurement.

Emotion recognition during the learning process may be a better solution. This involves real-time emotion assessment, with the potential to be time effective when an emotionally relevant modification occurs. On the other hand, real-time emotion automatic recognition faces greater technical challenges than the other possible timing options, and furthermore needs to be as truly automatic as possible so as not to disrupt the learning process. In consequence, a balanced recommendation is for real-time emotion recognition to take place in specific and critical learning moments.

In regards on *how* to detect emotions, a number of channels are described in the next paragraph. Before outlining individual modalities it is worth mentioning that considering emotion to be a componential process (Scherer, 1984, 2001) enables simultaneous inclusion of many different measures (Pantic & Rothkrantz, 2003). This approach enhances the likelihood of recognizing an emotional state, and partially reduces the risk of distortion due to factors such as social desirability and deliberate control of emotional expression (Pekrun, 2005). Each channel presents its own limitations, but these may be partially overcome by the adoption of a multimodal approach to emotion recognition, which integrates information from multiple sources and may be regulated depending on the context of use.

A Multimodal Approach to Emotion Recognition

Providing e-learning systems with the ability to *recognize* user emotions is a prerequisite for the enhancement of computer-based learning by integrating emotional experience. Recognition systems face two core challenges: (1) detection of the emotion-related signals provided by the users and (2) inference of the emotional state of the user according to the signals detected.

With regard to modes of detection, in addition to self-report measures, a number of channels are considered emotion sensitive. For instance,

studies have been carried out on the link between emotional states and modifications in each of the following channels: physiological correlates, facial expressions, gestures, verbal communication, vocal non-verbal communication.

Physiological correlates of emotions have been considered a reliable means of detection since the work of James (1884). Ekman, Levenson, and Friesen (1983) suggested that the identification of distinct emotions on the basis of autonomic nervous system (ANS) activity requires taking into account different indices simultaneously. Various instruments for the detection of physiological signals (e.g., blood volume pulse, respiration, skin conductance, electromyography, neurological response) are already in existence and are subject to constant enhancement, particularly in order to make them less intrusive by integrating them into more natural seeming devices, for example, incorporation of sensors in a mouse or wearable jackets. The main problem is recognized to be the extreme variability of these signals across people and situations and even within the same person. This is borne out by the fact that few studies have indicated the existence of specific patterns of autonomic activity for specific emotions (for a review see Cacioppo, Berntson, Larsen, Poehlmann, & Ito, 2000). The search for an invariant relationship between emotions and physiological responses should be abandoned in favor of the analysis of, under what conditions, and for which emotions, differential physiological activity is observed (Cacioppo et al., 2000).

A number of attempts at automatic emotion recognition from physiological measures have been made. Some researchers have tried to directly link a set of values to a set of emotions via various statistical algorithms (Nasoz, Alvarez, Lisetti, & Finkelstein, 2004). Others, using a dimensional model of emotion (where emotions are represented along some main axes, typically arousal and valence) have tried to use each physiological measure as an index of a single dimension (Picard, Vyzas, & Healey, 2001; Prendinger, Mori, & Ishizuka,

2005). What emerged from most of these studies is that physiological measures alone cannot provide enough information for emotion recognition: other information is needed (Scheirer, Fernandez, Klein, & Picard, 2002). In addition, awareness of the context can have critical significance for the interpretation of physiological data (Stemmler, 2003; Ward & Marsden, 2003).

Facial expressions of emotions have been investigated in depth. According to Ekman (1994), each emotion goes with a specific pattern of facial actions, as predicted by the Facial Action Coding System (FACS) (Ekman & Friesen, 1978). Although this bi-univocal link has been severely criticized, most of the research on automated emotion recognition is based on the FACS model. An early work carried out by Kaiser and Wehrle (1992) described a procedure for automatic detection of facial behavior independently of individual physiognomic differences, through the use of plastic dots affixed to predefined facial regions. A pattern-recognition algorithm identifies dot patterns that are classified according to the FACS by an artificial neural network. More recently, Cowie et al. (2001) outlined a system for the recognition of facial expressions by identifying Facial Animation Parameter Units defined in MPEG-4 standard, but the system is still not fully automatic and requires human assistance. Conversely, Kapoor, Qi, and Picard (2003) proposed a fully automatic framework that requires no manual intervention to analyze and recognize upper facial actions, corresponding to the regions of eyes and eyebrows. Tian, Kanade, and Cohn (2000) developed an automated system to analyze subtle changes in facial expressions, based on both permanent (brows, eyes, mouth) and transient (deepening of facial furrows) facial features in a nearly frontal image sequence. The system is based on multi-state templates that require manual set up in the first frame of the sequence; thus the system is not fully automatic.

In any case, the FACS model is not free of problems. Although prototypic expressions of some emotions, for example happiness, are natural, they occur infrequently in everyday life, since people tend to communicate more through subtle facial actions. In addition, emotions like confusion, boredom, and frustration do not have corresponding prototypic expressions. Furthermore, this method lacks temporal and detailed spatial information (Russell & Fernández-Dols, 1997).

Gestures are not generally linked to specific emotions. Although some studies have identified expression of emotional meaning through body movements (Wallbott, 1998), psychologists generally maintain that the meaning of gestures is mainly determined by the specific interaction context. Consequently, it is difficult to assume a direct link between gestures and specific emotional states.

The situation with regard to *posture* is even more complicated, since in the field of nonverbal behavior research there is no established and generalized criterion about how to classify postures or about the association between posture and emotional state. However, some attempts have been made to automatically detect emotion from postures and gestures. Mota and Picard (2003) presented a system for recognizing naturally occurring postures and associated affective states, relating to the interest level of children while performing a learning task on a computer. The system is capable of two kinds of recognition: (1) recognition of a static posture position and (2) recognition of a sequence of postural behaviors. The system is not fully automatic because it requires preliminary selection and coding of posture action units by human observers. Similarly, affective states linked to postures have to be selected and labeled manually by observers.

The *verbal communication* of emotions concerns terms and words produced in concurrence with an emotion, and it takes into account the cultural differences reflected in the terms adopted and in their meaning (the so-called emotional lexi-

con). The language-emotion relationship has been studied from various perspectives: lexicographic research on words that refer to emotions, highly related to the universality or culture-relativity of human emotions (Wierzbicka, 1995); syntactic research focusing on emotion verbs like *to fear*, and so forth; investigation of certain types of language use, such as hyperbole, repetition, the use of strong metaphors; conversational analysis, which studies the rules regulating the occurrence of emotionally expressive behavior in interaction.

Attempts at automatic emotion recognition based on verbal communication can be grouped into a number of categories: (1) *keyword spotting*, where text is classified into affect categories based on the presence of fairly unambiguous affect words like *distressed*, *enraged*, and *happy*, for example, *affective reasoner* (Elliott, 1993) and Ortony's affective lexicon (Ortony, Clore, & Collins, 1988); (2) *lexical affinity*, detecting more than just obvious affect words, the approach assigns arbitrary words a probabilistic "affinity" with a particular emotion; (3) *statistical natural language processing*, that is, by feeding a machine a learning algorithm with a large training corpus of affectively annotated texts, it is possible for the system to learn the affective valence of affective keywords as well as that of other arbitrary keywords (as in the lexical affinity approach), punctuation, and word co-occurrence frequencies.

The *vocal-nonverbal communication* of emotions deals with the differences that can be identified in some phonatory variables (e.g., intensity, tone, rhythm) when an individual is, for example, expressing happiness or sadness: Some patterns of vocal supra-segmental traits have been described (for a review see Juslin & Laukka, 2003; Scherer, 2003). Several studies have shown that each emotion is associated with a distinctive vocal profile in a systematic way.

A growing research corpus about automatic recognition of emotions from voice can be found in scientific literature. It should be pointed out that the motivations behind these studies range from

theoretical and scientific to application based. The first category focuses on acted speech and on a broader range of emotions, while the second includes, for instance, work on speech from automatic call centers (Batliner et al., 2000) and research on detection of stress during driving (Fernandez & Picard, 2003). As pointed out by Oudeyer (2003), research on automated vocal production and recognition of emotion has only been carried out for a short number of years. As well as systems aimed at automatically detecting some basic emotions independently of context, systems have been developed to focus on one/two target emotions, of particular relevance to specific application fields. For example, Batliner et al. (2000) proposed a system for the recognition of anger to enhance the effectiveness and usability of automatic dialog processing.

Self-report measures have also been proposed to detect emotions. Some researchers have developed questionnaires to be administered to participants in order to obtain information about their emotional experience (Russell & Mehrabian, 1977; Scherer, 1988). Besides questionnaires, other self-report measures based on nonverbal and pictorial methods (e.g., Self Assessment Manikin Scale; Bradley & Lang, 1984) were put forward; here users choose the images that best represent their emotional states, partially overcoming the limits inherent to linguistic and verbal expression.

This means of detection, on the one hand is non-intrusive, fast and cheap, but, on the other, can be affected by distortion due to social desirability factors and to the potential inability of the user to correctly express his/her own emotional experience.

What emerges from this review is that each channel has its own strengths and weaknesses that should be taken into account when trying to implement an automatic recognition model. Table 1 provides a brief critical assessment of the different channels reviewed, both from psychological and implementational viewpoints.

Table 1. Assessment of different detection channels

	CHANNEL EVALUATION	INTRUSIVENESS	TECHNICAL COMPLEXITY	PRICE / COSTS
<i>Physiological measures</i>	Advantages: Rapid and synchronous modifications. Biological foundations. Uncontrollable by the participant. Limits: Easily influenced by non-emotional events and environment. Wide variations across people, situations, and even within the same individual.	Very high. Future development of wearable devices may reduce it.	Hardware difficulties: Integration of specific devices. Software difficulties: (1) real-time data processing; (2) recognition algorithms.	Medium-high for physiological detection device.
<i>Facial expressions, gestures, and posture</i>	Advantages: Relatively spontaneous; easy to observe; objective. Limits: influenced by non emotional factors and by environmental events (context). May be culturally influenced. Gestures are linked to conversation.	Medium. People can be annoyed by cameras. Some systems require cameras positioned on participants' head.	Hardware difficulties: Integration of cameras. Software difficulties: (1) AU extraction; (2) posture tracking and extraction; 3) real-time processing.	High for cameras and AU recognition software.
<i>Speech (verbal)</i>	Advantages: Non intrusive; easy to collect. Limits: For emotion lexicon, difficult to know whether the reported emotion is a conceptualisation or the effective state; whereas linguistic indexes require long conversational sequences to be detected.	Low	Software difficulties: Integration of word recognition software and emotional semantic map.	Low for microphone. Medium for word recognition software
<i>Vocal non-verbal measures</i>	Advantages: Link to physiological changes; wide research tradition on emotional vocal patterns; low intrusivity. Limits: Technical difficulties; problems in noisy environments; possible problems with phonetic variability; few results for naturally collected data; recognition rate varies according to the database (number of emotions, mode of data collection, number of speakers); systematic confusion for some emotions.	Low	Hardware difficulties: Integration of a spectrograph. Software difficulties: (1) real-time data processing.; (2) recognition algorithms.	Low for the microphone and for spectrograph.
<i>Self-report measures</i>	Advantages: Simple to administer to the user. Limits: distortions due to social desirability, errors in the self-monitoring process, cultural differences, potential disruption of learning path.	Medium/low. Requires definition of timing, may disrupt the learning process.	None	Low

Guidelines for Designing an Inferential System of Emotion Recognition

Once emotion-related signals have been detected, the recognition system needs an inferential system in order to attribute an emotional state to the users.

The inferential system can be defined as a cognitive architecture that is able to integrate the

various input signals with other elements, so as to infer the user's emotional state.

Specifically, we propose that a cognitive architecture of emotions should be designed in order to output a possible emotional state, by working from four main inputs: (1) individual characteristics, (2) initial signal profile, (3) real-time signals, and (4) context modeling.

Firstly, the system should profile the user in terms of different psychological variables in

order to establish his/her individual personality characteristics. In other words, the user should be emotionally and motivationally profiled (e.g., Matsubara & Nagamachi, 1996), and these characteristics, subsequently, should be taken into account to weight the possible outcomes of the context modeling.

Secondly, an initial stage of interaction should be provided for, in order to detect the baseline values of physiological and vocal nonverbal signals for each user (physiological and vocal profiles). Due to the interpersonal variation for these signals, the inferential system needs a period to register the signal levels of the user at rest: these values will be considered the baseline for modifications detected during the interaction (Berntson, Uchino, & Cacioppo, 1994).

Thirdly, the inferential system should work on the outputs of different modality-specific modules (speech: vocal analysis module; visual analysis module; physiological signal module; self-report measures module; speech: verbal module). Each of these has its own limitations, and none can be fully relied upon to detect emotions in isolation from the others, whereas multimodal analysis may at least partially reduce problems (Pantic & Rothkrantz, 2003). All the modules provide information about behavior and physiological variations displayed by the user at a certain stage of the interaction: Variations should be processed by the inferential system in order to assess emotional state using an advanced statistical approach, including different learning and classification algorithms. To this end, it is critically necessary to define a training database, as a fundamental prerequisite for developing reliable classification algorithms (Anolli et al., 2005).

Fourthly, context modeling is one of the main features to be included, and it may be one of the more promising ways to enhance inferential reliability. If only physiological and communication measures are considered, distortions and mistaken emotional attributions may occur, since a key component of emotional experience is still

lacking. Emotions result from both an arousal component and from a cognitive component, the latter encompassing the appraisal of *arousal* and its attribution to an emotion eliciting event. Appraisal theories suggest that emotions are elicited and shaped by an individual's subjective evaluation of situations or events that affect the individual's needs or goals (Frijda, 1986; Scherer, 1984; Weiner, 1986). Environmental or proprioceptive stimuli are evaluated by the individual vis-à-vis a number of criteria and dimensions linked to individual meaning. As a result, the same stimulus can provoke very different emotional reactions among people (Lazarus, 1966), depending on the outcome of the subjective appraisal.

Appraisal theorists suggest that individuals use a fixed number of dimensions or criteria for evaluating the significance of the events. These criteria can be categorized into four major classes: (1) intrinsic characteristics, such as novelty; (2) significance for individual's needs or goals; (3) ability to influence or cope with the consequences of an event; and (4) compatibility with social or personal standards, norms, or values (Scherer, 1984).

The model of emotions proposed by Ortony et al. (1988) is one of the most used within affective computing, since it can be implemented in computer software. The authors do not represent affect as a set of basic emotions nor as emotions defined within a dimensional space, but group emotions according to the eliciting cognitive conditions.

The inclusion of context modeling to address the cognitive component of emotion may require the definition of an additional module (registry module). This module would take into account relevant information about events happening to the user, pertinent both to the learning context and the learning process, for example, a failure while using a certain software or the loss of some data due to a system error.

While it is not possible to register what is happening outside of the concrete interaction, it may be useful to consider the events of the learning

interaction itself, for example, failure in a test phase could be presumed to be negative valenced and to influence emotional state according to corresponding appraisal criteria. In other words, the system could be provided with some appraisal criteria that would partially define the emotional significance of events occurring to users.

The cognitive architecture should be able to process variations within each modality, integrate them, and attribute a potential meaning to them depending on the initial state and profile of the specific user and output of the registry module.

CONCLUSION

A topic of key interest to educational researchers is the search for strategies capable of inspiring the interest and active participation of learners (Bransford, Brown, & Cocking, 1999). In traditional face-to-face learning this hinges on the ability of the teacher. Teasing out and replicating all the components of this ability remains a huge challenge for e-learning designers. One possible way forward, according to Picard et al. (2004), is to approach these learning goals by incorporating affective information into the e-learning path. This line of enquiry appears all the more feasible, as a growing number of relevant technologies

are coming on stream, especially in the field of emotional detection.

Recently, a number of projects have addressed the inclusion of affect in learning and education environments (see Kapoor, Mota, & Picard, 2001; Zhou & Conati, 2002). For instance, as cited previously, a preliminary system for the automatic detection of children's interest levels during learning situations, based on a combination of posture and facial expressions, was designed at the Massachusetts Institute of Technology Media Lab (Picard et al., 2004).

In this paper we have described a possible way to enhance an automatic emotion recognition system. The key defining characteristics of our proposal are multimodality, that is, the inclusion of multiple detection channels and contextual awareness of events occurring within the learning path. Both of these characteristics can contribute to creating a more effective system.

Nonetheless, some key limitations of the proposal should be discussed. Currently, it is not possible to identify the optimum combination of real-time measures and other sources of information required for emotion recognition. A "golden truth" is still lacking, both for the individual channels reviewed and how best to combine them. As already stressed, each channel presents specific reliability problems, and some have additional

Figure 1. Ideal representation of a possible emotion recognition system

drawbacks that partially hinder implementation (e.g., intrusiveness in detecting physiological signals). In order to minimize technical obstacles, more suitable and comfortable devices are needed, which may be wearable or integrated in normally used instruments (mouse, keyboards, etc.).

In addition to technical and scientific limitations, researchers should be aware of ethical issues raised by the implementation of devices connected with emotions. Ethical considerations should be continuously taken into account at all stages of research and development, from the preliminary phase of emotional data collection (in particular if data is acquired through induction procedures) to the final concrete implementation of recognition platforms within everyday applications, because of their potential to detect learners' emotions beyond their conscious wish to disclose them.

In conclusion, it should be pointed out that a recognition system is not an end in itself, but a means to design instructional technology environments to be more effective in supporting user learning experience. Once a system has detected and recognized an emotional state, it can take this information into account in selecting those subsequent actions held most appropriate to improve learner performance, according to the pedagogical strategy in use. Although some scattered attempts have been made to incorporate emotions into models of learning (e.g., Kort, Reilly, & Picard, 2001; Mandler, 1984), no widely shared theoretical model can be identified. The main issue to be investigated along with the definition of emotion recognition systems remains the development of a generally accepted theoretical model of how to use affective information in learning.

KEY TERMS AND DEFINITIONS

Affective Computing: Affective computing is a research field that aims at including emotions within information technology design. It deals specifically with three different levels of emotion integration: (1) the detection of user emotions, (2) the expression of emotions by computers, and ultimately, (3) the possibility for a computer to "have" emotions.

Appraisal: Appraisal refers to the cognitive evaluation antecedent to an emotional episode. Appraisal theoretical models are characterized and differentiated by the appraisal dimensions included.

Autonomic Nervous System (ANS): ANS is the part of the nervous system that regulates individual organ function and homeostasis, and for the most part, is not subject to voluntary control. It is usually divided into sympathetic and parasympathetic.

Computer Anxiety: Computer anxiety is the individual fear or apprehension of using a computer directly or the anticipation of having to use it.

Emotional Intelligence: Emotional intelligence is the underlying general competence that comprises a variety of emotional skills. Such skills vary according to the different models of emotional intelligence proposed.

Facial Action Coding System (FACS): FACS is a system originally developed by Paul Ekman

and Wallace Friesen in 1978 to taxonomize human facial expression. It is the most used method to measure and describe facial behaviors, coded through action units (AU).

Modality (of Emotional Detection): Modality is each of the different channels that are considered to be emotion-sensitive (i.e., physiological

measures, vocal non-verbal measures, self-report measures, facial expressions, posture and gestures, and verbal content).

Multimodal Emotion Recognition: Multimodal emotion recognition is where one is inferring an emotional state and integrating inputs coming from multiple emotion-sensitive sources.

Chapter 5.10

Behaviorism and Developments in Instructional Design and Technology

Irene Chen

University of Houston Downtown, USA

INTRODUCTION: THE BASICS OF BEHAVIORISM

The *theory of behaviorism* concentrates on the study of overt behaviors that can be observed and measured (Good & Brophy, 1990). In general, the behavior theorists view the mind as a “black box” in the sense that response to *stimulus* can be observed quantitatively, ignoring the possibility of thought processes occurring in the mind. Behaviorists believe that learning takes place as the result of a response that follows on a specific stimulus. By repeating the *S-R* (stimulus-response) cycle, the organism (may it be an animal or human) is *conditioned* into repeating the response whenever the same stimulus is present. The behavioral emphasis on breaking down complex tasks, such as learning to read, into subskills that

are taught separately, has a powerful influence on instructional design. Behaviors can be modified, and learning is measured by observable change in behavior. The behavior theorists emphasize the need of objectivity, which leads to great accentuation of statistical and mathematical analysis. The design principles introduced by the behavior theorists continue to guide the development of today’s computer-based learning. In distance-education courseware and instructional software, key behavior-modification principles are used. For example, a typical course Web site usually states the objectives of the software; uses text, visual, or audio to apply appropriate *reinforcers*; provides repetition and immediate feedback; uses principles to shape, chain, model, punish, and award the learners; incorporates a scoring system as a part of the system; and provides status of the progress of the learner. Major learning theorists associated with behaviorism are the following:

DOI: 10.4018/978-1-60960-503-2.ch510

- Pavlov
- Thorndike
- Skinner
- Watson
- Gagné

The major educational technology developments in America that can be attributed to behaviorism are the following:

- The behavioral objectives movement
- The teaching machine phase
- The programmed instruction movement
- The individualized instructional approaches
- The computer-assisted learning
- The systems approach to instruction

Major instructional design theorists associated with behaviorism are as follows:

- Glaser
- Gagné and Briggs
- Dick and Carey
- Mager

BACKGROUND: BEHAVIORISM AND LEARNING THEORIES

The advent of behavioral theories can be traced back to the elder Sophists of ancient Greece, Cicero, Herbart, and Spencer (Saettler, 1990). Behaviorism, as a learning theory, can be traced back to Aristotle, whose essay “Memory” focused on associations being made between events such as lightning and thunder. Other philosophers that followed Aristotle’s thoughts are Hobbes (1650), Hume (1740), Brown (1820), Bain (1855), and Ebbinghaus (1885). Franklin Bobbitt developed the modern concept of behavioral objectives in the early 1900s. More recently, the names associated with the development of the behaviorist theory include Pavlov, Thorndike, Watson, and B. F. Skinner.

Pavlov (1849-1936)

The Russian physiologist Ivan Petrovich Pavlov is the precursor to behavioral science. He is best known for his work in classical conditioning or stimulus substitution. Pavlov’s experiment involved food, a dog, and a bell. His work inaugurated the era of S-R psychology.

Pavlov placed meat powder (an unconditioned stimulus) on a dog’s tongue, which caused the dog to automatically salivate (the unconditioned response). The unconditioned responses are natural and not learned. On a series of subsequent trials, Pavlov sounded a bell at the same time he gave the meat powder to the dog. When the food was accompanied by the bell many times, Pavlov found that he could withhold the food, and the bell’s sound itself would cause the dog to salivate. The bell became the *conditioned stimulus* that caused the conditioned response of salivating (Thomas, 1992). In 1904, he was awarded the Nobel Prize for his research on digestive processes.

The stimulus and response items of Pavlov’s experiment can be summarized as follows:

- **Food:** Unconditioned Stimulus
- **Salivation:** Unconditioned Response
- **Bell:** Conditioned Stimulus
- **Salivation:** Conditioned Response

Pavlov also made the following observations (Mergel, 1998):

- *Stimulus generalization:* Once the dog has learned to salivate at the sound of the bell, it will salivate at other similar sounds.
- *Extinction:* If you stop pairing the bell with the food, salivation will eventually cease in response to the bell.
- *Spontaneous recovery:* Extinguished responses can be “recovered” after an elapsed time, but will soon extinguish again if the dog is not presented with food.

- *Discrimination*: The dog could learn to discriminate between similar bells (stimuli), and discern which bell would result in the presentation of food and which would not.
- *Higher order conditioning*: Once the dog has been conditioned to associate the bell with food, another unconditioned stimulus, such as a light, may be flashed at the same time that the bell is rung. Eventually the dog will salivate at the flash of the light without the sound of the bell.

Thorndike (1874-1949)

Another influential contributor to establishing education as a science was Edward L. Thorndike. Thorndike's laws were built upon the stimulus-response hypothesis of Pavlov. He was also a strong advocate of educational measurement.

Around the turn of the century, Thorndike conducted researches in animal behavior before becoming interested in human development. He was interested in discovering whether animals, such as cats and dogs, could learn their tasks through imitation or observation.

Thorndike's *laws of learning* for humans, based on *connectionism*, stated that learning was the formation of a connection between stimulus and response. His behavioral learning theory studied increasing a behavior with the use of rewards, punishment, and practice. Three major laws in Thorndike's laws of learning are the *law of effects*, which suggested that the strength of connection is dependent on what follows, the *law of exercise*, which suggested that practice strengthens the connection while disuse weakens it, and the *law of readiness*, which suggested that if physically ready, the connection is satisfying for the organism.

Close temporal sequence is not the only means of insuring the connection of the satisfaction with the response producing it. The other equally important factors are the frequency, energy, and duration of the connection, and the closeness with which the satisfaction is associated with the response.

The result is most clearly seen in the effect of increasing the interval between the response and the satisfaction or discomfort. Such an increase diminishes the rate of learning. Minimum delay in reinforcement has a crucial impact on the learning process. What is called attention to the response or *knowledge of the results* counts also. A slightly satisfying or indifferent response made often may win a closer connection than a more satisfying response made only rarely.

Thorndike believed that when the response was positive, a neural bond would be established between the stimulus and response, and learning takes place when the bonds are formed into patterns of behavior (Saettler, 1990). This is the origin of the linear style using trial and error in laboratory research for inquiry-based learning.

Watson (1878-1958)

John B. Watson is credited with coining the term behaviorism. Like Thorndike, he was originally involved in animal research, but later became involved in the study of human development. Watson believed that humans are born with a few reflexes and emotional reactions of love and rage, and all other behaviors are established through stimulus-response associations through conditioning.

Watson demonstrated classical conditioning in an experiment involving a young child named Albert and a white rat. Originally, Albert was not afraid of the rat. Watson made a sudden loud noise whenever Albert touched the rat. Frightened by the loud noise, Albert became conditioned to fear and to avoid the rat. The fear was generalized to other small animals. Watson then extinguished the fear by presenting the rat without loud noises. Research of the study suggests that the conditioned fear was more powerful and permanent than it really was (Good & Brophy, 1990; Harris, 1979; Samelson, 1980).

Watson's work demonstrated the role of conditioning in the development of emotional responses

to certain stimuli. This helps to explain certain fears, phobias, and prejudices that people develop.

Skinner (1904-1990)

Like Pavlov, Thorndike, and Watson, Burrhus Friederich Skinner believed in the stimulus-response pattern of conditioned behaviors. His theory ignored the possibility of any processes occurring in the mind and directly dealt with changes in observable behaviors. In other words, actual behaviors are the focus of concern in his theory, rather than emotions, thoughts, or other hypothetical constructs (Maddux, Johnson, & Willis, 1992).

Most of Skinner's research was centered around the *Skinner box*. A Skinner box is an experimental space that contains one or more operands, such as a lever, that may be pressed by a rat. The box also contained various sources of stimuli. Skinner contributed much to the study of operant conditioning, which is a change in the probability of a response due to an event that followed the initial response (Skinner, 1968). The theory of Skinner is based on the idea that learning is a function of change in behavior. When a particular S-R pattern is reinforced (rewarded), the individual is conditioned to respond. Changes in behavior are the result of an individual's response to events (stimuli) that occur in the environment. In his early career, Skinner started with experimenting with animals such as pigeons and rats. He later turned his research interests from animals to humans, especially his own daughters.

Principles and Mechanisms of Skinner's Operant Conditioning

- **Positive reinforcement or reward:** Behavior that is positively reinforced will reoccur; intermittent reinforcement is particularly effective. A reinforcer is anything that strengthens the desired response. A

reinforcer could be verbal praise, a good grade, or a feeling of satisfaction.

- **Negative reinforcement:** Responses that allow escape from painful or undesirable situations are likely to be repeated. A negative reinforcer is any stimulus that results in the increased frequency of a response when it is withdrawn. It is different from aversive stimuli, or punishment, which results in reduced responses (Good & Brophy, 1990).
- **Punishment:** Responses that bring painful or undesirable consequences will be suppressed, but may reappear if reinforcement contingencies change.
- **Extinction or nonreinforcement:** Responses that are not reinforced are not likely to be repeated.
- **The schedules of reinforcement:** The schedules of reinforcement can govern the contingency between responses and reinforcement and their effects on establishing and maintaining behavior. Schedules that depend on the number of responses made are called ratio schedules. The ratio of the schedule is the number of responses required per reinforcement. If the contingency between responses and reinforcement depends on time, the schedule is called an interval schedule.

For an animal to learn a behavior, such as pressing a lever to produce food, successive approximations of the behavior are rewarded until the animal learns the association between the lever and the food reward. To begin the shaping process, the animal may be rewarded for simply turning in the direction of the lever, then be rewarded for moving toward the lever, be rewarded for brushing against the lever, and finally be rewarded for pawing the lever. If placed in a cage, an animal may take an extended period of time to figure out that pressing a lever will produce food. Behavioral

chaining occurs when a succession of steps needs to be learned. Information should be presented in small amounts so that responses can be reinforced or shaped. The animal would master each step in sequence until the entire sequence is learned.

Due to stimulus generalization, reinforcements will generalize across similar stimuli producing secondary conditioning. Once the desired behavioral response is accomplished, reinforcement does not have to be present every single time. In fact, it can be maintained more successfully through partial reinforcement schedules. Skinner explained partial reinforcement schedules including interval schedules, ratio schedules, fixed-interval schedules, variable-interval schedules, fixed-ratio schedules, and variable-ratio schedules. He found that variable-interval and variable-ratio schedules produce more persistent rates of response because the learners cannot predict when the reinforcement will occur (Milhollan & Forisha, 1972).

Difference between Classical and Operant Conditioning

Skinner's work differs from that of his predecessors (classical conditioning) in that he studied the operant behaviors that are voluntary behaviors used in operating on the environment. The organism can emit responses instead of only eliciting a response due to an external stimulus. (Table 1)

He also emphasized the use of positive reinforcement in a repetitive manner. Another distinctive aspect of Skinner's theory is that it attempt-

ed to provide behavioral explanations for a broad range of cognitive phenomena. For example, Skinner explained motivation in terms of deprivation and reinforcement schedules.

Implications for Educational Technology

Skinner's operant conditioning has been widely applied in behavior modifications as well as teaching and instructional development, particularly in areas such as classroom management and programmed instruction. His influential book, *The Technology of Learning* (1968), explained how classroom instruction should reflect the behaviorist principles of operant conditioning.

Many of Skinner's instructional techniques are still widely used today (Roblyer, 2006). Consider the implications of Skinner's theory as applied to the development of programmed instruction (Markle, 1969; Skinner, 1968):

1. Practice should take the form of question-answer (stimulus-response) frames that expose the student to the subject in steps.
2. Require that the learner make a response for every frame and receive immediate feedback.
3. Try to arrange the difficulty of the questions so the response is always correct, resulting in a positive reinforcement.
4. Ensure that good performance in the lesson is paired with secondary reinforcers such as verbal praise, prizes, and good grades.

Table 1. Difference between classical and operant conditioning

Classical Conditioning	Operant Conditioning
Uses the term response	Uses the term behavior
Main components: stimulus and its response	Main components: behavior and its consequence
Cannot be used to shape behavior	Can be used to shape behavior
The stimulus causes the response	The consequence influences the behavior
Association between stimuli and responses	Reinforcement
Based on involuntary reflexive behavior	Based on voluntary behavior

The general criticism about Skinner is that he denies the existence of *free will* or human freedom. Skinner defines these values as self-control, which he believes humans do not possess. Many critics labeled him one-sided because he fails to consider any options other than what is “easily observed and manipulated” (Schellenberg, 1978).

Robert Gagné (1916-2002)

Like Skinner, Robert Gagné emphasized the use of positive reinforcement in a repetitive manner. Between 1949 and 1958, when Gagné was the director of the perceptual and motor skills laboratory of the U.S. Air Force, he began to develop some of his ideas that comprise his learning theory called the *conditions of learning* or *cumulative learning theory*. Although Gagné’s earlier work is grounded in the behaviorist tradition, his current work seems to be influenced by the information-processing view of learning and memory. He has published with David Merrill, Leslie Briggs, Walter Wager, and several other authors.

Gagné is best known for three of his contributions: the events of instruction, the types of learning, and learning hierarchies (Roblyer, 2003).

The Events of Instruction

Gagné identified the following nine events of instruction as elements of a good lesson (Gagné, Briggs, & Wager, 1992):

1. Gaining attention
2. Informing the learner of the objective
3. Stimulating recall of prerequisite learning
4. Presenting new materials
5. Providing learning guidelines
6. Eliciting performance
7. Providing feedback about corrections
8. Assessing performance
9. Enhancing retention and recall

The Types of Learning

The early writings by Gagné, Briggs, and Wager (1974) identified three categories of human factors that affect the learning event (see Table 2).

According to Gagné, each new skill learned should build on previously acquired skills. When designing instruction, the prerequisite lower-level skills and knowledge required have to be explained for an instructional objective.

In the 1990s, Gagné et al. (1992) identified several types of learning behaviors that students demonstrate after acquiring knowledge:

- Verbal information
- Intellectual skill
- Cognitive strategy
- Attitude
- Motor skill

Table 2. Human factors that affect the learning event

Major Categories	Human Factors
External Stimulus Factors	• Contiguity: time relationship between stimulus and response • Repetition: frequency of exposure to a stimulus • Reinforcement: follow-up to the stimulus
Internal Cognitive Factors	• Factual information: from memory • Intellectual skills: ability to manipulate information • Cognitive strategies: ability to process meaningful information
Internal Affective Factors	• Inhibition: reluctance to react to a stimulus • Anxiety: tension

Learning Hierarchies

Robert Gagné developed his taxonomy of learning to explore the practice-observable behaviors in 1972. Gagné distinguished the following eight different classes of intellectual skills in which human beings learn. These intellectual skills can be categorized on a dimension of complexity, ranging from simple recognition to abstract processes (Gagné et al., 1974):

1. **Signal learning:** The individual learns to make a general, diffuse response to a signal. Such was the classical-conditioned response of Pavlov.
2. **Stimulus-response learning:** The learner acquires a precise response to a discriminated stimulus.
3. **Chaining:** A chain of two or more stimulus-response connections is acquired.
4. **Verbal association:** The learning of chains that are verbal.
5. **Discrimination learning:** The individual learns to make different identifying responses to many different stimuli that may resemble each other in physical appearance.
6. **Concept learning:** The learner acquires a capability of making a common response to a class of stimuli.
7. **Rule learning:** A rule is a chain of two or more concepts.
8. **Problem solving:** This kind of learning requires the internal events usually called thinking.

The more complex kinds of intellectual processing are based upon these simpler varieties. To teach a skill, a teacher has to identify its prerequisite skills and ensure that the student possesses them. Gagné et al. (1992) called this building process “a learning hierarchy.”

Today, Gagné is considered an experimental psychologist who is concerned with learning and instruction. The model he proposed is a widely

accepted model used to inform the design process. He has impacted instructional design for K-12 schools as well as for business, industry, and the military.

MAIN FOCUS: BEHAVIORISM AND THE DEVELOPMENTS IN INSTRUCTIONAL DESIGN AND TECHNOLOGY

The following major educational technology developments in America can be attributed to behaviorism (Saettler, 1990):

- The behavioral objectives movement
- The teaching machine phase
- The programmed instruction movement
- The individualized instructional approaches
- The computer-assisted learning
- The systems approach to instruction

Behavioral Objectives Movement

The behaviorist theory is sometimes referred to as *objectivist* because the behaviorists emphasize the need for objectivity, which leads to great accentuation of statistical and mathematical analysis. They believe behaviors can be modified, and learning is measured by observable changes in behavior. As of today, learning objectives written by teachers are still widely recognized and very useful. Here is an example of a learning objective:

After having completed the unit, the student will be able to answer correctly 85% of the questions.

The behavioral objectives movement can be traced back to Benjamin Bloom in the 1950s and 1960s. At a time when the primary learning theory was behaviorism, an approach that viewed students as passive recipients of learning provided by their teachers and parents, Bloom presented

his taxonomy organization in *Taxonomy of Educational Objectives: Book I, Cognitive Domain* (Bloom, Englehart, Furst, Hill, & Krathwohl, 1956). The view was that learning involved pupils' accumulation and remembering of varied pieces of information. Bloom and his colleagues began development of a taxonomy in the *cognitive*, *affective*, and *psychomotor* domains. Cognitive is for mental skills, affective is for growth in feelings or emotional areas, while psychomotor is for manual or physical skills.

Bloom's cognitive taxonomy is organized into six levels:

- Knowledge
- Comprehension
- Application
- Analysis
- Synthesis
- Evaluation

Bloom's "learning for mastery" defines mastery in terms of specific educational objectives, and mastery of each unit is essential for students before they advance to the next one.

Each teacher begins a new term or course with the expectation that about a third of his students will adequately learn what he has to teach. He expects about a third to fail or just "get by." Finally, he expects another third to learn a good deal of what he has to teach, but not enough to regard them as a "good student." (Bloom, Hastings, & Madaus, 1971, p. 43)

The affective domain includes the manner in which we deal with things emotionally, such as attitudes, motivations, feelings, values, and appreciation. The major categories listed in order are as follows (Bloom, Mesia, & Krathwohl, 1964):

- **Receiving phenomena:** Awareness, willingness to hear, selected attention

- **Responding to phenomena:** Active participation on the part of the learners
- **Valuing:** The worth or value a person attaches to a particular object, phenomenon, or behavior.
- **Organization:** Organizes values into priorities.
- **Internalizing values (characterization):** Has a value system that controls his or her behavior.

The psychomotor domain includes physical movement, the use of the motor-skill areas, and coordination. Most of the time, the development of these skills requires practice, and is measured in terms of speed, precision, distance, procedures, or techniques in execution. The major categories listed in order are as follows (Bloom et al., 1964):

- **Perception:** The ability to use sensory cues to guide motor activity.
- **Set:** Readiness to act. It includes mental, physical, and emotional sets.
- **Guided response:** The early stages in learning a complex skill that includes imitation and trial and error.
- **Mechanism:** This is the intermediate stage in learning a complex skill.
- **Complex overt response:** The skillful performance of motor acts that involve complex movement patterns.
- **Adaptation:** Skills are well developed and the individual can modify movement patterns to fit special requirements.
- **Origination:** Creating new movement patterns to fit a particular situation or specific problem.

According to Bloom et al. (1971), nearly all students can achieve mastery of material in a course when given the time and quality of instruction that they need. Therefore, to reach mastery, the student needs to get 80% to 90% of the answers right. The basic instructional task was to define

the course into educational units and find methods and material to help the students to reach the set level. The student would be tested with a formative test that would either indicate mastery or emphasize on what still needed to be learned in order to reach the next level.

By the late 1960s, most teachers were writing behavioral objectives (Mergel, 1998). Other names for objectives are “learning targets,” “educational objectives,” and “pupil outcomes.” Virtually all the tests pupils take in school are intended to measure one or more of the cognitive processes, and instruction is expected to focus on assisting students attain mastery of some subject area. The learning success may be measured by tests developed to measure each objective. To develop objectives, a learning task must be broken down through analysis into specific measurable tasks. Teachers began to write behavioral objectives for their lessons that were descriptions of specific, terminal behaviors manifested in terms of observable, measurable behavior. Cognitive objectives focus on memorizing, interpreting, and other intellectual activities.

A good objective states learning objectives in specified, quantifiable, terminal behaviors. As of today, Bloom’s taxonomy is still widely recognized and very useful. In a popular textbook used by teacher-training programs in the United States, Peter W. Airasian wrote, “Although teachers’ objectives may be explicit or implicit or clear or fuzzy, it is best that objectives be explicit, clear, and measurable. Regardless of how they are stated and what they are called, objectives are present in all teaching” (Airasian, 2001, p. 74).

Similarly, Robert Mager wrote *Preparing Instructional Objectives* in 1962, which prompted the interest and use of behavioral objectives among educators. In the book, Mager described an objective as “a description of a performance you want learners to be able to exhibit before you consider them competent. An objective describes an intended result of instruction rather than the process of instruction itself” (1984, p.

21). Objectives are important because teachers need an objective to find out if learning has been accomplished, and students need an objective as the means to organize their own efforts toward accomplishment. There is no sound basis for the selection of instructional materials when clearly defined objectives are lacking.

According to Mager, an objective must include the three major components:

1. **Performance:** What the learner should be able to do
2. **Conditions:** Under what circumstances
3. **Criterion:** How well it must be done

Later, Gagné and Briggs developed a set of instructions for writing objectives that is based on Mager’s work.

Teaching Machines and Programmed Instruction Movement

Although the elder Sophists, Comenius, Herbart, and Montessori used the concept of programmed instruction in their repertoire, B. F. Skinner is the most current and probably the best known advocate of teaching machines and programmed learning. Other contributors to this movement include Pressey and Crowder.

Edward Thorndike described the premise of computer-based instruction half a century before the feasibility of such a system became possible. Thorndike (1912, p. 165) wrote, “If, by a miracle of mechanical ingenuity, a book could be so arranged that only to him who had done what was directed on page one would page two become visible, and so on, much that now requires personal instruction could be managed by print.”

In his machine, Sidney Pressey sought to incorporate Thorndike’s vision. Noticing that objective tests were becoming common in schools, in the 1920s, Pressey began experimenting with a machine for testing and scoring in his introductory psychology courses. Soon he recognized its

potential for teaching and learning. Pressey (1926, p. 374) stated, “the procedure in mastery of drill and informational material were in many instances simple and definite enough to permit handling of much routine teaching by mechanical means.” Pressey maintained that the teacher is “burdened by such routine of drill and information-fixing.”

Pressey’s teaching machine resembled a typewriter carriage with a window that revealed a question with four answers. The user pressed one of the four keys that corresponded to different answers. When the user pressed a key, the machine recorded the answer on a counter and then displayed the next question. Once finished, the person scoring the test slipped the test sheet back into the device and noted the score on the counter. Pressey demonstrated his multiple-choice machine at the 1925 American Psychological Association meeting (Travers, 1967).

Despite his confidence that the machine he developed would lead to an “industrial revolution in education” (Pressey, 1932, p. 672), this type of machine was never widely used. In the same year that Pressey predicted the revolution, the unemployment rate was over 20% high due to the Great Depression, and new developments in educational technology were delayed until after World War II.

More than 30 years later, among the group of farsighted researchers, Skinner had a vision of machines that could teach. He envisioned the following (1954, 1958):

- Machines are able to arrange appropriate contingencies of reinforcement by which specific forms of behavior could be set up by the use of specific stimuli.
- The learner should be able to put together his or her own response rather than select from alternatives.
- The learner must pass through a carefully designed sequence of steps. Each step must be small enough that it can always be

taken, yet in taking it, the student moves closer to fully competent behavior.

- The student must not be able to proceed to the following step until the first has been accomplished.
- The machine stimulates constant interaction between the program and the user.

This teaching machine has good record-keeping facilities of students’ progress. According to Maddux et al. (1992, p. 105), “Skinner’s machine presented the questions in 30 radial frames on a 12-inch disk.” They continued, “He called the material in the frames the program. Programs that led each user through the same materials in the same sequence were referred to as linear programs.” Skinner thought the success of such a machine depends on the material used in it. The learner’s concentration is improved by the use of these packages addressing the environmental factors that should be inductive to learning. Its other features also free the educator of rote work.

Skinner’s teaching machine required the learner to compose an answer rather than simply choose from a list of options. Also, the machine required the learner to proceed through a series of steps in a prescribed sequence, or through *linear programs*. Each step had to be small so that everyone would be successful, yet each step had to lead closer to the target behavior (referred to as *task analysis*; Maddox et al., 1992). Skinner’s machine was demonstrated in 1954. If used effectively, these machines would take the role of a private tutor, bringing one programmer (educator) into contact with a large number of students.

Skinner’s work on teaching machines has stimulated a large body of research. Today, his criteria for the teaching machines are still important components in developing modern computer-based learning programs (Maddox et al., 1992). Even though Skinner’s teaching machine stimulated a large body of interest, the device was not widely adopted by educators. However, his

idea of a teaching machine has led to programmed instruction.

Later on, Norman Crowder (1959) did not agree with Skinner that every learner should progress in the same sequence. His programs varied the sequence to some learners or omitted certain frames for others, depending on learner responses (referred to as *branching programs*). These modern programs come in various forms in the current educational software market: computerized drill and practice, simulations, and tutorials.

Today, the Education Thesaurus of UNESCO's International Bureau of Education (2002) defines teaching machines as, "Devices that mechanically, electrically and/or electronically present instructional programs at a rate controlled by the learners' responses."

Early Use of Programmed Instruction

Sometimes called *programmed learning*, programmed instruction is a book or workbook that employs the principles proposed by Skinner in his design of the teaching machine, with a special emphasis on task analysis and reinforcement for correct responses (Maddox et al., 1992). Skinner was also a proponent of programmed instruction, and much of the system is based on his theory of the nature of learning. It is an innovation that was more widely accepted in education than a teaching machine.

Believing that by tightly structuring the environment, students' behaviors can be shaped to achieve learning, Skinner envisioned lessons that use carefully planned steps of stimulus-response pairing and reinforcement to reach a goal. The lessons are to be administered in small, incremental steps.

Skinner and J. G. Holland experimentally used programmed instruction in the 1920s and 1930s. Early use of programmed instruction tended to concentrate on the development of hardware rather than course content. In the late 1950s, they first used programmed instruction in behavioral

psychology courses at Harvard. The first practical implementation of programmed instruction was achieved in 1960 by Basic Systems Inc. (Mechner, 1977). In the early 1960s, the proponents led by Skinner defined programmed instruction as using (a) an active response by the learner, (b) immediate reinforcement of correct responses, and (c) successive approximations toward the knowledge to be learned, in a sequence of steps so small that the learner can take each one without difficulty (1977).

The use of programmed instruction appeared in American elementary and secondary schools at around the same time (Saettler, 1990). Programs have been devised for the teaching of arithmetic, foreign languages, physics, spelling, reading, psychology, and several other subjects (*The Columbia Encyclopedia*, 2001-04). Industry and the military used programmed instruction to train personnel. Osguthrope and Zhou (1989) discussed the popularity of this approach in the 1950s and 1960s.

Although many educators agree that programmed instruction can contribute to more efficient classroom procedure and supplement conventional teaching methods, there has been considerable controversy regarding the merits of programmed instruction as the sole method of teaching (*The Columbia Encyclopedia*, 2001-2004). Programmed learning died out in the later part of the 1960s (Reiser, 1987). Researchers agreed that programmed instruction did not appear to live up to its original claims (Criswell, 1989; Reiser; Tillman, & Glynn, 1987). Concerned developers moved away from hardware development to programs based on analysis of learning.

By the early 1960s, there was a strong backlash against the use of both teaching machines and programmed instruction. Fitzgerald (1970) listed the rigidity of these devices in skimming as one of the overriding disadvantages. He also suggested that both teaching machines and programmed instruction would lead to dehumanization due to over reliance on machines.

Decades later, Skinner (1986) explained why programmed instruction and teaching machines were never popular:

The machines were crude, the programs were untested, and there were no ready standards of comparison. Teaching machines would have cost money that was not budgeted. Teachers misunderstood the role of the machines and were fearful of losing their jobs. (p. 105)

Today, the Education Thesaurus of UNESCO's International Bureau of Education (2002) defines programmed instruction as, "Learning in which the students progress at their own rate using workbooks, textbooks or electromagnetic resources that provide information in discrete steps, test learning at each step and provide immediate feedback about achievement."

Individualized Approaches to Instruction

Similar to teaching machines and programmed instruction, individualized instruction began in the early 1900s and was revived in the 1960s. The *Keller Plan* (sometimes called *Keller Method*, *personalized system of instruction* or PSI), *individually prescribed instruction* (IPI), *program for learning in accordance with needs* (PLAN), and *individually guided education* are all examples of individualized instruction in the United States (Saettler, 1990). Also similar to the previously mentioned behavioral objectives movement, teaching machine phase, and programmed instruction movement, the movement of individualized approaches to instruction represents the achievements for the neo-behaviorist systems approach to instruction. All had their foundation in the behavioral theories and psychological principles to the technology of education and have shown to generate a significant educational result.

The Keller Plan

The Keller Plan was developed by F. S. Keller, his colleague J. Gilmore Sherman, and two psychologists at the University of Brazilia. The Keller Plan is derived from the behaviorists reinforcement psychology with influence from teaching machines and programmed instructions. The group had in mind that students would perform better if they found satisfaction in their work (Buskist, Cush, & DeGrandpre, 1991). They argued that positive consequences (praise, good grades, feeling of achievement) were more important than the negative ones (boredom, failure, or punishment). Briefly, "those features which seem to distinguish (PSI) from conventional teaching procedures" include the following (Reboy & Semb, 1991, p. 213):

1. Mastery criteria
2. Self-pace
3. Stress upon the written word
4. The use of proctors
5. Lectures used for motivation rather than sources of information

The Keller Plan was developed for higher education, whereas Bloom's mastery was to accomplish mastery learning in K-12. A PSI course is divided into units and students have to show a mastery of the unit to be able to go ahead. Students are allowed to individually pace their own learning. The mastery level is usually set at 85% to 100% results (Buskist et al., 1991). The course is based upon a standard textbook, a study guide, journal articles, and other readings. Other common characteristics of PSI are the use of proctors. Proctors are undergraduate students who have successfully finished the course and are aware of the problems of new students. The proctors assist the students, score their quizzes, and react as feedback to the instructor of the course in general. The instructor's lectures and demonstrations in the PSI plan are not for instructional purpose but for enrichment and to provide motivation.

Individually Prescribed Instruction (1964)

In 1962, Robert Glaser synthesized the work of previous researchers and introduced the concept of IPI in 1962. IPI is an approach where the results of a learner's placement test are used to plan learner-specific instruction. The main features of IPI include prepared units, behavioral objectives, planned instructional sequences for various subjects, as well as a pretest and posttest for each unit, and materials to be used to continually evaluate the learner to meet behavioral objectives (Saettler, 1990). The use of IPI dwindled in the 1970s when it lost funding.

Program for Learning in Accordance with Needs (1967)

Headed by John C. Flanagan, PLAN was developed under sponsorship of American Institutes for Research (AIR), Westinghouse Learning Corporation, and several U.S. School districts. The main features of PLAN include selected items from about 6,000 behavioral objectives; instructional modules that took about two weeks of instruction each and was made up of approximately five objectives, mastery learning, and remedial learning plus retesting (Saettler, 1990). PLAN was abandoned in the late 1970s because of upgrading costs.

Computer-Assisted Instruction (CAI)

During the 1950s, CAI was first used in education, and training with early work was done by IBM. The mediation of instruction entered the computer age in the 1960s when Patrick Suppes and Richard Atkinson conducted their initial investigations into CAI in mathematics and reading. Developed through a systematic analysis of curriculum, Suppes' (1979) CAI provided learner feedback, branching, and response tracking.

CAI grew rapidly in the 1960s when federal funding for research and development in education and industrial laboratories was implemented. To determine the possible effectiveness of CAI, the U.S. government developed two competing companies, Control Data Corporation and Mitre Corporation, who came up with the PLATO (Programmed Logic for Automatic Teaching Operations) and TICCIT (Time-Shared, Interactive, Computer-Controlled Information Television) projects. Another significant development in the instructional applications of computers during the 1960s and 1970s was the development of the IBM 1500 computer. Kinzer, Sherwood, and Bransford (1986, p. 25) stated that the IBM 1500 was "the only computer ever developed specifically for computer-assisted instruction, rather than as a general-purpose computer for widespread applications."

PLATO is the first large-scale project for the use of computers in education. It is a project developed through the partnership between Control Data Corporation, the University of Illinois' Computer Education Research Laboratory (CERL), and the National Science Foundation. Designed to use a mainframe-based system, PLATO allowed a sizeable library of programs available for students, a sophisticated record-management system to keep track of individual students' progress, and a large number of simultaneous users (Pagliaro, 1983).

The PLATO IV system, introduced during the early 1970s, enabled up to 600 students to simultaneously access educational software (Alessi & Trollip, 1985). Each terminal serviced one terminal display and keyboard. The several thousand terminal systems served undergraduate education as well as elementary school reading, a community college in Urbana, and several campuses in Chicago (Office of Technology Assessment, 1982). During the early 1970s, PLATO IV was introduced, a large time-shared, instructional system. All data and programs were stored on a central computer.

The original PLATO system continued to grow throughout the 1970s and early 1980s to over 1,000 terminals throughout the country (Alessi & Trollip, 1985). Control Data Corporation started setting up PLATO systems around 1975. They already had over 100 PLATO systems operating by 1985.

The design principles introduced by Suppes continue to guide the development of today's instructional software. In CAI packages, key behavior-modification principles are used. A typical CAI software usually states the objectives of the software; uses text, visual, or audio to apply appropriate reinforcers; provides repetition and immediate feedback; uses principles to shape, chain, model, punish, and award the learners; incorporates a scoring system as a part of the system; and provides status of the progress of the learner (Mergel, 1998).

By using the CAI packages, individual learners can master the subject matter on their own time and at their own pace. As the student continually is kept on track of his or her performance, motivation is also enhanced. In contrast to being a mere receiver of information, the learner now more actively participates.

Despite money and research, by the mid-1970s, it was apparent that CAI was not going to be the success that people had expected due to the following reasons (Mergel, 1998):

- CAI had been oversold and could not deliver.
- Lack of support from certain sectors
- Technical problems in implementation
- Lack of quality software
- High cost

Some researchers also argue that CAI was very much drill and practice, which is controlled by the program developer rather than the learner. Little branching of instruction was implemented in the programs (Saettler, 1990).

Systems Approach to Instruction or Instructional Systems Design (ISD)

The systems approach involves setting goals and objectives, analyzing resources, devising a plan of action, and continuous evaluation and modification of the program (Saettler, 1990). This approach is rooted in the military and business world, was developed in the 1950s and 1960s, and has dominated educational technology and educational development since the 1970s. The systems approach to curriculum design is an attempt to use a process of logical development and ongoing monitoring and evaluation to allow continuous evaluation of the curriculum.

The onset of World War II introduced the huge instructional problem of training thousands of military personnel quickly and effectively. The answer at the time was an enormous influx of mediated learning material: films, slides, photographs, audiotapes, and print materials. In the 1960s, the military was rapidly infusing instructional systems development into their standard training procedures. This period was distinguished by the articulation of components of instructional systems and the recognition of their system properties.

The systems approach to instructional design was often accredited to James Finn. Seels (1989) described Finn as the father of the instructional design movement because he linked the theory of systems design to educational technology and thus, encouraged the integrated growth of these related fields of study. Finn has also made educational technologists aware that technology was as much a process as a piece of hardware (1989).

The systems approach views a system as a set of interrelated parts, all working toward a defined goal. Examples of systems include the human body and a community. Parts of a system will depend on each other for input and output. The entire system uses feedback to determine if the goal is achieved. In 1962 Robert Glaser employed the

term instructional system and named, elaborated, and diagramed its components.

Robert Gagné's *The Conditions of Learning* (1965) is a milestone that elaborated the analysis of learning objectives and related different classes of learning objectives to appropriate instructional designs. Gagné introduces behaviorist literature into the systems approach. His work has contributed greatly to the field of instructional technology in the aspect of instructional design. A systems-approach model of designing instruction is utilized to help learners understand the process of instructional design. Gagné also introduced the idea of task analysis to instructional design. Through task analysis, an instructional task could be broken down into sequential steps: a hierarchical relationship of tasks and subtasks. Gagné built on the principles of the systems approach that Skinner explored in programmed instruction.

The current version of the systems approach is a process comprised of a series of phases. Sometimes referred to as the ADDIE model, the systems approach of instructional design contains the following major phases: analysis, design, development, implementation, and evaluation.

- **Analysis**
 - Determine the instructional goal.
 - Analyze the instructional goal.
 - Analyze the learners and context of learning.
- **Design**
 - Write performance objectives.
- **Development**
 - Develop instructional strategies.
 - Develop and select instruction.
 - Develop assessment instruments.
- **Implementation**
 - Implement the system.
 - Revise the instruction if necessary.
- **Evaluation**
 - Design and conduct the formative evaluation of instruction.
 - Conduct summative evaluation

Each step receives input from the previous step and provides output for the next step. A system is modified if the goal is not achieved. Each component is carefully linked.

In the field of education, the systems-approach model first focused on language laboratories. The instruction can be viewed as a systematic process in which every component is crucial to achieve the goal of successful learning. These components include the learner, instructor, instructional materials, and the learning environment. The many components of the system interact to achieve learning. The focus is on what the learner will be able to know when the instruction is concluded. The systems approach does not prescribe or promote any particular teaching methodology. No one method will be appropriate for all objectives or for all students. Rather, it is a vehicle that helps teachers to think more systematically and logically about the objectives relevant to their students, and the means of achieving and assessing these. These early efforts of ISD in education led to several ISD models that were developed in the late 1960s at Florida State University.

Design models can be defined as the visualized representations of an instructional design process, displaying the main phases and their relationships. Each phase has an outcome that feeds the subsequent phase.

Currently, there are more than 100 different ISD models, but almost all are based on the generic ADDIE. The more commonly known models are the *Dick and Carey Model*, the Kemp Model, the ICARE Model, and the ASSURE Model. While a number of versions of the ISD model exist, the Dick and Carey model is very popular in current instructional design programs. The ADDIE model has been in use for training development for several decades. Today, Walter Dick and Lou Carey are widely viewed as the torchbearers of the approach with their authoritative book *The Systematic Design of Instruction* (1978).

Dick and Carey's model, the systems-approach model for designing instruction, is based on the

assumption that there is a predictable link between a stimulus and the response that it produces in a learner. It describes the phases of an iterative process that starts by identifying instructional goals and ends with evaluation. This model includes analysis, design, development, formative evaluation, plus needs assessment in a nonlinear relationship (Dick & Carey, 1978).

In a classroom setting, the instructional material is linked to the response that it produces in a learner through the learning of the materials. Instruction is specifically targeted on the skills and knowledge to be taught, and supplies the appropriate conditions for the learning of these outcomes.

The Dick and Carey model prescribes a methodology for designing instruction based on breaking instruction down into smaller components. The designer needs to identify the subskills the student must master that, in aggregate, permit the intended behavior to be learned, and then select the stimulus and strategy for its presentation that builds each subskill.

The instructional implication of the model is that learning is based on mastering a set of behaviors are predictable and therefore reliable. This model assumes that the correct instructional analysis and instruction will lead to demonstrable skills.

The following is a list of the elements of Dick and Carey's model explained in *The Systematic Design of Instruction*:

1. Determine the instructional goal.
2. Analyze the instructional goal.
3. Analyze the learners and contexts.
4. Write performance objectives.
5. Develop assessment instruments.
6. Develop instructional strategy.
7. Develop and select instruction.
8. Design and conduct formative evaluation.
9. Revise instruction.
10. Use summative evaluation.

Establishing an instructional goal or goals is typically preceded by needs assessment. The needs assessment is a formal process of identifying discrepancies between current outcomes and desired outcomes for an organization. Dick and Carey described the performance objectives as a statement of what the learners would be expected to do when they have completed a specified course of instruction, stated in terms of observable performances. Subordinate objectives are objectives that must be attained in order to accomplish a terminal objective; terminal objectives are objectives the learner will be expected to accomplish when they have completed a course of instruction. Through the learner and context analysis, key learner characteristics and the context in which the learning will occur are identified. The information provides the basis for developing accurately targeted instruction.

The designer conducts instructional analysis for an instructional goal in order to identify the relevant skills, their subordinate skills, and information required for a student to achieve the goal. The technique of hierarchical analysis is applied for goals in the intellectual skills domain to identify the critical subordinate skills needed to achieve the goal and their interrelationships. Formative evaluation is used to collect data and information that is used to improve a program, conducted while the program is still being developed. And finally, summative evaluation is conducted after an instructional program has been implemented and formative evaluation completed to present conclusions (<http://www.ic.arizona.edu/~teachorg/nlii03/isd.htm>).

FUTURE TRENDS AND CONCLUSION: BEHAVIORAL TEACHING AND LEARNING

Behavioral approaches to teaching generally involve the following:

1. The skills and information to be learned are broken down into small units.
2. Students' work is checked regularly and feedback is provided as well as encouragement (reinforcement).
3. Teaching is "out of context." Behaviorists generally believe that students can be taught best when the focus is directly on the content to be taught. Behavioral instruction often takes the material out of the context in which it will be used.
4. Instruction is direct or "teacher centered." Teachers must direct the learning process.
5. Learning is passive.
6. Students must learn the correct response.
7. Learning requires an external reward.
8. Knowledge is a matter of remembering information.
9. Understanding is a matter of seeing existing patterns.
10. Applications require "transfer of training," which requires "common elements" among problems.

Educational Implications

The behavioral emphasis on breaking down complex tasks into subskills that are taught separately is very common in American schools today.

The behavioral approaches to instruction, such as programmed instruction, are outcome based and emphasize small step size, overt responses, and frequent reinforcement of responses. From the behavioral viewpoint, the learner responds to a stimulus during instruction. Through reinforcement, successive approximations of the response are transformed into desired behaviors. Only the overt response is accepted, while the learner's thought is virtually ignored. Learning is understood to be the result of a casual link between instructional stimuli and student responses, which are strengthened or weakened through reinforcement.

Behavioral teaching and learning tend to focus on skills that will be used later. You learn facts about American history, for example, because it is assumed that knowing those facts will make you a better citizen when you are an adult. You learn basic mathematics and computational skills because you may need them when you get a job. Behavioral learning does not, however, generally ask you to actually put the skills or knowledge you learn into use in a "real" or "authentic" situation. That will come later when you graduate and get a job.

These effects are critical to the effectiveness of a computer program because they influence the learning events of a lesson. The behavior theorists give a great deal of attention to individual responses during interactions with computers. Behaviorists favor software designed for drill and practice and tutorial instruction. Drill-and-practice and tutorial applications have their roots in the early works on teaching machines and programmed instruction.

During computer-assisted learning, the effectiveness of a program depends on the internal responses to a stimulus, the senses used, and the ease of use of the computer so as to minimize distractions. Table 3 compares the basic behavioral roots, the general implications of the roots to general instructional design, and the implications of the behavioral roots to instructional technology.

What are the strengths and weaknesses of using the behavior approach to instructional design? Mergel (1998) pointed out the weakness that the learners may find themselves in a situation where the stimulus for the correct response does not occur, therefore, he or she cannot respond. For example, a worker who has been conditioned to respond to a certain cue at work stops production when an anomaly occurs because of lack of understanding of the system. The strength of using the behavior approach to instructional design, pointed out by Mergel, is that the learner is focused on a clear goal and can respond automatically to the cues of that goal. For example, World War II pilots were con-

Table 3. A comparison of basic behavioral roots, the general implications of the roots to general instructional design, and the implications of the behavioral roots to instructional technology

Behavioral Roots	Implications to General Instructional Design	Implications to Instructional Technology
1) Skills and information to be learned are broken down into small units.	There must be definite goals to accomplish.	The computer program can provide these attributes. • Practice should take the form of question-answer (stimulus-response) frames that expose the student to the subject in gradual steps. • Information should be presented in small amounts so that responses can be reinforced (“shaping”). • The first level of a program must be mastered before the learner can continue on to the next level. • The difficulty of the questions is arranged so the response is always correct and hence results in a positive reinforcement. • The content is divided into small modules or units. • Prerequisites are textually displayed. • Prerequisites are graphically displayed.
2) Students’ work is checked regularly and feedback is provided as well as encouragement (reinforcement).	Correct responses must be followed with immediate feedback or reinforcement. Stimuli can be positive or negative. The sensory perception in learning is very important.	The computer program can provide these attributes. • Depending on the function of the program, there can be positive or negative feedback. • The stimuli can be changed in a program if the response is not satisfactory. • It ensures that good performance in the lesson is paired with secondary reinforcers such as praise, prizes, and good scores. • The sound, animation, audio, and color in a program are important to give immediate feedback and have to do with the sensory perception of the learner. • Positive feedback can be given regularly. The learner can stop the program immediately if he or she does not like it.
3) Teaching is “out of context.” Behavioral instruction often takes the material out of the context in which it will be used.	Students can be taught best when the focus is directly on the content to be taught.	The computer program can provide these attributes. • It divides content into small modules or units. • The computer program plays the role of a teacher in posting the problems to be solved. • The content is textually displayed and reviewed. • The content is graphically displayed and reviewed.
4) Instruction is direct or “teacher centered.” Teachers must direct the learning process.	The learning environment must be controlled.	The computer program can provide these attributes. • Lectures, tutorials, drills, demonstrations, and other forms of controlled teaching guide the design of the software. • The teacher or program controls the presentation sequence and display rate. • The content is textually displayed. • The content is graphically displayed. • Attention-focusing devices such as animation, sound, pointers, and so forth are used. • The computer program plays the role of a teacher in posting the problems to be solved.
5) Learning is passive.	Learning is a change in behavior in which a stimulus in the environment has an influence on the learning and behavior of the learner.	The computer program can provide these attributes. • The purpose of the software is stated clearly. • A computer program can be very linear. • The teacher or program controls the presentation sequence and display rate. • Attention-focusing devices, such as animation, sound, pointers, and so forth, are used.

ditioned to react to silhouettes of enemy planes, a response that, one would hope, became automatic (1998). There were also researchers who questioned the breaking down of subject material into small parts, believing that it would lead away from an understanding of the “whole” (Saettler, 1990).

There are two journals that contain current behaviorist research: the *Journal for the Experimental Analysis of Behavior* (JEAB; <http://seab.envmed.rochester.edu/jeab/index.html>) and the *Journal of Applied Behavior Analysis* (<http://seab.envmed.rochester.edu/jaba/index.html>).

Table 3. continued

Behavioral Roots	Implications to General Instructional Design	Implications to Instructional Technology
6) Students must learn the correct response.	The exercise can be checked once it is completed.	The computer program can provide these attributes. • The exercise can be checked by the computer once it is completed. • Problems can be randomized, and the same problem can be repeated until the learner answers correctly. • It repeats content not mastered. • It displays the score or correct answers. • It helps screen for incorrect answers. • It provides outcome guides coordinated with performance tasks (e.g., activity check sheets). • It provides answer keys. • It requires that the learner make a response for every frame and receive immediate feedback.
7) Learning requires an external reward.	Extrinsic motivation plays a critical role in behaviorism.	The computer program can provide these attributes. • Extrinsically motivated, the learner wishes to get a better score.
8) Knowledge is a matter of remembering information.	Learning is taking place through memorizing.	The computer program can provide these attributes. • A drill program with repetition of problems is emphasized. • It reviews prerequisite content and vocabulary.
9) Understanding is a matter of seeing existing patterns.	The learner has learned something when you can observe his or her behavior.	The computer program can provide these attributes. • The scoring and evaluation functions of a program are two ways to decide if the learner has learned. • The progress of the learner can be monitored by the computer program. • It conducts performance tests. • It provides questions on new content. • It allows a limited response time for memory-level questions. • It uses computers for context-rich testing.
10) Applications require “transfer of training,” which requires “common elements” among problems.	A transfer of knowledge is taking place.	The computer program can provide these attributes. • It cross-references content to similar examples. • The computer program can provide additional information or examples.

Neo-Behavioral Theories

Classic behaviorism suggests that human nature is neither inherently positive nor negative but, rather, is shaped by influences from the person’s environment (Ormrod, 1999). In this view, learning emphasizes the attainment of measurable objectives that are achieved through a systematic instructional design process. Penland (1981) suggested a variation on the theme of behaviorism that is called a neo-behaviorist perspective. Neo-behaviorism departs from classic behaviorism in that, while the latter is concerned exclusively with observable behaviors, the former acknowledges the importance of self-direction that is internal to the individual. Thus, whereas classical behavior-

ism is only concerned with the environment as a determinant of behavior, neo-behaviorism stresses the interaction of the individual and environment.

KEY TERMS AND DEFINITIONS

Classical Conditioning: The Russian physiologist Ivan Petrovich Pavlov is the precursor to behavioral science. He is best known for his work in classical conditioning or stimulus substitution. Pavlov's experiment involved food, a dog, and a bell. His work inaugurated the era of S-R psychology. Pavlov placed meat powder (an unconditioned stimulus) on a dog's tongue, which caused the dog to automatically salivate (the unconditioned response). The unconditioned responses are natural and not learned. On a series of subsequent trials, Pavlov sounded a bell at the same time he gave the meat powder to the dog. When the food was accompanied by the bell many times, Pavlov found that he could withhold the food, and the bell's sound itself would cause the dog to salivate.

Computer-Assisted Instruction (CAI): During the 1950s, CAI was first used in education, and training, with early work, was done by IBM. The mediation of instruction entered the computer age in

the 1960s when Patrick Suppes and Richard Atkinson conducted their initial investigations into CAI in mathematics and reading. Developed through a systematic analysis of curriculum, Suppes' (1979) CAI provided learner feedback, branching, and response tracking. CAI grew rapidly in the 1960s, when federal funding for research and development in education and industrial laboratories was implemented.

Instructional Objectives: A description of a performance you want learners to be able to exhibit before you consider them competent. An objective describes an intended result of instruction rather than the process of instruction itself.

Keller Plan: The Keller Plan (sometimes called Keller Method, personalized system of instruction or PSI), individually prescribed instruction (IPI), program for learning in accordance with needs (PLAN), and individually guided education are all examples of individualized instruction. The Keller Plan was developed by F. S. Keller, his colleague J. Gilmore Sherman, and two psychologists at the University of Brazilia. The Keller Plan is derived from the behaviorists reinforcement psychology with influence from teaching machines and programmed instructions.

Operant Conditioning: Skinner contributed much to the study of operant conditioning, which is a change in the probability of a response due to an event that followed the initial response. The theory of Skinner is based on the idea that learning is a function of change in behavior. When a particular S-R pattern is reinforced (rewarded), the individual is conditioned to respond. Changes in behavior are the result of an individual's response to events (stimuli) that occur in the environment. Principles and Mechanisms of Skinner's Operant Conditioning include: Positive Reinforcement or Reward, Negative Reinforcement, Punishment, and Extinction or Nonreinforcement.

Programmed Instruction: Sometimes called *programmed learning*, programmed instruction is

a book or workbook that employs the principles proposed by Skinner in his design of the teaching machine, with a special emphasis on task analysis and reinforcement for correct responses.

Schedules Of Reinforcement: The schedules of reinforcement can govern the contingency between responses and reinforcement and their effects on establishing and maintaining behavior. Schedules that depend on the number of responses made are called ratio schedules. The ratio of the schedule is the number of responses required per reinforcement. If the contingency between responses and reinforcement depends on time, the schedule is called an interval schedule.

Skinner Box: Most of Skinner's research was centered around the Skinner box. A Skinner box is an experimental space that contains one or more operands such as a lever that may be pressed by a rat. The box also contained various sources of stimuli. Skinner contributed much to the study of operant conditioning, which is a change in the probability of a response due to an event that followed the initial response. Changes in behavior are the result of an individual's response to events (stimuli) that occur in the environment. In his early career, Skinner started with experimenting with animals such as pigeons and rats. He later turned his research interests from animals to humans, especially his own daughters.

Teaching Machines: B. F. Skinner is the most current and probably the best-known advocate of teaching machines. Other contributors to this movement include Pressey and Crowder. Noticing that objective tests were becoming common in schools, in the 1920s, Pressey began experimenting with a machine for testing and scoring in his introductory psychology courses. Soon he recognized its potential for teaching and learning. Despite his confidence that the machine he developed would lead to an "industrial revolution in education," this type of machine was never widely used.

Chapter 5.11

Harnessing the Emotional Potential of Video Games

Ian Pitt

University College Cork, Ireland

ABSTRACT

This chapter explains the importance of acknowledging users' personalities, learning styles, and emotions in the design of educational games. It argues that the application of educational theories combined with knowledge of subjects' personality traits and an increased emotional depth offer a substantive approach to understand and improve the nature of learning in educational games. The authors hope that understanding the underlying motivation and behaviors of learners through the use of personality profiles will not only inform researchers of a better design of educational games, but also assist in understanding the intricate relationship between game design, instructional design, and users' personality at both cognitive and emotional levels.

INTRODUCTION

Background and Motivation for the Study

Since the 1970s, a new generation of students has emerged: the digital natives (Prensky, 2001). They are technology-savvy, use digital devices, process information in parallel, and play games frequently. For this generation, video games have become a medium for entertainment, for socializing, performing collaborative activities, and also for learning (Gallarneau, 2005). On the other hand, traditional teaching does not always acknowledge the needs of this new generation and, as a result, learning in traditional settings is often perceived as boring or unappealing. Furthermore, digital natives develop skills that are not always acknowledged or measured by traditional instruction. For example, the Flynn effect suggests that

young children's IQs are constantly increasing but their academic results in mathematics are still poor.

The development of educational games has served the purpose of creating content that is both appealing and educational for this new generation. Using these games, players learn by doing and by experimenting in a constructivist manner. Indeed, video games represent ideal learning environments in which users can improve their skills and learn in a safe and controlled manner. They often implement well-known instructional strategies such as social learning, discovery learning, or zone of proximal development (Vygotsky, 1978). According to Gee (2004), a variety of learning principles are built into good video games. Such skills include critical learning, design principles, semiotic principles, and semiotic domain principles.

Despite an unsuccessful start with edutainment technology (education + entertainment), serious games are now much more appealing and can compete with commercial off-the-shelf (COTS) games thanks to more affordable and manageable technology (of e.g., game engines). They are increasingly accepted as a truly potential educational medium (Van Eck, 2006). However, despite promising features, there is a lack of experimental studies on their effectiveness at both motivational and educational levels. The findings on their effectiveness are often contradictory and the evaluations anecdotal, descriptive, or judgmental (Leemkuil, De Jong, & Ootes, 2000), and there is no consensus on a common standard for the design of educational games (Squire, 2002).

The authors suggest that one of the reasons for the discrepancy in the design techniques used and the results collected is that users differ in their personalities and learning styles. They believe that, because users' personalities dictate the way they interact in the game and ultimately the way they learn, there is a need to tailor the content in a way that appeals to each user and that promotes learning activities. Because video games represent a highly emotional experience as well as a structured problem-solving system, their potential

can be employed in a "user-centred" approach, to provide educational content that individually stimulates users' emotions and cognitive skills. The expectation is that by "reaching" students and adapting to their needs, the learning activity will be seamless and more effective.

User-Centred Approaches to Improve Educational Games Design

For a long time, traditional teaching methodologies focused on the content and educational objectives rather than the user. Because students have different expectations, preferences, and learning styles, a given educational content might not be effective across a wide range of students. User-centred learning offers a shift from traditional methodologies; it allows tailoring of teaching methods and content to users. In such environments, users' preferences, abilities, and reactions are evaluated and accounted for to maximise the learning outcomes (Levine, 1999).

Students Have Different Needs and Abilities

Students often differ in their predisposition for particular topics. These different approaches to learning can be illustrated by the theory of multiple intelligences, introduced by Gardner (1993), who proposed the existence of eight (initially seven) autonomous intelligences: linguistic (e.g., reading and writing), logical (e.g., problem-solving and mathematics), musical, visual/spatial (e.g., arts and map reading), bodily/kinaesthetic (e.g., sports), interpersonal (interpersonal skills), intrapersonal (knowing about one's strengths and weaknesses), and more recently naturalistic (e.g., enjoy learning about plants and animals). This theory has been gradually accepted in the educational system as a means to provide different approaches to teaching. The eight intelligences allow educators to "reach" students more easily, to adapt to their learning styles, to allow them to "grow", and is

particularly relevant for students with disabilities or special needs. The introduction of ICT and multimedia technology in schools has provided a means to accommodate different learning styles and to apply this theory. For instance, the use of video accommodates students with visual/spatial intelligence, whereas storytelling accommodates students whose primary intelligence is linguistic.

Throughout their childhood, children can possess and develop special abilities for topics such as sciences or languages. Research has found that infants have a clear understanding of basic biological and physical concepts or early numbers. For instance, they understand that objects need support not to fall, or that animated objects have the potential to move but inanimate ones don't (Bransford, Brown, & Cocking, 2000). They can also see a difference in the number of items represented. Children develop an early attention to language and gradually distinguish language differences. They actively attempt to understand the language spoken around them by making sense of what they are told in a particular environment. However, they need to practice actively to improve their language skills.

Yet, if children's abilities for "preferred subjects" can improve and speed up the way they learn, these abilities can prove to be problematic for topics that they do not prefer because their perception needs to adapt to new concepts (e.g., whole numbers and fractions).

ICT Should Accommodate Different Learning Styles

Children regularly use digital technologies that allow for a high degree of personalisation, and they ought to avail of learning environments that also meet their personal needs and expectations (Green, Facer, & Rudd, 2006). Focusing on users' needs can help improve educational outcomes because effective teaching strategies are those that focus on the learner. Therefore, the focus of modern education should be on meeting and

respecting each student's diversity and unique talents (Lambert & McCombs, 2002). Learner-centred teaching methodologies can prevent common problems encountered by traditional teaching such as boredom, fear of failure, lack of relevance, or lack of interest in the topic taught. Such methods are effective because they address users' needs at both cognitive and meta-cognitive levels, but they also account for their motivation, emotions, and individual differences (Lambert & McCombs, 2002).

User-centred learning can promote students' motivation and achievements. More importantly, it can help in the design of better educational games by addressing some inherent design difficulties such as the use of intrinsic/extrinsic motivation, linear/open/ended content, and so forth.

For example, on the one hand, it is felt that serious games should be developed so that players enjoy learning with no need for extra motivation (intrinsic learning). It is believed that rewards do not always guarantee motivation and they won't make-up for an uninteresting game (Alessi & Trollip, 2001; Becta, 2001). Mitchel & Savill-Smith (2004) support this view and believe that the structure of a video game is likely to have more impact on players' motivation than the game content itself. On the other hand, Rouse (2001) believes that users' accomplishments should be rewarded (extrinsic motivation) to keep them both confident and motivated.

However, the motivation to play an educational game, be it learning, fun, socialisation, and so forth, varies across users, and the correct use of extrinsic or intrinsic motivation should be based on the player. As suggested by Rouse (2001), the ideas associated with winning the game should appeal to each user and fulfill their motivation for playing: competition, learning, associating oneself with a character, working in teams, or being part of an imaginary group. This suggests that knowing a user's motivation and personality can help to create a learning environment in which they are willing to stay. The following section ex-

plains how psychology can be used to understand players' motivations and allow the game content to be adapted accordingly. It also explains how emotions improve the cognitive process.

ADAPTING CONTENT TO USERS' PERSONALITIES CAN IMPROVE EDUCATIONAL OUTCOMES

Players' Personalities Affect Their Behaviour in Video Games

New Understanding of the Relation between Games and Personalities

When video games first appeared as a mass-entertainment medium, they suffered from many stereotypes and it was believed that they had a negative influence on players' behaviours and health (eyestrain, neck pains) and to cause isolation (players reluctant to engage in social activities), violence (game as a motivation and vector of violent behaviours), sexist and homophobic behaviours, and the inability of the players to dissociate themselves from the content of the game. Some of these assumptions were unfounded. Studies showed that children are able to distance themselves from the game they are playing and that they can also decipher the games' goal and main components (Howard, 1998). Additionally, it was revealed that games, like any other activity, could be damaging if they were used beyond a reasonable period of time. Health issues might arise but mostly because of inappropriate use (Mitchel & Savill-Smith, 2004).

As noted by Jenkins (1993), it was felt that educators and parents needed to understand the potential of games at a less superficial level and to situate games in a social and educational context. There has been a shift from the initial preconceptions, and some researchers have been focusing on harnessing the emotional and psychological effects of video games for therapeutic or edu-

cational purposes. For the latter, the idea is that students' personalities dictate their preferences for games and also determine their objectives within the game. Knowing how players might react to stimuli at a cognitive or emotional level might help to customize their experience and hence make the educational game more effective.

It is now agreed that playing video games is a very personal experience, and that motivations for playing, as well as goals and source of enjoyment in video games, can vary across users (Griebel, 2006). Users play video games to prove themselves, for social interaction, for acceptance, to exercise, to improve their skills (Crawford, 2003; Salen & Zimmerman, 2003) but also to fulfill emotional needs (Lazzaro, 2004). However, as suggested by Freeman (2003), games often lack the emotional depth found in movies. He has therefore designed a set of techniques, borrowed from the film industry, aimed at improving the emotional experience in games so that users feel more engaged and emotionally fulfilled. Techniques to improve emotional depth include: dialogues, characters, relationships, game moments, and plots. Even if this approach has the potential to increase users' experience, it was suggested that it should be applied more systematically in order to offer an efficient yet easy-to-follow framework for deeply emotional video games (Kane, 2004). Creating emotions in games also raises the issue of determining the state of users' emotions to adapt emotions accordingly (Perron, 2005).

Profiling Players

Some recent studies have tried to categorise users' profiles (Rosewater, 2006) to understand their motivation and predict their actions. Bartle (1996) identifies four types of players in MUDs (multi-user dungeons):

- **Achievers** strive to gather points and progress to higher levels.

- **Socializers** are interested in people and inter-player relationships. They often sympathise and empathize with other players.
- **Explorers** are willing to understand the game mechanics and to discover new ideas or locations.
- **Killers** enjoy imposing themselves on others and particularly causing distress or pain to other players.

It was suggested that this categorisation lacked accuracy because the four types may overlap and also because the factors associated with each of the traits might not be describing the full spectrum of motivations behind MUD players' actions (Yee, 2002). In a study based on the work of Bartle, Yee (2002) identified five factors that could explain players' motivation in MMORPG (massively multi-player online role playing game): relationship, immersion, grief, achievement, and leadership. This categorisation was further refined (Yee, 2007) as "achievement" (advancement, game mechanics and competition), "social" (socializing, relationship, and teamwork), and "immersion" (discovery, role-playing, customization, and escapism). It proved that, contrary to the ideas of Bartle, players could belong to more than one category; the study also showed that the tendency for socialization is gender independent but that the goals behind socialization differ between genders.

Video game players' profiling is at an early stage and evidence suggests that traditional psychological personality models such as MBTI (Myer-Briggs Type Indicator) and 5-Factor can be used for user profiling. They can be applied to explain and predict some of the user's behaviours in games and in particular in educational games. According to Hopson (2001), psychology can offer a framework to help understand players' reactions in video games. Conati and Zhou (2003) show that pupils' personalities, as measured in the light of the Big-5 model, influence their behaviour, goals, and actions within educational games (e.g., some want to have fun and to learn

whereas others strive to avoid losing). Griebel (2006) shows that some players project part of their personality in their player character (PC) and that their playing style is directly affected by their dominant personality trait.

About Personality Traits

The field of personality addresses human individual differences and uniqueness. It accounts for consistent patterns of thinking, feeling, and behaving (Pervin, Cervone, & John, 2004). It helps to explain individuals' characteristics, their origins, and consequences for their behaviour. In psychology, individuals can be analysed and categorised through personality types or personality traits. For the former, people can be classified under a number of personality types, while for the latter, individuals are assigned to a position in a 5-Dimensional space.

Introduction to the 5-Factor and MBTI Models

The MBTI and 5-factor models are two of the most well-known personality models. They provide a way to measure personality and also provide a framework to predict associated behaviours. Studies have focused in particular on how users learn and seek information based on their personality traits. Such findings could be directly applicable to educational games should they account for player's personalities.

In the 5-factor model, researchers try to find basic units of personality by analysing the words that people generally use to describe themselves. It includes five personality traits: openness (eager to learn and open to new experiences), conscientiousness (hard worker), extraversion (enjoys social interaction), agreeableness, and neuroticism (prone to stress). The 5-factor model is also referred to as the Big-Five, because each of the five factors or traits includes a number of more specific traits. Goldberg et al. (2006) initiated this model

and McCrae and Costa (1992) then developed a personality test called the NEO-PR-I to evaluate the Big-Five personality factors. The NEO-PR-I can easily be transferred to an online personality test in the form of the IPIP (International Personality Item Pool). The IPIP (2006) provides a means to obtain personality profiles based on 50 or even 20 questions (Donnellan, Oswald, Baird, & Lucas, 2006). The former format provides relatively accurate results, while the latter is less precise but easier to include within an educational game (e.g., questions asked by a non-player character).

The MBTI (Myers Briggs Type Indicator) categorises personalities as: extraversion-introversion (E-I), sensing-intuition (S-N), thinking-feeling (T-F), and judgment-perception (J-P). It has been the subject of a wide range of studies, especially those establishing links between personality traits and learning styles. It is less practical to use for online questionnaires, but there is a correlation between the two models (McCrae & Costa, 1989): E-A and S-N are strongly related to extraversion and openness (respectively -0.74 and 0.72) whereas T-F and J-P are more weakly related to agreeableness and conscientiousness (respectively 0.44 and -0.49). The emotional stability dimension of the Big-5 is largely absent from the MBTI. Also, this model does not account for the emotional state of the user, which is represented by the neuroticism trait in the 5-factor model.

Learning Styles

A significant amount of literature has been dedicated to predicting behaviours, learning styles, and preferences linked to specific personality traits (Briggs-Myers & McCaulley, 1985; Heinström, 2003; Keirse, 1998). The following summarizes the state of the research so far and draws some conclusions for the design of successful user-centred educational games:

- **Neuroticism:** Users with a high level of neuroticism often consider lack of time as

a barrier. They need to increase their control and it is better to show them documents that confirm previous knowledge or ideas.

- **Extraversion:** Users with a high level of extraversion tend to privilege social activities but find solitary activities difficult and seek information through peers. They learn better by explaining to other students, they have a preference for thought-provoking documents and discussions and visible results. However, extraverted students do not tend to be systematic and often don't perform deep analysis of the material given.
- **Introversion:** Introverted students seek to interconnect knowledge relevant to the subject in hand. They like chunking, grouping, and interconnecting data. They learn best through quiet mental reflection and prefer reading, lectures and written work to oral work. Also, they prefer independent work and need sufficient time to process information.
- **Openness:** Users with a high level of openness are naturally curious and have a critical mindset. They are eager to find information (ideally from different sources), enjoy discovery learning, and as a result are open to accidental discovery. They focus on general concepts (they see the "big picture") and tend to forget about the details unless they relate to a pattern. Users with a high level of openness enjoy new material, and find repetition boring once they have understood the pattern. Ideal environments for this type of student should allow for creativity and provide them with different ways to solve problems.
- **Conservatism (Low levels of Openness):** Conservative students prefer clearly and recently written documents recommended by teachers and they like linear, structured and organized information. They learn through their senses, and because they are

very practical, they like to learn material related to real-life situations.

- **Agreeableness:** Users with a high level of agreeableness enjoy working in harmonious groups, they feel rewarded when they can help others but they can have difficulty when the material does not relate to people, human values, or relations.
- **Competitiveness:** Users with a high level of competitiveness like clear course and topic objectives. They are usually good at problem solving and enjoy feedback on their objective and achievement. They show a base for sceptical and critical thinking but can easily become impatient during learning activities.
- **Conscientiousness:** Users with a high level of conscientiousness are often willing to work hard to achieve their goal. They are ready to seek, analyze, and reconsider information.
- **Easy Going Students (Low Level of Conscientiousness):** Easy going students tend to be impulsive, easily distracted, careless, and hasty. They have a predilection for information that confirms their previous knowledge and their choice is often guided by a need for a quick answer. Because they reach conclusions too quickly, it is advisable to challenge their knowledge, to encourage them to consider pros and cons of the answer and to consider alternative solutions.

Users' Emotions Can Affect Learning

Before the appearance of formal education, learning was often passed through generations thanks to storytelling; This format was more engaging for learners as it often triggered an emotional response and hence more involvement from the audience (Decastel, 1999; Kort, 2005). However, for many years, learning in formal education has been perceived as a purely cognitive activity

where emotions were interfering with rather than helping the learning process. It is only in recent literature that the impact of emotions on learning has been acknowledged and built into learning models and strategies. Emotions can increase our receptivity to information; they keep us focused, interested, and durably linked to the information we are processing. They affect our memory and our cognitive process and can also be used for self-motivation. The next section describes how emotions can affect the cognitive process and memory.

Emotions and Memory

Research suggests that stimuli that create emotional responses tend to be more easily remembered than those that don't (Rapaport, 1950). Emotions can have a positive or negative impact on memory depending on the learners' emotional state and on the emotional content of the learning material. According to Parrott and Spackman (2000), there are three factors that govern the link between emotions and memory:

- The quality of the material to be remembered (content);
- The emotional state of the user when encoding information (encoding); and
- The state of the user when recalling information (recall).

There is an interaction between these three characteristics. Users' existing emotions and emotions elicited by the content can interact to impact positively or negatively at encoding or recall. This gives rise to three types of interaction:

- **Mood-congruent encoding:** Learning is increased when emotions conveyed by the content match user's emotions and moods. At the time of encoding, intense emotions can improve memory for central details.

- **Mood congruent recall:** Learning is increased when the user's emotions match the emotions conveyed by the content to be recalled. Recall is usually better for positive moods than for negative moods (Singer & Salovey, 1988).
- **Mood-independent recall:** Memory is increased when the mood of the user at the time of recall matches their mood at the time of encoding. This is particularly efficient for users with relatively stable moods.

It is also interesting to note that individuals tend to prefer stories that match their present mood (Green, 1997).

Positive and Negative Emotions

Emotions can facilitate thinking, and it was shown (Salovey, Bedell, Detweiler, & Mayer, 2000) that: (1) addressing a problem while in different moods might enable individuals to consider this problem from different perspectives, and (2) emotions create different information processing styles. Positive moods promote creativity and an open-minded approach whereas negative feelings are usually characterised by a slow problem-solving process associated with more focused and deliberate strategies.

The influence of emotions on cognitive tasks depends on the task in hand (Isen, 2000). For example, positive emotions tend to promote exploration and openness especially in safe situations whereas in dangerous situations, individuals tend to act more cautiously. It has been accepted for a long time that positive emotions had a positive bias on perception and memory whereas negative moods resulted in negative distortions.

Being in a good mood does not necessarily lead to better cognitive performance, and it was shown that tests or activity requiring executive functions (forward planning and sequencing of events) was disrupted by a positive mood (Carlson, Buskist, & Martin, 2000). Furthermore, according to Stege,

Tergwogt, and Koops (1994), positive moods have a more important impact on cognitive processes than negative moods. This asymmetry in the effect of emotions tends to level off as people grow up because they learn strategies to cope with negative feelings (mood repair).

Using Emotional Intelligence to Increase Cognitive Efficiency

Whereas emotions are often a reaction to our environment, some persons have the ability to use these emotions for motivation purposes. For example, while some students might strive to remain positive about an exam and reassure themselves about the outcome, other students who often work better under pressure use the idea or prospect of failure as a motivation to meet deadlines (Salovey et al., 2000). Such persons can be described as emotionally intelligent because they use their emotions strategically.

Emotional intelligence (EI) refers to the ability to perceive, appraise, and express emotions, the emotional facilitation of thinking, understanding, and analysing emotional information and regulating emotions. Individuals create strategies that affect their emotions and learning abilities, and their motivation as a result. Individuals' abilities to control their emotions increase as they mature. EI is considered to be an important factor for academic success as it helps with self-motivation and mood management (Goleman, 1994).

A Review of Educational Models Based on Emotions

As emotions have become more accepted for educational applications, several instructional design methods that include emotions have been developed such as: FEASP, ARCS, or CEO. They acknowledge the effect of emotions on learning and propose theoretical frameworks for sound emotional educational environments.

- The ARCS model is an instructional model based on motivation. Its core component covers: attention, relevance (intrinsic motivation), confidence, and satisfaction. It aims at encompassing the necessary conditions to motivate learners. It is more relevant in a corporate setting and, as opposed to the flow theory, the motivation is extrinsic rather than intrinsic.
- The CEO model is developed for Web-based education and emphasizes safety, challenge, and new thinking (MacFadden, 2000). It develops support for safety (support, acceptance), challenge (confusion, anxiety, frustration, disequilibrium), and new thinking (“ahah” moments).
- The FEASP model (fear, envy, anger, sympathy, pleasure) (Astleitner & Hermann, 2000), promotes the creation of instructional experiences based on positive feelings. It aims at reducing negative feelings (FEA) and at increasing the positive ones (SP).
- Regardless of the learner’s initial emotional state, a learning experience is often emotionally dynamic because the learner feels various emotions: curiosity, fascination, surprise, anxiety, confusion, bewilderment, frustration, anguish, chagrin, hope, perplexity, elation, satisfaction, and confidence. Experiencing a mix of feelings is necessary to progress, to make sense of our experience and to accelerate the learning process (Kort, 2005). The idea of experiencing a mix of positive and negative feelings and the ones developed in the FEASP model are, however, not contradictory. The FEASP model focuses on the learning environment (not on the content), providing safety, collaboration opportunities, a reduction in users’ frustrations and a feeling of fairness. It allows learners to experience a mix of feelings but in a safe and controlled environment.

More recently, attempts have been made to create educational games models that combine instructional design, game design, and also account for user’s emotions. Kiili (2005, 2006) offers a model for educational games that combines both instructional design and the flow theory. It provides players with both meaningful challenges and educational tasks. Amory and Seagram (2003) and Amory (2007) believe that educational games should be based on sound educational theories and have developed an object-oriented model that combines game development and instructional design. The GOM (game objective model), POM (personal outlining model), and the GAM (game achievement model) address students’ motivation and educational goals. They help to develop non-linear games and to meet educational objectives. However, this approach seldom accounts for a user’s preferences and learning style.

Video Games as Sound Emotional Experiences

Video games can be described or analysed through the instructional models mentioned in the previous section, and as such provide an emotional dimension that can help learning. As described by Crawford (2003) they can be compared to an emotional rollercoaster where users experience a wide range of emotions but always in a safe environment. They are in-line with the FEASP model because they reduce the negative feelings linked to the environment (ease of use, interface, computer crashing, etc.) and increase positive feelings such as sympathy and pleasure. They also provide attention, relevance, and confidence by means of easy learning curves.

Consequences for Game Design: Guidelines for User-Centred Educational Games

The following section interprets the findings reviewed previously and discusses the conse-

quences for educational game design. It contrasts user-centred approaches with traditional game design techniques.

Using Emotions to Improve the Cognitive Process

In the previous section, the authors have explained how emotions can impact on the cognitive process and how some strategies can be applied to accommodate students. However, detecting user's emotions can be very difficult. Despite the existence of techniques to detect facial expressions, very few studies have successfully managed to detect emotions based on standard devices (mouse, keyboard, colour-selection, icon selection, keystroke intensity, etc.). Inducing an emotional state in a user can prove to be difficult. However, evidence has shown that when presented with visual and audio information, the latter was predominant (Anderson & Casey, 1997), suggesting that audio information could be used effectively to induce an emotional state in a user. Freeman (2003) also suggests that the use of symbols or dialogues within the game can be used to elicit particular emotions.

Emotions in educational games could be used as follows:

- Increase memory retention: Mood-independent encoding and recall might be efficient for users with a low level of Neuroticism (stable mood). Inducing in them a particular mood at the time of encoding and recall should improve memory (recall).
- Using NPC dialogues, users can be either reassured about their results (users with a high level of Neuroticism) or challenged to do better (users with a high level of Competitiveness).
- Use positive emotions to support creative activities (open-ended strategies).
- Spend a considerable amount of time play-testing so that frustrating issues are avoid-

ed (e.g., game crashing often, game not adapted to the platform).

- Demonstrate the game in the classroom and provide helpers that can explain the game if needed.
- Design the game with the target population in mind (age group, gender, skills, etc.).

Customizing Information Content and Structure to Players

Information in video games can be managed in many different ways:

- Information “flow” and feedback: By managing the flow of information in a game it is possible to inform users and increase their motivation. Four types of information can be provided to users: accurate, misleading, partial and false (Alessi & Trollip, 2001; Teem, 2001). If designers want to increase challenge and motivation for users with a high level of openness or competitiveness, they can provide misleading, partial or even false information. Students with a high level of openness will find an opportunity to use their critical thinking abilities and curiosity. This is particularly effective in games where the player is investigating as a detective. However, in this case, players should be made aware of the possibility of the computer using false information. For students with a high level of neuroticism, accurate information that conforms to their previous knowledge will be more effective. Feedback should be given to users in obvious forms to enable them to reflect, reconsider, discuss options, and develop successful strategies (Becta, 2001). Players should be made aware of their progress, and information such as ranking should be used, especially for users with a high level of competitiveness.

- Learning about the game using booklets and built-in demo levels: Game designers often proscribe the use of booklets, as they believe that users ought to learn solely by playing (Rouse, 2001). On the other hand, Alessi and Trollip (2001) advise that booklets be available to players. In the light of educational theories, students with a high level of neuroticism, conservatism, or introversion would benefit from booklets that refer to information previously learnt during classes and provides them with a sense of control. However, students with a high level of extraversion might prefer to ask their peers instead. In this case, referring students to booklets might prove inefficient. Moreover, students with a high level of openness will enjoy a demo level where they learn the game mechanics. The same applies to students with a low level of openness because they are very practical.

Customizing the Game Play Using Linear and Open-ended Content

The game structure plays a significant part in players' involvement and motivation. According to Alessi and Trollip (2001), the game structure is one of the keys to a good educational game. Aldrich (2001) identifies three types of content: linear, cyclical (drill and practice), and open-ended. Non-linearity provides more interaction and allows players to reach their objectives in different ways, giving them more choice and hence making the game more fun (Rouse, 2001). One of the best ways to achieve an entertaining game is to implement interactive storytelling mixing linear and open-ended content so that the players enjoy both an interactive/immersive experience but also the dramatic qualities of the story.

Linear content might be especially suitable for users with a low level of openness because they like clear objectives and structured material. On the other hand, open-ended content might ap-

peal more to users with a high level of openness who show a high degree of creativity and enjoy exploration. Techniques to implement non-linear game-play can apply to both game structure and content. They include:

- Storytelling, multiple solutions (different ways to achieve a goal).
- Dialogs with NPCs: This option might be especially suitable for users with a high level of Agreeableness if the NPC relates to people and if the player is asked for help.
- NPC behaviours
- Books: Finding a book (or any written material) within the virtual world might be best appreciated by users with a high level of introversion because they enjoy written work.
- Computer terminals

Although repetition drills can be useful, especially for users with a high level of neuroticism (it increases their confidence), users with a high level of openness might rapidly find them boring. Alternative learning opportunities based on exploration and discovery should be put in place for these users.

A Case Study on the Effects of Users' Personalities in Educational Games

In March 2006, the authors conducted a study in two Cork secondary schools in order to evaluate the impact of student's personalities on the design of educational games. It was aimed at assessing two hypotheses formulated by the authors:

1. Displaying time in educational games impacts negatively on users with a high level of neuroticism; and
2. Displaying ranking information impacts positively on users with a high level of competitiveness.

The authors developed an educational game called MathQuest using Java3D. This game was designed to teach mathematics. It featured a 3-D-maze in which players had to navigate and find the exit to the next level in less than 12 minutes. Each level included a set of doors that players had to open to progress further in the game. To open a door, players had to solve a linear equation. Solving an equation consisted of 5-6 steps.

While progressing through each step to solve equation, information was recorded such as time to solve the equation, success rate, and so forth. The game included a tutoring system that followed student's progress throughout the game and that provided them with feedback. In the first level, the system assessed students' skills in solving a linear equation and determined what skills needed improvement. Data recorded in the game were saved on a remote server for further analysis.

The game was designed to change its content (time displayed, feedback, and ranking information) according to players' personality and to record their progress.

Points were awarded to players based on:

- Their proficiency at solving equations (each successful step in solving an equation was rewarded); and
- The number of levels achieved (bonuses were given at the end of each level based on how fast they completed the level; the faster the more points were awarded). The score for each user was updated regularly on the remote server and the ranking was updated accordingly.

Eighty 1st and 2nd year secondary school students took part in the study. They were identified with a unique ID composed of the initials of their teacher, a number corresponding to their class, and another random number (e.g. RF_01_02). This ensured that the results of the study would be totally anonymous.

The pupils initially took an online personality test developed by the authors and based on the IPIP. It consisted of 50 questions. The students were identified only with their ID and the results were stored in a remote database. Results for the test were assessed for their validity and reliability and proved to fulfil both criteria. Reliability of each personality test (Lumsden, 1976) was evaluated using the split halves method ($P(23) > 0.648$; $p < 0.05$). Validity measurement (overuse of the same answer and social desirability) showed that only two students overused the same answer, and two students answered in a socially desirable manner.

Following the personality test, pupils were divided into four groups according to their personality profile: one experimental group (A) and one control group (B) for each of the hypotheses.

- Students with a high level of neuroticism were used to assess the first hypothesis [Displaying time in educational games impacts negatively on users with a high level of neuroticism] and were assigned to either group A1 or B1.
- Students with a high level of competitiveness were used to assess the second hypothesis [Displaying ranking impacts positively on users with a high level of competitiveness] and were assigned to either group A2 or B2.

Conducting the Study

The study was conducted as follows:

- Users did a 10-minute written test on equations
- Users played the game for 25 minutes
- Users did a 10-minute written post-test on equations

Both pre- and post-tests were created in accordance with the Irish curriculum. The game was

initially demonstrated to the pupils so that they could gain a basic understanding of what was expected from them and how to use the different controls in the game. Helpers were available during the game. They were composed of the teacher, the authors and 3-4 5th year students who had been previously acquainted with the game. Users were equipped with headphones and played the game individually (one computer per student). They were asked to raise their hand should they have a question.

As mentioned in the previous section, the game adapted the content according to the user's personality:

- At the start of the game, users were asked to enter their ID.
- The game would then connect to a remote database, retrieve the users' personality traits and group (A1, B1, etc.).
- For the students belonging to the group A1 (experimental group for the first hypothesis), there was no time limit and as a result no time was displayed on the screen during the game.
- For the students belonging to the group B1 (control group for the first hypothesis) a countdown was displayed at the top left corner of the screen.
- For the students belonging to the group A2 (experimental group for the second hypothesis), no information on their current rank was displayed on the screen.
- For the students belonging to the group B2 (control group for the second hypothesis), player's rank was displayed on the screen in real time (e.g. 2/80).

Results of the Study

The data recorded and used to assess the two hypotheses were as follows:

- Pre-test
- Post-test
- Average time to solve an equation in the game
- Number of equations solved in the game

In the light of the data collected, the results were as follows:

- The first hypothesis (displaying time in educational games impacts negatively on users with a high level of neuroticism) was not supported. Instead the results showed that, on average, students for whom time was displayed in the game had improved their academic results more significantly than students for whom time was not displayed (respectively 81% and 43%). Moreover, a statistical analysis of the results using the Mann-Whitney test showed that displaying time in MathQuest had increased players' proficiency at solving equations ($U(14,12)=39$; $p<0.05$) as well as their confidence ($U(8,5)=1$; $p<0.05$)).
- The second hypothesis (displaying ranking in educational games for subjects with a high level of competitiveness increases their proficiency in solving mathematical equations) was partially supported. Raw data showed that on average, subjects for whom ranking information was displayed had improved their test results more significantly than students for whom ranking was not displayed (respectively 15% and 11.3% improvement). Also, the former seemed to have become more proficient at solving equations than the latter as the average time to solve an equation in the game was lower for the former than for the latter (respectively 41.92 seconds and 82.37 seconds). These results, however, were not supported by a statistical analysis probably

due to the small number of subjects available to assess this hypothesis.

Discussion

Whereas the first hypothesis was not validated, the authors noticed that more than 65% of the subjects (17 out of 26) who belonged to both group A1 and group B1 and who had played the game also possessed a high level of competitiveness. It suggests that when subjects possessed high levels of both competitiveness and neuroticism traits, displaying the time for these students acted as a motivating factor rather than a constraint. This study has shown that user profiling can be difficult due to the fact that users have several prominent personality traits rather than one. It has also illustrated that traditional personality models and educational theories offer a good starting point to understand how users learn and behave in educational games, but further research is needed to refine these models when applied to educational games.

CONCLUSIONS AND IMPLICATIONS

General Implications

Students have different learning styles and needs due to their different personalities. ICT should accommodate these learning styles with tailored educational content. By doing so, students' motivation can be increased as well as the educational outcomes. Despite pre-conceptions about the negative effect of games, it is now clear that games can have a positive impact on users' behaviours and emotions. They help users to feel better about themselves and also to engage in creative, educational and social activities.

Developers need to harness this potential to create software that is both entertaining and educational. However, since the field of educational games is still at an early stage there is a lack of

models to increase both educational effectiveness and emotional depth. User profiling allows the creation of a more personalized and engaging experience by predicting users' behaviour and adapting the content to their emotional needs. Models created by Yee offer a promising start; however, educational game development could benefit significantly from the use of existing psychological models such as the MBTI or the Big 5. Serious game developers can also benefit from existing research dedicated to user-centred teaching and learning. By combining these two approaches, we can obtain educational games that are firmly grounded in both educational and psychological theories and that offer reliable and reproducible results.

Furthermore, since games represent rich interactive and emotional experiences, emotions should be used to increase not only enjoyment but also the cognitive process through NPCs, sound, and dialogues. More emphasis should be put on developing frameworks to increase emotions in games, and use them as a cognitive support tailored to individuals needs. Games are systems that provide information, emotions, a high level of interaction and a story line that can be delivered in many different ways. All of these should be tailored to users' personality and needs at both emotional and cognitive levels.

Studies should be designed not only to evaluate user's motivation and learning outcomes but also to draw correlations between users' personalities, game design features and educational outcomes. However, as suggested by Rittel and Webber (1973), learning is a "wicked" problem; many factors can contribute to or interfere with the learning process and cause inconsistent results across experiments. Such inconsistencies can be caused by experimental design flaws, as suggested by Brown, Fisher, and Brailsford (2007):

- Questionnaires on learning styles lack reliability and validity and can invalidate results collected during the experiments.

- Control groups are not always used but doing so would limit placebo effects.
- Studies do not always employ “*real users*” and, as a result, the findings cannot reliably be generalized.
- Observation time is too small (longitudinal studies are preferable for long time effects).
- Subjects are not always naïves and they should be selected at random.
- Models usually adapt to user’s previous knowledge but should focus on their learning style.

Consequences for Researchers

Researchers need to focus on longitudinal studies using well-known reliable and valid tools to assess users’ personalities and learning styles so that results are consistent and easily reproducible on a larger scale. Further studies need to be carried-out to categorise more accurately game players and learners. However, traditional psychological personality tests such as the MBTI or the Five-star model and the work of Yee (2007) offer a good starting point.

Consequences for Policy Makers

Policy makers need to consider video games as an effective tool for education. Time should be set aside for teachers to become familiar with this technology so that they can play, explain the game, and animate de-briefing sessions which offer an opportunity for pupils to relate their experience and share their understanding of the concepts explained in the game.

Multi-disciplinary teams that include teachers, developers, and psychologists should be formed to provide an approach that provides a better understanding of the learning process at motivational, cognitive and emotional levels.

Consequences for Developers

Developers should offer games with a wide range of educational opportunities and diversity to motivate players and accommodate different learning styles (Becta, 2001; Mitchel & Savill-Smith, 2004). They should offer a combination of both linear and open-ended content, a choice of interfaces (e.g., various combinations of video, audio and text, use of colour, etc.), and a choice of character (both female and male). Serious games should account for ethnicity differences, offer a range of themed activities relevant to a wide range of interests and skills, and include alternative input/output for people with special needs.

Serious games should also include built-in processes to detect and accommodate user’s preferences. At a cognitive level, this can be implemented using intelligent tutoring systems; however, at an emotional level, traditional gaming techniques such as dialogues, sound, and video, should be used to provide a more convenient approach than questionnaires.

KEY TERMS AND DEFINITIONS

Big-5: The Big-5 is an instrument used in psychology to measure subjects' personality traits in a 5-D space.

Emotional Intelligence (EI): Refers to the ability to perceive, appraise, and express emotions, the emotional facilitation of thinking, understanding, and analysing emotional information and regulating emotions.

Information and Communication Technology (ICT): In the context of education, it includes any communication devices and applications such as: radio, video, mobile phones, computers, and network hardware and software used to enhance the learning experience.

Intelligent Tutoring System (ITS): Used in educational software to replace a human tutor.

Myer-Briggs Type Indicator (MBTI): The MBTI is an instrument used in psychology to measure subjects' dominant personality type.

Non-Player Character (NPC): Character in a computer whose actions are not controlled by a human player.

User-Centred Learning: Learning environment that accounts for users' preferences, abilities, and reactions to maximise the learning outcomes.

Chapter 5.12

Students' Attitudes toward Process and Product Oriented Online Collaborative Learning

Xinchun Wang

California State University, Fresno, USA

ABSTRACT

Although the pedagogical advantages of online interactive learning are well known, much needs to be done in instructional design of applicable collaborative learning tasks that motivate sustained student participation and interaction. In a previous study based on a Web-based course offered in 2004, Wang (2007) investigated the factors that promote sustained online collaboration for knowledge building. By providing new data from the same Web-based course offered in 2006 and 2007, this study investigates students' attitudes toward process- and product-oriented online collaborative learning. The analysis of 93 post course survey questionnaire data show that the overwhelming majority of students have positive experience with online collaborative

learning. Data also suggest that students are more enthusiastic about process-oriented tasks and their attitudes toward product-oriented collaborative learning tasks are mixed.

INTRODUCTION

The pedagogical advantages of student interaction in collaborative construction of knowledge are grounded in the social constructivist perspective of learning. From the social constructivist perspective, all learning is inherently social in nature. Knowledge is discovered and constructed through negotiation, or collective sense making (Duin & Hansen, 1994; Kern, 1995; Wang & Teles, 1998; Wu, 2003). Pedagogically sound tasks in an online learning environment should, therefore, reflect social learning and facilitate interactive learning and collaborative construction of knowledge.

DOI: 10.4018/978-1-60960-503-2.ch512

Interactive Learning and Factors Influence Online Collaboration

From a student's perspective, online interaction in learning takes place at two different levels: interaction with the contents, including interactive computer software and multimedia system, and interaction with instructors and between peers (Evans & Gibbons, 2007; Gao & Lehman, 2003). There is evidence that pedagogically well-designed interactive learning tasks actually increase rather than decrease student access to instructors; increase interactions between instructors and among students; and increase students involvement of course content as well (Lavooy & Newlin, 2003; Mouza, Kaplan, & Espinet, 2000; Wu, 2003). Interactive learning tasks also promote greater equality of participation (Mouza, Kaplan, & Espinet, 2000), more extensive opinion giving and exchanges (Summer & Hostetler, 2002), empower shy students to participate, and promote more student-centered learning (Kern, 1995; Wang & Teles, 1998)

At the level of interaction with content, students benefit more from producing explanations than receiving explanations. Such proactive learning engages students in a higher level of thinking than the reactive type of learning (Gao & Lehman, 2003; Wu, 2003). Additionally, students who reported high levels of collaborative learning in an online course tend to be highly satisfied with their learning and they also tend to perceive high levels of social presence in the course (So & Brush, 2007).

Despite these advantages, research also indicates that online interactive learning and collaboration are not always sustainable and students' participation in Computer Mediated Communication (CMC) tasks may wane after the assessed tasks that require the postings are completed (Macdonald, 2003). In a survey on college student's attitudes toward participation in electronic discussions, Williams & Pury (2002, p.1) found that "contrary to much literature on electronic collaboration suggesting students

enjoy online collaboration, our students did not enjoy online discussion regardless of whether the discussion was optional or mandatory." Like any other form of learning, learning collaboratively in an online course is also characterized by individual differences. Collaboration as a process of participating to the knowledge communities is not an equal process to all the members of the community (Leinonen, Järvelä, & Lipponen, 2003). Much needs to be done to explore factors that promote sustained student interest in online interactive learning and collaboration.

One challenge for developing sustainable online collaborative learning tasks lies in the nature of the CMC system itself. Although CMC supports interaction and collaborative learning, it also has inherent shortcomings. Disadvantages include the time it takes to exchange messages and the increased difficulties in expressing ideas clearly in a context reduced learning environment and the difficulty in coordinating and clarifying ideas (Sumner & Hostetler, 2002). The increased time it takes to reach consensus and decisions (Kuhl, 2002; Sumner & Hostetler, 2002) and to produce a final product (Macdonald, 2003). Given all these difficulties students need to overcome in order to collaborate effectively in interactive learning environment, online instructors need to address these obstacles with careful instructional design and provide support for collaborative learning with appropriate interactive learning tasks.

Research has also shown that computer mediated communicative tasks require more active role of students than traditional instruction in the face-to-face environment does (Wang & Teles, 1998). Students need to be willing to send a formal written question rather than have a casual conversation with peers or with the instructor in order to have their questions answered (Kuhl, 2002). To communicate effectively with peers and the instructor, students need to create the context through written messages, which requires the writing skills to identify their problems and express them precisely in order to have the ques-

tions answered. Team work and negotiation for meaning are necessary skills in CMC that cannot be assumed. Students need to learn to be familiar with the discourse of the discipline and academic genre for an online synchronous and asynchronous forum (Kuhl, 2002; Macdonald, 2003).

In addition to negotiation skills online, previous research has identified a number of other factors that influence student participation and interaction in a web-based learning environment. Among others, the assessment of collaborative learning tasks plays a crucial role in ensuring student participation (Kear, 2004; Kear & Heap, 1999; Macdonald, 2003) and it directly influences the level of participation (Wang, 2007). In general, assessed collaborative learning tasks attract student participation at the cost of unassessed tasks. Furthermore, grade for discussion was also positively related to students' perceived learning (Jiang & Ting 2000).

The structure of discussion in CMC is found to be another important factor in ensuring the amount of participation and level of interaction and collaboration among the peers. Such structure includes the size of the discussion groups, the nature and types of discussion topics (Williams & Pury, 2002), and whether the collaboration emphasizes on the process of learning or the end product of such collaboration, or both (Kear, 2004; Kear & Heap, 1999; Macdonald, 2003; Wang, 2007). Research also indicates that student facilitators play an important role in attracting their peers' participation in online group discussions and the success of such roles are closely related to the depth of the discussion threads that often lead to more than six or more rounds of student postings (Hew & Cheung, 2007). The interaction level between the students and the teacher and among the students was found to be a significant factor in determining the effectiveness of the teaching method (Offir, Lev & Bezalel, 2007).

In addition, class size and level of participation in terms of note writing and reading is also found to be related. Data show that large classes

are related with an increase in the number of notes written, a decrease in average note size, and an increase in note scanning rather than reading (Hewitt & Brett, 2007).

To summarize, although the pedagogical advantages of online collaborative learning are commonly recognized, such learning is sometimes difficult to sustain due to a number of factors. Among others, online negotiation skills, the direct link between collaborative tasks and assessment, the structure of online discussions such as the nature and types of discussion topics, the size of the group, and the differences between process and product oriented collaborative tasks are some of the factors that influence student participation, interaction, and collaboration.

Process and Product Oriented Online Collaborative Learning

Online collaboration can be either process or product oriented. Forum discussions regarding course contents or related issues are commonly process oriented as the sharing of ideas help learners understand the issues without necessarily leading to a final product. Students are assessed individually based on their participation and quality of their contributions. Alternatively, online interaction and collaboration may lead to a final product such as an essay, a project, or a webpage, etc. There can be two assessment elements to such tasks, a common grade for the group for the overall quality of the collaborative product and individual grades for the contribution of each individual to the collaborative endeavor (Kear, 2004; Kear & Heap, 1999; Macdonald, 2003). The similarities and differences of process and product oriented online collaborative learning tasks are summarized in Table 1.

For a product oriented collaboration, simply assigning learners to work on a group project does not necessarily mean that they will work collaboratively. Learners tend to use a task specialization approach where tasks are divided among group

Table 1. Similarities and differences between process and product oriented online collaborative learning tasks

Process oriented tasks	Product oriented tasks
Exchange of views to share ideas that may or may not lead to agreements	Exchange of views that are consensus building to reach agreements
No end product	End product: a project, report, etc.
Relatively easy to interact and share views	Difficult to reach agreement by a time line
Individual grade	Common and/or Individual grade

members. Therefore, learners may not look for opportunities to develop mutual engagement, knowledge and skill exchange, and interpersonal communication skills (So & Brush, 2007). Therefore, the instructional design of product oriented online collaborative learning tasks need to take measures to ensure real collaboration among peers.

The Study

In a previous study based on a web-based course offered in 2004, Wang (2007) investigated the factors that promote sustained online collaboration. The current study extends the previous study by providing new data from the same web-based course offered in 2006 and 2007. In addition to investigating the factors that promote sustained collaborative learning in a web-based course using asynchronous conferencing system as its main learning tasks (Wang 2007), this study further investigates the students' attitudes toward collaborative learning. In particular, it investigates the learners' perspectives of process and product oriented online collaborative learning tasks. Both types of interactive learning activities were implemented as the main learning tasks of the web-based course under study.

The research questions are:

1. What are students' overall attitudes toward collaborative learning as the main learning tasks in a web-based course?
2. Are there any differences in student attitudes toward process and product oriented online

collaborative learning tasks? If so, what are the factors that influence students' different perspectives toward such tasks?

3. What pedagogical implications do the findings have?

COURSE INFORMATION AND DATA COLLECTION

Course Information

The course under study is an upper division general education course on Bilingualism and Bilingual Education delivered entirely on Blackboard at a state university in California. In a previous study, (Wang 2007), data were collected from a post course questionnaire in Spring and Fall 2004 semesters when this web-based course was first offered. A total of 60 students, 22 in the Spring Semester class, and 20 and 18 students in the two Fall Semester classes completed the course. A total of 53 of the students completed the post course survey questionnaire and the results were reported in the previous study (Wang, 2007). The current study further investigates students' attitudes toward online collaborative learning with additional 93 survey questionnaires completed by the students who took the same course during the Fall 2006 and 2007 semesters. Course structure remained unchanged for the most part.

Forum discussions on course readings and related issues formed the core interactive learning activities that were 45% of the course grade. These were process oriented interactive learning

tasks for which individual grades were assigned for each student based on their quantity and the quality of postings in the forums. Small groups of 4-6 people were formed at the beginning of the semester for the weekly asynchronous group forums. During the 16 week semester, a total of 18 discussion forums were completed in each online group. For each forum, the instructor assigned a reading chapter along with comprehension questions and discussion topics to help the students to grasp the contents. Students divided the reading questions among themselves in their groups and posted the answers to each question for the first round of postings. They were also required to make comments on at least one peer's answers in the second round of postings to carry on the discussions.

To ensure participation, strict deadlines for each round of postings were enforced and each student's answers to the questions and comment messages were assessed by the instructor who assigned up to 3% of the course grade for participation of each discussion forum.

The other major collaborative task was a product oriented group project that constituted 12% of course grade for which all the students in the same group received a common grade based on the level of collaboration and the quality of the final written report. There was no individual assessment component for the group project. The interdependent grading (a common grade for all members of a group only) was aimed at promoting more collaboration among the peers to produce a true collaborative product with individual contributions. The group project was closely related to one of the course themes on types of bilingual education programs. Each student was required to visit a local school to interview a bilingual teacher to gain first hand information about bilingual education programs implemented in California. Students then shared and synthesized the interview data to produce a group report. They were not required to meet face-to-face for the group project but they exchanged information in an online forum

that was mostly procedural to plan, negotiate, to reach agreement and to produce the final product. The process of planning and producing the project required negotiation, cooperation, and collaboration among peers to actually arrive at consensus to produce a report. Though not graded, the progress of each group in the online forums was closely monitored by the instructor. The only deadline for submitting the group project was imposed to ensure the completion of the work for the first two semesters when the course was offered in 2004 (Wang, 2007).

During Fall 2006 and 2007 semesters when the course was offered (two classes for each semester), strict intermittent deadlines for each step (such as the completion of the interview, the posting of interviews in the Group Forums, and the completion of the first draft of the group project) were enforced in addition to the final deadline for the submission of the Group Project. These measures were taken to ensure that the "slow" students must stay on the course and complete their tasks according to the schedule at every step.

Other course activities included two individual written assignments (8%) and three online exams (35%) that assessed the learning outcomes of the course readings and group discussions. Table 2 summarizes the course activities and grading.

Data Collection: Post Course Survey Data

At the end of the semester, an online survey was administered in each class to collect information about students' learning experience and their attitudes toward the course, in particular, their experience with online collaboration in both the weekly conference discussions and the group project. The survey questionnaire, which consisted of 17 multiple choice questions and 4 open-ended questions (see Appendix) was uploaded to the survey area of the course on Blackboard. Students were able to access and complete the survey questionnaire anonymously during the week after the final exam.

Table 2. Course activities and grading

Activities	Grading	Description
Weekly group forums	45%	Structured discussions on course readings
Weekly class forums	0%	Required postings of moderator's summaries from each weekly group forum (Spring Semester class only)
Group project	12%	Final product graded interdependently (same grade for each member of the group)
Individual assignments	8%	No interaction among students required
Three exams	35%	Online exams on course contents to assess outcome of learning

Blackboard automatically calculated the results of the multiple choice questions in percentage. The transcripts of the survey responses for all three classes were printed out for analysis. Ninety – three students completed the survey questionnaire. Therefore, the analysis of the survey data is based on the 93 completed questionnaires. These new data were also analyzed along with the 53 survey questionnaire data reported in Wang (2007) study that were based on the same course offered in the Spring and Fall 2004.

RESULTS

Students' Attitudes toward Collaborative Learning

Table 3 presents students' responses to the question "what are your thoughts about the structure of the course?" Students took this web-based course overwhelmingly preferred the interactive learning structure of the course to the weekly quizzes if they were given the choices. Although the percentage of students who preferred weekly quizzes based

on the readings increased from 8% in 2004 to 24% in 2006 and 2007, the overall majority of them still preferred the current course structure.

An additional question about the learners' overall experience with this web-based course was included in the survey for the 2006 and 2007 classes and the results are summarized in Table 4. Ninety-eight percent of the students reported that their experience with this web-based course was "very positive" and "positive". Therefore, even though about a quarter of the students preferred 'weekly quizzes' type of less interactive learning if there were given the choices, they still reported that their overall experience with the course was "positive" and "very positive".

What factors encouraged students to participate in this form of active and interactive learning throughout the semester? Did the students really think that they learned from building on each other's insights? What were the effects of such learning as reflected by students' responses in the survey data? The survey questionnaire addressed these issues in a number of questions. Table 5 summarizes students' responses to the effectiveness of group discussions.

Table 3. Students' responses to "what are your thoughts about the structure of the course?"

Choices	2004, N= 53	2006-2007, N= 93
I like the way the course is structured in terms of forum discussions because we learn from each other.	92.5%	76%
I prefer weekly quizzes based on the readings rather than answering questions and joining the group discussions.	7.5%	24%

Table 4. Students' responses to the question "my experience with this web-based course:" (N=93)

Choices	2006-2007, N=93
Is very positive	53%
Is positive	44%
Is negative	1%
Is very negative	1%

Chi Square analyses of students' responses to the questions in Table 5 along the scale of strongly agree to strongly disagree were all significant beyond 0.0001 level. About 90% of the students agreed or strongly agreed that answering questions and participating in discussions helped them understand the readings better and that online discussion was helpful because they collaborated more and learned more from each other. Additionally, 72% of the students responded that they learned more from online discussions than they would have learned from the lectures. Furthermore, 89% of the students responded that group cohesion and mutual trust was an important factor in their group.

Level of Participation

Students' participation in group discussions was not only required but was also directly linked to the assessment of their postings in the forums. The

required postings and their assessment appeared to play an important role in motivating the students to participate the discussions. Table 6 summarizes students' responses to the level of participation in their group discussions if the postings were *not* required and graded. The new data from the 2006 and 2007 classes were more or less the same as the previous data when the course was offered for the first time in 2004. Overall, 45% -50% of the students responded they would post some but not as many messages, 21% said they would post very few and 6%-8% responded they would not post any messages at all! Only 21% -28% (an increase of 7% in the new data) responded they would post the same number of messages. One might argue that the survey data may not reflect the real level of participation in discussions if the postings were not required or assessed because all the postings in this course were actually required and assessed. Therefore, a firm claim of the effect of assessment on forum contributions must be tested with a treatment group whose postings in forums were assessed and compared with a control group whose postings in forums were optional and unassessed. Nevertheless, students' responses to this survey question still reflect the "if not" situation because they had just completed the weekly postings for the entire semester and such learning experience would certainly affect their responses. Therefore, the "if not assessed"

Table 5. Students' views about group discussions (N=53)

Survey Questions	% Responses				Chi ²
	Strongly agree	Agree	Disagree	Strongly disagree	
My answers to the questions and comments on peers' messages help me to understand the readings better.	30%	62%	8%	0%	49.717
My peers' answers/comments helped me understand the readings better.	32%	57%	11%	0%	39.453
I learned more from online discussions than I would have learned from lectures.	25%	47%	25%	2%	21.792
The online discussion is helpful because we collaborate more and learn from each other more.	38%	55%	6%	2%	41.415
The group cohesion and mutual trust is an important factor in our group.	53%	36%	11%	0%	36.132

Table 6. Students' responses to "would you post the same number of messages as you actually did over the semester if these postings were optional, not required or graded?"

Choices	2004, (N= 54)	2006-2007, (N=93)
Yes, I will post the same number of messages	21%	28%
I will post some messages but not as many	51%	45%
I will post very few messages	21%	21%
I will not post any messages	8%	6%

situation was contrasted against the real situation of "assessed" postings.

In addition to the number of postings, the amount of time spent on reading peers' messages in an asynchronous forum also reflects the level of participation of collaborative learning. When the course was offered in 2006 and 2007, the survey questionnaire asked an additional question about the reading of peers' messages in the forums, also an important indication of interactive learning. The results are summarized in Table 7.

Thirty-seven percent of the students responded that they read all the messages posted by the peers while 47% of the students read most but not all the messages. Adding the answers to these two items up, the overall majority of the students, 84%, read most if not all the postings in their groups. Still, 10% of the students read only some messages while 6% of them responded that they did not read these messages often. Unlike the required postings by the deadlines in an asynchronous forum, it is relatively more difficult to enforce the reading of each posting in such learning en-

vironment. Therefore, the request to make comments on peers' messages for a required second round of posting is the only direct measure to enforce the reading. Still, 16% of the students read only some of the messages. It is very likely that these students chose to read one or two peers' postings on which they made comments. Previous studies have examined the relationship between group size and the amount of reading of postings of online asynchronous forums. It is important to point out that group size and number of postings in a forum may have a direct impact on the number of messages the students actually chose to read. The students' self-reported amount of reading of messages will be further discussed in the next session.

Group Formation

Table 8 summarizes students' responses to the question on group formation. The 2004 data were based on the 37 questionnaires from the Fall semester students as the Spring 2004 semester course did not have this question in the survey. Not much noticeable differences were observed from the new data when the course was offered in 2006 and 2007. There is a slight increase of percentage of students, from 8% to 15%, who wanted to work with different people in a group every few weeks. Almost the same percentage of students, 30% vs. 31% for the two sets of data, responded that it made no difference for them to work with the same or different people in a group throughout the semester. More than half other students

Table 7. Students' responses to "In our group discussions," (N=93)

Choices	2006-2007, N=93
I read all the messages posted by my peers	37%
I read most but not all the messages by my peers	47%
I read some but not all the messages	10%
I do not read these messages often	6%

Table 8. Students' responses to "what is your view about group formation?"

Choices	Fall 2004 N=37	2006-2007, N=93
I want to work with the same group members the way it is now because we know each other better.	62%	53%
I want to work with different people in a group every few weeks because we will learn from other students we never meet.	8%	15%
It will not make a difference to me working with the same people or different people in a group.	30%	31%

responded that they preferred to work with the same people for their group discussions because they knew each other better and the number was even higher (62%) for the Fall 2004 class data.

It appears that the group as a community for online learning established deep roots in this course. Except for some course related general forums in which questions regarding course activities were exchanged, students generally did not have access to the majority of the fellow students in their class. It would not have been surprising if students had expressed their desires to learn the discussions in other groups through some form of exchanges on a class level, or, through reshuffling groups. Yet, the survey responses suggest that at least two thirds of the students did not express the need to work outside their fixed small groups.

It is important to note that the survey data reflected the students' views towards their working groups that were fixed for the entire semester. If they actually had the chance to work in different groups in this online course, they might have different views. To explore the advantages and disadvantages of fixed or dynamic small groups in a web-based course that uses weekly forum discussions, both group types need to be included in the data in future studies.

Process vs. Product Oriented Collaboration

Table 9 presents students' responses to a question that allowed for multiple choices about the group

project. In this "choose all that apply" multiple choice question, the first two choices were aimed at assessing whether the assignment itself was important for the course in the students' eyes because the importance of the group project may affect their overall performance, or, vice versa. As seen in Table 9, 70% of the students from the 2004 classes felt that the group project was a good assignment and agreed they learned a lot through doing it. Sixty-eight percent of the students also responded that the project made the course readings more meaningful and relevant. About half of the student population, 48% -52%, in the 2006 and 2007 classes viewed the group project as an important task, a noticeable decline for the previous semesters in 2004.

The Fall 2004 semester post course survey asked an additional question about their experience with the group project and the responses are summarized in Table 10. (This question was not included in the Spring 2004 post course survey.) New data from the 2006 and 2007 classes were also included in Table 10.

As seen from Table 10, the new data of 2006 and 2007 were almost identical to the Fall 2004 class, despite the fact that the number of students who perceived the importance of this group project actually went down for the students in the 2006 and 2007 classes.

While 24% of the students preferred to work with peers because they had no problems to collaborate, exactly another 24% of them did not like to depend on other peoples' schedules because some just did not get the work done

Table 9. The group project about bilingual programs in our local schools

Multiple choices (choose all that apply)	2004, N=53	2006-2007, N=93
Is a good assignment and I learned a lot through doing the project.	70%	48%
Makes the course readings more meaningful and more relevant to me.	68%	52%
Is a good assignment but takes too much time to complete.	17%	20%
Could be an individual assignment focusing on one school rather than a group project that involves more collaboration.	30%	24%
Is not very important for this course.	4%	2%

Table 10. Students' response to the group project

Choices	Fall 2004, N=37	2006-2007, N=93
I prefer individual work leading to a project of my own even though I only have information about one school.	32%	27%
I prefer to collaborate with peers the way it is now because it is not a problem with me to collaborate.	24%	24%
I prefer to collaborate with others for a group project but I do not like to depend on other people's schedule because some just do not get their work done on time.	24%	24%
Even though it is hard to collaborative for the group project, it is still worth doing it because we learn more about our bilingual programs in different schools through doing it together.	22%	25%

on time. It is surprising that the percentage of responses to these two choices were identical for the two sets of data, even though more intermittent deadlines were imposed at different stages for the group project in 2006 and 2007 classes as new measures to facilitate the collaboration among peers. Twenty-five percent of the students in the 2006 and 2007 classes felt it worthwhile to collaborate for the group project despite the fact that it was difficult, only a slight increase of 3% from the Fall 2004 class. Similarly, 27% of the students preferred individual work leading to a project of their own even though they would not accomplish as much, a slight decrease of a 5% from the previous data. Compared to the overall positive responses toward collaboration in forum discussions (see Table 3 and Table 4), students' attitudes toward online collaboration in producing the group project were mixed.

Such differences were also reflected in some student comments on the group project in the open-end questions. One student wrote "I think

it's too inconvenient to try and get a group project together online. I also don't like having someone's performance affect my grade. I would rather do the project on my own." It appears that the end product type of collaborative tasks demands more consensus-building collaboration. When students were timed for such intensive interaction and collaboration, they became less enthusiastic about it.

DISCUSSION

Students' Overall Attitudes toward Collaborative Learning and Their Level of Participation

The new data based on the 2006 and 2007 classes support the earlier findings about students' attitudes toward online collaborative learning. Ninety-eight percent of the students reported that they were "positive" and "very positive" with this web-based course. The overall majority of them

also stated that they preferred the forum discussions to weekly quizzes as the main learning tasks, if they were given the choices.

As summarized in Wang (2007) findings, a number of factors contributed to the sustained small group discussions in this course. One of the factors may be the structure of the forums that required two rounds of postings. Students not only always had "something to say" in each forum but knew exactly what specific questions they were expected to answer in advance. These written exercises required in the first round of postings kept each individual student accountable for knowing the contents through reading. Therefore, students' interaction with the course readings, the first level of interaction with the material, was enhanced by producing written answers to be commented by peers in the group forums. The enthusiasm in group discussions never waned forum after forum because each forum focused on a new reading chapter.

Furthermore, the comment messages required students to exchange information by building on each other's ideas to negotiate for meaning and to collaboratively construction knowledge. Such interaction between peers and between students and instructors provided another level of interaction for learning. Students' positive experience with the semester long forum discussions was related to the benefits of proactive learning and learning from each other for knowledge construction. While the advantages of online interactive learning have long been proved in previous studies (Kern, 1995; Lavooy & Newlin, 2003; Mouza, Kaplan, & Espinet, 2000; Summer & Hostetler, 2002; Wang & Teles, 1998; Wu, 2003), this study provided new data for the use of small group discussion as the core interactive learning tasks through the application of carefully prepared discussion questions that elicits proactive learning and through peer interaction and collaboration. When online collaborative learning tasks become main course pedagogy, such interactive learning is likely to be more sustainable and effective.

With regard to levels of participation in collaborative learning, previous research indicates that the size of online learning community affects the level of comforts which influences the level of participation (Hewitt & Brett, 2007; Williams & Pury, 2002). Hewitt & Brett (2007) reported that large classes were related with an increase in the number of notes (messages) written, a decrease in average note size, and an increase in note scanning rather than reading. The current findings suggest that students were comfortable with their peers in a group of 4-6 members and group cohesion and mutual trust was an important element for their collaborative learning. However, data also show that such trust and comfort with a smaller group size is no guarantee of semester-long sustainable interactive learning in the asynchronous forums. Overall, only 28% of the students responded that they would post the same number of messages in their forums if the postings were not required and graded. Forty-five percent of the students responded they would post some but not as many messages and 21% percent of the students said they would post very few messages. What is more, 8% of the students responded they would not post *any* messages at all. These numbers from the new data were almost identical to the previous data. Taken together, these data support the previous research findings that the assessment of collaborative learning tasks plays a crucial role in ensuring student participation. Macdonald (2003) reported that students actively contributed to the discussions when the tasks were assessed but participation of discussions waned when the postings became optional. Grade for discussion was also positively related to students' perceived learning (Jiang & Ting 2000). Apparently, any optional interactive learning tasks would not have sustained for the entire semester.

Another indication of the level of participation is the amount of reading of messages posted by the peers in their group forums. Thirty-seven percent of the students reported that they read all the messages posted by the peers while 47% of

them read most but not all the messages. However, 16% of the students responded that they read only some messages or did not often read the messages posted by the peers. Unlike the required postings by the deadlines in an asynchronous forum, it is relatively more difficult to enforce the reading of each posting in such learning environment. It is important to note that the size of the group (4-6 students) is relatively small for asynchronous forums and it was assumed that such a size would generate sufficient responses from each other. On the other hand, the number of messages produced by each member was manageable and easy to keep track of. Future studies need to investigate the level of participation of collaborative learning with different group sizes and with different learning tasks.

With regard to group formation, the majority of students reported that they preferred working with the same members of the group for the entire semester rather than rotating the peers. Obviously, it takes time to establish such mutual trust, even in a small group of 4-6 members. Therefore, it is very likely that the group cohesion and mutual trust comes from the semester long of interaction, cooperation and collaboration online. The new data showed a slight increase of the percentage of students who expressed the desire to work with different peers during the semester. Future studies need to investigate the benefits and disadvantages of dynamic group formations in which students are given the chance to work with different online peers during the semester.

Students' Attitudes toward Process and Product Oriented Interactive Learning

Very few studies have dealt with the differences between process and product oriented interactive learning tasks and how these differences influence peer interaction and collaboration (Kear, 2004; Kear & Heap, 1999; Macdonald, 2003; Wang, 2007). This web-based course applied both process

and product orientated interactive learning tasks that required different types and levels of interaction and collaboration. As discussed earlier, in the weekly group forums, the debate and exchange of ideas focused on the process of learning that did not lead to a final product. In contrast, the group project was a product driven collaborative task in that the interaction and collaboration among the peers through sharing and exchange of ideas and negotiation must help to reach certain consensus to produce a group report. Survey data suggest that students were more enthusiastic about process oriented group discussions than the group project.

In the previous study based on the same course offered in 2004, Wang (2007) found that among others, the main reasons for students' frustration about the group project were the difficulties in reaching agreement according to a time frame, especially in the online environment. The differences in working pace and conflicts of schedules, and, perhaps more importantly, differences in level of devotion to the collaborative task in online environment made it more difficult for the peers to reach consensus in the process of doing the group project. The early birds who preferred to start and complete their parts of the work in a timely fashion conflicted with those who procrastinated in getting the work done. As peers in the same group would receive a common grade only for their project, there was pressure for them to compromise to reach agreements in completing the project.

In order to reduce the frustration caused by the schedule conflicts between the peers, a few intermittent deadlines were imposed when the course was offered in 2006 and 2007 years. Students had to meet each deadline (individual interviews, sharing the interview summaries, and draft the project) at each step to avoid the last minute rush that usually delayed the progress of the group work. The new data about the group project from 2006-2007 classes were collected after these new measures were taken.

As seen from Table 9 and Table 10, these new measures did not appear to address these challenges the groups faced in completing the projects. In fact, only 24% of the students from the current data, (exactly the same 24% of the students in the previous study) responded that they preferred to collaborate with others for a group project but they did not like to depend on other peoples' schedule because some just did not get their work done on time. Similarly, 24% of students in the current data (exactly the same percentage as found in the previous study) responded that they preferred to collaborate with peers because it was not a problem for them to collaborate. Only a slight increase of the number of students, from the previous 22% to the current 25%, responded that even though it was hard to collaborative for the group project, it is still worth doing it because they learned more about the bilingual programs in different schools through doing it together. There was also a slight decrease of number of students, from the previous 32% to the current 27%, who stated that they preferred individual work leading to a project of their own even though they only have information about one school. These data suggest that, overall, students' attitude towards the group project was mixed. There was less enthusiasm for the group project than for the weekly forum discussions.

In addition to the differences in working schedules and level of devotion to the group project, the common grade assigned to students for their group project appeared to be another factor that caused the frustration for this collaborative task. Although the common grade can be used as a useful instructional strategy to implement end product driven collaborative tasks to encourage collaboration, the frustration and stress caused by the schedule conflicts and different levels of devotion toward such collaboration calls for more careful instructional design of such tasks. Perhaps some form of individual grading in addition to the interdependent grading are necessary to measure each individual student's efforts and contribution. In fact, Kear & Heap (1999) reported

that students expressed a preference for a higher individual grade component when both common and individual grades were assigned for their group project. It is important to balance the level of collaboration among the students and the individual flexibility of online learning. Future studies need to address the pedagogical design of end product driven collaborative tasks in web-based courses.

CONCLUSION

The new data in the current study further supported the earlier findings (Wang, 2007) about students' positive attitudes toward collaborative learning as main learning tasks in a web-based course. The overall majority of them also stated that they preferred the forum discussions to weekly quizzes as the main learning tasks, if they were given the choices. Among others, the structure of the online discussion, group cohesion, direct link of the interactive learning tasks to the assessment, and strictly imposed deadlines are some of the important factors that influence students' learning experience and level of participation in collaborative learning. The differences in process and product driven interactive learning tasks also have a different impact on student online collaboration. In general, students were more enthusiastic about process oriented than product driven collaborative tasks. Despite the new measures taken in the form of imposing more intermittent deadlines for the preparation of the group project, a product oriented collaborative task, a substantial number of students still preferred to do an individual project on their own, if they were given the choices. Many of them expressed their concerns about their grades being affected by their peers' work. It appears that assigning a common grade to all the members of the group may not be the best way of assessing such a product oriented collaborative task. Some element of individual assessment component might be necessary to reflect the different level of devotion of the students.

Finally, as the current data are based on one web-based course that was mainly a reading course, the findings may not be generalized into a broad scope. Because of this limitation, the current findings may not be directly applicable to other courses that have a different online pedagogical approach. Yet, a few recommendations may be made for designing and implementing similar interactive learning activities to promote sustained and effective online collaboration.

- Although a very good tool for promoting interactive learning and collaboration, online discussion is not always sustainable if not well planned and structured. It is recommended that instructors carefully design each forum discussion with direct involvement of course contents with pre-determined specific questions to engage students in a high level of thinking through providing written answers to the topics for which peer critiques are required.
- To continue to motivate the students, link the assessment with all interactive learning tasks utilizing specific grading scales.
- Impose strict deadlines for each round of postings in each discussion forum.
- Form small groups of 4-6 as learning communities for discussions so the peers will have sufficient input from each other yet still find it easy to keep track of all the postings in each new thread.
- Use process oriented interactive learning tasks to facilitate continuous online interaction and collaboration and yet still give each student sufficient amount of freedom in completing the assessed learning tasks.
- When design product oriented interactive learning tasks, much care needs to be taken in order to prepare the students to reach consensus. Give sufficient time for completing such learning assignment. Incorporate both common and individual grades in grading an group project.

APPENDIX: SURVEY QUESTIONNAIRE

1. Is this your first web-based (entirely online) course?
 - a. Yes.
 - b. No, I already took one entirely online course before this one.
 - c. No, I took two or more other entirely online courses before this one.
 - d I took one or more web-enhanced course (partially online) before this web-based (entirely online course).
 - e. No, I have never taken any web-based nor web-enhanced course.
2. This reading course is structured on group discussions with individual and group assignments. What are your thoughts about the structure of the course?
 - a. I like the way the course is structured in terms of forum discussions because we learn from each other.
 - b. I prefer weekly quizzes based on the readings rather than answering questions/joining group discussions.
3. Will you post the same number of messages as you actually did over the semester if these postings were optional, not required and graded?
 - a. Yes, I will pos the same number of messages.
 - b. I will post some messages but not as many.
 - c. I will post very few messages.
 - d. I will not post any messages.
4. Please circle one answer for each of the following:
 - a. In our group forums, my answers to the questions and comments on peers' messages help me to understand the contents/readings of the course better.
strongly agree
agree
disagree
strongly disagree
 - b. My peers' answers/comments helped me to understand the readings better.
strongly agree
agree
disagree
strongly disagree
 - c. I learned more through online discussions than I would have learned from the lectures.
strongly agree
agree
disagree
strongly disagree

Students' Attitudes toward Process and Product Oriented Online Collaborative Learning

- d. The online discussion is helpful because we collaborate more with each other and support each other.
strongly agree
agree
disagree
strongly disagree
 - e. The group cohesion and mutual trust is an important factor in our group forums.
strongly agree
agree
disagree
strongly disagree
 - f. I prefer individual work to group work and would have done better if I did not have to collaborate with my peers in my group for **discussions**.
strongly agree
agree
disagree
strongly disagree
 - g. I prefer individual work to group work and would have done better if I did not have to collaborate with my peers in the group for the **final project**.
strongly agree
agree
disagree
strongly disagree
 - h. The deadlines for the readings and postings in each forum are very important because they help me to complete the readings and the course.
strongly agree
agree
disagree
strongly disagree
 - i. The overall course contents are interesting and I have learned a lot about bilingualism and bilingual education from taking this course.
strongly agree
agree
disagree
strongly disagree
5. Choose one of the following:
- a. I wanted other group members to read our group discussions and I also missed the discussions in other groups.

Students' Attitudes toward Process and Product Oriented Online Collaborative Learning

- b. Every group should have summarized their forum discussions each week and post it to a general forum so that interested students could comment on the discussions in other groups.
 - c. Reading and responding to peers' messages in our own group discussions is sufficient for me to understand the course contents. It would take too much time to read and respond to summary messages from other groups.
6. What is your view about group formation?
- a. I want to work with the same group members the way it is now because we know each other better.
 - b. I want to work with different people in a group every few weeks because we will learn from other students we never meet.
 - c. It will not make a difference to me working with the same people or different people in a group.
7. The pace of the course, including readings and postings
- a. Is neither too fast nor too slow for me.
 - b. Is too fast for me because I always try to catch up with the readings.
 - c. Is too slow for me and we could have read more chapters.
 - d. Should be OK for a course like this but I found it too fast for me because I work many hours a week and have limited time for course work.
8. Course documents:
- a. I printed out all the lecture notes and review guides (or some of them) because they are helpful.
 - b. I read the lecture notes and the review guides online but did not print them all.
 - c. I never printed out nor read the lecture notes and the review guides because they are not essential for me.
9. The videos on reserve in the music library are used in all other face to face sessions of the same course. I found these videos
- a. worth seeing because they are informative and very relevant to the course content.
 - b. relevant to the course content, but it is hard for me to make special trips to the university to watch them all.
 - c. are not relevant to the course content and can be omitted.
10. You took all the three exams online in this semester. Do you think the online exam should be kept the way they are now, or do you prefer to take these exams in a classroom on a certain date?
- a. I prefer online exams the way they are now.
 - b. I prefer to come to a classroom to write the exams.
 - c. I have no preference.
11. Exam format:
- a. I prefer multiple choice exams.
 - b. I prefer essay question type of exams.
 - c. It does not make a difference for me.

Students' Attitudes toward Process and Product Oriented Online Collaborative Learning

12. The group project about bilingual programs in our local schools (circle all the answers that apply to you)
 - a. Is a good assignment and I learned a lot through doing the project.
 - b. Makes the course readings more meaningful and more relevant to me.
 - c. Is a good assignment but takes too much time to complete.
 - d. Could be an individual assignment focusing on one school rather than a group project that involves more collaboration.
 - e. Is not very important for this course.
13. For the group project:
 - a. I prefer individual work leading to a project of my own even though I only have information about one school.
 - b. I prefer to collaborate with peers the way it is now because it is not a problem with me to collaborate.
 - c. I prefer to collaborate with others for a group project but I do not like to depend on other people's schedule because some just do not get their work done on time.
 - d. Even though it is hard to collaborate for the group project, it is still worth doing it because we learn more about our bilingual programs in different schools through doing it together.
14. Overall, my experience with this web-based course
 - a. Is very positive.
 - b. Is positive.
 - c. Is negative.
 - d. Is very negative.
15. Experience with the Blackboard and the online forums: circle all apply to you.
 - a. I found it challenging at the beginning but quickly picked up and like it now.
 - b. The interface is straightforward and easy to learn, although I was not very experienced with any online courses.
 - c. It was never a problem for me because I am good at technology.
 - d. It was a plus because I learned the technology as well as the course contents
16. If I have the choice in future,
 - a. I will take a similar web-based course.
 - b. I will not choose to take a similar web-based course.
 - c. It will not make a difference, web-based or face-to-face version.
17. Would you recommend a friend to take this web-based course?
 - a. Yes
 - b. No
 - c. Not sure

Students' Attitudes toward Process and Product Oriented Online Collaborative Learning

18. Please take some time to answer the following questions:
- a. Please describe your experience with the forum discussion part of the course. (positive, negative, expectation, effect on learning, etc. anything you think is relevant)
 - b. What do you like the most, or dislike the most about this course?
 - c. In your opinion, what are the most important elements for a web-based course like this to be successful?
 - d. To improve the course for future students, what changes do you recommend?

Chapter 5.13

Plagiarism and the Community College

Teri Thomson Maddox
Jackson State Community College, USA

ABSTRACT

Although plagiarism is a problem in all educational institutions, the diversity of the community college student population and of the community college mission creates even more challenges. The purpose of this chapter is to discuss characteristics of community college students, define intentional and unintentional plagiarism, and provide methods that faculty can use to help students avoid both kinds of plagiarism.

INTRODUCTION

Most sources agree that plagiarism is a major problem for educational institutions (Breen & Maassen, 2005; Ercegovac & Richardson,

2004; Furedi, 2004; Martin, 1994; Ryan, 2004; Standler, 2000). In their literature review of academic dishonesty and plagiarism, Ercegovac and Richardson (2004) quote a Bronfenbrenner et al. report, *The State of Americans*, “Virtually every high school student in 1989 (97 percent) admits having let another student copy from his or her work” (p. 311). More recently, the Internet has helped make copy and paste plagiarism fast and easy; furthermore, Internet paper mills are relatively inexpensive and offer papers that are harder for teachers to detect (Bloomfield, 2004; Bombak, 2005; Edlund, 2000; Ercegovac & Richardson, 2004; Harris, 2004; Howard, 2001; Leland, 2002; McKenzie, 1998; Murray, 2002; Plagiarism.org, 2005; Rocklin, 1998; Ryan, 2004; Scanlon, 2003; Standler, 2000; Sterngold, 2004). Amazon.com has a “Search Inside the Book” feature that allows users to search for ideas and content within specific texts (Sterngold, 2004),

DOI: 10.4018/978-1-60960-503-2.ch513

certainly a valuable research tool but also a plagiarist's golden opportunity. The Council of Writing Program Administrators (WPA) states that the ease of Internet plagiarism "has begun to affect teachers at all levels, at times diverting them from the work of developing students' writing, reading, and critical thinking abilities."

If technology has amplified the problem of plagiarism for all educational institutions, the problem seems especially pronounced in the community college setting because of the diversity of the student population and because of the emphasis that community colleges put on meeting their students' changing needs. This chapter will define plagiarism, describe the growth of the community college and characteristics of community college students, and provide instructional approaches faculty can use to help students avoid both intentional and unintentional plagiarism.

PLAGIARISM CONFUSION

Students and faculty have difficulties with plagiarism on college campuses because the concept of plagiarism is misunderstood (Breen & Maassen, 2005; Ercegovic & Richardson, 2004; Scanlon, 2003). Even though almost every institution's Web site contains definitions of academic dishonesty and plagiarism, Breen and Maassen (2005) state that it is clear that "the existence of a policy was not sufficient in and of itself to eliminate plagiarism." Scanlon (2003) says that the "amount of misconception on this topic appears to have grown exponentially in the past few years, as access to the Internet becomes nearly universal." He cites several studies that suggest that students are not sure what plagiarism is and that they do not think it is as serious an issue as faculty does.

Faculty also may be unclear about plagiarism definitions, types, and consequences (Breen & Maassen, 2005; Ercegovic & Richardson, 2004; Scanlon, 2003). In their literature review of academic dishonesty, Ercegovic and Richardson

(2004) cite a study by Burke of faculty at a two-year college: "The fact that 86 percent of the studied faculty suspected academic dishonesty in their classroom but did not perceive it to be a major problem should be investigated further" (p. 310). They cite other studies that find that although faculty members complain about cheating and plagiarism, "many do little or nothing about it ... It seems there is a lack of alignment between offences and punishment and a lack of communication among administrators, faculty, parents, and students" (p. 311).

The WPA Council Web site, "Defining and Avoiding Plagiarism," states that students may be confused because "academicians and scholars may define plagiarism differently or more stringently than have instructors or administrators in students' earlier education or in other writing situations." For Murray (2002), these definitions vary widely even "across and within departments, allowing students wiggle room and making it tempting for faculty to ignore potential problems."

DEFINITIONS OF PLAGIARISM

McLemee (2004) cites the Oxford English Dictionary's definition of *plagiarism*: it is derived from the Latin *plagiarius*, meaning "one who abducts the child or slave of another," and "the word plagiarism was first used in its current sense by the Roman poet Martial, in the first century AD, as a sarcastic put-down of another writer who had cribbed some of Martial's verse" (p. A9). Today, most educational institutions consider plagiarism a threat to ethical standards; The Purdue Online Writing Lab (OWL) says that "There are few intellectual offenses more serious than plagiarism in academic and professional contexts," (Stolley, 2006), and Bolkan (2006) calls it "the unoriginal sin" (p. 13).

The Council of Writing Program Administrators (WPA) seems to take a moderate approach to the issue, defining plagiarism in the following

way: "In an instructional setting, plagiarism occurs when a writer deliberately uses someone else's language, ideas, or other original (not common knowledge) material without acknowledging its source." The key term here seems to be *deliberately*. The WPA Council distinguishes between plagiarism and misuse of sources:

students are not guilty of plagiarism when they try in good faith to acknowledge others' work but fail to do so accurately or fully. These failures are largely the result of failures in prior teaching and learning: students lack the knowledge of and ability to use the conventions of authorial attribution.

Like the word *deliberate*, the words *in good faith* take into account student *intentions*, not just the results. Several sources agree that many plagiarism cases are probably inadvertent (Breen & Maassen, 2005; Martin, 1994). Martin (1994) says, "Students are apprentices, and some of them learn the scholarly trade slowly" (p. 37).

On the other hand, other sources do not try to judge whether the use was deliberate or not and make no distinction between plagiarism and misuse of sources. In fact, for Standler (2000), "the intent of a plagiarist is *irrelevant*. The act of quoting material without including the indicia of a quotation is sufficient to convict someone of plagiarism. It is *no defense* for the plagiarist to say 'I forgot.' or 'It is only a rough draft.' or 'I did not know it was plagiarism.'"

Like Standler, several university Web sites do not take into account the writer's intention. Stolley, on the Purdue OWL Web site, "Avoiding Plagiarism," warns students that even "inadvertent mistakes can lead to charges of plagiarism ... A charge of plagiarism can have severe consequences, including expulsion from a university or loss of a job, not to mention a writer's loss of credibility and professional standing." These are very strong words, perhaps intending to scare students into taking the issue seriously. The Georgetown University "What Is Plagiarism?" Web site informs

students that "even using one of [a source's] small, characteristic phrases without quotation marks is considered plagiarism." Similarly, McLemee (2004) defines plagiarism in this way: "A writer who fails to give appropriate acknowledgment when repeating another's wording or particularly apt term, paraphrasing another's argument, or presenting another's line of thinking is guilty of plagiarism." These definitions make no distinction between deliberate plagiarism and inadvertent plagiarism or misuse of sources.

These examples seem to illustrate that there are major differences that hinge on whether institutions make allowance for intention or deliberateness. However, McCullen (2003) acknowledges that "it is not so easy to draw a hard and fast line between what is a deliberate case of plagiarism and an unintentional error in citation" (p. 40).

Because community colleges attract diverse students with diverse educational goals, faculty members need to acknowledge the problems their students face when given a writing or research project and help them avoid both intentional and unintentional plagiarism. Intentional plagiarism, which takes place when a student buys a paper from a paper mill, uses another student's paper as if it were his or her own, or fabricates sources or citations, can be addressed by restructuring assignments, helping students develop better time management skills, and using learner-centered teaching methods. Unintentional plagiarism, which occurs when the student uses a phrase from a source and cites it but does not put it in quotation marks, when the student copies and pastes to such an extent that he or she loses control of the paper, or when the student inaccurately records source material, can be addressed using student/teacher conferences, portfolios, and peer evaluations.

In order to understand why plagiarism is a problem in community colleges, a discussion of the characteristics of community college students is provided.

GROWTH OF COMMUNITY COLLEGES

Since the beginnings of the community college system in 1901 when Mt. Juliet Community College in Illinois was begun as an outgrowth of high school, community colleges have altered the American postsecondary educational system, making college more accessible and more affordable. Kasper (2002-2003), an economist for the Office of Occupational Statistics, states, “No other segment of postsecondary education has been more responsive to its community’s workforce needs. At community colleges, students can learn at any point in their lives while taking advantage of low tuition, convenient campus locations, open admissions, and comprehensive course offerings” (p. 14). Enrollments in community colleges have grown faster than four-year institutions. According to Kasper, “enrollment at public four-year colleges and universities roughly doubled from 1965 to 1999, while enrollment at public community colleges increased about fivefold” (p. 14). Kasper states that although 26 percent of all students attending public degree-granting institutions in 1965 attended community colleges, that percentage had almost doubled in 1992 to 48 percent (p. 14). More than 11.5 million students attend nearly 1200 community colleges (Lamkin, 2004).

Community colleges might have begun as a low cost alternative for students seeking a four-year degree who were denied access to universities, but the mission of community colleges has expanded to include career certificate training, workplace training, continuing education opportunities, associate degrees, and associate of applied science degrees. Many students attend a community college to transfer to a four-year institution, but others want to fulfill short-term goals. This diversity of mission is one way that community colleges differ from four-year institutions. Carnevale (2001) highlights the advantages of a community college education:

Unlike company-training programs, which usually omit academic preparation, and four-year colleges, which provide academic challenges but rarely link them to occupational constructs, community colleges are able to provide students with the tools they need to sustain career in the modern economy by developing a curricula that incorporates both academic knowledge and occupational skill training.

This goal of bridging academia and the work place can be accomplished by focusing on student needs, but this task is made difficult because of the diverse student population in the community college.

THE COMMUNITY COLLEGE STUDENT

Besides the differences in their educational mission, community colleges and four-year institutions also differ in student diversity. According to Lamkin (2004), the image of a typical college student as “a recent high school graduate, a young, white, middle-or upper-income person pursuing a four-year degree on a residential campus” (p. 12) has changed. Perhaps this image may describe students at many four-year institutions, but not community colleges, which now account for about half of the U.S. postsecondary student population (Sampson, 2004). Lamkin (2004) states, “attracting particularly high proportions of underserved students, including low-income students, first-generation college-goers, and students of color, community colleges enroll 46 percent of all African American, 55 percent of all Hispanic, and 55 percent of all Native American students” (p. 12). Asians and Hispanics are the fastest growing minorities (American Association of Community Colleges, 2000). “As with other groups before them, upwardly mobile ethnic and racial groups will rely on community colleges as

their on-ramp to the higher education highway” (Carnevale, 2001).

Lamkin (2004) reports that community college students are often at-risk; more than half of them have at least two of the seven characteristics that have been shown to influence drop out rates: delayed enrollment after high school graduation, lack of a high school diploma, part-time enrollment, full-time work (at least 30 hours a week), financial independence from parents, dependants other than a spouse, or single parenthood. “Low income and students of color are especially likely to exhibit these characteristics” (p. 12).

Teaching students how to avoid plagiarism may make sense in the white majority American culture with its emphasis on the importance of the individual, copyright law, and the legality of ownership of individual ideas. However, other cultures may not value this kind of individual ownership, so plagiarism of words and ideas may not be something community college students from non-white cultures see any reason to avoid. English as a second language (ESL) students may have particular problems understanding plagiarism issues since they have a language as well as a culture difference from mainstream America (Breen & Maassen, 2005; Ercegovic & Richardson, 2004).

UNDERPREPARED STUDENTS

The open door policy of most community colleges allows students who would never have been able to attend a university to begin a college education, even with poor high school GPAs, low placement tests, and limited financial resources. Shemo (2006) describes hundreds of thousands of students arriving at community college doors, “eager but unready.” Many of these students are the first in their families or neighborhood to attend college, so they have no mentors in their families or peer group. Most underprepared students lack academic writing and research skills. They may not be able to comprehend a syllabus description

on how to avoid plagiarism or understand Web site examples of plagiarism.

On its Web site, The University of Alberta lists the following reasons why students plagiarize, all of which may be exacerbated by underprepared students’ lack of academic experience:

- Lack of research skills
- Problems evaluating Internet sources
- Confusion between plagiarism and paraphrasing
- Careless note taking
- Confusion about how to properly cite sources
- Misconception of plagiarism
- Misconception of intellectual property, copyright, and public domain
- Misconception of common knowledge
- Perception of online information as public knowledge
- Poor time management and organizational skills
- The commodification of knowledge and education

Although most campuses have some kind of tutoring centers that provide free support for students who are delving into writing or research projects, the irony is that underprepared students often are the very ones who do not take advantage of the opportunity. They know they have academic limitations, but they are afraid to take the very public step into an academic assistance center for fear of announcing their weaknesses to the world. Faculty can help students overcome their embarrassment by sharing information and statistics from the centers that show that many A and B students take advantage of tutors and academic support. Another suggestion is to have the staff from the center visit the classroom, or even better to take the entire class over to visit the center so that students will be familiar with the people and environment. Often a class visit

is all it takes to give underprepared students the confidence to ask for help.

Since their scholastic experience is limited, underprepared students are often confused by the idea of common knowledge. A definition is given by Stolley on the Purdue OWL Web site: “Generally speaking, you can regard something as common knowledge if you find the same information undocumented in at least five credible sources. Additionally, it might be common knowledge if you think the information you’re presenting is something your readers will already know, or something that a person could easily find in general reference sources.” However, underprepared students might have problems understanding the meaning of “undocumented,” “credible sources,” and “general reference sources.”

Paraphrasing is also difficult for underprepared students. Lacking formal academic language, they often cannot state in their own words what a source is saying. In order to avoid plagiarism, they instead quote whole sections of source material rather than summarizing or paraphrasing. Until underprepared students have the expanded vocabulary that comes with educational experience, paraphrasing will remain a difficult task for them. Faculty who receive an overly quoted paper should realize that the student is trying to follow the academic rules of citing sources and needs to be guided to gain control over those sources in small steps. Requiring students to print out and attach source material to their research paper rather than allowing students to rely on copying and pasting is one way teachers can help students begin the critical thinking process it takes to paraphrase and summarize.

A research paper or project is “one of the most challenging projects students undertake in college because it requires strong research, writing, and critical thinking skills to carry out successfully” (Sterngold, 2004), and the lessons learned from such a project are crucial to students’ educational experience. Unfortunately, because of the bad experiences community college faculty have had

when they get poorly documented papers, riddled with organizational and grammar errors, many stop requiring a research paper.

To help support underprepared students, many colleges offer developmental courses. Nordstrom (1997) states that according to the National Center for Education Statistics (NCES), 78 percent of all postsecondary institutions offered at least one developmental reading, writing, or mathematics course in 1995. Virtually all public two-year institutions and 81 percent of public four-year institutions offered developmental courses, while 63 percent of private two- and four-year institutions offered them. Developmental classes help older students review academic skills they may have forgotten and help recent high school graduates develop college-level skills they may have never been taught. Students who graduate from high school on a technical track, for example, may not have taken a foreign language, history, algebra, or academic writing class, so if they decide to attend college, they are deficient in many college-level areas.

FIRST GENERATION STUDENTS

Community colleges are often the choice for first generation students, but being the first person in the family to attend college is intimidating. Bureaucratic red tape, which is frustrating for most all students, is almost insurmountable for students who have no family or peer mentors. Technology has made it possible to put many of the traditional print-based institutional documents online, including class schedules, the catalog, and the student handbook. In addition, the admissions process, financial aid process, class selection process, and registration process at many institutions are also online, so students may feel like they have no face-to-face help to advise them either at school or at home. In addition, first generation students are often unprepared for college demands; Pas-carella et al. (1996) suggest that first generation

students enter college academically at risk and are not likely to experience conditions positively related to persistence, performance, and learning. They have weaker reading and creative thinking skills, lower degree aspirations, study less, take fewer humanities and fine arts courses, work more, complete fewer hours, less frequently attend racial or cultural awareness activities, and receive less encouragement from friends to continue enrollment.

MINORITY STUDENTS

Even though community colleges attract a high percentage of minority students, the degree attainment rates for minority students are dismal. Laden (2004) reports that in 2000, over 230,000 students earned community college degrees, with three-fourths of those degrees going to white students. "Despite the growing presence of nonwhite students, only 9.6 percent of associate degrees were awarded to African Americans, 10.1 percent to Hispanics, 5.3 percent to Asian American and Pacific Islanders, and 1.0 percent to American Indians and Alaska Natives" (p. 9). Many factors play a role in why many minority students fail to complete a degree, so institutions should continue to focus on the social, financial, and academic problems facing students and provide prompt assistance when warning signs appear.

SOCIOECONOMIC FACTORS

Community students often have financial issues. Tuition and fees have increased at community colleges, but not as fast as four-year institutions. Kasper (2002-2003) states that in-state tuition for community colleges for the academic year 1976-77 was an average of \$283 and by 2001-2001 had increased to \$1,359, an increase of 380 percent, while four-year public institutions' tuition rose

from an average \$617 to \$3,506, an increase of 468 percent.

Two out of five students enrolled in developmental courses receive some form of financial aid (Boylan, 1999) and Knopp (1996) found that nearly one quarter (22 percent) of those taking developmental courses reported an annual family income of less than \$20,000, while only 14 percent of those not enrolled in these courses reported the same income level. Many of these students do not have computers at home, so they may be as unsure of the rules of the Internet as they are the methods of online research, factors that might lead to unintentional plagiarism.

ADULT LEARNERS

In "Facilitating Responsibility for Learning in Adult Community College Students," Howell (2001) states that more than 2.5 million adult students (age 25 and older) attend community colleges, and Phillippe (2000) uses statistics from the National Center for Educational Statistics to show that in 1997, 32 percent of community college students were 30 years of age or older and 46 percent were 25 or older. Nordstrom (1997) found a 50 percent increase in the number of college students in the U.S. who are 25 years old or older, and the total number of adult students increased from 32 percent of the population in 1991 to 40 percent in 1995.

Many adult students need remediation, according to Roueche and Roueche (1999), who state that high school graduates who do not enroll in college immediately after leaving high school are more likely to need remediation in more than one subject area than graduates who enroll immediately. Therefore, as the adult population in college swells, so does the number of under-prepared students.

Even though adult students may need developmental courses or extra support services to brush up on academic skills they may have forgotten,

most studies including one by Whisnant, Sullivan, and Slayton (1992) find that older, nontraditional students perform at a higher academic level than younger, traditional students. Most college faculty are happy to have nontraditional students in their classes because they bring experience, life-lessons, maturity, and what Whisnant et al. call “an educationally focused personality” with them, attributes which motivate them to have a serious academic bent. Many are paying for their classes themselves since they are no longer dependent on parental support, so they intend to get their money’s worth.

Focusing on adult learners as a separate area of study from younger learners was first championed by Knowles (1984) who proposed a new label for adult learning, *andragogy*, to distinguish adult learning theory from *pedagogy*. Knowles’ model lists the following characteristics of adult learners:

1. Adults both desire and enact a tendency to be self directed;
2. Adults’ experiences are a rich resource for learning;
3. Adults are aware of specific learning needs generated by real life tasks or problems;
4. Adults are competency-based learners: they want to apply newly acquired skills or knowledge to their immediate circumstances; and
5. They are problem-centered rather than subject centered.

Although there is a debate about whether andragogy can be defined as a distinct learning theory (see Merriam & Caffarella, 1999, pp. 272-278), it offers educators a new way of looking at their students, allowing them more opportunity to choose, plan, and evaluate their educational experiences. Because adults want to apply their learning to their immediate circumstances, they may become frustrated with writing a research paper for its own sake, especially if the topic seems irrelevant or the task seems overly burdensome. Adult learners want to be able to connect mate-

rial to their own experiences; learning needs to be relevant and practical, so adults may feel that typical writing or research assignments are busy work. Bloomfield (2004) states, “If students believe an assignment is ‘busy work,’ some will be busy cheating.” Pearson (2004) states that “given the pressures students feel to produce a number of papers and to get good grades, they may feel it is not worth their time to write an original paper for a class not in their major.”

Adult learners bring a certain set of characteristics with them according to Horne and Carroll (1996): they are more likely to attend part-time, to enroll intermittently, to work full-time, and to support dependents, often as single parents. In the technology-filled classroom, adult learners may feel far inferior to their traditionally-aged fellow students who seem to have been born with a computer in their hands. They may make more inadvertent plagiarism mistakes because they are not familiar with Internet research.

Adults may take their classroom experiences more personally than traditional students, according to Zemke and Zemke (1988): “Self-esteem and ego are on the line when they are asked to risk trying a new behavior in front of peers and cohorts. Bad experiences in traditional education, feelings about authority and the preoccupation with events outside the classroom affect in-class experience” (p. 610). They may be embarrassed to ask for help from the teacher, especially in front of their classmates.

Adults who have worked in business before coming back to the community college for their first or second degree are familiar with the “just-in-time” system of inventory. Most businesses cannot stay profitable if they must store unneeded inventory. Many adult students transfer this idea to their learning and ask difficult questions of teachers. Exactly why do I need to learn this material? Exactly how will this class help me in my job and my life? According to Ryan (2004), “A just-in-time theory of knowledge says that it’s actually a waste of effort to learn things that

can be easily referenced. And as time becomes a premium commodity in our society, this may be an attractive concept” (p. 64). Ryan continues, “Yet educators know that the life-changing effects of thinking require introspection and examination, neither of which can be achieved through just-in-time knowledge acquisition” (p. 64).

Although this discussion has given examples of adult characteristics and reasons why adult students could be tempted to plagiarize intentionally, there is no evidence that adult learners would be more likely to do so than traditional college students. In fact, most evidence is to the contrary. Ercegovic and Richardson (2004) cite a large-scale study of students in the United Kingdom that found that cheating declines with age. Unintentional rather than intentional plagiarism may be the bigger problem for adult students because they have been out of school for several years and may not be aware of academic conventions.

TIME MANAGEMENT

One of the most common excuses students use for intentionally plagiarizing is lack of time (Breen & Maassen 2005, WPA Statement on Best Practices). According to the American Association of Community Colleges (2006), 80 percent of community college students work full or part-time jobs, and work often interferes with study time. The National Center for Education Statistics Report, “Special Analysis 2002: Nontraditional Undergraduates,” states that 46 percent of students who worked found that working limited their class schedule, 39 percent thought that working limited the number of classes they could take, and 30 percent found that working limited their access to the library. Almost half of the students reported that working has a negative effect on their grades.

Many students do not intend to plagiarize. Those who do usually have run out of time for their school work, and because of pressures from scholarships, family, or work, or because of un-

realistic goals, they see plagiarizing as a better choice than failing the assignment (Pearson, 2004; WPA Council). It often does not occur to them that the penalties for being caught plagiarizing can be much greater than failing a paper or even a class. Teachers who have not built contingencies into deadlines may actually be inviting plagiarism. A more balanced approach might be to give students who have a reasonable excuse an extension or to deduct points for late assignments, but still allow them to be turned in. This approach may encourage students to complete their assignments successfully rather than being tempted to plagiarize.

Many community college students lack time management skills. They are not just students; they are workers, husbands and wives, parents, volunteers, and daughters and sons, with tremendous responsibilities and real-life problems outside the classroom. Many community college advisors notice that students want to schedule their classes back-to-back, with no times for study or meals. Students try to squeeze every available second into attending class before they rush off to jobs, pick up children from school, or take care of aging parents. First generation or underprepared students may not have thought about the possibility of attending part-time to keep their grades high because they are so eager to complete a degree and move on with their lives and careers. Advisors could encourage students to schedule study time on campus. The campus library, computers, access to tutors, and technology access at most colleges is superior to what students have at home at their disposal, so students who stay on campus to study can do so without worrying about children’s needs, the doorbell ringing, and the pull of household chores.

Two-day-a-week classes are popular on community college campuses, especially with rising gas prices. Since most community colleges are commuter campuses, rising gas prices have hurt those students who have no options for public transportation or reasonably-priced dorms. Many community college students take a full load of classes on two days a week so they can attend

school full time and still work the other three days and weekends. First generation students may be unaware of the amount of studying time that college faculty expect, not taking seriously the statement in their class syllabus that two hours study is expected for every hour of class. They often slide by, attending class but not truly digesting material, until the results of first test confirm that they did not spend the appropriate amount of time outside of class studying.

Faculty who schedule more frequent assignments and tests help their students by making the amount of material that must be learned smaller and more concentrated. Boylan's (2002) *What Works: Research-Based Best Practices in Developmental Education* lists frequent testing as one of the most valuable study aids teachers can provide, a key component being testing over each unit of instruction (p. 78). Frequent testing can include paper and pencil tests, computer tests, practice tests, pre-post tests, quizzes, verbal questioning, recitation, group and individual projects written papers, reports, class presentation, or completion of exercises (p. 79). Another way teachers can help students with time management is for faculty to use a class discussion to take their students through a personal day by day calendar, having students input the number of hours per week they must attend classes, commute, work, and sleep to give students a picture of the requirements of their daily lives. Then students must include study, time with family, recreation, as well. The Academic Advancement Center at Ohio University has a useful exercise on their Web site called "The 168-Hour Exercise: How Do I Use My Time Now?" Students enter the number of hours they spend in class, in study, on personal care, on meals, on commuting, at work, and at sleep to get their total fixed hours. The computer will calculate how much flexible time they have left over and students can evaluate the results.

Many underprepared students have unrealistic goals. Giving them research projects that are set up in small steps—turning in a topic, then a working

bibliography, then notes, then a rough draft, then a peer-reviewed draft, then a final copy—helps them avoid procrastination. In addition, focusing on the process of writing a paper rather than the finished product means that students are less likely to buy a paper off the Internet and then backtrack to complete the required steps. Helping students manage their time is an important way faculty can reduce the possibility of plagiarism.

CRITICAL THINKING

Writing is thinking, so many of the problems community college students have with writing and research are actually critical thinking problems. Chaffee (1992) states that critical thinking is essential for college success, but few students are taught these skills in high school. In order to bridge the gap, problem solving and critical thinking should be taught as a part of each college course. Articles, research, resources, and conferences about critical thinking can be found at the Critical Thinking Community Web site. Boylan (2002) cites the model used by LaGuardia Community College in New York City which emphasizes the following skills: to solve challenging problems; to analyze complex issues and arrive at reasoned conclusions; to establish appropriate goals and design plans for action; to analyze complex bodies of information and make informed decisions; to communicate effectively through speaking, discussing, and writing; and to critically evaluate the logic, relevance, and validity of information (p. 96).

Students who are taught how to think logically and critically will be more ready to tackle writing and research projects with confidence and not be as tempted to plagiarize. Professors can use time at the beginning of the semester to suggest study strategies in their particular discipline, leading a class discussion about individual preferences and examples of students' successful or unsuccessful research attempts. Students might fill out a study

inventory with questions such as: what time of day do I study best? Do I prefer a quiet atmosphere? Does music help me study? What kind/s? How do my study techniques differ from course to course? Where do I like to study? Do I like to study alone or in a group?

Another helpful technique at the beginning of the semester would be to encourage students to take one or more of the dozens of online learning style inventories and write a short response paper about the results so that they may more completely understand their own learning preferences. A good source is Community College's Web site "How to Study," which has a list of learning styles sites (MacDonald, 2007).

MORE ACCESS TO TECHNOLOGY

Because one of the missions of community colleges is to provide career training, computers and technology are an integral part of many classrooms. However, this easy access to computers and the Internet may invite copy and paste plagiarism, which concerns teachers and administrators "who want students' work to represent their own efforts and to reflect the outcomes of their learning" (WPA Council). Scanlon (2003) states: "In the not-so-distant past, plagiarism at least required time-consuming physical work: going to the library, searching, reading, and copying. Now a student can cobble together a paper from online sources literally in minutes" (p. 164). Georgetown University's Web site confronts the copy and paste syndrome this way:

The trouble comes when you start to use someone else's words all throughout your paper. Pretty soon your paper looks like nothing but a field of quotation marks with a few country roads in between (your few sentences) connecting them. This does not represent very much intellectual work on your part. You have assembled a paper rather than writing one.

Technology has also meant that online classes have made higher education more accessible for students, especially for those who work swing shifts, are disabled, must take care of dependents at home, or have transportation problems. Enrollment in these classes is growing. However, faculty witnessing student plagiarism problems in the traditional classroom wonder if those problems are compounded by online classes because of the lack of face-to-face contact. Additionally, underprepared students may have particular problems with online classes since many of these students lack academic reading experience. Online classes demand a higher level of reading comprehension than traditional classes as well as careful time management, computer expertise, organizational expertise, and critical thinking skills, areas underprepared students may not have mastered. Without a face-to-face teacher to provide quick answers to the dozens of questions underprepared students might face in a typical research or writing assignment, inadvertent plagiarism should probably be expected.

Scanlon (2003) cites recent studies that suggest that instances of plagiarism have not necessarily grown because of easy access of the Internet. A study by Scanlon and Neumann in 2002 found the same levels of copy and paste plagiarism occurred as were found by a 1996 survey by McCabe and Trevino, approximately 25 percent. "Of course, no one should be happy that 'only' a quarter of college students surveyed self-reported Internet plagiarism, even if this number argues against popular notions of an epidemic of online cheating" (p. 162).

ADJUNCT FACULTY

Depending on adjunct faculty is one way community colleges fulfill their mission to connect education and the work world, and a high percentage of adjuncts teach developmental classes. Boylan (2002) cites a study by the American Association

of Community Colleges that found that over 65 percent of developmental faculty is part-time, and there is no evidence that adjunct teachers are any less successful than full-time teachers (Boylan, Bonham, Claxton, & Bliss, 1992). Many adjunct faculty members work full-time in business or industry and teach night or weekend classes, bringing the relevancy to the classroom that community college students demand. In addition, relying on adjunct faculty helps keep costs down for community college students. However, adjunct faculty, who are paid a fraction of the salary that full-time faculty receive and who may only be on campus for three hours a week, may not have the same kind of time or the same kind of academic bent that full-time faculty have, which could include trying to keep plagiarism issues at the forefront. Sterngold (2004) states, "Planning, managing, and evaluating research assignments are difficult tasks, and having to worry about plagiarism only adds to the burden" (p. 17). In addition, industry boilerplates and ghost writing are common occurrences in the business world, so some adjunct teachers may not be overly concerned by seemingly slight offences.

Because some adjuncts may not have taken education courses or may not be able to attend in-service professional development opportunities at the college, they may rely on the teaching methods that were used when they were in college, some of which Sterngold says, "invite cheating" (p. 16). He elaborates:

The traditional paradigm favors lecture-based courses, orderly classroom environments, and limited interaction between professors and students. . . [and] in the absence of strong institutional incentives to adopt learning-centered methods, many instructors rationally choose to continue using familiar, lecture-based teaching methods that are easier, safer, and less time-consuming to practice. (p. 17)

Most adjunct faculty are highly qualified, caring individuals who teach for little compensation because they have altruistic motives: they want to share their expertise with others. However, they probably cannot be expected to direct the same kind of attention to plagiarism problems as full-time faculty. Community colleges must provide adjunct faculty with the same kinds of in-service training about plagiarism issues that they provide full-time faculty, as well as giving information on the institution's Web page or in an adjunct handbook so that all instructors know the institution's stand on plagiarism and where to go for help if needed. Boylan (2002) states that adjunct faculty should be invited to attend faculty meetings, social activities, and professional development workshops. In staffing developmental classes, he suggests that institutions should only hire adjuncts who have a desire to teach those classes and that mentoring of adjuncts is important.

RESEARCH ACROSS A THE CURRICULUM

Many community college students arrive on campus with preconceived notions about plagiarism. Having an institutional policy that is clear and understandable for students is a beginning, but much more is needed. Discussing how the research process takes place in a particular discipline is every content teacher's responsibility, and no faculty member should assume that students know how to conduct research. Students in a history class need to know ethical ways to conduct ethnography research and students in a biology class need to know ethical ways to conduct scientific research. A Research Across the Curriculum emphasis is just as important at community colleges as a Writing Across the Curriculum emphasis because composition courses cannot possibly include all the ways different disciplines conduct research. When students hear about how to gather evidence, organize findings, write a report, and cite sources

ethically from all their professors, not just from their English instructors, they will realize that proper research is an issue that is important in their future jobs.

SOLUTIONS

In helping diverse community college students learn the writing and research process, no one teaching method has emerged as the best. Instead, faculty should use as many different kinds of methods as possible (Boylan, 2002). Although many community college teachers still use the lecture method followed by drill work, best practice institutions use a variety of methods including: distance learning, self-paced instruction, individualized instruction, peer review of student work, collaborative learning, computer-based instruction, mastery learning, small-group work, and other active learning techniques (Boylan, 2002, p. 73). Group projects and collaborative writing are methods many business, science, health, and agriculture faculty use to mirror real-world work practices. Faculty can give students information about learning styles, helping them understand their own preferences and perhaps experiment with different learning approaches. Many community college students are visual or kinesthetic learners, so the lecture method may not be the best way for them to learn. They should have the opportunity to use manipulatives, videotapes, computer graphics, models, labs, and field trips (Boylan, 2002, p. 75). The key is diverse teaching methods for diverse students.

Most sources agree that faculty should be proactive rather than reactive in their efforts to teach research and writing skills to students by using pedagogically sound course and assignment design rather than punitive after-the-fact methods (Akers, 2002; Bloomfield, 2004; Carbone; Davis, 1993; Ercegovic & Richardson, 2004; Harris, 2004; Martin, 1994; McDonnell, 1999; Pearson, 2005; Scanlon, 2003). For Ercegovic & Richardson,

2004, "It is simply not enough to define plagiarism, distribute neatly prepared citation templates for different formats, and say that plagiarism is wrong, punishable, easily detectable, and against honor code." Some sources suggest taking most of the punishment away from plagiarism. Martin (1994) states that plagiarism

is given too much attention and condemned in far too extreme terms. Given the pervasiveness of plagiarism, it should be treated as a common, often inadvertent problem rather like speeding on the road or cheating on income taxes. Most cases should be dealt with as matters of etiquette rather than 'theft'. (p. 44)

In his Web article, "Talking About Plagiarism," Carbone begins the plagiarism dialog with his syllabus. He disagreed philosophically with the typical syllabus in his course, which had a brief definition of plagiarism that concluded with the punishment a plagiarist would receive if caught. "My conflict here is that I don't lead any other discussion with threats, so why one on plagiarism? Why start off scolding? Why build anxiety and fear when I know that I'll be asking students to learn complex literacy skills, writing skills, and academic conventions?" He suggests that plagiarism is a matter of Dos and Don'ts in a list for students that he uses in class discussions throughout the semester.

McDonnell (1999) also suggests faculty use a proactive approach to plagiarism. He lists the following suggestions: 1) create and/or find assignments so unique to your teaching style that they can not be duplicated outside it; 2) use authentic assignments based on experiential learning such as service learning, writing for action, or writing for the community; 3) stress collaborative learning; 4) use the writing process and become involved in all five steps: prewriting, writing, evaluation, rewriting, and editing; and 5) include primary research in as many projects as you can such as interviews, telephone calls, or family documents.

The “Preventing Plagiarism” Web site from the University of Alberta Libraries suggests that plagiarism be discussed as a moral issue: “The relationship between faculty and students is based on trust; teach students the value of academic honesty and outline the responsibilities of being a junior member of the academic community.” In addition, this site suggests that faculty discuss the benefits of citing: “proper attribution shows that the student has done thorough research and that the student has been exposed to a diverse range of thought and opinion. As a result, the paper will likely be stronger.”

In her chapter “Preventing Academic Dishonesty,” Davis (1993) lists general strategies faculty should start with to help students understand academic conduct; defines plagiarism, paraphrasing, and direct citation; discusses how to pick appropriate paper topics; and lists ways faculty can provide students with help during the writing process.

Harris (2004) has a very helpful Web site for faculty, discussing the reasons why students cheat, strategies for prevention, and strategies for detection. Suggestions that Harris gives to help teachers prevent plagiarism include: make the assignment clear and specific; provide a list of specific topics and require students to use one of them; require specific components such as one or more sources written within the past year or incorporation of information the teacher provides; require a metalearning essay—an in-class essay about what students learned from the assignment. He also gives a list of detection strategies.

Coastal Carolina University’s Web site “Cheating 101: Easy Steps to Combating Plagiarism” suggests that the writing or research topic be tied into class experiences.

- Have writing assignments that have students analyze classroom activities or discussions in light of the text.
- Use local issues as topics.

- Ask students to include a section in their term paper that discusses their topic in light of what was covered in class.
- On the final exam, ask students to summarize the main points of their research paper.

The Electronic Plagiarism Seminar from Lemoine College (2005) by Gretchen Pearson, Public Services Librarian, also has good suggestions for faculty. Her list includes: talk about plagiarism, focus on research skills, lower the stakes so that a single paper is not the entire grade, require primary research, think about the primary purpose of the assignment, and be wary of the request for a last-minute change in a topic. She also has suggestions for using the writing process to prevent plagiarism and detect plagiarism.

Bloomfield (2004) reminds us that in order to prevent plagiarism,

...students need to be taught that the act of writing is intrinsically valuable to them. It crystallizes one’s thoughts in a way that nothing else can. As a physicist, I find that I often learn more from writing papers and proposals that I do from working in the laboratory. I rarely find writing easy, but I always find it rewarding.

ACTIVE LEARNING TECHNIQUES AND THE LEARNING COLLEGE

A radical educational shift from a focus on teaching to a focus on learning has motivated community college leaders in the past decade, a shift championed by the League for Innovation in the Community College. The Learning College is one which “places learning first and provides educational experiences for learners anyway, anyplace, anytime.” This emphasis on cultivating an organizational culture that supports learning as the major priority has as one of its project goals “to create or expand learning-centered programs

and strategies to ensure the success of underprepared students.”

Sterngold (2004) refuses to agree that plagiarism is a product of “students’ laziness, lax morals, or ignorance of the rules ... Before placing all the blame on students, we should consider how conventional teaching methods invite cheating, and how strategies designed to improve student learning can prevent it” (p. 16). He continues:

It turns out that many of the learning-centered teaching practices reformers have been advocating for years can help deter plagiarism as a byproduct of improving student learning and performance These strategies discourage plagiarism by making it difficult for students to cheat and also by eliminating many of the incentives to cheat. At the same time, these strategies allow instructors to treat most instances of plagiarism as fixable errors rather than fatal violations of academic policies. (p. 17)

Johnson (2004) also gives strategies for combating plagiarism in his article, “Plagiarism-Proofing Assignments” by listing Low Probability of Plagiarism (LPP) assignments. He states that LPP projects:

1. Have clarity of purpose and expectations
2. Give choices to students
3. Are relevant to students’ lives
4. Ask students to write in a narrative rather than an expository style
5. Stress high-level thinking skills and creativity
6. Answer real questions
7. Involve a variety of information-gathering activities
8. Tend to be hands-on
9. Use technology to spur creativity
10. Use formats that engage multiple senses
11. Can be complex but can also be broken down into manageable steps

12. Are often collaborative and can produce better results than individual work
13. Share results with people who care and respond
14. Are authentically assessed
15. Allow learners to reflect, revisit, and improve their final projects
16. Are encouraged by adults who believe that, given enough time, resources, and motivation all students are capable of original work

Scanlon (2003) suggests that using plagiarism checker software is not necessarily a good teaching strategy because the software could cloud whether the plagiarism was inadvertent and could “introduce an element of distrust” which turns faculty into “detectives with new—and as yet unproven—high-tech tools at their disposal, rather than teachers instructing students in what, for many of them are baffling principles and techniques” (p. 165). He suggests using mechanical means of detection during the writing process rather than afterwards “as a teaching tool... to provide an opportunity to discuss the proper handling of sources” (p. 165). Other examples of using well-designed assignments and topics to prevent plagiarism are discussed by Bolkan (2006), Carbone’s “Thinking About Plagiarism,” Fister, (2001), Leland (2002), McCullen (2003), McKenzie (1998), and Murray (2002). Fister lists a useful bibliography that includes general discussions of student research processes and problems as well as sources for specific assignments. Ercegovic and Richardson (2004) use Kohlberg’s States of Development in Moral Reasoning to chart how research can be put into practice at all educational levels.

PORTFOLIOS

Portfolios have been defined as a collection of student work (O’Malley & Pierce, 1996), so portfolios can be used effectively to collect all of the information gathered in the research process.

One method is to divide the research process into sections: topic selection, working bibliography, copies of source materials, first draft, peer-reviewed draft, final draft, and evaluation. The sections may have distinct due dates and may be kept together in a large mailing envelope, so the teacher can judge whether the student is making adequate progress or needs further instruction. Portfolio criteria often include a metacognitive essay in which the student evaluates his or her progress, learning process, goal achievement, and other categories. O'Malley and Pierce (1996) consider this self assessment to be the "key" to the portfolio process, so students are urged to become "independent evaluators of their own progress" (p. 38).

In his article "Using Portfolios to Avoid Plagiarism in Your Class," Carbone lists several ways that portfolios can benefit students: they help students manage time and set smaller goals and deadlines; teachers can tie the portfolio into issues of plagiarism; teachers can see how students research; teachers can see student work from the start; teachers can identify struggling students; failure to do a portfolio can result in the final paper graded as incomplete. Carbone also states that portfolios can also give students the opportunity to write before researching, which "helps avoid the get-a-stack-of-sources-cobble-quote-cite-and-then-patch-a-paper-together-thing that often results in voiceless, bland, unengaged research writing." Carbone suggests that the portfolio begin with a "knowledge of inventory: a list of everything [students] think they know about their given topic" which lets students "get their voice on paper."

LOWER CLASS SIZE

Community college faculty may be able to react to plagiarism problems more readily than four-year faculty because their class size is often smaller, making it possible for them to know their students

by name and by their writing style. Knowing their students means that community college faculty, who have more required office hours than four-year faculty, can personally meet with students who might be having problems with research. Trust builds between community college faculty and students, enabling faculty to deal with plagiarism problems "as educators first" (Scanlon, 2003). Large classes are listed as a factor that was positively correlated with academic cheating and plagiarism according to a study of nineteen colleges in the U.K. by Ashworth, Bannister, and Thorne (1997).

CONCLUSION

Although technology has made plagiarism easier than ever, educators have many strategies to combat both intentional and unintentional plagiarism. Bolkan (2006) says, "The final deterrent strategy, solid assessment and good teaching, can't be over emphasized....Motivation, of course, is the key. Motivated and engaged learners are much less likely to take shortcuts. If they're only in your classroom to get a grade and move on, the potential for plagiarism will be greater" (p. 12). Intentional plagiarism can be addressed by restructuring assignments, helping students develop better time management skills, and using learner-centered teaching methods. Unintentional plagiarism can be addressed using student/teacher conferences, portfolios, peer and self evaluations. Writing and researching are critical thinking skills that should be incorporated in every class. To Sterngold, "Indeed, acquiring strong research and writing skills may be more important to students' future careers than acquiring subject-matter expertise that may become outdated soon after the students graduate or that may become irrelevant when students switch jobs and careers."

Section VI

Managerial Impact

This section presents contemporary coverage of the social implications of instructional design, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be facilitated within organizations. Section 6 is especially helpful as an addition to the organizational and behavioral studies of section 5, with diverse and novel developments in the managerial and human resources areas of instructional design. Typically, though the fields of industry and education are not always considered co-dependent, section 6 provides looks into how instructional design and the business workplace help each other. The interrelationship of such issues as educational design, quality improvement, work ecology, teacher self-confidence, technology skills, and professional development are discussed. In all, the chapters in this section offer specific perspectives on how managerial perspectives and developments in instructional design inform each other to create more meaningful user experiences.

Chapter 6.1

Prevention is Better than Cure: Addressing Cheating and Plagiarism Based on the IT Student Perspective

Martin Dick

Judithe Sheard

Monash University, Australia

Maurie Hasen

Monash University, Australia

ABSTRACT

This chapter adopts a four-aspect model to address cheating and plagiarism in universities: education, prevention, detection, and consequence. The research focussed on the two aspects of education and prevention as the authors feel that this area has not been considered in detail by the research. Building on past research, a series of eight focus groups (72 students) were conducted with students from information technology degrees at an Australian university. The students were asked to comment and discuss the phenomenon of cheating from their perspective. The chapter presents in detail the responses of the students as analysed by the researchers and then builds a set of guidelines for educators to use in the areas of education and prevention in relation to student cheating.

INTRODUCTION

The problem of cheating is a long-standing one. Despite recent claims that the Internet and a decline in moral standards has caused a large increase in cheating, the evidence is that cheating has been a problem in universities over many decades (see for example: Bowers, 1964; Hetherington & Feldman, 1964; Stern & Havlicek, 1986). Yet most universities have not seriously addressed the problem unless forced to by events. The WIRA incident at the University of Newcastle in Australia where a blatant cheating situation was ignored by senior management as long as was possible is an exemplar of this approach and which led to an inquiry by the New South Wales Independent Commission against Corruption and the condemnation of the relevant senior management (Cripps, 2005; Longstaff, Ross, & Henderson, 2003).

DOI: 10.4018/978-1-60960-503-2.ch601

Where universities have addressed the issue of cheating, the predominant approach has been one of punishment. Taking a broader view, we see the process of addressing cheating as having four aspects:

- **Education:** putting in place educational processes that provide students the necessary skills and knowledge to allow them to avoid cheating and to understand why cheating is undesirable. It also covers the education of academics to ensure that they understand the processes of the university in relation to cheating and that they implement good educational practice that will reduce cheating.
- **Prevention:** designing assessment so that cheating is both difficult to do and counter-productive for the student to attempt.
- **Detection:** establishing processes that allow academics to detect cheating when it occurs and also establishing processes for students to identify problems with their work prior to submission, for example, allowing students to submit work to a plagiarism detection service.
- **Consequence:** creating fair and equitable processes for dealing with cheating situations appropriate to the circumstances of individual cases.

We believe that in order to properly address these four areas, it is necessary to have a good understanding of the major actors in the situation, that is, the students, the academics and the university. We address in detail only the first group of actors, the students, as this chapter intends to provide assistance to individual academics in their approaches to reducing cheating as opposed to the development of general university policy. Subsequently, the chapter examines the aspects of *education* and *prevention* because the aspects of *detection* and *consequence* have been covered in

detail in previous work (see Jude Carroll's work [Carroll & Appleton, 2001] for an excellent and comprehensive discussion of the policy issues surrounding cheating and plagiarism). The aspects of *detection* and *consequence* are more appropriate to the strategic approach needed in the policy area as opposed to the tactical approach needed in the teaching area. In addition, dealing with cheating once it has been detected is both time-consuming and difficult in the best of situations. By focusing on *education* and *prevention*, the overall time and effort required to manage cheating is reduced.

Education and *prevention* are not sufficient lenses in themselves to understand the student perspective. It is also necessary to determine the student's understandings of, and motivations for cheating. From this framework we aim to develop guidelines for educational curriculum and for designing assessment for academic programs.

BACKGROUND

This section addresses four questions that are raised by the current discussions of cheating in the community and which are necessary to inform our understanding of the student perspective:

1. What is cheating?
2. Should we be concerned about cheating in the university sector?
3. What influences students to engage in cheating?
4. How are universities currently addressing this problem?

What Is Cheating?

There are many ways that tertiary students may cheat, making it difficult to arrive at a simple definition of cheating. A search of the literature has shown that cheating is often defined using multiple dimensions. These typically are described

by sets of practices that encompass illegal, unethical and immoral behaviours, and behaviours that are against generally accepted institutional codes of practice. In some cases, however, whether a practice is cheating or not can depend on the rules set by an educator within a particular educational environment or for a particular task. For example, students may be encouraged to collaborate on a particular task but instructed to work individually on another. Cheating is a complex concept to define, leading to confusion as to what constitutes cheating (Ashworth, Bannister, & Thorne, 1997). We have defined a behaviour to be *cheating* if it violates the rules that have been set for an assessment task or it violates the accepted standard of student behaviour at the institution (Sheard, Markham, & Dick, 2003).

Why Is It A Concern?

Along history of studies indicate alarmingly widespread and high rates of cheating in universities (Bowers, 1964; Franklyn-Stokes & Newstead, 1995; Marsden, Carroll, & Neill, 2005; McCabe, 2005; Sheard et al., 2003)). Of further concern is that there are indications that the incidence of cheating is possibly increasing (Cole & McCabe, 1996; Diekhoff, LaBeff, Clark, Williams, Francis, & Haines, 1996). Major factors in this trend are changing assessment practices (e.g., online tests) and the increased use of technology enhanced teaching and learning environments (such as WebCT, Blackboard, and Moodle), which allow students more opportunities and a greater variety of ways to engage in cheating behaviour.

Levels of cheating and the changes in cheating patterns form a complex picture that needs to be viewed in light of changing educational practices, new learning environments and changing student work practices. Cheating can have many harmful consequences, but for the authors cheating is fundamentally about failing to learn. As educators we find that unacceptable and therefore a major concern.

Influences on Cheating Behaviour

When investigating cheating behaviour, it is important to determine the reasons why students cheat and the factors that prevent them from cheating. A number of studies of tertiary students have found that the most common reasons for cheating are time pressures and the need to pass or gain better grades (Davis & Ludvigson, 1995; Franklyn-Stokes & Newstead, 1995; Sheard & Dick, 2003). These studies also found that a commitment to learning and a desire not to engage in unethical or dishonest behaviour influenced students not to cheat. The comparative study of undergraduate and graduate students by Sheard, Markham, and Dick (2003) found that the reasons for cheating were the same for both groups of students; however, the reasons were rated more strongly for the undergraduate students and, in most cases, these were significant. In contrast, the factors that influenced students not to cheat were higher for the graduate students. A consistent finding across many studies is that fears of detection and punishment were not rated highly as factors that would prevent cheating.

Addressing the Problem

As stated in the introduction, the four major aspects for addressing cheating have been education, prevention, detection and consequence. Our particular focus on the education and prevention fronts has been predated by many studies and a brief review should provide a sense of development in both areas.

The establishment of honour codes has addressed both issues of education and prevention and seems to offer a reliable level of ensuring cheating is minimised, at least within the North American experience (McCabe & Trevino, 1993). Peer disapproval was assessed as having the greatest effect on cheating levels (McCabe & Trevino, 1997). Particular success seems to be found in the US, in smaller or military based colleges and

universities where students share common values (Maramark & Maline, 1993). But as the size of classes and institutions rises, so too does student anonymity and the honour code loses its potency (McCabe, 2005). Honour codes have also not been part of the largely non-residential university population in Australia, and therefore have not been used in the local response to cheating practices.

Davis and Ludvigson (1995) are also sceptical about external deterrents and emphasise the importance of students learning to take greater responsibility. They posit that it is "...only when students have developed a stronger commitment to the educational process and an internalized code of ethics that opposes cheating will the problem be eradicated" (p. 121).

Asophisticated concept that would have IT students taking on more responsibility over unethical practices both at university and in the workplace, can be found in the model proposed by Greening, Kay, and Kummerfeld (2004). Their proposition suggests an integration of scenario-based ethical problems into the computing curriculum as a means of institutionalising ethical study as core content. The authors would use a survey as a teaching implement rather than a research one, to spark interest and engagement, and in so doing, enhance student awareness of a vast array of questionable practices.

Plagiarism detection programs such as Turnitin which might otherwise cause fear and loathing can be used as educational tools to inform students of accepted academic practice (Barrett & Malcolm, 2006). In such programs, students are encouraged to scan their work until the program indicates it is clear of plagiarism.

In a similar attempt to allay student anxiety about inadvertent plagiarism, McGowan (2005) maintains that students must begin their academic careers with an appreciation of the conventions and values of academic inquiry. If the university can achieve this objective, then students will be far more positive in their approach to learning and

less concerned with plagiarism and its detection; as McGowan puts it: "plagiarism minimisation."

Reynard (2000) is mindful of both the unintentional and deliberate cheater and the efforts required to reveal and prosecute them. Her response is to bypass that process and design "Cheater-Resistant Assignments." Usually these tasks involve contributing something of one's own experience. Therefore, she suggests that an assignment that might typically ask for an analysis of the plot of *The Odyssey* could be framed as an exposition of a student's life journey, and how it might share some qualities with that of Odysseus. Reynard identifies several critical elements that help to cheat-proof a paper. For example, changing topics from year to year, being more specific when choosing topics for assignments, and monitoring all the stages of the writing process, are some of the many helpful suggestions.

Zobel and Hamilton (2002) address specific IT issues by recommending "verifiable submission" which involves presenting assignments electronically so that each will be identified by a user-name and a date-stamp. They suggest that students be required to submit draft submissions as well as source archives that will allow tracking the development of the assignment. This would overcome the last minute panic phenomenon that might otherwise encourage desperate responses.

In their comprehensive and insightful guide to dealing with plagiarism, Carroll and Appleton (2001) echo Reynard's suggestions, and add,

...reconsider the learning outcomes for the course and decrease those that ask for knowledge and understanding, substituting instead those that require analysis, evaluation and synthesis... (p. 10)

Perhaps Carroll and Appleton's most significant contribution is their emphasis on changing the atmosphere of the learning environment to one of engagement and commitment. This notion of cultural change is by no means new, with stud-

ies such as that by Dick, Sheard, Bareiss, Carter, Joyce, Harding and Laxer (2003) suggesting the provision of orientation programs for new students, as well as programs designed for academics to embrace cultural change.

RESEARCH METHODOLOGY

The goal of the research was to obtain a deeper understanding of the student perspective in relation to student cheating and plagiarism. In order to do that, we concentrated on the following issues with the students:

- Understandings of cheating and plagiarism
- Motivations for cheating and plagiarism
- Methods by which the university can reduce cheating and plagiarism

While survey research has been the mainstay of most cheating and plagiarism research, there have been exceptions (for example, Carter, 1998). In our study, we saw the need to extend the sources of data beyond that provided by surveys. A qualitative approach was used to provide a richer level of detail than that provided by the authors' past survey research. Observational techniques were considered to be impractical in this area, so this led us to the decision to use interview techniques. While individual interviews could have been used, it was felt that the interactive nature of focus groups led by a trained facilitator would be more likely to surface valuable material from the students than interviewing individual students in isolation.

Students were recruited to the study via announcements in a number of lectures. One of the authors presented the research process to the students and answered any questions. Students then nominated via a form, to participate in the focus groups. Students then were contacted and asked to attend one of the groups.

The distribution of students in the focus groups was stratified. Firstly, it was decided that it would be useful as well as practical to be able to distin-

guish between the traditional campus students and the technology campus students as there may be differences in the culture at the two campuses. This was considered likely, not only due to the different backgrounds of the campuses (traditional campus – originally a traditional university, technology campus – originally an institute of technology), but also because the students are enrolled in different degrees. Traditional campus students are enrolled in either a three-year bachelor of computer science or a four-year bachelor of software engineering. Technology campus students are enrolled in a three-year bachelor of computing. Our previous research had also indicated that there were some differences in levels of, and attitudes to, cheating at the different campuses.

Secondly, full-fee students were separated from Higher Education Contribution Scheme¹ (HECS) students for two reasons. Full-fee students are nearly entirely international in the student body and in the focus groups there were no domestic full-fee students. The first reason was that we felt that international students may feel freer to talk if there were no domestic students present. The second reason was the belief amongst some academics (Dick et al., 2003) and also in the general community that international students are more likely to cheat than Australian students. Our previous research does not support this belief, but we felt that it was worthwhile to explore the differences in opinion between international and domestic students. Our belief is that if there is any difference between international and domestic students, it is more likely to arise from the economic imperatives of full-fees than cultural differences.

Finally, the focus groups were divided on the basis of year level. Second and third year students were grouped together as they had both had significant experience of the university environment, and our previous research had shown little difference between the two year levels. First year students have had less experience of the university environment, therefore it seemed likely that separating them from the other year

levels would be useful. No fourth year students from the bachelor of software engineering were involved in the focus groups.

The eight focus groups were organised on the basis of campus, fee status, and year level. Table 1 shows the profile of the focus groups that took place.

The gender balance of the focus groups approximates the gender balance of the student populations in the relevant degrees.

The interviews were conducted in an open manner with the facilitator directing the discussion in a light way. The students were free to range around the general issues introduced by the facilitator. The focus group discussions were audio-taped and then transcribed. Transcriptions of the focus group interviews were analysed with the NVivo tool using a grounded theory approach (Strauss & Corbin, 1998).

Ethical Issues

In conducting the focus groups it was inevitable that examples and possibly even admissions of

cheating would occur. In order to ensure that no harm came to the participants in the focus group in the event that they admitted to cheating, a variety of measures were undertaken. An independent facilitator with no links to the university was hired to conduct the focus group; none of the academics who had any connection with the students was involved. The audiotapes were then transcribed by another independent person in such a way that students were only identified by their gender and it was not possible to attribute any statement to a particular student. Students also were advised of the process prior to participating in the focus groups to ensure that they were fully informed.

A final ethical issue was that the students were paid for their participation in the focus groups. As students were spending one to two hours in the focus group, the authors felt that it was appropriate to reimburse them for their time participating in the study. Students were paid a fee of Aus\$30.00 to participate. The research was approved by the Monash University ethics committee (Application number 2004/494).

Table 1. Focus group profiles

Focus Group	Campus	Fee Status	Number of 1 st Year Students	Number of 2 nd Year Students	Number of 3 rd Year Students	Male	Female	Total
1	Technology Campus	Full Fee	8			2	6	8
2	Technology Campus	HECS	9			7	2	9
3	Technology Campus	Full Fee		3	4	5	2	7
4	Technology Campus	HECS		5	3	6	2	8
5	Traditional Campus	Full Fee/HECS (6/2)	8			8	0	8
6	Traditional Campus	HECS	10			7	3	10
7	Traditional Campus	Full Fee		6	5	7	4	11
8	Traditional Campus	HECS		6	5	8	3	11
Totals			35	20	17	50	22	72

THE STUDENT PERSPECTIVE

This section details the results of the analysis of the focus groups based on the framework presented in the introduction. This framework consists of the four concepts of:

- Understandings of cheating and plagiarism
- Motivations for cheating and plagiarism
- Education to prevent cheating and plagiarism
- Prevention of cheating and plagiarism

In each section, the dominant concepts that arose from the focus groups will be presented with quotes to illustrate them.

Understandings

Student understanding of cheating phenomena is overall shallow and literal, as will be seen from the following concepts which arose from the analysis of the focus groups. As opposed to this shallow conceptual understanding, students displayed a sharp understanding of the practicalities of cheating when asked about the cheating methods that they were aware of.

Cheating is About Plagiarism

The first concept to arise from the interviews was that “Cheating is about plagiarism.” At the start of each interview, the facilitator asked the students to indicate what their understanding of the purpose of the focus groups was. The great majority of students indicated that the purpose was to address the issue of plagiarism, for example “It’s a focus group about plagiarism” or:

The university’s educational emphasis has been on plagiarism as opposed to other forms of cheating and students have taken this attitude on board. Further probing by the facilitator was usually able to elicit more broad understandings of cheating from the students, but it was clear that

for many students their salient understanding of cheating was restricted to plagiarism.

Cheating is Easy

One of the clear statements from students that arose out of the focus groups was that students believe that it is easy to cheat. A perception that cheating is not difficult is highly likely to encourage cheating amongst the student population.

It’s pretty easy especially with IT, the technology, just copy and paste from other files. A lot easier than pen and paper where you have to read it and then copy it.

Cheating is Inevitable

Many of the students saw cheating as the natural way of things and that it was inevitable. Exemplars of this attitude were:

For example, if you can get the material from someone else it’s easy. You can see it everywhere. It’s kind of like a human network. You know this person, you know another one. And if you can cheat you take the opportunity to cheat.

Seriousness of Different Types of Cheating

One of the understandings that arose from the focus groups was that they saw cheating as a range of behaviours and that the seriousness differed depending upon the type of behaviour. The most serious form of cheating was that done in exams as the students exhibited some trust in the exam to assess them fairly, despite as we will see later on, their considerable knowledge of ways around exam protocols.

I think we all trust the exam process though.

Overall, students reported that they considered exam cheating to be a “bad thing.”

But like if you go into an exam and you pull out cheat notes or something like that, I think that's much worse than just copying an assignment and then not referencing it properly.

Literal copying was also considered to be serious by many students:

Unacceptable, I think, would be like direct copy.

Though quite a few students did not find literal copying to be a particularly serious matter:

See if a friend of mine wanted to copy off me I wouldn't be too impressed. But it would only bother me in terms of not giving him the work if I thought there was a chance of getting caught. Otherwise I'd be happy for him to just take it

What was considered to be significantly less serious, was assistance for the purpose of learning, even where this might be considered by lecturers to be cheating. For example, the student above who referred to copying a substantial portion of a program extended his comment:

I've got no problem with someone looking at my program even if they look at every line of it and ask me why do you do this. ...I've got no problem with it because they've learnt that and the next time they do that it wouldn't be considered cheating.

This student amongst others made a clear distinction between copying where the purpose was to learn as opposed to just completing an assessment task without attempting to understand the material. The following student made a similar point:

It also depends on what people classify cheating as. Like if you look at someone else's work because you don't understand something and you write it

down and then you learn from it well then do you call that cheating? If you're learning from something that you've been given by someone else...

6 Words or More

In several courses in the degrees, students are provided with the following rule:

Six words or more in a row without quotes or references is plagiarism!

The aim of the lecturers in these courses is to provide students with a clear, objective measure of plagiarism and thereby allow the students to easily avoid it. Unfortunately, the student response is that they are far from reassured that this assists them to avoid plagiarism. In fact, it seems to create significant stress for the students with its arbitrary size:

If you get like 6 words the same you get caught and some people would do it by accident.

Boundaries of Cheating

The students were clearly confused about where the boundaries of cheating were, especially in the area of collaboration (acceptable) versus collusion (unacceptable). In all the degrees these students were enrolled in, many courses emphasized to the students that they should share ideas and work with other students. This was not always the case though, in some courses, the rule was that all work must be done by the individual and no collaboration was allowed.

I guess copying so much isn't so good but often lecturers will say it's good to try and teach other people. Because it helps reinforce the knowledge and I agree. I think to try and help somebody do the problems is the best way as well no, you got to write, it helps you know as well.

The lines are fuzzy. It's not defined really.

Pointlessness of Cheating

A key point for many students was that they considered cheating to be a pointless activity for two reasons. Firstly, cheating prevented them from learning and secondly they would be unprepared for their future careers.

What's the point of cheating if you don't learn anything.

I don't understand why you do it. ... Like when you get out of here you don't know anything and you pay this money you might as well learn it and understand it or change courses or do something else. Cheating is a waste of time.

Motivations

In attempting to reduce cheating in the classroom situation, it is important to understand the perceptions of students in relation to their and other student's motivations to cheat. It is also important to listen to what students say about what motivates them to choose not to cheat. The previous section on Understandings overlaps with student motivations in two areas. One of the reported motivations for cheating which has already been mentioned in the section on Understandings, is the inevitability of cheating. Where students believe that cheating is inevitable, it becomes a motivation for them to cheat themselves. On the other hand, clearly the student's understanding of cheating as pointless provides us with information as to the motivation for not cheating. Students who value learning will be far less likely to cheat. Other motivations that were presented by the students are reported in the following sections.

Laziness

The most commonly raised reason for cheating by the students was that cheating students were lazy. This is a rather damning statement about

their fellow students but it was consistently raised without any prompting by the facilitator.

Some people are just lazy and they just want to get by without doing anything.

I think what leads to cheating is just some people are lazy.

If students perceive other students as lazy, they are less willing to collude in cheating with their fellow students by providing assistance.

It depends why they need it as well. If somebody who really doesn't understand...has been going to lectures and doesn't understand and they've got a prac coming up and they need help with something its different from if somebody is just... they know what they're doing but they're just lazy and haven't done it and they just want to copy you because they couldn't be bothered.

Financial Pressure

Both local and international students reported that financial pressures can be a factor in causing students to cheat.

And with international students they have like... not all of them, but some of them have a financial burden. Like they got to look after their rent. Their general fees. They don't get concession on buses and trains and stuff and it all adds up in the end and they need to work for it. Do you know what I mean.

With HECS as much as it is people are under a lot of pressure. They don't want to fail. It'll cost you about \$800 to repeat a subject. And it's just not something most people can afford.

Family Expectations

It was mentioned several times that if students are under significant pressure from their family to perform well at university, then this can create a strong temptation to cheat.

I guess it's also the pressure from parents who push their children

The first time I brought home a C my mum flipped. I've never seen her so angry at me. And I know some parents are like that. Even when you're at uni. They can see how, but when it comes to grades they seem pretty harsh. And you get scared and you get desperate and...

Peer pressure

Far more commonly reported than family pressure was peer pressure to assist other students in their cheating. This took two forms: the first form was pressure from friends to assist them and the difficulty of refusing the friend because of the relationship.

I just reckon probably the top reason is like some people are pressured into cheating like giving their work to others.

Student: *Also that could be your friend who asks you. And you just don't want to...*

Facilitator: *...so you collude in their cheating because you can't get out of it.*

Student: *Yes*

The second form is where students feel an obligation to assist their friend when they have suffered some form of setback and that not helping causes the student to feel guilty.

When someone is under pressure or something you kind of feel bad and you want to help them out.

No Connection to the Degree

A motivation that was strongly supported by the students was that many students felt no real connection to the content of the degrees that they were studying and that many students had enrolled in the degree by default, rather than because they felt a passion for an IT career.

Some people do a course just to get the certificate, the degree. They just want a pass.

I know people that are doing the course just because they got into it. They put it on their VTAC² and they got in and they're stuck here.

Doing the stuff that you enjoy doing so that's probably a deterrent to cheating itself because if you're enjoying it you want to understand.

Lack of Relevance or Importance

Assignments where the students felt that the material was irrelevant or of little value to their final mark were likely to encourage cheating according to a number of students.

I personally take a fairly laid back approach and my style of thinking is if I need to cheat to get to a near pass or just to get a pass mark then I shouldn't be cheating, ... And the only exception is when you have a subject you don't feel it has any relevance, the core subject doesn't lead onto anything else and it's just an addition.

The exams seem to be worth a lot sort of 80% so that's why it doesn't bother me that people cheat on assignments cause they're going to make up maybe 5% of their mark.

High Stakes/Failing Hurdles

Related to the issue of work that was irrelevant or unimportant in the student view, were assessments that were high stakes in terms of the result, but did not have a major effect on the final mark. In this case, students felt that it was a reasonable response to collaborate/collude with other students.

There is this particular subject where in the pracs, it's either pass or fail so you finish the mile stones ... and you understand them and explain them and everything is there so you pass. So only 2 grades. Pass or Fail. But I remember it was so hard as they say you can't really finish it because you have like 10 milestones and no matter how early you started the prac, still until the end you can't finish it because it's that hard. Then suddenly what people started doing is okay I do the first 3 and then the last 4 and will explain to each other and you take part of mine and I take part of yours and we will work it out from there. Make it different or anyhow. So what do you call that, cheating as well. Or cooperating or helping.

In uni there's very strict conditions about hurdles and all that sort of stuff. So basically what they say is you failed 2 pracs. You failed a prac hurdle. You failed a unit. You know you're going to have to catch up in summer which is quite scary for some people. So they're willing to cheat just so they don't have to do that

Status with Peers

At the traditional campus, many computer science students feel that there is a real division in the student body between those who are good at programming and those who are not:

You'll assimilate in the first year, like computer programming, computer science, either you will get 50% of people getting HDs and 50% of people getting passes.

Students in the lower performing group, then feel a social pressure to improve their results and see cheating as one way of doing this.

... and what I was saying about stigma. If you get lower marks or whatever. There seems to be this thing you've got to be a star student or you're nothing. You know hero or zero.

Availability of Support

Students reported that the level of availability of support from tutors and lecturers influenced the likelihood of students cheating. When students were unable to access help, they felt that it justified cheating to some extent.

Like there's not enough time for the prac person to go around and help everybody. Like you ask them [the tutor] for help and they go oh it's prac, I can't help you with that.

Poor Time Management

A reason commonly put forward by students in the focus groups was that an inability by students to manage their time often led to the necessity of cheating.

Sometimes people do cheat. Like I've seen my friends because 3 assignments are due on Friday so what do you do? And the assignment they are carrying like 15% of the assessment. You have to do all 3 and if you're not catching this stuff as quickly as other people are, then you have to resort to other measures.

Sometimes you get stuck in some way and you will be very tempted to refer to someone else.

Internal Conscience

The reason that students most commonly put forward as a motivation for not cheating was

that it would be a burden on their conscience to have cheated.

So I need something internal that will tell me the reason for every movement I make or everything I do and say ah, this is not good, even if I really need it and I have to cheat in this situation but it's no good, the consequences will be worse.

I could never fathom it. I'd just have too much of a guilty conscience.

Other Motivations

A number of motivations that had been indicated in our earlier research as impacting on the decision to cheat were not strongly supported by the students in the focus groups. Language difficulties as a motivation to cheat was only raised by one student and received little if any support from the other members of their focus group. As well, there was little support for the theory that cheating was a matter of misunderstanding, except in the case mentioned earlier of the confusion between collusion and collaboration. Fear of failure and the fear of getting caught had weak responses in the survey (Sheard et al. 2003) as reasons not to cheat. Focus groups supported this result, barely mentioning these fears.

Education

This section on the student perspective addresses two issues. First, how do students perceive the educational instruction that they have received about cheating? Second, what education should be provided to them to help them understand cheating?

Awareness of Education Efforts

In general, students clearly knew of the educational efforts made by the university to inform them about cheating and plagiarism. Nearly all the students

acknowledged that the university provided some education in courses about these issues.

I guess this university makes a start when at the beginning of each lecture or lecture of each subject the lecturer tells you that plagiarism is not allowed. In tutorials they say you're not allowed to plagiarise or cheat or anything like that.

In the first semester we had something in class which was about how to cite stuff and how to quote it and what plagiarism was

Impact of Educational Efforts

However, while students were aware of the education efforts made by the university, the impact of those efforts was clearly marginal. A strong consensus from the students was that these efforts were not very effective. They perceived the educational efforts as perfunctory and paid little attention to them.

Student: *Yeah. Every subject has like a lecture dedicated to try and scare you into not doing anything at all, ever.*

Facilitator: *Okay. But the rest of you did it scare you? What was the impact of that? Those lectures.*

Student: *I kind of zoned out.*

Student 1: *I'm just saying generally I just don't read anything that's got to do with cheating. Just because I couldn't be bothered with reading it.*

Student 2: *We've heard it so many times.*

Some students who were studying double-degrees contrasted the educational effort in their IT courses unfavourably with the effort in their non-IT courses.

Prevention is Better than Cure

I think it was definitely helpful like as you were saying in Law like at the start of the year in our lectures they actually...when you had an assignment coming up they actually sat down and spent 15 minutes going through what plagiarism is and what does actually constitute cheating and plagiarism and what you can do and what you can't do. Whereas with computer science ... that was just give you a piece of paper that has rules on it and nobody actually explains anything.

Clear Definitions

When asked about ways to improve the education provided on cheating and plagiarism, one issue came up again and again; the need for the university to provide clear definitions. This supports the findings on confusion regarding collaboration and collusion we saw earlier.

I think student need to be explained clearly what is cheating and what is plagiarism really.

They should say exactly what you shouldn't do or say anything that's not expressly permitted is forbidden. Something like that.

Where as they say how big they are on referencing but they don't fully explain what they mean. So they'll give a student a P and say yeah you didn't reference properly but there've never really sat down and explained to people what is plagiarism. How even if you paraphrase you still need to reference.

Education Won't Work

A common, but not universal, attitude expressed by the students in the focus groups was that regardless of the efforts the university might make, it will not be able to eliminate cheating.

I don't think telling people would make a difference.

A lot of...like if you try to tell people what cheating is I think a lot of people just find it boring and don't...like when I put on the cheating paragraph to my projects or I read it or whatever I have to ... I just ignore it. I copy, paste and put my name in, that's it. I don't read anything to do with cheating.

Suggestions for Improvement

A variety of suggestions were received from students about measures the university could use in their educational efforts to reduce cheating. One suggestion was to provide examples to help students understand what cheating and plagiarism really meant.

Maybe if they gave examples. Like just made it kind of more interactive when they explained it instead of read this.

Another suggestion was to ensure that students were informed about the sources of help available to them, so that cheating became less necessary. It follows from this that the provision of adequate help systems is a necessary first step.

How to get help and where you get the help from and having lecturers tell you constantly this is a point...

Other issues raised were educating students on how to handle situations where they know of other students cheating or when they are pressured to assist students to cheat.

Students aren't told how to deal with other people plagiarising.

Facilitator: *Do you think you should be told how to deal with other people plagiarising?*

Student: *Yeah. Cause they say don't plagiarise and you don't plagiarise. You need to know what*

to do if someone is plagiarising or cheating on your work.

Finally, a common suggestion was to focus the educational efforts on why cheating is a bad thing, by pointing out that by cheating, the student reduces their learning to a minimal level and that this will impact upon their ability to perform in industry when they graduate.

Well you'd have like associate it to life experience. For example if you just cheated your way through university and then towards the end like you get out of university and you get a job like 6 months later, you have no clue what to do.

Prevention

This section looks at the student perspective in terms of how cheating may be prevented from occurring or at least reduced.

Interviews

A common practice at the technology campus was the use of oral exams to assess the assignment work of students. Students in the focus groups were strongly in favour of this approach as a means of preventing cheating.

I don't know if it's done in other code classes but with the Java [a programming course] that we're talking we're actually tested on whether our work is ours by taking it in there and reviewing. So I think that's a good way of dealing with it.

And after each assignment and stuff like they should like in one of our subjects the first year after you did the assignment a few weeks down the track or whatever they mark you and they have a mark on the side but they interview as well. Interview you to make sure that you know the stuff that you wrote down. Like that was a pretty good system

Teacher Approachability

A very common issue raised by the students was that lecturers and tutors needed to be approachable. If a student felt that they could not approach a teacher for help, they were more likely to cheat as they had no alternative.

I think somebody raised about the tutors. The fact that some tutors are unapproachable or some people are too scared to ask questions. If we could somehow encourage more interaction between students and tutors and student groups and whatever, whoever is responsible I think that would sort of alleviate the problem with plagiarising.

Student 1: *...well they tell you that you can ask any question they want. The silly question or whatever. But when you start asking them that's when the reaction is not all that good.*

Student 2: *They're always getting frustrated with the questions you're asking.*

Caring

Students in the focus groups were very quick to categorise lecturers and tutors according to whether they felt they cared or not. When teachers were considered to be uncaring, it was felt that this encouraged students to cheat.

That can be difficult to when the lecturers are swapping around. Especially if the lecturer has gone overseas ... and the replacement guy comes in and he just says well I'm here for a fortnight. I really don't care about you guys.

The ones who don't make it look like they're just doing it because they're getting paid. Like the ones who look like they actually want to teach something and they interact with you well.

Levels of Interaction

Students felt that high levels of interaction in the course were one means of preventing cheating from occurring.

The other thing is I think the best place for all these things to start solving all these problems is in a tute where you feel friendly. I mean free to talk with the tutor and some tutors are not all that experienced. They've just done their degree. They know their subject but then you also you should know how to get those student to interact with you on a really friendly basis. I think if you have that you learn. Anyone would ask questions and they learn.

But before the exam it's just that we have [consultation sessions] ...but if we have them throughout the whole semester it will reduce the number of cheaters.

Relevance of Work

In situations where students couldn't see the relevance of an assessment item, they felt that this heightened the incidence of cheating.

Where I've seen more occurrence of cheating is where people feel the topic is irrelevant to them on the assignments and they don't see where they all contribute to their final goal.

Positive Teaching Approach

A strongly held attitude expressed by the students in the focus groups was that teachers that had a positive approach to students really discouraged students from cheating.

Because he gave me that good help which is here a positive attitude. Instead of pushing me down when I'm already down. Instead of pushing me

down again because it seemed to be a very stupid question.

I remember I had this particular tutor, demonstrator; I really couldn't do anything in my first 2 pracs and he just started talking positive to me and he knew that I couldn't do it and he just went I know you are smart, you can do it, you can do it, you are smart, and that helped me to revive myself from the incident and I knew I could do it.

Poor Teaching Practices

Students were particularly scathing of teachers that used poor teaching practices and felt that this was likely to increase the amount of cheating.

We've got a programming [course]. We've got Lecturer 1 and Lecturer 2 and I find that Lecturer 1 is like he's good. Interesting. Talks through his stuff. He's really that involved with people making sure everyone understands. Explains. Does plenty of examples. And then you've just got the other one Lecturer 2, that's just like wave after wave waiting for information.

One tutor is like really shy so she wouldn't ask anybody to...she'll just stand there waiting for someone to put their hand up.

Dobbing In

While honour codes have had some success in the United States as was mentioned in the Background section of this chapter, students reacted quite negatively to the idea that they might report cheating by their fellow students. It was only raised as a possibility where another student had stolen their own work.

Facilitator: *Would you ever dob anyone in?*

Student 1: *No.*

Student 2: *Not a chance.*

Student 3: *Unless it was really blatantly obvious and bad.*

Student 4: *Unless they copied you, you didn't know, they just stole your work.*

Facilitator: *If you know of someone who doesn't have that motivation and has cheated what do you do? How do you deal with it?*

Student: *I don't care.*

Facilitator: *You don't care.*

Student: *Firstly I wouldn't report them.*

Group Work

A positive idea presented by the students in the focus groups as a means to prevent cheating was to use group work, so as to avoid situations where a student feels the need to cheat to cope with the work.

I think if a person just by themselves and they're trying to work it out then that's where they're going to feel oh no I can't do this. If they're in a group that's very, I mean it's not like 5 people are all not going to be able to do the problem. Because they can think together. Bounce ideas off each other. If you've just got one person and they can't do it well then there's going to be a high chance of them cheating.

An interesting accommodation to the reality of cheating was noted by one student in relation to group work.

Actually had an occasion last semester where one of the guys in our group assignment we knew that he plagiarised in a previous assignment so we sort of just...we actually limited the amount of work

that he did. Don't know if that was the right way to go about it.

Exam Cheating

While as we saw earlier, many students have a belief that the use of exams prevents cheating, a belief accepted by many academics, students were well aware of methods to cheat in the exam environment.

I think in major exam it's easy to cheat. The thing is the individual privacy and the cheat has no conflict. For example if the person wants to cheat, the toilet during exam you can't supervise them in the toilet. Some students maybe have some notes and look at notes in the toilet.

Student 1: *You can send in like mobile SMS. By the choice answer, multiple choice.*

Student 2: *From someone outside of the uni.*

Student 1: *Yeah. otherwise you finish first and then turn on my mobile and then he send me the SMS and look at....*

Student 2: *...actually cool.*

If you're going to bring your mobiles into the exams ..., there's nothing to stop you from storing everything in your mobile.

Examples

A suggestion to reduce the need for cheating and assist in learning was that lecturers should provide examples of the assessment items that they wish students to produce.

...because I know in one course the lecturer I had he actually provided past assignments you know this is what we're looking for. Like it was a totally different case study but he goes oh okay

Prevention is Better than Cure

you have to do diagrams that look like this. We have to produce documentation though. We knew what was required of us. So if they don't know what's required of them they're more likely to go and ask someone else and then take the easy way which is just copy most of it.

I think as she said, give the examples to the student. I'm thinking give the student past student assignment example when the student is doing the assignment

Access to Help and Facilities

An issue that arose very commonly in the focus groups was that cheating is often caused by a lack of access to help and facilities. If a student is unable to access the relevant computer facilities for example, or unable to talk to a tutor about their assignment, then cheating becomes a more attractive option.

Student 1: *...and just knowing there's going to be computers available at any time that you require it.*

Student 2: *Its not just access to facilities and access to tutors and access to lecturers.*

Student 3: *More consultation time with tutors.*

well you don't tend to get help [in pracs]. And you have to finish it. You didn't have enough time to ask the tutor because everyone else needs the tutor as well. It's not just you. It's like there's not enough resources in that way. Like the classes need to be a bit smaller maybe.

Staged Assessment

Another idea that students felt assisted in the effort to reduce cheating was that assignments could be submitted in stages rather than in one single submission.

I have a subject which the assignment it's based on stages and it progresses all the time so rather than submitting the whole thing at the end of the week you actually have to show to the tutor what you have done and you know for stages and I find that useful.

There's another way to do it. Put something to submit every week. It will be a big job. It will be possible to finish it like in one or two days and then submit it each week and you definitely wouldn't have [to cheat]

Repeated Assignments

One practice that students felt increased the likelihood of cheating was the repetition of assignments from one year to the next.

Facilitator: *Okay so you're saying it's easy to cheat from other people's work or from X. How do you get hold of work from previous semesters?*

Student 1: *Your friends.*

Student 2: *Networking.*

APPROACHES TO ADDRESS CHEATING

In this section, we examine the approaches in the areas of education and prevention that we feel arise out of the information provided by the students in the focus groups.

Education

Analysis of the focus groups' responses indicate that students are in need of education about cheating and plagiarism. Looking at this information provided by the focus groups, the curriculum of an effective educational program to reduce cheating and plagiarism would have these characteristics.

1. Some aspects of cheating are well understood by students to be unacceptable, for example, cheating in exams or the wholesale copying of material from other students, books and the Internet and therefore these don't need to be addressed in detail in the curriculum.
2. Students are clearly confused about the difference between collusion and collaboration. Any curriculum about cheating should concentrate on distinguishing between these two concepts. The line between collusion and collaboration varies from class to class, course to course, and university to university, so no single definition suffices. From our perspective, collusion is where the level of collaboration exceeds that which is permitted for a particular assessment task. It follows that the acceptable level of collaboration needs to be clearly set out for each assessment task.
3. Students are uncertain about what constitutes plagiarism and how they should handle references in their work. Simple mantras such as "No more than six words" are in some ways counter-productive. The curriculum needs to ensure that students have a deep understanding of the issue as opposed to trying to inculcate simple rules into the students.
4. Simple statements and definitions of what constitutes cheating are insufficient for students to understand the issues of cheating and plagiarism. Curriculum needs to be example-driven so that students can place cheating behaviours into a concrete context that they can relate to their own experiences as a student.
5. Students are easily bored by the repetition of statements about cheating and educational efforts in this area must be interactive and not be routine announcements. The curriculum must be placed so as to be distinguishable from the normal classroom activities.
6. The curriculum should not over-emphasise the issue of plagiarism in comparison with other forms of cheating.
7. It is highly recommended that the curriculum focuses on the long-term impacts of cheating on a student's career, rather than presenting cheating as simply something that is wrong to do and that will be penalised if caught.
8. It also is recommended that the curriculum addresses the issues of the impact on learning of cheating and the need to have a moral compass on this issue. Overall, the curriculum should get students to examine their own reasons for why they might cheat or not cheat and thereby raise their consciousness about the issue.
9. The concept that "cheating is inevitable" and therefore students shouldn't worry about the issue needs to be addressed in the curriculum.
10. The issue of time management skills needs to be addressed in any educational program that wishes to reduce cheating.
11. The curriculum needs to provide students with methods to handle the pressures from the peers to assist them in their cheating. It is not reasonable to expect students at this stage of their life to easily resist peer pressure.
12. The curriculum should not attempt to scare students or use fear of consequences to motivate students to not to cheat. Students are well aware that cheating is easy and unlikely to be caught, so scare tactics will for most students be ineffective. This is not to say that the consequences of being caught should not be discussed.
13. Educational programs about cheating need to emphasise the sources of assistance that are available to students to aid them in their studies.

Prevention

A variety of methods have been proposed in the literature to prevent cheating, as earlier sections have discussed. In addition, the students in the focus groups have raised significant issues with regards to prevention. This section looks at both

sources of data and applies the information from the student perspective to present a critical analysis of the various methods proposed to prevent cheating. It should be understood that we are not presenting any of these methods as a panacea for cheating or even all of them in concert as the solution. As the students made clear, there will always be cheating in university courses, but these ideas seem likely to assist in the ongoing process of reducing cheating.

Caring and Being a Good Teacher

One of the methods of preventing cheating that arises from the research is that having academics who clearly care about the students and their course and who apply good teaching practices to their courses is likely to reduce the level of cheating. Students clearly respond well in this situation. Students also appear to respond well in this area to increased levels of interaction in the classroom. The provision of high levels of interaction has been recognised as an indicator of good teaching practice for many years. Poor teaching practices such as repeating assignment material from year to year or presenting voluminous quantities of material in lectures without providing interaction opportunities is likely to increase cheating.

Interviews and Presentations

The practice of assessing student work via oral exams is seen by the students as being highly effective in reducing cheating. In an oral exam students need to be able to demonstrate mastery of the material and this is significantly less likely if the student has copied the material or received excessive assistance. It should be noted that it is not impossible for a student who has copied from other students to do well in an interview situation. Two of the authors who regularly use this technique have seen several examples of this happening (Dick, 2005).

Presentations can achieve similar results to an interview as the presentation of material also relies to some extent on the student's mastery of it. However, it is probably less effective as it is not the one-on-one environment of the interview and the level of interaction is reduced.

Set Literature

One possible method to reduce plagiarism has been the use of a set reference list for an essay. By limiting the possible references to be used by the students in a piece of work, it reduces the likelihood that they will plagiarise material. In such a situation students will still be able to gain the capability of synthesising a body of literature into a cohesive whole; however, it downplays the learning of skills such as gathering and evaluating literature. To some extent, it sidesteps the issue of developing the student's understanding of plagiarism and does not equip them for handling such issues in the future. We believe that this method is of limited utility in an overall degree, though it may be of some use in particular circumstances. An example might be where the major learning objective is for the students to master a particular body of knowledge embedded in the set reference list.

Individual Assignment Specification

Students are confused about the difference between collaboration and collusion and find it difficult to resist allowing their peers to copy from their assignments. A method of prevention that addresses this issue is to provide each student with an individual assignment. If each student is required to solve a different problem, then the solutions they propose must inherently be different and it thereby makes copying, to a large degree, pointless. In many technical subjects, a simple program can be used to generate many individual assignments, alternatively the techniques proposed by Reynard (2000) can be used in non-technical subjects. Another alternative is

to allow students to set their own question with guidance from the teacher and thereby ensure minimal collusion and copying. In multiple-choice assessment, the development of question banks can allow individualised tests. One drawback is that this often can require extra effort on the part of the academic to develop and/or to mark. The use of individual assignments may not be suitable in all circumstances, but a wide range of assessments may benefit from their use in relation to reducing cheating.

Peer Assessment

Peer assessment has many positive aspects and theoretically should be effective in preventing cheating as students are far more likely to be aware of the cheating of their peers than the teacher. The results of the research reveal a problematic aspect to peer assessment. Many students don't seem to care if other students cheat unless they are directly involved. Given this attitude, it is likely that students will not punish their peers for cheating and the possible deterrent effect of peer assessment may not exist. Of course there are many other good reasons to use peer assessment, but reducing cheating is probably not one of those reasons.

Monitored Assessment

The classic case of a monitored assessment is the traditional exam with invigilators, silence and strict rules, yet along with previous research, the focus groups reveal that students are well aware of how to subvert exam protocols. Academics would be well advised not to place too high a reliance on the use of exams and other forms of monitored assessments to control and reduce cheating. Universities need to consider measures to handle cheating practices in exams, for example deploying mobile phone jammers in exam venues.

Continuous Assessment

One method that seems to have promise, according to the focus groups, is assessment that is not concentrated into one or two major submissions, but instead has many submissions throughout the semester. A continuous assessment regime provides incentives to students to manage their time better and possibly reduces the stress associated with assessment. Both of these effects would be likely to reduce the possibility of a student cheating.

Relevant Assessment

When designing assessment, the relevance of the assessment to the students should always be considered by the academic. It should also be made explicit to the students. Academics should not assume that the relevance of an assessment or indeed of course material is obvious to the students. By avoiding assessment that the students see as irrelevant to them, the incidence of cheating on the piece of assessment is likely to be reduced.

Clarity and Consistency of Assessment Rules

Students can easily be confused if the assessment rules for an item of work are not made clear. If a piece of work must be worked on by a student alone, then this must be made very clear, as well the rationale for this approach to the assessment also should be made explicit to the students. The rules for assessment for a specific piece of work or a specific course should also take in to consideration the general rules of assessment used in that degree. If most other assessments in the degree encourage collaboration between students, a piece of assessment that insists on no collaboration often will find this assessment rule breached. Rules for assessment that are inconsistent with norms the student expects must doubly be emphasised.

Inappropriate Student Attitudes

Two of the major issues raised in the focus groups were that cheating is often motivated by laziness and/or students having no interest in the content of their degree. There is little that any one course can do to address large personal issues for a student like this. One possible solution at a higher level is different selection practices to try and ensure that commencing students have a genuine interest in the degree, rather than just rely on the ENTER³ score of applicants. A related solution is for universities to ensure that transfer between degrees is easy. It is difficult for a student at the end of their secondary education to be sure as to what path they want their career to take. Many students will pick the wrong degree, so within reason, it should be made possible for students to transfer to a different degree with minimal penalties and hurdles. Of course, there would need to be measures to ensure that this transfer mechanism was not used to bypass ENTER score requirements for a degree.

Honour Codes

While honour codes have met with some success in the USA, they rely on a culture amongst the students that places honesty and integrity above peer pressure and apathy. The results of the focus groups indicate that this culture currently does not exist amongst the students and that it would require long-term and large-scale efforts by the university to develop that culture.

CONCLUSION

We have examined the IT student perspective on cheating in order to generate ideas about education and prevention. It is clear that the traditional concentration of universities on detection and punishment is an insufficient response to cheat-

ing and plagiarism and that individual academics must take responsibility for their teaching and use a wide variety of techniques to reduce student cheating. It is the opinion of the authors that the application of many of these techniques will not only reduce student cheating but also result in increased student learning. If we can prevent students from cheating in the first place, through improved education and prevention techniques, many students and academics will be spared a discipline process that is traumatic for both and a more positive learning environment established.

Chapter 6.2

Structuring a Local Virtual Work Ecology for a Collaborative, Multi-Institutional Higher Educational Project: A Case Study

Shalin Hai-Jew
Kansas State University, USA

ABSTRACT

This chapter focuses on a multi-institutional shared curricular-build project (2009) out of Kansas State University, Johnson County Community College, Kansas City Kansas Community College, and Dodge City Community College. This project involved the building of a range of digital learning objects for modules for an online course that will be taught at the various institutions in both online and hybrid formats. This collaboration is unique in that it brought together experts from cross-functional domains (from both the empirical sciences and the humanities) for an interdisciplinary freshman level course. The team collaborated virtually through computer mediated communications and built e-learning based on instructional design precepts. The curriculum was built to the standards of the

public health domain field, the Quality Matters™ rubric (for e-learning standards), federal accessibility guidelines, intellectual property laws, and technological interoperability standards (with the curriculum to be delivered through four disparate learning / course management systems). This chapter focuses on the socio-technical structuring of a local virtual work ecology to support this “Pathways to Public Health” project.

INTRODUCTION

In higher education, with the geographical dispersion of talents and skill sets, many more subject matter experts work on virtual teams. A more recent phenomena has been that of local (vs. global) virtual teams, with peers from institutions of higher education that are within reasonable commuting distances, similar time zones, and even

DOI: 10.4018/978-1-60960-503-2.ch602

some co-located members. Demanding schedules make it difficult to meet face-to-face, but collegial and interdisciplinary work requires collaboration and shared decision-making. The nature of the work and team will determine some of the strategies for structuring the local virtual work ecology, which includes both a shared electronic environment and structured interactions between the team members. This chapter will be based on the research literature and practitioner research based on one recent case.

REVIEW OF THE LITERATURE

With growing interorganizational alliances, virtual teams have become commonplace (Kahai, Carroll, & Jestice, 2007). Virtual teams are generally defined as those where team members are not co-located, but are distributed geographically and connected via computer-mediated technologies to collaborate on a shared work project.

Virtual teams are “groups of geographically, organizationally and/or temporally dispersed individuals brought together by information and telecommunications technologies to accomplish one or more organizational tasks” (Powell, Piccoli, & Ives, 2004). There may be differing levels of team virtualization. Zigurs proposes four dimensions of virtuality: “temporal dispersion,” “geographic dispersion,” “organizational dispersion,” and “cultural dispersion” (Sarker, Sarker, & Schneider, 2009, p. 77). A local virtual work ecology refers to the interactions between virtual team members and their technological and physical environments.

VIRTUAL TEAM STRUCTURES

Differing levels of team virtualization may exist, with some virtual teams including sub-group co-location. Baskerville and Nandhakumar cite Mowshowitz’s concept of a virtual workgroup

as a basis for their thinking, which plays with the meaning of “virtual” as in virtual memory: “A team’s virtuality regards the potential for an imagined team to become a real team, giving the organization the ability to assemble teams on an as-needed basis for highly specific purposes” (Baskerville & Nandhakumar, 2007, p. 18). Virtual teams are new organizational forms enabled by more powerful computer technologies (Powell, Piccoli, & Ives, 2004, p. 6). Partially distributed teams (PDTs) involve sub-teams of co-located members working from different geographic locations (Peters, Ocker, & Rosson, 2008, p. 273). Dyadic teams are those that are formed by two people and have been found to result in higher team satisfaction, which is a predictor of virtual team effectiveness (Karayaz & Keating, 2007, p. 2593). The way work is designed may be one of the five critical factors that may support high creativity (Nemiro, 2004, p. xxvii).

THE CHALLENGES OF VIRTUAL TEAMING

The research on virtual teaming highlights a range of supervisory challenges that extend beyond typical management duties. These include:

- difficulty establishing trust (Coppola, Hiltz, & Rotter, 2004; Jarvenpaa & Leidner, 1999; Jarvenpaa et al., 2004);
- difficulty establishing a shared team identity (Armstrong & Cole, 2002; Cramton, 2001);
- managing conflict (Hinds & Bailey, 2003; Hinds & Mortensen, 2005; Montoya-Weiss, Massey & Song, 2001);
- maintaining awareness of members’ activities (Hinds & Mortensen, 2005);
- coordinating team member efforts (Maznevski & Chudoba, 2001; Malhotra et al., 2001; Sarkey & Shay, 2002);

- effective leadership (Bell & Kozlowski, 2002; Kayworth & Leidner, 2001);
- knowledge sharing (Cramton, 2001, Griffith et al., 2003); and
- determining the appropriate task technology fit (Qureshi & Vogel, 2001, as cited in Ocker & Fjermestad, 2008, p. 52).

Virtual teams may experience the forming of fragmentation and in-groups (particularly among collocated members vs. the distributed or distant ones). This researcher switched some team members' locations halfway through the experiment to see what effect it would have on in-groups:

People who changed from being isolated 'tele-commuters' to collocators very quickly formed new collaborative relationships. People who were moved out of a collocated room had more trouble adjusting, and tried unsuccessfully to maintain previous ties. Overall, collocation was a more powerful determiner of collaboration patterns than previous relationships (Bos, Olson, Cheshin, Kim, Nan, & Shami 2005, p. 1917).

The concept of resilience in virtual teaming is critical especially after intended or unintended disruptions, with some findings of high human adaptability and "bounce back" (Mark & Semann, 2008, p. 137). Virtual teaming requires on-going sense-making through technology mediation (Bansler & Havn, 2003, p. 135).

VIRTUAL LEADERSHIP

Virtual leadership requires an ability to create a virtual ecology. The supervisory work requires a mix of high engagement at times and hands-off interactivity at others. Leaders have to get a team established "on a good trajectory and then to make small adjustments along the way to help members succeed, not to try to continuously manage team behavior in real time." Applied to a virtual team

context, the work ecology is this context for the team's work success. Hackman suggests that successful teams need "a compelling direction, an enabling team structure, a supportive organizational context, and expert team coaching" (*Leading Teams*, 2002, p. ix). Leadership on virtual teams may be explicit and implicit, with the conclusion that good coordination involves a "subtle mixture of both approaches" (Boulthier, Charoy, Perrin, Saliou, Bignon, Halin, & Malcurat, 2001, p. 135).

According to the literature, different types of leadership may be brought into play in virtual spaces.

- *Participative leadership* is defined as the equalization of power and sharing of problem solving with followers by consulting them before making a decision.
- *Directive leadership* is defined as providing and seeking compliance with directions for accomplishing a problem-solving task. Participative leadership and directive leadership are considered parallel to transformational leadership and transactional leadership respectively (Zhang, Fjermestad, & Tremaine, 2005, pp. 1 - 2).

Managers often find a greater need to troubleshoot virtual team challenges (Thomas, Bostom, & Gouge, 2007; Crowston, Howison, Masango, & Eseryel, 2007; Sarker, Sarker, & Schneider, 2009, p. 75). Team conflicts may arise from "differences, discrepancies, incompatible wishes or irreconcilable desires" (Paul, Seetharaman, Samarah, & Mykytyn, 2005, p. 1). They may mitigate conflicts through video-conferencing (Rutkowski, Vogel, van Genuchten, Bemelmans, & Favier, 2002, p. 227). For those in some industries, the amount of work done virtually affects their satisfaction with their work lives and their retention (Ferratt, Enns, & Prasad, 2001). There have been gender preferences found in the virtual team experience (Lind, 1999, p. 280).

Technologies may be brought into play to replace some on-site leadership. Kerr and Jermier (1978) offered a leader substitutes theory that suggests certain enhancements of leadership through “mechanisms and alternatives for the various functions of the formal leader.” Enhancers augment the leader-outcome relationship; supplements contribute to the varied “effects on the subordinates’ performance but do not cancel out or augment the leader’s direct effects,” and substitutes make “the leadership impossible or unnecessary” (Bass, 1990, pp. 682 – 683). Applied to virtual teaming, the leadership substitute theory shows that technologies may “stand in” for a present physical team leader.

However, there are built-in constraints to virtual teaming that may make “effective coordination, visibility, communication and cooperation” more challenging (Casey & Richardson, 2006, p. 66). The more interdependency and the more complex the work flows, the more reciprocal coordination and collaboration are needed (Corbitt, Gardiner, & Wright, 2004). Virtual teaming may be used in both low-risk and high-risk situations. The research literature includes descriptions of tense interchanges and misunderstandings in time- and safety-critical situations that were mediated virtually (Bayerl & Lauche, 2008, p. 424).

Virtual leadership in the Internet Age “is communication” (Skovolt, 2009, p. 1). Individuals’ communications styles, which stem from personality factors (Balthazard, Potter, & Warren, 2002), may be categorized as constructive, passive, and aggressive styles.

The constructive style is characterized by a balanced concern for personal and group outcomes, cooperation, creativity, free exchange of information, and respect for others’ perspectives. The constructive style enables group members to fulfill both needs for personal achievement as well as needs for affiliation. The passive style places greater emphasis on fulfillment of affiliation goals only, maintaining harmony in the group, and

limiting information sharing, questioning and impartiality. The aggressive style places greater emphasis on personal achievement needs, with personal ambitions placed above concern for group outcome. Aggressive groups are characterized by competition, criticism, interruptions, and overt impatience” (Balthazard, Potter, & Warren, 2002).

Tensions stemming from outsourcing may also cause stresses on virtual teams. Challenges communicating the requirements for a project may be compounded “by cultural and language differences, lack of communication, distance from the customer, different process maturity levels, testing tools, standards, technical ability and experience” (Casey & Richardson, 2006, p. 66).

THE SELECTION OF COMPUTER MEDIATED COMMUNICATIONS (CMC) TECHNOLOGIES

Information Technology (IT) must help a virtual team maintain a sense of continuous communications discourse (Albin-Clark, 2008). There must be connective richness without overwhelming complexity. People may generally be assumed to function on the so-called Principle of Least Effort when it comes to computer mediated communications (Bos, Shami, Olson, Cheshin, & Nan, 2004, p. 430). Technologies have to fit in with the leaders’ choices (Samarah, Paul, & Tadisina, 2007) in the virtual team and must also be accessible (Sivunen & Valo, 2006, p. 57).

Successful virtual teams tend to have high message frequency characterized by positive messages and “appropriate feedback.” Such teams prefer a variety of communication media (Dekker & Rutte, 2007, p. 3). High performing virtual teams “out-communicate” low performing ones (Ocker & Fjermestad, 2000, p. 1). Rich dialogue techniques help teams make up for the loss of “proxemic, haptic, and environmental cues” (Guo, D’Ambra,

Turner, & Zhang, 2009, p. 3) and may promote team cohesion (Guo, D'Ambra, Turner, & Zhang, 2009, p. 5) and a sense of "mutuality and shared frame" (Sarker, Sarker, Nicholson, & Joshi, 2005, p. 201). Teams that are homogeneous in terms of "shared backgrounds, interests, attitudes, and values" may find it easier to be cohesive (Panteli & Davison, 2005, p. 192) but may have greater challenges with innovations.

TECHNOLOGIES FOR INTERCOMMUNICATIONS

Social presence theory suggests that the perceivable physical presence of partners in a communication would have better interpersonal relationships via greater apparent presence (Short, et al., 1976, as cited in Ehsan, Mirza, & Ahmad, 2008, n.p.). Social exchange theory suggests that individuals engage in social interactions for financial and social rewards, which might suggest reciprocity behaviors on virtual teams such as knowledge sharing (Chen, Zhang, Vogel, & Zhao, 2009, p. 2).

Media Richness Theory suggests that the greater the range of communications cues, the more an individual may personalize a message and control the interactions. Media richness is defined as the ability of information to change understanding within time interval (Dekker & Rutte, 2007, pp. 1 - 2). The richness of a medium is focused around five functions: the immediacy of feedback, symbol variety, parallelism, rehearsability, and reprocessability:

Immediacy of feedback is the extent to which the medium enables users to give rapid feedback on the communication they receive. Symbol variety is very similar to multiplicity of cues from Media Richness Theory. Parallelism is the number of communications that can exist simultaneously. Rehearsability is the ability to go over the message before communicating it to the sender. Finally, Reprocessability is the ability to reexamine the

message within the communication event (Dekker & Rutte, 2007, p. 2).

Medium-richness theory (Daft & Langel, 1986) suggests that two factors are critical for rich communications: "(1) The ability of communication medium to transmit personality cues of interaction partners. (2) The extent of the immediate feedback" (Ehsan, Mirza, & Ahmad, 2008, n.p.).

Without media richness or nonverbal cues, some researcher suggest a possible "downward spiral of decreased trust and commitment in a group," less information-sharing, misinterpreted messages, and eventually "conflict, damage group cohesion, and lower trust" (dePillis & Furumo, 2007, p. 93). These then would result in higher transaction costs, with team members double-checking each other and taking fewer creative risks. Fear and social inequities also have negative effects on a virtual team's innovativeness and team cohesion (Casey & Richardson, 2008, p. 170). Social dominance by group members may result in low levels of team creativity (Ocker, 2007, p. 204).

Mutual trust is built on the exchange of information (Alexander, 2002, p. 68). Recursiveness in interactions and interchanges may lead to the building up and maintenance of trust (Baskerville & Nandhakumar, 2007). Shared expressed and ethically-justifiable values may enhance trust and also bring a group closer (Xiao & Wei, 2008). High levels of trust can exist on virtual teams particularly in initial relationships among members but will need to be maintained through confidence-building measures and non-exploitation of members (Hung, Dennis, & Robert, 2004).

Face-to-face (F2F) is the richest communication medium, and is followed "by Telephone, Email, Letter, Note, Memo, Bulletin etc. in the medium richness hierarchy" (Ehsan, Mirza, & Ahmad, 2008, n.p.). Different types of messages require different mediums. Technologies may de-individuate individuals by restricting the amount of identifying information about each other: "Lack

of information regarding interpersonal differences among group members causes them to be more sensitive to available information about their personal or social identity” (Kahai, Carroll, & Jestice, 2007, p. 64). Group cohesion has been found to support group performance (Salisbury, Carte, & Chidambaram, 2006, p. 147), so a lack of human connectedness via the formal and informal communications may be inhibiting of virtual team work (p. 148).

Synchronicity may play a role in presence (Dennis & Valacich, 1999, as cited in Ehsan, Mirza, & Ahmad, 2008) and immediacy. Synchronous interactions on a team may often be done for collaborating on a common task; promoting group well-being, and supporting members in difficult situations, according to the Time, Interaction, and Performance theory (McGrath, 1991, as cited in Mirza & Ahmad, 2008, n.p.).

Research later found that the technologies used for computer-mediated groups could be more social than F2F interaction, via the Social Identity model of De-Individuation Effects (Postmes, Spears, & Lea, 1999; Reicher, Separs, & Postmes, 1995; Spears & Lea, 1994, as cited in Ehsan, Mirza, & Ahmad, 2008). Others argued that the human interactions and organizational contexts affect the richness of media (Dekker & Rutte, 2007, p. 2). Virtual teams’ preferences for particular media often resulted in a particular rhythm in media selected and used.

Immersive 3D spaces may also provide a venue for human-embodied avatar-based intercommunications. Here, the human imagination makes virtual worlds more potent and social, with engaging sense of telepresence and social presence. “The objective of virtual worlds was to achieve a feeling of telepresence, immersion and participation from a distance” (Jäkälä & Pekkola, 2007, p. 12). Cooperative online game experiences “even without any direct communication interactions” can impact people’s liking for others (Dabbish, 2008, p. 353), and immersive virtual games have

been employed as team ice breakers (Ellis, Luther, Bessiere, & Kellogg, 2008).

The research unequivocally suggests the importance of intercommunications, with a continual flow of creating, assessing and exchanging information around both task-driven and social-driven needs (Wang, Huang, & Wang, 2006, n.p.). Virtual team members co-build shared cultures (Andrews & Starke-Meyerring, 2005, p. 26). The social aspects of virtual collaboration are so critical that researchers conduct social network analyses to understand virtual teams (Lin & Chen, 2004, p. 1). Some collaborative technologies “facilitate ad hoc contact with remote professional expertise within the organization...as well as beyond the organization at reduced costs” (Sole & Applegate, 2000, p. 581).

UNDERSTANDING / NOT MISUNDERSTANDING ... SILENCE

How team members understand others’ silence depends in part on the understanding of what else is taking the time of team members or “distractions”. The accuracy of the attribution of silence depends on information sharing and access (TerBush, 2006). While such cues may be instituted into socio-technical collaboration systems, the author notes: “Participants themselves can improve their virtual team experience by learning to build and maintain mental maps about the environments of their remote partners and recognizing that environmental factors may be responsible for their partner’s periods of silence. By starting with situational attributions, group efficacy may be improved” (TerBush, 2006, p. 8). For others, silence comes from social politeness and cultural expectations but may be misread as agreement (Anawati & Craig, 2006, pp. 50 - 51).

Computer mediated communications involve both synchronous and asynchronous interactions, and light and media-rich interactivity. Optimally, socio-technical systems need to offer the greatest

ranges of freedom of expression (Nunamaker, 1999) for greatest utility.

SHARED MENTAL MODELS, COORDINATION, VISUALIZATION AND MODELING, AND KNOWLEDGE-SHARING AND LEARNING

The technologies employed not only promote communications but the building of shared mental models of the work. Per Dourish & Bellotti's work, group awareness refers to "an understanding of the activities of others which provides a context for your own activity"; technologically, this awareness is achieved synchronously with presence indicator widgets (such as on instance messaging systems), user lists, and remote viewports (Schümmer & Lukosch, 2006). Virtual team members have a need for on-going sense-making (Bansler & Havn, 2003).

Technologies may help team members coordinate their schedules and collaborative strategies. They may help individuals be aware of the work processes (Dustdar & Gall, 2002). They may indicate the different phases of teamwork. They may help with the structuring of tasks and work flows. Project management methods and tools need to be built into systems to benefit virtual teams and to accommodate for various types of diversity in the team members (Beise, 2004). In systems where these are not yet coded in to the software, human coordination has to be stand in the gap.

They may promote the exploration of creative and "outlandish" ideas (Ocker & Fjermestad, 2008, p. 53), their multi-dimensional visualization, and digital modeling. There needs to be a virtual team climate to support innovation, with a tolerance of diverse opinions and constructive conflict. Research into computer-supported collaborative work (CSCW) offers some insights on virtual spaces that support co-design, for example. Technologies extend the affordances of human endeavors.

Technological systems may raise team members' awareness of knowledge possessed by their co-workers, which may be valuable for "team effectiveness in learning, viability, and overall performance" (Shen, 2007, p. 228). Information sharing has a positive effect on virtual team performance and satisfaction (Dekker & Rutte, 2007, p. 3). The designs of socio-technical systems may foster knowledge sharing (Powell, Piccoli, & Ives, 2004). Information exchanges need to be technologically secure (Pripuzić, Gjenero, & Belani, 2006, p. 266) to maintain virtual team trust.

Trust or the extent to which a person is confident in another—has been linked to "virtual team efficiency, collaboration and performance" and the sharing of various information types (Mogan & Wang, 2007, p. 43). The ability to create trust may be seen as a virtual skill: "The work by Jarvenpaa & Leidner (1998) suggests that factors associated with online competence, responsiveness, leadership and performance, as well as communication aimed at socialisation become inextricably involved in the process of creating trust in GVTs" (global virtual teams). (Clear & Kassabova, 2005, p. 55).

Discovered knowledge has to flow back into the virtual environment (Biuk-Aghai & Simoff, 2001, p. 61). Virtual work needs to be structured in a space and environment to create a "landscape of work artifacts" (Churchill & Bly, 1999, p. 40). The credibility of the knowledge transfer information is based on trust and reputation (Sarker, Sarker, Nicholson, & Joshi, 2005, p. 204).

Virtual teams also need to capture events and decisions taken by one subgroup or the main group, with sufficient details for later review (Bayerl & Lauche, 2008, p. 425). Such collaboration systems may help in the archival and delivery of digital resources and artifacts. Researchers point to the importance of learning collaboration and also learning while collaborating (Kildare, Williams, & Hartnett, 2006).

SOME CRITIQUES OF VIRTUAL COLLABORATION SYSTEMS

There have been various criticisms of the technologies supporting virtual team ecologies. The design of collaborative virtual spaces may involve insufficient consideration for the “exigencies of living with the system” (Tan & Kondo, 2008, p. 2046), which may force a virtual team to be more adaptable. Others suggest that collaborative technologies need to create symbioses between “project management tools and collaborative ones” for effective virtual project management (Donker & Blumberg, 2008, p. 41). Others suggest that bridging the socio-technical gap will require new computing paradigms, potentially without “rules, hierarchies and control” (daSilva, de Souza, Prates, & Nicolaci-da-Costa, 2003, p. 145).

THE IMPORTANCE OF TEAM CONTINUITY

Continuity is seen in the research as something positive in terms of team trust and mutual understandings (Panteli & Davison, 2005, pp. 192 - 193). Researchers have found risks to short-duration virtual projects: “Our results indicate that at least for projects of short duration, virtual teams yield significantly lower performance, lower satisfaction, and a lower results-to-effort ratio. Virtual teams appear to excel only at lowering commitment, morale, and performance...” (dePillis & Furumo, 2007, p. 95).

Teams that have a sense of continuity outperform new teams. “Members develop familiarity with one another, their collective work, and the work setting, so they are able to settle in and focus on working together rather than waste time and energy getting oriented to new coworkers or circumstances. They develop a shared mental model of the performance situation, one that, with time and experience, is more integrative than the individual models with which they began. They

develop a shared pool of knowledge, accessible to all, and build what social psychologist Dan Wegner calls ‘transactive memory’ (that is, members themselves serve as memory aids to one another, providing the possibility of collective recollection that exceeds the capacity of any single individual)” (Hackman, *Leading Teams*, 2002, pp. 55 - 56).

Teams also seem to have a mid-point inflection in terms of performance. This is a time of a major transition.

*In a concentrated burst of changes, they dropped old patterns of behavior, reengaged with outside supervisors, and adopted new perspectives on their work. Following the midpoint transition, groups entered a period of focused task execution, which persisted until very near the project deadline, at which time a new set of issues having to do with termination processes arose and captured members’ attention” (Gersick, as cited in Hackman, *Leading Teams*, 2002, pp. 177 – 178).*

Time seems to be a critical factor in bringing virtual team members together: “In the case of computer-supported groups it has been shown that given adequate time teams will exchange enough social information to develop strong relational links” (Beranek, “A comparison of...,” 2005, p. 1; Casey & Richardson, Project management with..., 2006). Relationship history has also been found “to positively impact openness, trust, and information sharing in computer-mediated teams” (Lojeski, Reilly, & Dominick, 2007, p. 3); this shared past affects current work (Hung, Dennis, & Robert, 2004, p. 1).

Researchers have found more “deadbeats” with non-contributing behavior and “deserters” on virtual teams (dePillis & Furumo, 2006, p. 318). Others note the loss of “organizational memory, corporate history and process knowledge” with ad hoc virtual teams (Sengupta & Zhao, 1998). Bringing on the team members with the right skill sets, virtual teaming skills and level of commitment is critical (Cordes & Spine, 2007). Virtual

team members need to have an ability to work independently and to execute on the promised work by deadline. There are also motivational patterns in virtual team collaboration (Clear & Kassabova, 2005).

Managers should consider the full lifecycle of social ties in terms of virtual teaming between local and remote sites. This is especially true for projects which unify professionals in a state with staff members who represent elite and mission-critical skill sets, as was this case with the Pathways to Public Health endeavor. Oshri, Kotlarsky, and Willcocks suggest that development of social ties move from Introduction to Build-up to Renewal. They also suggest that F2F meetings are not a panacea for distributed teams (2008, p. 78). Mixed factors may contribute to virtual team success (Paré & Dubé, 1999, p. 480)—technologies, project context, team dynamics and processes, leadership and project management, and even wildcard factors.

PATHWAYS TO PUBLIC HEALTH: THE PROJECT'S BACKGROUND

The project involved the collaboration between Kansas State University and three colleges (Johnson County Community College, Kansas City Kansas Community College, and Dodge City Community College) to build a freshman-level public health course. This would be an entry-level semester-long course to draw learners into this field to fill a deep personnel gap in Kansas; this would optimally bring in those who are working in the field with plenty of experience but potentially little formal training. This would be an online prototype, the first course of an undergraduate program and then a graduate program, all in development, as part of a state-wide endeavor. This would also serve as an anchor in the statewide endeavor to professionalize and establish credentials for public health. The processes, the forms, and the relationships formed during this project would have large potential impacts into the future.

One way to understand a project is to understand its progress “trajectory” and shared local virtual team experiences. Important project milestones may be analyzed. Nemiro (2004) highlights three work design approaches used in the creative process. The Wheel Approach focuses on the use of one individual to be the hub for communications, and that individual is usually a high-powered one. The Modular Approach begins with a brainstorming approach by the group and then individual teams breaking up to address different parts of the build. The Iterative Approach involves back-and-forth development cycles where work is presented to the team, critiqued, and returned to the individual developers to revise (pp. 15 – 16). All three methods were used, except The Wheel Approach did not use a high-status team member but rather an outside support staff member. This was by necessity given the busy schedules of the principal investigators. Figure 1: A Composite of Images from the Virtual Work Ecology represents the complexity of the curricular elements at play. The logo represents the branding endeavor. A screenshot of Axio™ L/CMS evokes some of the work spaces. Some stills from video presentations and interviews highlight the expert contributions from across campus. The slide captures show the global nature of public health with open copyright releases from world health organizations. Another screenshot shows the deep structure of the various modules and the rich mix of HTML-delivered directions, audio-narrated slideshows, transcripts, videos, and learning activities.

IMPORTANT “PATHWAYS” PROJECT MILESTONES

The Creation of the Team

An interesting challenge with dispersed virtual teams is that the members hail from different institutions with different organizational mandates, stakeholders, and authorizing environments. Orga-

Figure 1. A composite of images from the virtual work ecology

nizational culture plays a role in the “acceleration of virtual world technology adoption” (Fuller, Hardin, & Scott, 2007, p. 43) and the adaptivity to virtual spaces. Some members are full-time faculty at their universities or colleges, and others are full-time staff who are sub-contracting on the project. In a sense, this organizational structure fits with Weick’s definition of a loosely coupled system, with relatively autonomous and independent units that influence each other and little need for coordination. A loosely coupled system may allow for a greater “number of mutations and novel solutions” to problems given that “the identity, uniqueness, and separateness of elements is preserved” (Weick, 1976, p. 7). Orton and Weick note that a loose coupling is not a decoupling with less “connectedness, responsiveness, and interdependence” (1990, p. 207); rather, these connections are a critical part of the virtual structure promoting both the strategic cohesions and sparks of innovation. Such social modularity reduces “the number of necessary relationships”

(Page-Jones, as cited in Orton & Weick, 1990, p. 210), which implies streamlined efficiencies.

A Centralized Digital Ecology

The virtual work ecology for this half-year multi-institutional curricular build focused on the Axio™ Learning / Course Management System (L/CMS). The technological setup allowed collaborators from off-campus to create accounts and to have full access to the socio-technical system. Using a democratic participative leadership model, all the principal investigators on the four campuses would need full ability to act as primary instructors (in terms of role-based access)—to build contents to the shared course. This access level would mean each member could ostensibly edit anyone else’s contents, and each could actually delete the entire work site. (The Axio™ system’s “indestructible” back-up would actually protect all contents though in case of a total work site deletion.) This team used a loosely coupled and flat structure. If the

control of communications and information is a form of virtual leadership (Skovolt, 2009), then it's critical that all members of the distributed participative team have equal access and equal voice—even at risk to the larger project. After all, each of the campuses would be taking ownership of the shared course, once completed.

Technologically, this site would provide plenty of collaboration tools: a third-party Wimba Classroom™ web conferencing tool, an asynchronous text message board, built-in audio capture and distribution capabilities, a shared calendar, and grouping tools. It also offered a space for the archival of digital learning objects, their annotation, and their organization into modules. There was a shared announcement board. There was a built-in survey system to allow for the surveying of live learners. A broadcast email system is also built into Axio™. The extensive context-sensitive help system made the acclimating easier for those new to the system.

Getting the team onto the work site early on was important, particularly with the need for early successes (Weick's concept of "small wins") to raise user confidence and self-efficacy. This involved posting necessary contents online but also making it available through email and other means.

Lean Communications Channels

Lean-channel communications technologies—telephones, emails, electronic mailing lists—were also tapped to enhance the connectivity of the development team. The different institutions had their own ways of maximizing the co-location of their team members, through electronic mailing lists, face-to-face meetings, and others. The idea was to have both formal and informal channels for information sharing, to promote both.

Researchers point to the importance of structure in virtual teaming (Rutkowski, Vogel, Ven Genuchten, Bemelmans, & Favier, 2002). That need for structure applies to role definitions;

work definition; socio-technological structures, and policies.

Shared Curricular Design

Team members had met face-to-face to determine the contents of the co-created curriculum. Once this was designed, the various faculty and their campus teams worked with their respective curricular committees to get the courses approved. This was a critical part of the project in terms of shaping shared academic aims. This also gave all members a voice at the table, so their expertise would be represented in the curriculum. The curriculum was designed as follows:

- Module 1: Overview and Basic Principles
- Module 2: Epidemiological Principles
- Module 3: Population Health Tools
- Module 4: Disease and Disability: Determinants, Burdens, and Interventions
- Module 5: Healthcare and Public Health Systems (Public Health Administration)
- Module 6: Special Topic Areas (These areas included ones focused on One Health; Infectious Disease and Zoonosis; Food Safety, Security, and Defense—Food Chain Security, Public Health Nutrition and Physical Activity, and Public Health Future Direction and Challenges.)

A Pre-module was proposed but was eventually folded into some other modules. The concept of the Pre-module was to offer "scaffolding" for learners totally new to the field with a particular focus on the biological sciences, biostatistics, and e-learning.

Stylebook Design

A critical step in the curriculum design was meeting face-to-face to co-create a stylebook, which would set the standards and expectations for the work; define accessibility and intellectual property

guidelines; set technological expectations, and start the clock on the distributed development. The Quality Matters rubric standards would also be integrated, with the needs for curricular coherence and segues. This stylebook also recorded the importance of building and infusion of diversity and learning scaffolding for both novices (freshman students) and “experts” (those who may have worked in public health for years but not studied formally in the academic field or a related field) in the curriculum.

The stylebook was created also to have a “common language to facilitate the work” (Suchan & Hayzak, 2001, p. 174). Virtual teams need a clear sense of mutual purpose (Keyzerman, 2003) and role coordination (Sutanto, Phang, Kuan, Kankanhalli, & Tan, 2005, p. 1), which the stylebook recorded. Determining understandings early was done to head off wasted effort. For example, the team members were trained on intellectual property, to head off possible illegalities in the use of information, imagery, audio, or video. The team also reviewed the importance of maintaining raw footage and imagery for possible non-lossy uses.

A stylebook works as an evolving document. It supports the planning stages, the curricular build, and the standards design for future changes to a curriculum. For example, this particular stylebook has projections into possibly building tangibles (such as CDs or DVDs), related e-books, and an instructional handbook. Considering options—depending on the time, energy, and resources available once the core curricular build was done—was motivating to the group.

Distributed Digital Learning Object (DLO) Development

The various distributed teams then met on their own to develop their portions of the curriculum, usually either whole modules or whole modules with additional segments. People concurrently worked in small-teams on their campuses and

through computer mediated communications with a centralized instructional designer.

Virtual and F2F Meetings

The team met virtually to discuss progress and concerns once the first deadline for initial digital learning objects had been met. This meeting set future “soft” deadlines for intermediate work against the backdrop of hard grant-driven deadlines. Team decision-making was created using virtual voting procedures, an approach that suggests a more democratic approach (Ferscha & Scheiner, 1999). A “checklist” of quality factors were captured at this meeting and distributed to the team.

Another critical point came with the structured critique of the different modules. Here, the team used their self-created “checklist” that had been co-created in a collaborative virtual meeting in order to create feedback for their colleagues.

This team found it helpful to have several core “go-to” people for various basic functionalities: project oversight and logistics, technology troubleshooting, funding, and subject matter expertise.

Curricular Revisions

The critiques resulted in a flurry of discussions among the team members. Based on the specific feedback, the team members revised their curriculum. They added audio files as over-lays to existing slideshows. They filled in the missing contents.

As the main modules were getting near finalizing, the project leaders came up with new ideas for more value-added learning. One endeavor involved the use of video captures of leading experts in related fields. The other involved the creation of Web-based automated mysteries highlighting aspects of the content domain. The group had created a culture of flexibility, innovation and efficiency that allowed these add-ons to be included into the final curricular build. Near the end of the build, the team decided to add student guides to

help learners navigate the curriculum through the selection of important learning points.

The finalized curriculum was aligned with the Quality Matters™ standards, with a special focus on the annotation and flow of contents and on accessibility standards. Extra contents would be used for other electronic trainings in public health.

Alpha and Beta Testing

Alpha testing involved in-house testing of the technologies and curriculum among the team members. Beta testing involved taking the e-learning out to a larger public, with live-testing of learners in a blended course in the summer of 2009. Continuing information collection and formal testing would involve datamining (of the L/CMS) and continuing learner surveys. (These were not formally addressed before the submittal of this chapter.)

ELEMENTS OF A LOCAL VIRTUAL TEAM ECOLOGY

The factors that created the virtual work ecology for this local virtual team involved four main elements:

1. social elements (both formal role structures and social relationships),
2. time elements (shared mutual time, asynchronous time, and deadlines),
3. informational elements (domain knowledge structures and quality standards), and
4. socio-technical elements (virtual spatial structures and communications channels).

A structured ecology enables a group to collaborate by setting shared expectations, upholding group standards, promoting professional rapport and camaraderie, and guiding and enabling the shared work. A local virtual team ecology supports individual and shared work across time and

through digital environments. These four factors are represented in Figure 2: Elements of a Local Virtual Team Ecology.

LEARNING ABOUT LOCAL VIRTUAL TEAMING

While the members of the team were all professionals in their respective fields, there was a range of attitudes towards e-learning and collaborative technologies. The research suggests that technology acceptance depends on computer self-efficacy and perceived usefulness of IT support mechanisms for group work (Yager, 1999, p. 73). One rural-based campus had continual issues with low Internet connectivity, and another was getting rewired with a new security system which caused connectivity challenges. A web conferencing meeting was missed by one local team because of scheduling challenges, and others who did participate had latency challenges.

Outsider Leverage and Distributed Hubs of Expertise

The concept of social capital appeared in this virtual team experience, with an “outsider” brought in to support the e-learning curriculum design, in part to preserve the social relationships of the subject matters experts who will be collaborating well into the future.

Changes to the Virtual Work Ecology

The virtual work site (on the Axio™ L/CMS) evolved over time, with much activity just prior to, during and after shared deadlines. The work site was the center for all the shared work. In the building and co-design phases, the work folders got congested and a little disorderly. However, when it came time to formally present curriculum to colleagues, the work areas were tidied, with raw files and research moved so as not to confuse those

Figure 2. Elements of a local virtual team ecology

critiquing the work. The work site also changed before the various co-located teams were about to download the curricular contents to their various L/CMses. A work site's purposes are very different than a cleaned-up ready-to-go-live site, so much of the development materials and raw files were archived and hidden away for the master course (the pristine version that would be maintained by one of the partners and which would be revised over time based on the best practices by each of the teams). While team members' names played a major role in the development of the contents early on (for clear work assignments), the team decided to remove their names from each of the respective slideshows (but not the videos) and instead have an "Introduction to the Pathways Development Team" form developed, which included brief biographies, headshots, contact

information, and data about what each member contributed to the course.

Uploading onto L/CMses

Once the curriculum was finalized, the curriculum was uploaded on the four learning / course management systems (L/CMses). The lack of interoperability between these systems meant tedious manual uploading and deployment of contents using zipped files. Each of the "playable" elements had to be re-tested in each system. The e-learning trajectory and branding also had to be rebuilt in each course, along with the assessments, message boards, and grade books. In another endeavor, the master course had to be moved onto a different server, so one of the teams from a college could use teach using this more flexible platform. While

the move went smoothly, the master worksite was essentially erased off the server, and all the team members had to be re-enrolled in a back-up master of the finalized course. Some interchanges and messages, though, would be unrecoverable from the Message Board.

The Human Touch

Interestingly, the various team members seemed to prefer communicating in-person or by telephone and email. They used the online site to share and archive their digital learning artifacts but not so much for direct collaboration or communications (synchronous or asynchronous). The direct human touch played an important role in team bonding and collaborating. The collaborators chose to meet face-to-face to wrangle through some difficult curricular decisions, such as what parts of the draft course to keep in the final version and what revisions had to be made to each other's work. This reluctance to use the L/CMS mediated resources for direct communications may have been a factor of the poor connectivity of some of the colleges to the Internet. Some of the collaborators had never taught online before and were familiarizing themselves with the L/CMS technologies as the collaboration proceeded.

Open Source Contents

The team had challenges pursuing "public domain" contents made available through federal agencies and some non-governmental health organizations, both in getting documentation of release and in getting the actual digital contents. These involved alt-texted imagery, videos, audio podcasts, and transcripts of these multimedia contents.

Consistency and Expectations Management

Templates of slideshows were used to offer some consistency and quality standards. While guide-

lines were created for the building of various contents, most development teams needed actual live samples and critiques of those samples to understand what was desirable (based on their peers' insights). Templates were also used to maintain a design look-and-feel consistency for each module, as multiple members of distributed teams would contribute to each of the modules.

Building for the Hand-off

One central practice of the project was to archive and protect all the work created by each team member for the eventuality of a hand-off. During the 6-month curricular build, there were occasions for the sharing of work, but no major team member dislocations occurred.

IT'S A WRAP: INTRODUCTION TO PUBLIC HEALTH

The course was finalized in the summer, and two sections of it were offered at two of the colleges for Fall Semester 2009. An external office has been enlisted to formally evaluate this course to identify ways to strengthen the curriculum and learner experience—based on learner feedback at the end of this first semester. The launch of a One Health Kansas site later that summer hailed the beginning of a long-term publicity plan. A playlist off of the K-State portal on YouTube™ was under consideration at press time, to showcase some of the expert videos captured for this course.

A multi-year schedule has been tentatively planned for this course, and other endeavors to build up a public health track are in the works. This course will be a central introductory and feeder course for this undergraduate and graduate public health series. In-house at Kansas State University, this course is also used as a model for developing other courses in epidemiology and public health. The standards of e-learning quality, accessibility,

intellectual property, documentation, and faculty comfort will be carried over to other online courses.

CONCLUSION

Local virtual teaming offers a hybridized way of collaborating with colleagues who are within a reasonable interactional distance from each other. This combination of realities offers opportunities to maximize the co-location (Saxenian's concept of "regional advantage") of team members as well as the distance of distributed colleagues. Examining local virtual teaming also shows the collaborative need in the selection of technologies. This chapter highlights the importance of setting up team member expectations and structures based around social, time, socio-technical and informational elements to support the work and frame the virtual ecology. This also shows the benefits of the loose coupling of a team at a higher abstract level but with tighter coupling up close on particular campuses to actualize the work.

ACKNOWLEDGMENT

This project was supported by the United States Department of Agriculture Cooperative State Research, Education, and Extension Service under Higher Education Challenge Grant number 2008-38411-19052.

I am deeply appreciative of the project principal investigators (PIs) Drs. Beth Montelone and Lisa Freeman, for their support and professionalism. There's a lot to be said for the complex factors that comprise leadership for virtual teaming—to have the room to innovate and explore and to form long-term professional alliances. I appreciated the gentle and direct supervision of Dr. Kimathi Choma, the humor of Dr. Mary McElroy, and the encouragement of Dr. Deanna "Go for It!" Retzlaff. Kent H. Nelson and Joseph D. Chapes provided superb videography work. The many members of

the virtual team were creative and hard-working, and it was a pleasure to work with them all; however, they are too many to name. Well after the completion of this chapter, Drs. Cindy Shuman and Valerie K. York (of the Office of Educational Innovation and Evaluation) conducted a debriefing of the communications and collaboration aspects of this work, and their interview reaffirmed the specialness of this local virtual collaboration for me. Thanks to R. Max.

KEY TERMS AND DEFINITIONS

Accessibility: The nature of being attainable or able to be used; meeting guidelines for being usable (in a technological and human sensory sense).

Attribution: Interpreting, assigning a quality or idea to someone or some action.

Co-Location: The state of being in the same vicinity.

Collaboration: The act of working together on a shared project, from planning to development to critique; teamwork.

Critique: A criticism or constructive feedback.

Discourse: A formal conversation.

Dispersed: Spread over a wide geographical area.

Ecology: The interdependence of people within a particular environment, and their interactions with that environment.

Hybrid: A blend of types, usually referring to electronic learning (e-learning) and face-to-face (F2F) learning.

Inflection: A point of change; a turning.

Intercommunication: Mutual communications between people.

Interdisciplinary: Combining two or more fields of study, consisting of the influences of multiple disciplines.

Leverage: Power.

Local: Close by geographically; nearby.

Loose Coupling: The concept of less interdependence between entities for greater adaptivity in an organization or organizational unit.

Media Richness: The state of having high communications cues through mediated communications.

Mental Model: The conceptualization of a particular system, held by individuals (vs. conceptual models, which are held by subject matter experts in a particular knowledge domain).

Milestone: A significant event or stage in a process.

Module: A separate stand-alone learning component that may be interchangeable with others.

Non-Verbal Cues: Body language as a tool of communications.

Rehearsable: The ability to go over a message before sending it out.

Reprocessibility: The ability to re-examine a message within a particular communications event.

Resilience: The power to recover from difficulty.

Rubric: An assessment device that is characterized by its presentation via tables with informational cells.

Social Exchange: The relationships between people as a basis for work and interactions.

Stylebook: A document used in digital project management that defines standards.

Trajectory: A particular path or course.

Transactional: A type of relationship based on mutual exchanges.

Virtual Teaming: The work collaboration by individuals who are geographically (and often temporally) dispersed.

APPENDIX A

Draft Stylebook for the Pathways to Public Health

Subject Matter Experts (SMEs) and Developers

A stylebook guides the development of the curriculum and digital learning objects. It is unique to a project and is co-created by the members of the team. (**Redaction:** The team members' names, contact information, institutional affiliations, and areas of domain expertise were deleted here. A "To Do" list specific to the project and work flows also were redacted. A table of deadlines was also omitted.)

1. Team Work Flow

Note: A separate workflow is annotated and color-coded to show the three main phases of the project: (1) development, (2) alpha and beta testing, and (3) deployment and archival. Also, that included annotations of where decisions would get made and by whom—to assign responsibilities and to ensure clear cross-team understandings.

Figure 3. A team work flow

Figure 4. General steps to the online course design process

Note: The above flow communicates the general steps to the online course design process. The project-specific due dates have been redacted.

2. Modular Contents

This segment set expectations for the team about the sizes of the modules in terms of the hours that learners would spend on each and the length of each module (two weeks of learning per module for 9 hours of learning per week—or 3 hours online and 6 hours of homework).

The group defined the modular contents, so there would be a shared understanding of what was being built:

Table 1.

Defined Learning Objectives: Learning objectives (5-10 total) (related to the digital learning objects, activities and assessments)
Self-Explanatory Topical Slideshows: 1-3 slideshows (approximately 20 – 25 slides each, with between 4-8 images per each slideshow)
Multimedia: Audio and / or video files
Relevant External Links: 2-5 links to professional, related resources on the WWW (simulations, immersive learning, videos, slideshows, informative websites, and other contents)
Discussion / Interactivity Plans: case studies, current events, controversial issues
Field Study Ideas: Field trips, site visits
Practice Exercises: based on learner opt-in (flashcards, crosswords, automated multiple-choice, true-false, matching, and other exercises)
Assessments: An objective assessment (multiple choice, true/false, matching, etc.)

Based on the face-to-face meeting by the project subject matter experts, the curriculum was divided into a pre-module (to help novice learners acclimate to both online learning and the subject matter), and six other modules. There were learning outcomes linked to each module, and there were chapters of a shared textbook linked to each.

3. Development / Authoring Technologies

Tech Standards and Tools: Given the technological standards of the project, this part set the URL for the work site. It also pointed to various freeware that could add value to the project—such as a site that allows for the low-cost easy-moving of large digital files. The authoring tool software programs and their versions (2007), digital file types (for text, slideshows, still images, audio, video, automation, and others) were defined specifically. Included also were specs on imagery in terms of file sizes, for the greatest flexibility in terms of versioning. The three learning / course management systems that would be used in the execution of this project were also listed.

Raw Files: Content creators were asked to keep proper raw video, photos, diagrams, and other elements in their modular folders for possible later use and for the most information-rich versions of the files (before compression and / or integration into a polished, finalized digital learning object or experience).

4. Course Development Standards

To develop this online course, it was critical to have clear definition of standards. A special segment at the end addressed issues of copyright and intellectual property, and another addressed federal Section 508 compliance for accessibility.

Annotation, Record-keeping and Citations: All subject matter experts and content creators were asked to annotate imagery for alt text. They were asked to keep records of all intellectual property / copyright releases. Citations were to be done using the American Psychological Association (APA) citation method. Guidelines for the labeling of diagrams were included.

File Naming Protocols: This section addressed how to name files in a consistent way without limiting how the digital files could be used. (The idea of modularization is not to lock individuals into a set curriculum but to make digital learning objects interchangeable to different e-learning and hybrid-learning situations.)

Credits: Another segment explored how to add a credits page at the end of a digital learning object, if desired.

Instructor Telepresence Strategies: A way for an inheriting faculty member to create telepresence was addressed. A digital instructor's manual would be created to go along with this curriculum.

Quality Matters™ Curricular Standards: A live URL link to the Quality Matters™ rubric was offered as part of the standards setting along with a brief overview of the contents of the QM standards.

5. Course and Module Assessment and Feedback Loops

This section addressed a survey feedback instrument to gather user feedback from learners (See Appendix C.) during the summer hybrid test-run of the course. A version of this survey instrument could be used with each course offering for continuing feedback loops and revisions. (Logistically, there would have to be one “pristine” master course, which all members of the team would have access to...and a way to capture changes and have those delivered to learners.) This noted, too, that datamining would be set up on the various learning / course management systems to observe learner behaviors and to gather information about how to improve the course and the student learning.

Stylebook Appendix A: Why IP in E-Learning?

A segment addressed intellectual property issues in terms of the rationale behind intellectual property, Creative Commons® releases, and public domain objects. The tenets of intellectual property and the various laws [the US Copyright Act (1976); “fair use” via Section 107 of the Copyright Act, 1976; the Digital Millennium Copyright Act (1998); the Technology, Education and Copyright Harmonization Act (TEACH Act, 2002) related to performances; trademark tenets; patent tenets, and trade secret protections were all covered. There was a tips section for faculty to help in their establishing provenance of information. The proposed “orphaned works” legislation was not addressed given a lack of an official decision. The subject matter experts also were given links to open cost-free educational resources that could offer topic-specific resources which they could use in this curriculum. They were also asked to use links to various sites.

Stylebook Appendix B: Accessibility

Lastly, there were tips given to make courses accessible. These involved efforts to use universal product format file types and versioning file types for more robust accessibility. Text documents would not be digital image graphics but text-readable files. Documents would be tagged for document structure and markup, so users may understand headers from body text. The language would be clear, simple English, to help those using computerized language translators or reading the English as a second or foreign language. Informational graphics needed alt text labeling, and all audio and video needed transcription. PowerPoint slideshows would have to be made accessible based on using their extant templates instead of inserting text boxes (which are skipped over by some text readers). Color needed to be accessible for those who have low vision or color-blindness, so the use of color *alone* to communicate was discouraged. Data tables had to be summarized and created in a screen-readable way for clarity. Live events that were planned for the course needed to be accessible, with preliminary, during-event, and post-event work. If automations or sequenced actions were created, these had to be controllable by users to the largest extent possible.

APPENDIX B

Peer Feedback on the Modular Contents

1. Based on the **Pathways to Public Health Check List for Course Materials** (in the Stylebook Criteria folder in the online workspace), did you find (a) **anything missing** or (b) **needing revision** from the module? (**Note:** Please be specific. Name the lecture or item, and note the exact slide. If referring to a video, refer to an exact time. Provide specific suggestions for improvement.)
2. Based on **the Quality Matters rubric** in the Stylebook Criteria folder in the online workspace), did you find the following elements in the module you assessed? And did these come up to the course standards? If any parts do not come up to course standards, list below and specifically state why they do not. Provide suggestions to help bring them up to course standards. Please be specific in your comments.

Table 2.

Quality Matters review: (See Project Stylebook at K-State Online. Use QM Best Practice Guidelines)
Module Overview and Introduction
Learning Objectives
Assessment and Measurement
Resources and Materials
Learner Engagement
Course Technology (see -- stylebook pgs. 10, 12 and 13)
Learner Support
Accessibility (see Pathways stylebook)

3. Based on the **subject matter for the module**, did you find any curricular **information missing**? If so, what would you add?
4. Did you have any **technological problems** accessing the curricular contents? Please describe these in depth. (What were the file types?)

Submittal: Please keep a copy of this for your team, and make sure to send a copy to ---. She'll make sure that all the developers for a particular module receive a copy of the comments. She'll also maintain an archive of the critiques in the online workspace.

If you and your team have suggestions for the overall development of the modules, feel free to share that with the team. (You may email all team members via the Roster area of the worksite.) Thanks. (**Note:** A separate form will be used for critiquing the overall course later on.)

APPENDIX C

Proposed Learner Survey for Pathways to Public Health Curriculum Assessment

This 24-question survey will be used to enhance the online course "Pathways to Public Health." The first section consists of a series of statements, which may be evaluated based on your learning experience.

The second short section consists of two short-answer questions. This survey may take about 10 minutes to complete. Your help is appreciated.

Directions: Please read the following statements. Rank how true each statement is with the following scale.

Table 3

N/A	1	2	3	4	5
Non-applicable	Disagree	Somewhat disagree	Neutral	Somewhat agree	Agree

LEARNER BACKGROUND

1. I had the proper amount of prior knowledge to understand the contents of this introductory public health course.

LEARNER NEEDS

2. I needed more materials in order to understand the subject matter of this course.
3. My learning styles or preferences were met in this course.

CLARITY OF COURSE EXPECTATIONS

4. I was clear about the course expectations early on (through the syllabus and course postings).

TECHNOLOGIES

5. I was able to access all the digital files related to this course.

If not, I had problems with the following file types:

- Images
- Slideshows
- Audio
- Video
- Animated tutorials
- Simulations

6. The learning / course management system (the software through which you accessed the online course) was user-friendly.

COURSE CURRICULUM

7. The course curriculum was clear.
8. I had sufficient opportunities to apply the learning during this course.
9. The course materials related clearly to the course textbook.
10. The case studies helped me understand some real-world aspects of public health.
11. The field trips (if applicable) helped me better understand public health.
12. I have a better understanding of careers in public health.
13. My interest in public health careers has been enhanced.
14. I felt the learning showed diverse populations in an inclusive way.
15. The course assessments (quizzes, tests) aligned with the learning.
16. The textbook was helpful for my learning.
17. The external readings (in addition to the textbook) were helpful to my learning.

INTERACTIVITY

18. I felt engaged and interested throughout this course.
19. I experienced sufficient communications with my fellow students / peers.
20. I experienced sufficient communications with my instructor.

INSTRUCTOR SUPPORT

- 21. The instructor(s) was / were responsive to my learning needs.
- 22. The instructor(s)' response time and availability to answer my questions was adequate.

Short Answer Questions

- 23. Were there topics you wanted to learn more about in this introductory --- course that were not addressed? If so, please list them below.
- 24. Any suggestions on ways that this online course may be improved for future learners?

Thanks for your participation in this course and survey. If you would like to be contacted by a faculty member, please include your email below:

Chapter 6.3

Motivation and Multimedia Learning

Rena Low

University of New South Wales, Australia

Putai Jin

University of New South Wales, Australia

ABSTRACT

In the field of multimedia learning, although research on cognitive effects and their implications for instructional design is rich, research on the effects of motivation in a multimedia learning context is surprisingly scarce. Since one of the major goals of providing multimedia instruction is to motivate students, there is need to examine motivational elements. In this chapter, we focus on 4 major motivation theories—expectancy-value theory, self-efficacy, goal-setting and task motivation, and self-determination theory—and two motivation models—ARCS model and the integrated model of cognitive-motivational processes—that are derived from multimedia research; review the literature on motivation in multimedia learning contexts, suggest that researchers and practitioners

take into account a number of essential aspects to ensure that motivation features incorporated in multimedia learning resources optimize learners' experience; and point out future research directions in model building, hypothesis testing, examining individual differences, and carrying out longitudinal studies.

INTRODUCTION

Research in the area of multimedia learning so far has focused on the effectiveness of instructional methods and course design. Various approaches of delivery have been investigated and basic principles in terms of memory and associated cognitive processes identified (e.g., Fletcher & Tobias, 2005; Low & Sweller, 2005; Mayer, 2005). Research in this direction appears to be fruitful, although puzzling, sometimes conflicting results,

DOI: 10.4018/978-1-60960-503-2.ch603

do occur. As a convention, in an attempt to integrate or develop “mini theories”, more theories or models from information processing perspectives are proposed and further tested (e.g., Butcher, 2006). However, as pointed out by a number of researchers (Astleitner & Wiesner, 2004; Bernard et al., 2004; Clark & Feldon, 2005; Keller & Suzuki, 2004; Pass, Tuovinen, van Merriënboer, & Darabi, 2005; Volleyer & Reinberg, 2006), motivational aspects in multimedia learning should be regarded as essential elements and research with sound theoretical bases and methodological rigor is much needed.

In this chapter, we attempt to analyze and discuss motivational determinants in effective multimedia learning from social cognitive perspectives. The main issues covered here are as follows. First, we discuss why researchers and practitioners need to adequately consider motivational issues in multimedia learning. Second, we present well-founded motivation theories that are relevant to learning processes and task performance, and review models that can be specifically applied to multimedia learning, teaching and course material development. Finally, we highlight important factors, topics and directions for future motivational research to guide multimedia teaching and learning.

THE NEED FOR MOTIVATIONAL RESEARCH IN MULTIMEDIA LEARNING

It has been almost axiomatic since ancient times even before Aristotle and Confucius that meaningful learning is associated with motivation. However, despite the efforts of some experts in multimedia learning motivation (e.g., Astleitner & Hufnagl, 2003; Gao & Lehman, 2003; Keller & Suzuki, 2004; Song & Keller, 2001), research in multimedia learning at large has not taken motivational issues into account. Instructors may deem that multimedia material and associated operations

are more interesting (e.g., text + pictures + sound) or more accessible (e.g., e-learning at the user's convenient time) than conventional methods. The underlying assumption is that learners who have the opportunity to use multimedia resources should be highly motivated. However, if we scrutinize the literature, we will soon find that multimedia technology together with a certain type of course design may not lead to elevated motivation and superior learning performance. For instance, in a well-controlled study with initial motivational screen and randomization of subject assignment, online evaluation shows that medical students initially with positive attitudes towards computer-based learning (CBL) were not enthusiastic at the end of course, and learning outcomes were significantly affected by students' prior knowledge but not by their CBL use (Hahne, Benndorf, Frey, & Herzig, 2005). The implication is that CBL may hold too much promise in a curriculum scenario, and that hasty implementation of such curriculum-driven CBL program may carry a risk of deteriorating students' positive attitude towards CBL.

In another study which examined the data quality of questionnaire administration, the paper-based group was better than both computer-based and web-based groups, and the affective responses of participants favored the paper-based mode over computer- and web-based modes (Hardré, Crowson, Xie, & Ly, 2007). These results indicate that adopting information technology does not necessarily lead to high motivation. Hoskins and Van Hooft (2005) reported in a study on Web Course Tools (WebCT) that only those students already highly-motivated and academically-able benefited from bulletin board use, suggesting that motivation and academic ability are determinants of achievement in hypermedia learning.

The effect of motivation on multimedia learning was also highlighted by Hwang, Wang and Sharples (2007) in a quasi-experiment. The study found that although the experiment group using VPen (a multimedia annotation tool) appeared to be superior to the control group (learning without

a multimedia annotation system) in several learning activities, there was no significant difference between the groups in the final examination. This is a typical example of a Hawthorne effect in multimedia learning, that is, academic outcome is due to motivation to learn and not necessarily owing to the adoption of sophisticated multimedia support.

Previous reviews on the effectiveness of multimedia learning are consistent with the suggestion that motivation plays an important role in multimedia learning. In a comprehensive, strict criterion-based meta-analysis of empirical literature comparing classroom (face-to-face) instruction and distance multimedia instruction, Bernard and colleagues (2004) have identified a bi-modal pattern of multimedia learning effectiveness. They also report that the variability surrounding the mean effect size for achievement is considerably large, indicating that distant multimedia learning works extremely well in some cases and extremely poorly in other cases. According to their explanation, whether the learner is engaged in active learning is an essential issue. They further argue that interest (or satisfaction) may not automatically lead to high achievement, because learners may be just happy to choose a convenient study mode but do not make sufficient effort to study. They suggest that future research should explore student motivational dispositions such as task choice, persistence, effort, self-efficacy, and perceived task value. According to Clark (1983, 1994), the potentially unlimited and inclusive capacity of multimedia instruction does not necessarily facilitate learning. Arguably, the capacity of multimedia instruction to include learner's participation can give rise to motivation to be engaged in multimedia courses learning. However, studies have revealed that such interest does not incontrovertibly translate into achievement (Clark, 2005).

There is research evidence to suggest that instructional support in the form of animations may distract and interfere with learning rather than facilitate it (see Clark, 2005), and one common

problem in the use of hypermedia environments is the phenomenon of getting lost in the environment thus losing track of learning (Svinicki, 1999). In addition, meta-analytic evidence suggests that learning tends to decrease in multimedia courses as interest (and thus enrolment) in such courses increases, because learners may believe that such courses require less work (Bernard et al., 2004). Furthermore, in a recent review, Tallent-Runnels et al. (2006) concluded that learning outcomes of web-based courses are the same as traditional ones and suggested that the understanding of learner's goals, needs, and motivations in taking a course is essential for the instructional design of multimedia learning. It is necessary to scrutinize motivational factors in multimedia learning processes.

ACHIEVEMENT MOTIVATION: THEORIES AND APPLICATIONS TO MULTIMEDIA LEARNING

Many achievement motivation theories have been developed in psychological research to explain people's choice of achievement tasks, persistence on those tasks, and resulting performance (Wigfield & Eccles, 2000). Although there have been attempts to integrate these theories, the theories retain their distinctive features (Naylor, Pritchard, & Ilgen, 1980). In this chapter, we focus on expectancy-value theory, self-efficacy, goal-setting theory, self-determination theory, and specific models that have been applied to various multimedia learning processes.

Expectancy-Value Theory

According to Vroom (1964), valence, instrumentality, and expectancy (VIE) are the three major motivational determinants. Valence refers to the anticipated desirability (i.e. importance) of an outcome; instrumentality is the belief that performance will lead to a desired outcome; and expectancy refers to the subjective probability of

effort leading to a specific outcome. For example, in choosing a multimedia course, the ultimate outcome for an individual may be a good grade for the selected course. Therefore, valence in this case is the desirability of a good grade in the chosen course. Instrumentality is operationalized as the degree to which the student believes that doing well in the final exam (performance) will lead to a qualification or promotion, and expectancy is the student's belief that his or her effort will lead to a good grade. In the VIE theory, volitional and calculative processes play a critical role in human decision-making. Influence by Lewin's (1939) psychological field theory, Vroom (1964) use the term "force" as a metaphor for the integration of motivational components.

Despite its long history and the considerable amount of empirical support for the expectancy-valence theory, the underlying assumptions of the theory have been questioned. According to Vroom (1964), the choices individuals made are determined by their affective reactions to certain outcomes (valences), their beliefs about the likelihood of the actions leading to those desired outcomes (expectancies), and their perception of the relationship between primary and secondary outcomes (instrumentality). One comment of this type of model is that in making a decision, an individual will have to consider a wide variety of options, outcomes, instrumentalities, and probabilities before taking actions. This will require many mental computations and huge processing capacity (Lord, Hanges, & Godfrey, 2003). However, the human cognitive architecture often does not permit simultaneous processing of all available information. Such processing of information will involve an inordinate amount of working memory. In an attempt to sort out the discrepancy between Vroom's postulation and the limits of the working memory capacity, Lord, Hanges and Godfrey (2003) have presented simulation data to show that Vroom's motivation model holds if computations to reach a decision are performed by neural networks instead of serial processing. It

should be noted that the use of neural networks is possible only when there is extensive experience with a problem situation and with the knowledge structures organized in the form of schemas for automatic processing.

Moreover, in practice, individuals are not always privy to information that is needed. According to Simon (1945), individuals usually only consider a limited amount of information and stop searching alternatives once they believe that they have reached satisfactory (though not necessarily optimal) solutions. Consider the case in a multimedia on-line course, once learners know they have attained a satisfactory level of achievement, it is possible that some learners would stop engaging in the learning activities provided in the on-line course even though their valence, instrumentality and expectancy are high.

Another comment of Vroom's theory is at the operational level. The motivation score can be obtained as either a multiplicative or additive result of the three components, namely, valence, instrumentality, and expectancy. Originally, Vroom proposed a multiplicative model. Consequently, a number of researchers have used this method. However, in a meta-analysis, Van Earde and Thierry (1996) found that the additive model yielded higher effect size in relation to attitudinal criterion variables (e.g., intention and preference) than did the multiplicative model, and therefore argued for the use of the former over the latter. Using the additive model, Sanchez, Truxillo & Bauer (2000) reported that expectancy was positively related to test performance.

In the context of multimedia learning, Rheinberg, Vollmeyer and Rollet (2000) have posited a model of self-regulated learning which includes three types of expectancies: action-outcome-expectancies (the probability of success), outcome-consequence-expectancies (instrumentality), and situation-outcome-expectancies. The situation-outcome-expectancies (SOE) represents "the assumption that the just given situation will lead to the desired outcome on its own without the

need to take any action” (Rheinberg et al., 2000, p.510). SOE is regarded as a relatively stable, trait-like factor. Using the SOE model, Astleitner & Hufnagl (2003) investigated the effect of motivation on the learning outcomes of web-lectures consisting of both audio and visual presentations. The findings are: 1) high SOE learners tended to rate the statement “I do not need any activity for critical thinking because I understand everything at once” totally true or true; and 2) low SOE learners tended to rate the same statement not true or not at all true (p.369). Astleitner and Hufnagl (2003) argued that students with low SOE were motivated to be engaged in active learning and sought support to reach a given goal, whereas students with high SOE were not sufficiently motivated to learn because they were not convinced that engagement in learning would change learning outcomes in any significant way.

Self-Efficacy

While the traditional expectancy-value models have focused on outcome expectancies, Bandura (1977, 1993, 1997) has argued that efficacy expectations should also be considered as they are more predictive of performance and choice than outcome expectations. Self-efficacy and outcome expectations do not have the same meaning. Outcome expectations involve beliefs about the anticipated outcomes of those actions. For instance, a student may believe that a positive outcome will result from certain actions but also believe that they lack the competence to produce those actions. The concept of self-efficacy, developed from social learning theory, refers to perceptions of one’s capabilities to engage in courses of action that will lead to desired outcomes (Bandura, 1977, 1993, 1997).

There are two important features in Bandura’s construct of self-efficacy. First, self-efficacy operates within a specific context (e.g., incorporating internet resources to prepare a PowerPoint presentation on global warming). The second element of

the construct refers to judgments of the behavior one is capable of performing independently of the value one attached to the given actions. For example, an individual may have a high self-efficacy for doing a presentation but draws little self-worth if the task is perceived to lack value.

Research shows that self-efficacy can influence behavior in achievement settings (Bandura, 1993; Pajares, 1996, 1997; Schunk, 1989, 1991). Students with low efficacy for learning may avoid attempting tasks; those with high efficacy would participate more eagerly by expending greater effort and persist longer in the face of difficulties. In a study estimating the unique contribution of self-efficacy to work-related performance controlling for personality, general ability, and job or task experience, Judge, Jackson, Shaw, Scott and Rich (2007) found that self-efficacy predicted performance in low complexity task but not in medium or high complexity tasks. Based on Bandura’s (1986) guidelines of assessing self-efficacy for specific tasks, scales for computer self-efficacy were developed and validated (e.g., Murphy, Coover, & Owen, 1989; Zweig & Webster, 2004). In our study of students undertaking a teaching qualification, we look at the motivational factors involved in a compulsory computer skills course that consists of face-to-face instruction and self-paced web-based learning. We found a moderate correlation between self-efficacy and test results (Jin & Low, 2007).

Goal-Setting Theory and Task Motivation

As early as 1950s, Atkinson (1958) reported that task difficulty, as indicated by the probability of task success, was related to performance in a curvilinear, inverse function. However, in a meta-analytic investigation, Locke & Latham (1990) found a positive, linear function in that the highest goal produced the highest levels of effort and performance. They also discovered that specific, difficult goals tended to result in

higher performance than urging people to do their best. The explanation given to this finding is that do-your-best goals have no external framework of reference, whereas goal specificity can reduce ambiguity regarding what is to be attained. They suggest that goals with specific standards of performance increase motivation and raise self-efficacy because goal progress is easy to judge, and that challenging but attainable goals raise motivation and self-efficacy better than easy or hard goals. According to Locke and Latham (2002), for goals to be effective, feedback is a necessary component; if people do not have information about how they are doing, it is difficult for them to adjust their effort or strategies to match what the goal requires. In addition, individuals who participated in setting goals tended to set higher goals and performed better than those whose goals were assigned.

Based on findings from the empirical research on goal-setting, Locke and Latham (2002) proposed an expanded model of motivation relating assigned goals, self-set goals, self-efficacy, and performance. According to the model, assigned goal affects both self-efficacy and personal goal; self-efficacy influences personal goal; and both self-efficacy and personal goal are predictive of performance. Thus, the goal-setting theory appears to be compatible with Bandura's conceptual framework of self-efficacy in the wider context of social cognitive perspectives.

Goal-setting theory seems to be incongruent with Vroom's theory in that, whereas expectancy is linearly and positively related to performance, expectancy of goal success could be negatively related to performance under difficult goal conditions where goals are hard to attain. This apparent incompatibility is resolved, according to Locke and Latham (2002), when a distinction is made between expectancy within a certain goal level and expectancy between goal conditions. Locke, Motowidlo, and Bobko (1986) found that when goal level is constant (a situation assumed by valence-instrumentality-expectancy theory), higher expectancies lead to a higher levels of per-

formance. Across goal levels, lower expectancies, associated with high goal levels, are associated with higher performance. More recently, Louro, Pieters, and Zeelenberg (2007) suggest that in multiple goal environments, in addition to goal expectancies for success and goal proximity, positive and negative goal-related emotions contribute to goal-related behavior.

In the learning context, achievement goals or goal orientations refer to the motivational basis of learning (Karabenick & Collins-Baglin, 1997). Research shows that there are four types of goal orientations: learning (mastery) orientation, learning avoidance orientation, performance orientation, and performance avoidance (learned-helplessness) orientation (DeShon & Gillespie, 2005; Elliot & McGregor, 2001; Lee, Sheldon, & Turban, 2003; Midgley, Kaplan, & Middleton, 2001; Zweig & Webster, 2004). Researchers have conducted a number of studies on learning and performance orientations (cf. DeShon & Gillespie, 2005). Learning orientation is characterized by a desire to increase one's competence by mastering new skills while performance orientation reflects a desire to demonstrate one's competence (Bruning, Schraw, Norby, & Ronning, 2004). In the face of failure, individuals with learning orientation tend to adopt an adaptive response pattern while those with performance orientation are associated with a maladaptive response pattern. A typical adaptive response pattern is related to persistence, spending more time on-task, adopting more complex strategies, and seeking appropriate help in the face of difficult tasks. In contrast, a maladaptive response pattern is characterized by a tendency to quit in the face of difficult tasks, and a tendency to seek less challenging materials and tasks on which success is a likely outcome.

Although research on goal orientations and motivation is aplenty, in multimedia learning research, the contribution of goal orientations receives scant attention while the relation between instructional design and cognitive load (see Mayer, 2005) has been a major focus. According to a

series of studies on the effects hypertext-based instruction on learning outcomes conducted by Gerjets & Scheiter (2003), configurations of teacher goals, learner goals, as well as learners' processing strategies, may be important mediating variables. Researchers (Gerjets & Scheiter, 2003; Goldman, 1991) suggest that the cognitive load theory, which emphasizes the relationship between instructional design and learning outcomes (Sweller, 1994; Sweller, van Merriënboer, & Pass, 1998; Yeung, Jin, & Sweller, 1998), can be further expanded by inspecting the suitability of instructional procedures for attaining specific goals. For instance, in Gerjets & Scheiter's (2003) experiment using a hypertext environment that contained work-out examples, when the goal of instructor was just to encourage participants to learn very fast to solve problems in a way as shown in the instructional examples, the structure-emphasizing condition elicited more demanding cognitive processes and thus imposed additional cognitive load than did the surface-emphasizing condition. Consequently, participants spent longer time learning and had poorer performance under the structure-emphasizing condition than those under the surface-emphasizing condition. They suggest that different types of goals and learning strategies should be incorporated into the cognitive load theory.

Self-Determination Theory

According to self-determination theory (Deci & Ryan, 1985), one of two types of motivation, extrinsic or intrinsic, gives rise to an action. Intrinsic motivation refers to doing something because it is inherently interesting, and extrinsic motivation refers to doing something because it leads to a separable outcome (usually some kind of reward). Intrinsic motivation is viewed as an innate human need for competence and self-determination (Deci & Ryan, 1985; Deci, Vallerand, Pelletier & Ryan, 1991) and is therefore influenced by environmental and interpersonal

variables that affect experiences of competence and self-determination (Reeve, Nix, & Hamm, 2003). In self-determination theory, motivation is conceptualized as a continuum with intrinsic motivation at one end and extrinsic motivation at the other. In between are behaviors that were extrinsically motivated initially but have become internalized and self-determined. More recently, Ryan and Deci (2000) have added another construct, amotivation, to the theory. Amotivation refers to the state of having no intention to act and it resides next to extrinsic motivation.

Intuitively, intrinsic motivation is an important construct in educational contexts. Consider the situation where students enrolled in a compulsory multimedia computer skills course may want to avoid some difficult web-based activities but work on them to avoid failure (i.e., the students are extrinsically motivated). As they become more competent, they perceive a sense of control and self-determination over the multimedia learning (i.e., they become intrinsically motivated). The activities become more intrinsically motivating and positive social factors (feedback) assist the learning process. However, as some researchers (e.g., Pintrich & Schunk, 2002; Reeve, Nix, & Hamm, 2003) have pointed out, relatively little attention has been paid to educational implications of self-determination theory. Ryan and Deci (2000) have suggested that the basis for maintaining intrinsic motivation and becoming more self-determined lies in the social contextual conditions that support feelings of competence, autonomy, and relatedness. Therefore, in learning contexts, it is important to create instructional conditions that satisfy the innate needs to feel connected and effective as one acquires knowledge and skills. Recently researchers (e.g., Deimann & Keller, 2006; Kuhl, 2000) have reintroduced and validated a relevant construct "volition" (originally raised by James, 1902) to educational research. According to Deimann & Keller (2006), volition (or willpower) is "one's capability of maintaining attention and effort toward goals in spite of

possible distractions due to waning motivation or competing goals” (p. 139). They point out that, since multimedia learning design and processes are likely to encounter problems such as learner’s uncertainty, distractions, “seductive” details, and cognitive overload, research and teaching programs in the direction of volition enhancement are much needed.

The Attention, Relevance, Confidence, and Satisfaction (ARCS) Model

The ARCS model is an approach to instructional design using multimedia technology based on a synthesis of motivational concepts. Keller and his colleagues (Keller, 1987; Keller & Suzuki, 2004; Song & Keller, 2001) have identified four conditions that are essential for the learner’s motivation in e-learning contexts. The first condition is that a lesson must attract and sustain the learner’s *attention* (A). This requirement is based on research on curiosity, arousal, and boredom. The second condition for motivation is to build *relevance* (R). This requirement is based on research on intrinsic motivation and competence as highlighted in self-determination theory. The third condition for motivating learners is *confidence* (C). This requirement is based on research on self-efficacy and attribution. The fourth condition is *satisfaction* (S). This requirement is based on reinforcement theory and equity theory that have been commonly used in other areas such as I/O Psychology.

The ARCS model is a systematic ten-step design process for developing motivational elements in instructional settings: obtaining course information, obtaining audience information, analyzing audience, analyzing existing materials, listing objectives and assessments, listing potential tactics, selecting and designing tactics, integrating with instruction, selecting and developing materials, and evaluating and revising (see Keller & Suzuki, 2004). The model and its simplified versions have been validated in various learning

contexts (cf. Astleitner & Hufnagl, 2003; Gao & Lehman, 2003; Keller & Suzuki, 2004; Means, Jonassen & Dwyer, 1997; Small & Gluck, 1994; Song & Keller, 2001; Visser & Keller, 1990). For instance, Song and Keller (2001) conducted a motivational analysis of attention, relevance, and confidence in biology classes to examine the effects of a prototype of motivationally adaptive computer-assisted instruction (CAI). They found that the motivationally adaptive CAI resulted in higher effectiveness, motivation and attention than did the motivationally saturated CAI and the motivationally minimized CAI. In this experiment, the ARCS model was used to construct motivation measures, guide motivational design processes, and provide detailed motivational strategies. In the ARCS model, there are two types of motivational strategies: (1) motivation sustaining (e.g., “keep instructional segments relatively short with progressive disclosure”, p. 11), and (2) motivation enhancing (e.g., “use inverse and flash in text and patterns in pictures as attention getters”, p. 12). According to Song and Keller (2001), the motivationally adaptive CAI was effective because it was based on the ARCS model to provide optimal motivational stimulations to learners who were bored and to eliminate excessive motivational features that might be annoying or distracting for learners who were already motivated. In general, findings from research on the ARCS model demonstrate that a systematic analysis of learner motivation is an important aspect in the design and implementation of multimedia courses.

An Integrated Model of Cognitive-Motivational Processes

Astleitner and Wiesner (2004) have proposed an expansion of the multimedia learning theory summarized by Mayer (2001) and Hede (2002). The current multimedia learning theory is based mainly on evaluating research on cognitive processing of sensory (visual and audio) inputs (e.g. Low & Sweller, 2005; Mousavi, Low & Sweller, 1995;

Yeung et al., 1998). Such research is concerned basically with working memory limitation, an essential element of the cognitive load theory. Astleitner and Wiesner (2004) argue that, because motivation influences learning, and motivational processes need memory resources and therefore affect cognitive load, motivational aspects such as goal-setting and action control should be incorporated in a theory of multimedia learning.

Astleitner & Wiesner (2004) have suggested several avenues for motivational research to facilitate multimedia learning: a) the motivational quality of multimedia elements such as the relation between the utility of content and goal-setting, and the relation between variability in audio and visual effects and attention; b) the effects of learners' characteristics such as success- or failure-oriented learners and action- or state-oriented learners; and 3) motivational features that affect cognitive load in multimedia learning environments such as distraction, disruption, diversion, and saturation. Obviously, these research questions need to be systematically investigated with sound methodology.

ESSENTIAL ASPECTS OF MOTIVATIONAL RESEARCH IN MULTIMEDIA LEARNING

Theoretical Development

For multimedia teaching and learning to be effective, it is necessary to conduct appropriate motivational analyses before and during the implementation of courses. Such analyses should be derived from evidence-based motivational theories. Hence, it is important to develop relevant theoretical perspectives. According to Maddux (1999), major theories of the social-cognitive perspective of motivation share a limited number of important principles, processes and variables. Common basic conceptual elements include behavior-outcome expectancies, stimulus-outcome expectancies, self-efficacy expectancies,

outcome value, goal-setting, and competencies. Such similarities suggest that they are not different models of motivation but different versions of some basic elements. As such, it is sensible for the development of an integrated theoretical framework to guide research so as to determine the optimal conditions for best practices in multimedia learning contexts.

Recent research shows some promising developments. For instance, as mentioned earlier, in Astleitner and Hufnagl's (2003) study consistent with the ARCS model, situation-outcome-expectancies (a construct neglected in previous educational psychology research), in addition to action-outcome-expectancies and outcome-consequences-expectancies, was found to play an important role in multimedia learning. They reported that students who did not have strong assumption of "one can fulfil the tasks automatically in a given situation" tended to benefit from the ARCS strategies.

In another study implementing the ARCS strategies in WebCT learning environments, Gao and Lehman (2003) show that feedback plays a significant role: students in both reactive and proactive conditions performed better in achievement tests than those in a controlled condition; and students in the reactive interaction condition demonstrated higher motivational perceptions toward the instructional material than those in the control condition. The control condition was one where the website only incorporated typical, static hyperlinks; the reactive condition was one where the website incorporated an immediate feedback strategy which provided responses during learning; and the proactive condition was where the website incorporated a generative activity strategy which asked learners to generate a new situation after a learning section.

Future research in those aspects covered by Astleitner and Hufnagl (2003) and Gao & Lehman (2003) appears to be warranted. Other explorations to integrate motivational approaches in multimedia learning should be encouraged. For

instance, because self-efficacy is task specific and multimedia learning programs have many variations in the design of tasks and procedures, there is room for the expansion of self-efficacy research in this aspect.

Motivational Features and the Design of Multimedia Instruction

In a series of studies to develop and validate a taxonomy of reasons that gives rise to academic amotivation in high school students, Legault, Green-Demers and Pelletier (2006) have found that task characteristics affect task engagement, and unappealing characteristics of an academic task may lead to academic disengagement. This finding has instructional implications for multimedia teaching and learning. Ally (2004), Reed (2006) and Svinicki (1999) have suggested that designs that keep learners active doing meaningful tasks, and allow learners to construct their own knowledge, to control the learning process, and to evaluate their own learning (meta-cognition) are some features that can engage learners.

Learner Characteristics

Learner characteristics are another important aspect to consider in multimedia learning and teaching (Bernard et al., 2004; Tallent-Runnels et al., 2006). For instance, Mayer and Massa (2003) found that some individuals are visual learners while others are verbal. These two types of learners are distinguishable by three facets: cognitive ability, cognitive style, and learning preference. Multimedia learning resources should provide appropriate avenues and options for different types of learners. In a recent study, when learning style differences were considered in designing an interactive multimedia courseware of Mathematics, the program produced high learning motivation and positive learning experiences (Shiong, Aris, Ahmad, Ali, Harun, & Zaidatun, 2008).

Judge et al. (2007), in a meta-analysis, have found that personality (the Big-Five traits), as well as self-efficacy, affect work-related performance. The Big-Five traits are Neuroticism (the tendency to show poor emotional adjustment in the form of stress, anxiety, and depression), Extraversion (the tendency to be sociable, dominant, and positive), Openness to Experience (likely to be creative, flexible curious, and unconventional), Agreeableness (tendency to be kind, gentle, trusting and trustworthy, and warm), and Conscientiousness (likely to be achievement-oriented and dependable). In another meta-analytic review of research on relation between the five-factor model of personality and performance motivation, Judge and Illies (2002) found that the Big-Five traits are an important source of performance motivation. Among them, Neuroticism and Conscientiousness were the strongest and most consistent correlates of performance motivation. Effects of the other three personality traits on achievement motivation need to be investigated in future research.

Other learner characteristics that warrant consideration are goal orientation (Locke & Latham, 2002; Midgley et al., 2001; Lee et al., 2003), technological acceptance (Palaiogeorgiou, Siozos, Konstantakis & Tsoukalas, 2005; Saadé, Nebebe & Tan, 2007), adaptive learning environments including learner involvement (Song & Keller, 2001; Paas et al., 2005), procrastination in self-paced learning (Steel, 2007), and disappointment and motivation loss (Miceli & Castelfranchi, 2000). In an era of mass education and student-centered learning, especially in multimedia technology-rich settings, learner characteristics should be scrutinized and accommodated in the entire learning process.

Self-Regulated Learning Strategies and Motivation Training

Research in interactive learning environments, participatory multimedia learning, and learner control in hypermedia environment have recently

gained momentum (see Järvelä, & Volet, 2004; Kiili, 2005; Renkl & Atkinson, 2007; Scheiter & Gerjets, 2007). Narciss, Proske and Koerndle (2007) have argued for the promotion of self-regulated multimedia learning which can be applied to WebCT. Self-regulated learning (in the form of problem-based learning, blended learning, project-based learning, etc.) is a specific form of learning distinguishable from learning that is externally regulated in that self-regulated learners use cognitive strategies, metacognition, volition, and motivation to monitor their own learning process (Vollmeyer & Reinberg, 2006). Self-regulated learning involves many strategies of which time planning (involving time management, scheduling, and planning study time) and self-monitoring (involving goal-setting, attention focusing, and monitoring study activities) are important skills to be possessed (Boekaerts & Cascallar, 2006; Van Den Hurk, 2006). The assumptions underlying self-regulated learning are: 1) students construct their own meaning, goals and strategies based on the availability of internal or external information; and 2) students are capable of monitoring and managing aspects of their own cognition, motivation, behavior and learning environment (Pintrich, 2000).

Attractive multimedia platforms contain interesting but sometimes irrelevant information. Competent self-regulated learners need not only to use appropriate cognitive and meta-cognitive skills to determine relevant information for the tasks selected and effort invested in undertaking such tasks, but also are required to properly regulate motivation and attention (Narciss et al., 2007). In self-regulated learning, initial motivation affects learning outcome. According to Vollmeyer and Reinberg (2006), initial motivation is determined by probability of success, anxiety (or fear of failure), interest in the learning material, and challenge (to succeed in an important task). They also suggest that the influence of initial motivation on performance may be mediated by duration and frequency of the learning activity, systematic

learning strategies employed, motivational state during learning, and state of concentration/engagement during learning. Apart from incorporating motivational elements in multimedia learning and teaching, we may also consider motivation training, although evaluation of motivational programs is not an easy exercise (Schober & Zieger, 2002).

Evaluating Quality of Motivational Features in Multimedia Learning Resources

As highlighted by Keller and Suzuki (2004), motivational analysis should be an on-going process to ensure that multimedia resources are compatible with transient motivational factors as the learning progresses. The ARCS model (Keller & Suzuki, 2004; Song & Keller, 2001) has provided a number of specific measures to examine relevant motivational features in multimedia learning. In addition, Leacock and Nesbit (2007) have presented a framework for evaluating the quality of multimedia learning resources named LORI (Learning Object Review Instrument). LORI contains some items that can be used to assess the quality of motivation features incorporated in multimedia learning. These items are learning goal alignment, feedback and adaptation, motivating power (that is, the ability to motivate and interest learners), interaction usability, and accessibility. Items are rated on a 5-point scale. For example, for the aspect of motivating power, if a learning task (or activity or material) is irrelevant to a learner's goal, is too easy or too difficult for a learner, or draws attention at a superficial level, the task would receive a score of 1. In contrast, if a task is perceived as relevant, is able to gain and hold learners' attention, and offers the learner difficulty levels for learners to gain confidence and satisfaction from the learning activities, it would receive a rating of 5. To optimize learners' experiences, multimedia course developers and instructors are encouraged to use tools such as

LORI and ARCS to assess motivational qualities of programs.

CONCLUSION

In the field of multimedia learning, research on cognitive effects and their implications for instructional design is rich. Given the importance of motivation in learning and the extensive use of multimedia learning in educational contexts, research on the effects of motivation in a multimedia learning context is surprisingly sparse. One of the major goals of providing multimedia instruction is to motivate students. Abrahamson (1998) sums up this objective very well when he states that “a primary function of the use of television, computers, and telecommunications in distance learning is to motivate students rather than just to provide information to them” (p. 34). However, evidence for motivation in multimedia learning contexts is not solid. In this chapter, we identify four major motivation theories (expectancy-value theory, self-efficacy, goal-setting and task motivation, and self-determination theory) and two motivation models that are derived from multimedia research (the ARCS model, the integrated model of cognitive-motivational processes), review the literature on motivation in multimedia learning contexts, and suggest that researchers and practitioners take into account five aspects to ensure that motivation features incorporated in multimedia learning resources optimize learners’ experience. These aspects are: 1) theoretical development; 2) motivational features and the design of multimedia instruction; 3) learner characteristics; 4) self-regulated learning strategies and motivational training; and 5) evaluating quality of motivational features in multimedia learning resources. It is hoped that researchers and teaching professionals will devote more attention to the motivational issues in multimedia learning and teaching.

FUTURE RESEARCH DIRECTIONS

Future research should be theoretically driven and evidence-based. There are at least four lines of motivational research that is important in multimedia learning and teaching. First, the ARCS model has been used by researchers interested in motivational aspects of ‘multimedia learning and has generated some promising results. One line of research can continue to validate the ARCS model in various subject domains (e.g., second/foreign language learning, engineering, anatomy, etc.) and cultural contexts.

Second, there have been attempts to combine motivational factors with cognitive elements in an integrated model of multimedia learning. In practice, when engaging in learning, the individual usually does not separate cognitive processing from emotional involvement. Hence this integrated model resembles the natural learning process more than conventional models which tend to treat cognitive and affective aspects separately. Following this line of research, Astleitner and Weisner (2004) propose a comprehensive model from which a number of predictions can be derived. These predictions, including general predictions (e.g., the variability in audio and visual presentations will have differentiated effects on learners’ attention; excessive, irrelevant motivational stimuli will impose extraneous cognitive load; limiting links by embedding information will require less working memory thereby reducing negative motivations), and specific predictions (e.g., seductive details will disrupt the learning process; adaptive motivational strategies will improve learning outcomes) should be tested in future research with appropriate methodology.

The third line of research which appears to be fruitful is to examine individual differences in multimedia learning. On the one hand, researchers can identify dispositions and attitudes that are compatible with the nature of multimedia learning, such as self-efficacy, effective goal-setting

strategies (setting small, relatively difficult but achievable goals), and volition. On the other hand, researchers can investigate personal factors associated with attrition in multimedia learning, in particular, the nature and mechanisms of the loss of motivation (learned-helplessness tendencies). Previous research has, in general, neglects “students-at-risk.” Arguably, both success and failure in multimedia learning should have important educational implications. In addition, sometimes multimedia learning is undertaken collectively (e.g., group project). Group dynamics associated with this particular learning mode and its effect on individual motivation can be investigated.

Fourth, most previous studies conducted in the area of multimedia learning have thus far focused on achievement and task completion in the short term. There is evidence to show that conventional and “innovative” multimedia instruction may result in similar academic outcomes after a longer period of learning. Well-designed longitudinal studies are very much needed to assess the mediating effect of motivation on program effectiveness.

More and more researchers have realized that motivation is an indispensable aspect in multimedia learning and teaching. Despite the urging and suggestions of various researchers in this area, research is surprisingly limited. It is time to conduct systematic investigations in this potentially rich area.

Chapter 6.4

Making E–Training Cost Effective through Quality Assurance

Lichia Yiu

Raymond Saner

Centre for Socio-Eco-Nomic Development (CSEND), Switzerland

INTRODUCTION

Since the 1990s, more and more corporate learning has been moved online to allow for flexibility, just-in-time learning, and cost saving in delivering training. This trend has been evolved along with the introduction of Web-based applications for HRM purposes, known as electronic Human Resource Management (e-HRM). By 2005, 39.67% of the corporate learning, among the ASTD (American Society for Training and Development) benchmarking forum companies, was delivered online in comparison to 10.5% in 2001.

E-learning has now reached “a high level of (technical) sophistication, both in terms of instructional development and the effective management

of resources” in companies with high performance learning function (ASTD, 2006, p.4). The cost per unit, reported by ASTD in its 2006 State of Industry Report, has been declining since 2000 despite the higher training hours received per employee thanks to the use of technology based training delivery and its scalability. However, the overall quality of e-learning either public available in the market or implemented at the workplace remains unstable.

Findings from a recent European survey on quality and e-learning indicated that 65% of the 433 respondents (European training professionals) rated the overall quality of e-learning as “fair” or “poor.” Only 1% rated it “excellent” and only 5% rated it “very good” (Massy, 2002). Criteria used to evaluate quality in e-learning are in order of priority:

DOI: 10.4018/978-1-60960-503-2.ch604

1. Functions technically without problems across all users.
2. Has clearly explicit pedagogical design principles appropriate to learner type, needs, and context.
3. Subject content in state of the art and maintained up to date.
4. Has a high level of interactivity.

Lack of better match between learning design and learner needs and context could significantly reduce the intended impact of training. This shortcoming could be more effectively remedied by introducing a quality management system for training in general and for e-training in specific. However, most managers do not know how to measure the benefits of training and the return on training investment. ISO 10015: 1999 *Quality management—Guidelines for training*, provides answers to the crucial question: how to make training cost effective and more?

BACKGROUND

In response to global competition coupled with technological innovation, companies from European and North American economies have been shifting from industrial to knowledge-based production of goods and provision of services. Traditional advantages such as manufacturing know-how have been eroded due to competition from companies based in newly industrialized countries. For the advanced industrial nations, competitive advantage now depends on superior innovation, intellectual property, and intellectual capital—which, in turn, demand increasingly sophisticated human skills and knowledge. In this context, during the last decade

there has been a shift of attention from the formal education system as provider of knowledge and skills, towards the role of training in enterprises; the latter is increasingly recognized as already

having a significant contribution to knowledge and skill formation. (OECD, n.d., p.2)

On the other hand, developing countries are facing similar challenges as their competitors in OECD countries in terms of their need to ensure higher quality workforce based productivity gain. These countries can no longer count on cheap labor as key factor for their market success since least developed countries can offer even more favorable labor conditions and attract labor intensive foreign direct investment. For companies in developing countries, the move towards higher value added production and services has already become a reality and cannot be avoided any longer. Consequently, the old human resource stratagem of providing no training but relying on ample supply of cheap and unskilled labor to drive down the cost and push up the productivity became unattainable (Saner & Yiu, 2005).

Porter and Sölvell (1998) offer a more holistic explanation of regional competitiveness. Discussing innovation and sustainable competitive advantage of firms, he states:

... While some knowledge is embedded in materials, components, products and machinery, other knowledge is embedded in human capital, part of which is tacit. (p 447)

Findings from studies focusing on regional competitiveness support this view that availability of highly skilled labor is the most important factor in determining a region's competitiveness and prosperity (Koellreuter, 1997).

"knowledge" based production and services demand higher percentage of knowledge based jobs and a higher share of utilizing technology for innovation; both points to greater investment in human capital development through effective training. Lifelong learning is therefore not just "slogan" for the developed economy, but a must for all countries wish to move forward in terms of their economic development.

To keep pace with these changing market conditions and workplace practices, companies must continuously increase their re-investment in the upgrading of the competence of their human resources. Yet while most managers recognize the need to attract, develop and retain a highly skilled and innovative workforce, few feel comfortable with the idea of investing in people, especially with profit margins under pressure. Instead, reducing expenditure occupies top management thinking, and training budgets are cut without considering the effect on competitive advantage in the future and on the company's innovation capital (Edvinsson & Malone, 1997). Should training managers be able to provide documented evidence that training do contribute to business results, such occurrence would sure be dramatically reduced, if not avoided.

Most managers do not know how to assess the return on investment in training (Phillips, 2002), nor are they equipped with the necessary management tools to monitor the decision-making process of such investment and the quality of its implementation (Yiu & Saner, 2005).

So, how does one know if investment in staff training will return in the form of better performance, higher productivity, or new and more competitive goods or services? How can one measure the benefits of training and amortize investments in human capital? How can an organization be sure that recently trained employees will not simply walk away with their newly acquired knowledge and skills? Indeed the persisting question regarding training management has long been—*how can an organization ensure the quality of its training investments so that optimal return is guaranteed?*

Integrating the ICT as part of the delivery modality does not change the validity of this question. Instead it adds more urgency to it by the fact that technology-based learning requires substantial upfront investment and less amenable to customization and change.

This article examines the necessity of investing in training and of adopting technology based learn-

ing modality for upscaling of training coverage. It also highlights benefits of implementing the International Standard ISO 10015: 1999 *Quality management—Guidelines for training* within companies. While ISO 10015 may have been a relatively new and lesser known standard of the successful ISO 9001:2000 family, it is proving to be a highly effective tool for solving the problem of measuring the effectiveness of training thereby helping organizations to justify investment in training and in maximizing technology-based learning infrastructure.

INVESTMENT OR EXPENDITURE?

There is a discrepancy between what organizations may say—"people are our most valued asset"—and what they actually do. This gap is often self-evident when one scrutinizes the human resource management policies and practices of a company. One reason why few companies report on their training is because organizations are not required to report on its human capital in general and training investments in specific to shareholders, nor to society in general. Therefore, there is no external accountability regarding managerial responsibility for safeguarding the organization's human and intellectual capital.

According to the American Society for Training Development (ASTD) *2006 State of the Industry Report*, many major companies in North America and Western Europe spend up to 2%-3% of total payroll on training, amounting to tens and billions of U.S. dollars in expenditure. ASTD estimates that,

U.S. organizations spend \$109.25 billion on employee learning and development annually, with nearly three quarters (\$79.75 billion) spent on the internal learning function, and the remainder (\$29.50 billion) spent on external services. (2006 State of Industry Report, p.4)

However, the big corporations do not scrutinize such training investment as thoroughly as they do with other investments (Durfee, 2003). This is because training continues to be treated as an expense, rather than as an investment in an organization's capacity to compete and innovate (Yiu et al., 2005). This is also because the companies lack the tools in measuring the effects of training on business results (Phillips, 2003).

WHY INVESTMENT IN TRAINING IS A MUST?

Managers are understandably concerned about justifying and protecting their investments. However, since mobility of labor is part of the market economy, employees can leave without the organization recuperating an adequate return on its training investment. On the other hand, when downturn happens managers tend to seek short-term solution to the economic hardship by cutting the head counts as the first intervention in reviving the company's fortune. Therefore, a vicious cycle starts to perpetuate itself whereby companies are reluctant to invest in people for fear of employee turnover.

To be successful, companies must nonetheless manage this dilemma and invest in people, or lose ground as competitors abroad continue to do so. For example, U.S. employers spent an average of USD 677 per employee in 2000 and increased the spending to USD 1,424 per employee in 2005, representing about 2.2% of payroll, in spite of seemingly relentless price competition and a significantly more mobile labor market than Europe (2006 *State of the Industry Report*, p. 3). Continued investment in skill development and human capital in the U.S. coupled with the application of ICT (information and communication technology) and continued drive toward innovation help explain the economic dynamisms and sustained productivity gains in the U.S. (OECD, 2007).

However, similar examples *can* be found in Europe. A recent survey of 1,200 companies in Ireland showed that training averaged 3.01% of payroll in 2001 (Training Survey 2001). This is probably one reason why Ireland has become one of the most dynamic European economies. As OECD (1998) indicated in its international comparative studies that,

Human capital thus constitutes an intangible asset with the capacity to enhance or support productivity, innovation, and employability. It may be augmented, or may decline or become redundant. It is formed through different influences and sources including organized learning activity in the form of education and training. (p. 9)

MEASURING RETURN ON INVESTMENT

Measuring return on investment (ROI) from training is difficult—but not impossible. Since 1997, ASTD has been collecting data on company training investment in order to answer the question: *does it pay to train?*

Data collected from over 2,500 companies, measured against TSR (total stockholder return), indicated that organizations making higher training investments in 1996, 1997, and 1998 yielded higher TSR the following year (Bassi, Ludwig, McMurrer, & VanBuren, 2000). The sample included some European companies with similar links between higher training investment and TSR. These pioneering findings help confirm that training does pay off in terms of organizational performance. It supports the argument that investment in people *can* impact the bottom line. However, as with all investment portfolios, investment in training does not automatically result in performance improvement without smart strategy and competent management. Training management requires vision, strategy, expertise, *and* management tools.

ISO 10015: THE SOLUTION TO QUALITY IN TRAINING

Different quality management tools are available, such as TQM (total quality management), EFQM (European Foundation for Quality Management), EduQua (Education Quality Standard). However, they are either too cumbersome or too general; none address the decision making aspect of the training investment which affects the outcome of training.

International Standard ISO 10015: 1999 *Quality management—Guidelines for training* is something of an undiscovered gem in the ISO 9000 family of standards. It provides guidelines to assist organizations and their managers when addressing issues related to training. ISO 10015 offers three key benefits:

- Benefit 1: It offers a clear road map in terms of making training decision.
- Benefit 2: It makes explicit at the training design stage the measurements to be used in assessing training results.
- Benefit 3: It offers guidance focused on training technology and organizational learning, since it is designed specifically to meet training needs.

In addition, ISO 10015: 1999 has two crucially important features which provide management with a scientific base in managing people and performance related challenges. It provides the “soft” discipline with hard facts in taking strategic decision. These features are:

- Feature 1: ISO 10015 links training investment to organizational performance.

Testing the professional competence of trainers and verifying the pedagogical concepts of training programmes are vital. But the key to assessing return on training investment is its link to organizational performance and business results.

When asked, “Why do you pay for training?”, an organization should be able to track the decision process back to its defined performance objectives. In other words, the key “customer” is the organization itself, even more than the individuals being trained.

An organization must first recognize the performance challenge it faces and the causes (see the “decision tree” in Figure 1). For example, if sales have slumped, the obvious starting point is to find out why. Are the wrong products being produced, or are the right products being targeted to the wrong markets? Is product quality deficient because of old and unreliable production machinery? Is service quality poor because employees are not equipped to deal with customer requirements and complaints?

Following the decision tree exercise, if the performance gap is linked to under-performing human resources, then the organization should again ask itself why. are employees demotivated by poor pay levels, or by lack of leadership? Is it because their competencies do not fit the job requirements, or because of a differential between the skill levels of established and new employees? If either of the last two factors exists, then training could well be the solution (Figure 2).

ISO 10015: 1999 offers a clear road map towards sound training investment decisions by requiring top management to connect training to performance goals, and use it as a strategic vehicle for individual and collective performance improvement. As a result, training effectiveness is not only measured by improvement in individual professional competence, but also by the extent to which individuals have contributed to the organization’s performance. Feature 2: ISO 10015 requires training to be based on pedagogical and organizational learning principles.

Staff training should be implemented as an intervention strategy once an organization has identified it as the optimal approach to closing the performance gap. Consequently, the next critical phase of investing in people is to establish appro-

Figure 1. “Why training?” decision tree

© Centre for Socio-Eco-Nomic Development 2003

priate training design and learning processes. This is where ISO 10015 can be a valuable management tool by helping to ensure that training is organized

- *Efficiently* in the use of finances, time, and energy, and
- *Effectively* in enhancing performance.

Quality principles of the ISO 10015 ensures that knowledge, skills, competences, and other attributes are combined in different ways according to the individual and the *context of use*. It is in this design imperative resting the power of this training management tool.

ISO 10015 defines training as a four-stage process (see Figure 3):

1. defining training needs,
2. designing and planning training,
3. providing the training (including e-learning), and
4. evaluating the outcome of training.

Each stage is connected to the next in an input and output relationship (see Figure 3). As a quality management tool, ISO 10015 helps to specify the operational requirements for each stage and establishes procedures to monitor the process. Such a transparent approach enables training managers to focus more on the substance of each training investment, rather than merely on controlling expenditure.

Unlike other quality management tools, ISO 10015 helps an organization to link training

Making E-Training Cost Effective through Quality Assurance

Figure 2. The performance diagnosis and training decision

Figure 3. The input-output process of training (Copyright. Centre for Socio-Eco-Nomic Development, 2003)

pedagogy and evaluation to performance objectives. This approach provides an organization with constant feedback regarding its investment in human competencies. The International Standard also encourages companies to examine their training models, and validate their training approaches and premises via comprehensive data and documentation.

This data based approach to training management provides a unique opportunity for continuous improvement of training operation. Most importantly, it provides evidence based feedback to the training solutions adopted in solving performance issues at the workplace. Data concerning individual learning, opportunities to apply on the job, impact on productivity are collected to corroborate with the initial performance diagnosis thereby closing the loop of training intervention. Thus making it possible to actually measure the impact and contribution of training to business operation.

CONCLUSION

To sustain business development, companies need to invest in people more urgently than ever. Training is “mission critical” in a knowledge-based economy and should not be considered dispensable at times of economic difficulty. Only by raising the quality of its human capital can an organization ensure long-term competitive advantage.

In view of the fast changing customer requirements and continued product and service innovation, employees need to be trained more frequently on diverse topics. Learning will continue expanding its presence on-line in synchronous and asynchronous modes. How to avoid the quality deficit of traditional training in e-training processes is a concern needs to be addressed in order to avoid ineffective use of the technology and potential loss of investment.

Like any other major investment, (e)Training must be managed carefully. ISO 10015 offers a

transparent, logical and easy to follow four-stage process which can benefit any training programme. Above all, ISO 10015 is a training-specific quality management tool to strengthen the link between e-training and the organization's performance requirements and objectives. ISO 10015 based training management system provides a sound structure to carry out training that is critical to the long-term financial success of the company. It ensures that training will deliver results in improving the productivity of the company.

“What can't be measured can't be managed! What can't be measured and managed can't be improved” as the saying goes. Companies that act early in identifying and measuring the salient factors affecting their human capital development and (e)Training investments shall be able to leverage more effectively their human capital in achieving organizational objectives. To create value from (e)Training, managers must start viewing “(e) Training” not as expenditures but investments, and devising ways to bring such a process approach to training management. While recognizing that human capital is an intangible asset and its development might need time to bring to fruition in terms of productivity gains and innovation, a management system that links business objective and training intervention, regardless whether it is done through classroom teaching or on-line, must be the first step.

KEY TERMS AND DEFINITIONS

E-Learning: Learning activities conducted through Internet or Web-based course materials or activities. Learners engage in this activities alone or in groups. These learning groups could be geographically dispersed.

E-Training: Training delivered through the electronic means, which could be Web-based training programmes and activities.

ISO 10015 Quality Management (1999): It is an international standard provides guidelines

to assist organisations and their personnel to address issues related to training. It is applicable to all types of education and training.

Quality Management System: It is management system to ensure quality of performance and consists of quality policy, work processes, procedures, quality measures, and documentation system.

Regional Competitiveness: Competitiveness is seen as the economic capability to generate higher productivity and monetised values. The factors underlying regional competitiveness include human talent, innovation capacities, connectivity of the region and entrepreneurship.

Training: Process to provide and develop knowledge, skills, and behaviors to meet performance or task requirements.

This work was previously published in Encyclopedia of Human Resources Information Systems: Challenges in e-HRM, edited by Teresa Torres-Coronas and Mario Arias-Oliva, pp. 623-631, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 6.5

Using the Interpersonal Action–Learning Cycle to Invite Thinking, Attentive, Comprehension

Bob Zimmer
The Open University, UK

ABSTRACT

This chapter shows how the interpersonal action-learning cycle (IALC) can be used to invite thinking, attentive comprehension from learners in conversation. It explains what the IALC is, where it comes from, how it works, and why. In particular, it offers a logical demonstration that all interpersonal learning takes place within the IALC, and that all competition for dominance lies outside it—suggesting conscious use of the IALC as a desirable practice. The chapter goes on to explore linguistic factors that routinely disrupt use of the IALC, and that can hide its very existence. Strategies for restoring and stabilizing it are offered. Routine use of the IALC can have profound implications for teaching and instruction, collaborative learning, assessment, course evaluation, and professional development. These are explored.

DOI: 10.4018/978-1-60960-503-2.ch605

INTRODUCTION: YOUR OWN THOUGHTS

This chapter starts with a form of advance-organizer (Ausubel, 1968). You are invited to think about instructional design, by considering how you would answer six questions. If you think that you are in the business of meeting learners' needs, you might find these questions startling—they invite you to focus on a need of your own:

1. What do you most notice about how learners respond to you?
2. What do you imagine are the reasons?
3. How do you feel about that?
4. What is it that you need, that this feeling suggests?
5. What are you doing as a teacher to meet this need?
6. What responses from learners would help you most in doing so?

Although I cannot hear your thoughts, I imagine that as a teacher you would like to help people learn—so that in answer to Question 6, I imagine that the responses you would find most helpful from learners might be summarized as:

- Their attentiveness toward you
- Their accurate comprehension of what you regard as important, and possibly
- Their own relevant creative thinking

If so, then this chapter is addressed to you. It describes the three learning behaviors above, and presents an argument that just three conversational actions are needed in order to invite them. These three actions form the interpersonal action-learning cycle (IALC).

The following sections describe:

- Where the IALC comes from and how it works
- What routinely disrupts it
- How in practice it can be sustained

BACKGROUND: WHERE THE IALC COMES FROM AND HOW IT WORKS

The interpersonal action-learning cycle (IALC) results when the generic action-learning cycle is applied to interpersonal communication.

The Generic Action-Learning Cycle

Figure 1 shows the generic control model. Around it are arrayed the actions, ‘sensing / checking / planning & acting,’ which take place respectively at the sensor, comparator, and effector. They take place whenever a goal-oriented process is in play, and they make up the generic action-learning cycle.

The process itself, denoted by the blob in the centre of the diagram, is a transformational process of some kind—it transforms an input into an output.

Figure 1. The generic action-learning cycle: Sensing / checking / planning & acting

As time progresses, the output is sensed and then is checked against the goal. The difference between the two is used to plan the action that will be taken, in order to modify the input so that the output will more closely approach the goal. Once the action is taken, the output is sensed again to see how well the action worked—and so on around the cycle. Each time around, both the environment and the actor’s capabilities are being learned about.

The Subjective Action-Learning Cycle

Figure 2 shows how the cycle looks when it is made subjective—that is, when I myself do the sensing / checking / planning & acting. The transformation process becomes my engagement with my environment, and the transformation is from ‘myself before’ each turn around the cycle to ‘myself after.’

A well-known example of this subjective form of the action-learning cycle is Kolb’s cycle of experiential learning (Kolb, 1984). (see Box 1)

The Personal Action-Learning Cycle

Figure 3 shows what happens in addition, when I take conscious note of what I am doing. The cycle becomes my personal action-learning cycle:

Figure 2. A subjective form of the generic action-learning cycle

(Scale is set to match Figures 3 and 4)

Box 1.

Subjective cycle	Kolb cycle
I sense	Experiencing
I check	Reflecting
I plan	Abstracting
I act	Experimenting

- My sensing becomes noting what I notice in my environment and what I imagine about it

- My checking becomes comparing what I notice and imagine with what I need, and noting how I feel about the difference (Hussey, 1980)
- My planning & acting become deciding what I would like to do in order to get what I need, and what I would like to ask others to do to help

The output from the transformation process, 'myself after,' then becomes myself consciously aware of:

- What I notice and what I imagine about it
- How I feel about that because of what I need
- What I would like to do about it and to ask others to do

This formulation for capturing my own view has roots in several fields. 'I notice ..., I imagine ..., I feel ..., I want ...' is a standard sequence that is used for clear self-expression in Gestalt psychology (Houston, 1995). Variations of it are used in assertiveness training and in other areas of awareness training.

Figure 3. My personal action-learning cycle

(Scale is set to match Figure 4)

In addition, the principle that how we feel about what we notice depends on what we need, as in the second line of the formulation, is a cornerstone of non-violent communication (Rosenberg, 1999). Indeed, it can be argued that not only how we feel, but also what we notice in the first place, depends on what we need—for example, a barn owl’s hearing is tuned for the rustle of a vole in the grass, a film-projectionist’s vision is tuned for the end-of-reel marker, a mother’s hearing is tuned for the cry of her child, and so on.

The three-line formulation brings all of these strands together. It represents a concise way of capturing a clear view.

It also does something else. Traditional writing for instruction often assumes that there is an objective truth to be imparted, and that the author should not intrude. It perpetuates the myth of objective consciousness (Roszak, 1969). This entire paragraph is written in that objectivist style.

By contrast, the formulation above lets me take personal responsibility for what I notice and imagine, so that I can write explicitly from my own perspective—that is, report my own experience—which is the only truth that I actually have. Accordingly, I will be writing the rest of this chapter in this first-person, I-language (Gordon, 1970, 1974) way.

In my view, one of the most important properties of a view captured in the formulation above is that it never can be in disagreement with another person’s similarly-captured view, however different the two views might be. That is, difference does not mean disagreement.

In particular, ‘What I notice and what I imagine about it’ is a report of my own experience, and it leaves room for someone else’s experience to be entirely different. For example, I think that two people in a darkened room describing an elephant by touch are likely to produce very different descriptions, depending on which part of it they are touching. Their views will be different, but they would be mistaken to think that this difference meant disagreement.

Equally, I think that two people looking at a whole elephant—one from the side and one from the front—also will produce very different reports of what they see. Again, their views will be different, but they would be mistaken to think that this difference meant disagreement.

Likewise, ‘How I feel about that because of what I need’ is also a report of my own experience, again leaving room for someone else’s experience to be entirely different from my own. Even, ‘What I would like to do about it and to ask others to do’ is a report of my own experience, leaving room for someone else’s view to be different.

Indeed, so far as I can see, not even my need itself can be in conflict with the needs of other people (Gordon, 1974). The kind of need to which I am referring is not a desire to *do* something in particular, but is always a need *for* something—that is, a basic human need like the need for autonomy, for physical well-being, and so forth. There is an inventory of such basic human needs on the Nonviolent Communication Website (Center for Nonviolent Communication, 2002).

In other words, even when it comes to needs, difference does not have to mean conflict. My favorite way of saying it is that conflict is caused only by inadequate solutions for meeting people’s differing needs (Gordon, 1974). That is, it arises only when people take action to meet their needs, without ensuring that their chosen actions will be beneficial or at least acceptable for other people as well.

The result is that I can use:

- What I notice and what I imagine about it
- How I feel about that because of what I need
- What I would like to do about it and to ask others to do

As a basis for reporting my own view on any topic that I choose, without differences with other views having to cause disagreement or strife.

The Interpersonal Action-Learning Cycle (IALC)

Derivation

Once I am aware of my own view in these terms, I can contemplate engaging in learningful conversation with another person. For simplicity, I will take that other person to be you, the reader.

Figure 4 shows what happens when I use the action-learning cycle to interact with you. The action-learning cycle on the left is my personal action-learning cycle from Figure 3. Its output—my awareness of my own view—then becomes the reference criterion for the action-learning cycle on the right, which is where I engage with you. The result is a form of double-loop learning which transforms my experience of you and myself in potentially competitive debate, into an experience of you and myself in learningful discussion.

In classic double-loop learning (Argyris & Schon, 1978), the question that is asked at the right-hand comparator is, ‘How are we doing?’ The deeper question that is asked at the left-hand comparator is, ‘What is it that we are doing in the first place?’ In the more general form of double-

loop learning shown here, the question that I ask at the right-hand comparator is, ‘How does your view compare with mine?’ The deeper question that I ask at the left-hand comparator is, ‘Can I imagine a way in which my needs will be met?’

The right-hand cycle is what is referred to in this chapter’s title as the interpersonal action-learning cycle (IALC) (Zimmer, 2004a). It is the cycle that I use to engage with you in learningful discussion. For ease of reference, Figure 5 shows this cycle by itself.

As Figure 5 shows, when I use the action-learning cycle to engage with you:

- My sensing becomes my attentive *listening* to you
- My checking becomes comparing your view step-by-step with mine—that is
 - What *you* notice and what you imagine about it
 - How *you* feel about that because of what you need
 - What *you* would like to do about it and to ask others to do which becomes my comprehending *acknowledgment* of your view.

Figure 4. My double-loop learning to engage in learningful discussion with you

Figure 5. The interpersonal action-learning cycle (IALC)

- My planning and acting then become my thinking *expression* of my own view in the context of yours—that is:
 - What *I* notice and what I imagine about it
 - How *I* feel about that because of what I need
 - What *I* would like to do about it and to ask others to do

So these three components together can be summarized as offers of attentive listening, of comprehending acknowledgment, and of thinking self-expression.

You might recognize these three components of the IALC as essentially the three that Carl Rogers identified as the core of successful communication (Rogers, 1959, 1962). Their derivation here from the generic action-learning cycle specifies their operational sequence. An alternative derivation, from the principle of respect for autonomy, is also available (Zimmer, 2004a).

The third component of the IALC—thinking self-expression—represents a complete ‘I-statement’ (Zimmer, 2004b) made in ‘I-language’ (Gordon, 1970, 1974)—language that is used for

expressing one’s own view while leaving room for other views. An offer of the very similar second component—comprehending acknowledgment—is often referred to as ‘active listening’ (Gordon, 1970, 1974).

This means that in using the IALC, I am treating you as a sentient being like myself, so in systems terms I have to make sense of the ways in which you yourself make sense of things. This means that two layers of sense-making (Weick, 1996) are involved, so that I am operating at the level of second-order cybernetics (von Foerster, 1992; Zimmer, 2001) within social cybernetics (Geyer & van der Zouwen, 1998), also known as sociocybernetics (Geyer, 1995; Geyer & van der Zouwen, 2001). A discussion of orders of cybernetics is available in Umpleby (1997).

Dynamics

What I find most interesting about the IALC is that it invites itself in return, as Figure 5 shows, with the three appearances of the word ‘inviting.’ Figure 6 highlights this phenomenon, showing specifically how I can use the IALC to invite your reciprocal use of it.

Figure 6. How my use of the IALC invites your use of it

In more detail:

- I listen to you, offering my attentiveness, my essential response being a receptive ‘Yes’ to invite you to express your own view, that is, to offer your own thinking
- I acknowledge your view, offering my comprehension, my essential response being, ‘So you think / feel / need ...’ to invite you to listen to me, that is, to offer your attentiveness
- I express my own view in the context of yours, offering my own thinking, my essential response being, ‘My own view is this’ to invite you to acknowledge my view, that is, to offer your comprehension

I would emphasize that these essential responses are only schematics—many different wordings are possible, and sometimes they are conveyed by body language alone. That said, the essence of the conversation sounds like this:

Box 2.

My responses		Your responses
‘Yes’	►	‘My own view is this’
‘So you think / feel / need ...’	►	‘Yes’
‘My own view is this’	►	‘So you think / feel / need ...’
‘Yes’	...	...

In short, I offer my attentive, comprehending thinking to invite your thinking, attentive comprehension—which is where the title of this chapter comes from.

In so doing, I put my view literally alongside yours, as shown in Figure 6, for mutual enrichment of views and possibly for perception in depth. As Figure 5 shows, this transforms the two of us from yourself and myself in possibly competitive debate, into yourself and myself in potentially collaborative discussion.

In my view, this means that when two people use the IALC together, each does exactly what the other needs—that is, they do not get into a competition for dominance. So I see its use as a sufficient condition for collaborative discussion.

Equally, if I go backwards around the diagram in Figure 6, then once a conversation has got started:

- I cannot listen attentively to you unless I hear your comprehending acknowledgment of what I have already said. Otherwise whatever you are saying will be for me a *non sequitur*.
- I will not have said anything in the first place (i.e., I will not have offered my own thinking self-expression) unless I thought that you were listening attentively to me—which I do not think that you will have been doing...
- unless *you* felt comprehendingly acknowledged by me for what *you* already had said.

And so on.

In my view, this means that once a conversation has got started, use of the IALC is a necessary condition for collaborative discussion. Indeed, communication research has shown that the odds of understanding someone correctly without taking the IALC step of offering one’s comprehension for confirmation or correction are only 25% (Nolan, 1987).

So I conclude that use of the IALC is both necessary and sufficient, in order to have a collaborative discussion about any topic.

Implementation

If as a teacher I take responsibility for managing my use of the IALC, then it starts and ends with myself offering my attentive listening—as shown in Figure 6 by the start-finish arrows. This leaves you always free to continue the conversation by offering thinking self-expression of your own views, or to leave—whichever you choose.

This means that in using the IALC, I always go at least one and a third times around it:

- I offer my attentiveness to invite your own thinking
- I offer my comprehension to invite your attentiveness
- I offer my own thinking to invite your comprehension
- I again offer my attentiveness to invite your own thinking

A special case of this invitational process is the e-moderating skill known as ‘weaving’ (Feenberg, 1989), in which the second step of the cycle—offering my comprehension—is used to gather together the ideas and concerns of several participants, and the third step—offering my own thinking—then is used to ‘weave’ these together to raise new questions for discussion.

In general, I start by inviting your thinking, because I believe that learning is a sense-making activity—that is, that we cannot learn by having knowledge poured into us, but need to make sense of things for ourselves. This is the central tenet of constructivism (von Glasersfeld, 1995; Riegler, 2007)—not to be confused with social constructivism (Kukla, 2000). So starting in this way lets me invite not just your attentive comprehension, but your *thinking*, attentive comprehension. I believe that my teaching then will be more successful.

Equally, ending in this way lets me invite not just your attentive comprehension, but your attentive, comprehending, *own thinking*. This is where I get the benefit of your relevant creative thinking, if the course that I am offering is meant to encourage you in that.

This is not, however, necessarily easy to do. The next section describes ordinary behaviors that can stop the IALC in its tracks.

ISSUES: WHAT ROUTINELY DISRUPTS THE IALC

Offering attentive, comprehending thinking to invite thinking, attentive comprehension might seem like common sense. In my experience, however, it is anything but.

Dogma

In order to work, what the IALC needs most from the teacher is careful listening for the learner’s view, explicit presentation of the teacher’s view, and consistent awareness of the difference between the two. I find that this in turn requires a somewhat unusual use of language—namely, always speaking in such a way as to leave room for differing views.

I find that speaking in this way in the English language can require great skill. The English language at its simplest, presents any view as an objective report, which automatically casts any other view as fallacious. The preceding sentence is an example. I find that this phenomenon results easily in competition, among people claiming the rightness of their own view and the wrongness of all others. Soon they judge one another inferior, and then they start trying to dominate one another. I see the resulting competitive melee as the exact opposite of the thinking, attentive comprehension that the IALC invites.

For example, suppose that I say to you, ‘The cat sat on the mat.’ In so doing, I am claiming a

tremendous amount of authority. I am saying that I know what a cat is, I know what a mat is, and that there is no doubt whatsoever about what is what and what happened. I am leaving you no room whatsoever to have a different view—a view that could be equally valid. In particular, it might appear from where you are that the ‘mat’ is not a mat but a shadow on the ground. Who is to say?

A language like Aymara answers the question of, ‘Who says?’ within its very structure (Miracle & Yapita, 1981)—i.e. it is not possible to make a statement of ‘fact’ without also saying, in the very syntax of the statement, whose view that statement represents. But this is not so in English.

Even worse, in a noun-based language like English, I see no way in which a statement can be made about anything at all, without prior agreement between speaker and listener about what things are—for example, about what a cat is and what a mat is.

This problem is not inevitable. In Hopi, for example, there is a syntactic difference between the ‘unmanifest’ and the ‘manifest’ (Whorf, 1936; Todd, 2002; David, 2004), which makes it possible to build up a complete picture *before* projecting it onto the world ‘out there’ (Hussey, 1980). In my view, this kind of linguistic structure makes it much easier to put different views alongside each other, so as to have discussions rather than debates.

In other words, so far as I can see, the very structure of the English language encourages dogma—that is, telling other people what is what and thereby inviting approval or attack, instead of expressing one’s own views and inviting comprehension. If I were to engage in dogma, it would appear in Figure 7 in the lower half of the white box on the left.

Dogmatic Judgmentalism

It gets worse. Out of dogma can arise dogmatic judgmentalism—that is, praise or blame. This comes from the belief that since I am right about everything and therefore can tell you what is

what, if you do not agree with me then I am the victim of your disrespect, and I can blame you for that. Equally, if you do agree with me, then I am the beneficiary of your respect, and I can praise you for that.

The problem that I see with this, is that both praise and blame are ways of passing judgment on you, thereby gaining an upper hand and putting you down.

For example, suppose that I am a scientist conducting an experiment, that my observations tell me that two events occurred at the same time, and that I declare this as fact. On the other hand, you—conducting a similar experiment—find that the same two events occurred at different times. As it happens, this is perfectly possible if you were in motion relative to me—it is an experimentally corroborated prediction from Einstein’s theory of relativity.

But suppose that neither you nor I know about this theory and that you attack my results—as shown in Figure 7 in the lower half of the grey box on the left. If I were to react by indulging in dogmatic judgmentalism—praise or blame—then I could end up blaming you as incompetent. After all, you would be contradicting what I ‘know’ to

Figure 7. What I try to avoid doing

be ‘true.’ Such behavior on my part is shown in the lower half of the white box at the bottom of the diagram.

Equally, suppose that either your experiment or mine is sufficiently sloppy so that our results appear to agree, and you then approve of my results—as shown in Figure 7 in the lower half of the grey box on the left. ‘Knowing’ that my results are ‘true,’ I then could end up praising you for your work—‘You are good at that’—a very ordinary occurrence. Such behavior on my part also is shown in Figure 7, in the lower half of the white box at the bottom of the diagram.

The trouble is, neither my praise nor my blame lets us explore what has been observed by each of us so that we can arrive at a shared understanding. Both my praise and my blame are opposites to my inviting your possibly differing view. Yet the noun-based structure of English makes it all too easy for me to indulge in them—that is, to depersonalize you and label you as something other than yourself, for example, ‘You are bad’ or ‘You are good’.

Dogmatic, Judgmental Oppression

Worse still, out of dogmatic judgmentalism can grow dogmatic, judgmental oppression. This comes from the belief—because of my presumed ‘knowledge’ of what is what and my consequent propensity to talk down to you with praise or blame—that I have the right to subject you to approval or attack. These are like praise and blame—except that rather than being for what you do, which is bad enough, they are for what I define you to be, which I consider worse. As Maturana has said, ‘If we believe that we have privileged access to knowledge of objective reality, then sooner or later our relationships become demands’ (Maturana, 1997).

For example, in the situation described, suppose that instead of you attacking my results, I attack yours—as shown in Figure 7 in the lower half of the white box on the right. There are

several ways in which I might do this, but the most common ways that I have seen, amount to inquisitorial accusation.

I find the inquisitorial part commonplace. It involves probing you, looking for weaknesses, demanding answers about all aspects of your work, and possibly of your character. The messages that I would be sending you are essentially, ‘Where did you get that idea?’ and, ‘What is wrong with you, anyway?’

I find the accusatory part even more commonplace. It involves reading negligence or malice into you for your disagreement with me—and perhaps even trying to punish you for what I myself have read into you. The essential messages that I would be sending you, answering my own bullying questions from the paragraph above, are, ‘You are careless. You are evil.’—followed by, ‘You are out.’ If done online, this amounts to ‘flaming’ (Kiesler & Sproull, 1992; Shea, 1994).

Equally, in the situation mentioned, suppose that instead of you approving of my results, it is I who approves of yours—again as shown in Figure 7 in the lower half of the white box on the right. Although approval might seem desirable, I see it as oppressive—that is, if I engage in it, then for me it amounts to my putting my imprimatur on a view of your own, that is, my taking possession of something that you have created, saying that it is valid only because I approve of it.

In other words, it is still oppression. The essential messages—representing full dogmatic, judgmental oppression—become, ‘I know what is right. You are good—well done. You are in.’ Yet I will wager that this sounds like a perfectly normal use of English.

As with judgmental praise and blame, and as with dogma before them, I see these oppressive behaviors—approval and attack—as being made possible by the noun-based structure of English, and its consequent ability to depersonalize you and to label you as something other than yourself, for example, ‘You are out’ or ‘You are in’.

In summary, I see dogmatic, judgmental oppression as the diametric opposite of a collaborative exchange of thinking, attentive comprehension. I also see it as the unfortunate norm rather than the exception. I attribute this phenomenon to the noun-based structure of many languages including English—and in my view, it can hide from people the very possibility of non-competitive communication as represented by the IALC.

In particular, I sometimes hear people claim that interpersonal learning takes place during competitive exchanges. From the analysis in the preceding section, in which I found use of the IALC to be not only sufficient but also necessary for collaborative discussion, it is clear to me that whenever interpersonal learning takes place it is entirely due to whatever vestiges of the IALC are present. That is, interpersonal learning takes place not because of any competition but in spite of it.

In other words, I see competition for dominance as wholly inhibitory toward the collaborative exchanges that make up interpersonal learning, as shown in Figure 6 and in the upper halves of the boxes in Figure 7.

As a result, I see development of techniques for restoring and stabilizing the IALC as being of paramount importance. The next section describes the techniques that I have found.

SOLUTIONS: HOW IN PRACTICE THE IALC CAN BE SUSTAINED

In finding ways to restore and stabilize the IALC, the constraint with which I have found it most difficult to work, is that use of the IALC never can be imposed. In my view, to attempt to impose it would amount to judgmental oppression and would violate the very principles on which it is based. I believe that any such attempt would lead, as with most impositions, to a competition for dominance—thereby destroying any chance of collaborative learning.

Therefore, so far as I can see, use of the IALC cannot even be initiated by appeals to ‘netiquette’ (Shea, 1994) or to an institutionally enforced code of conduct. Its use can only be modeled and invited.

Within this constraint, however, I have found a number of techniques to be effective. This section describes them and gives examples.

Figure 8 shows the essential responses that these techniques embody. For each stage of the IALC—abbreviated as listening (L), acknowledging (A) and expressing (E)—four responses are offered. The first is the basic response of the stage, which can be used for stabilizing conversation. The remaining three are for responding, respectively, to:

- Silence (first-degree restoration)
- Ambiguity (second-degree restoration)
- Contradiction (third-degree restoration)

I would emphasize that, as the essential messages sent at each stage, these restoration responses also are only schematics. The wording shown for each is just one way of conveying its meaning. The specific wording used in any particular situation is likely to vary—or it might be conveyed by body language alone.

Figure 8. My actions to stabilize and restore my conversation with you

I also would emphasize that, especially for restoration responses, I do not always follow the steps of the cycle in strict order—sometimes iteration seems appropriate.

For the listening stage, the four responses are labeled in Figure 8 as L, L1, L2, and L3. For the acknowledging stage, they are labeled as A, A1, A2, and A3. For the expressing stage, they are labeled as E, E1, E2, and E3. All of the second-degree responses (L2, A2, E2) start schematically with, 'I'm not sure ...'. All of the third-degree responses (L3, A3, E3) start schematically with, 'That doesn't ...' and continue with an explicit description of the response being invited.

Following is more detail about each of these responses.

The Listening Responses

All of the listening responses invite the other person's thinking self-expression, which can be summarized as, 'My own view is this'.

Response L: 'Yes'

I use this response for ongoing stabilization of a conversation. As a starting point, it gives attention to the other person. As an ending point, it confirms the accuracy of the other person's comprehension—where the art of using it depends on finding things in the other person's comprehension that actually can be confirmed.

Response L1: 'Your reflections are welcome'

I use this restoration response when I hear simple silence in place of self-expression. It makes no demands, leaving the other person free to respond or not, as he or she chooses. In asynchronous communication, I use it as a standard ending/starting point for inviting further contributions.

Response L2: 'I'm not sure what you'd like to explore'

I use this restoration response when I hear apparent ambiguity about what the other person's purpose is. Given that the context is that of learning through discussion, a presumption is built into

this response that the other person's purpose is positive and has something to do with exploration.

Response L3: 'That doesn't tell me what you think and feel'

I use this restoration response when I hear outright dogmatism from the other person. It contains an explicit description of the kind of response that is being invited—that is, the other person's expression of his/her own view.

The Acknowledging Responses

All of the acknowledgment responses invite the other person's confirmation and attentive listening, which can be summarized as, 'Yes.'

Response A: 'So you think / feel / need / want ...'

I use this response for ongoing stabilization of a conversation. In my view, it is the most important response of all—the one that allows the other person to say, 'Yes,' whether or not his/her view and mine happen to differ. This is the response that allows me to put the other person's view alongside my own, so that collaborative discussion can take place.

Response A1: 'Perhaps you are saying that ...'

I use this restoration response when I have heard the other person as a bit cryptic but I think that I have got the gist. This response normally needs to be completed with some version of Response A.

Response A2: 'I'm not sure that I've heard you correctly'

I use this restoration response when I am not sure what the other person wants to do and why. It can be followed with Response A1.

Response A3: 'That doesn't tell me if I've got anything right for you.'

I use this restoration response when I hear outright judgmentalism from the other person. It contains, as with Response L3, an explicit description of the kind of response that is being invited. It embodies explicitly the philosophy that only the

speaker, not the listener, is in a position to judge whether he/she is being accurately understood.

I would make a note of caution here—I have found that the commonly used wording, ‘I hear you saying ...’ can be heard as patronizing, that is, as not leaving enough room for confirmation or correction. Instead, I use, ‘I hear you as saying ...’—or else I dispense with the ‘I’ altogether, as suggested in Response A.

The Expressing Responses

All of the expressing responses invite the other person’s comprehending acknowledgment, which can be summarized as, ‘So you think / feel / need / want ...’.

Response E: ‘My own view is this’

I use this response for ongoing stabilization of a conversation. This is the response that allows me to put my own view alongside the other person’s, so that both views can be combined for possible perception in depth.

Response E1: ‘I’d welcome your sense of what I’m saying’

I use this restoration response when I have said something that I care about, and have not received any response at all. In asynchronous communication—for example, in online conferencing—I sometimes also use it before inviting further reflections by means of L1, in order to try to ensure that the reflections will be about what I am actually trying to convey.

Response E2: ‘I’m not sure what I’ve got across to you’

I use this restoration response when I have said something that I care about, and the response that I receive does not sound to me like comprehension. If the other person has changed the subject to him/herself, then this response changes it back. If the other person has changed the topic of discussion, then this response changes it back. Yet it does not blame or otherwise judge the other person. It simply refuses to accept absence of acknowledgment.

Response E3: ‘That doesn’t reflect what I was getting at’

I use this restoration response when I hear outright oppression as coming from the other person. As with Response 2, if the other person has changed the subject to him/herself, then this response changes it back; if the other person has changed the topic of discussion, then this response changes it back; yet it does not blame or otherwise judge the other person—it simply refuses to accept absence of acknowledgment.

It also goes further. In describing the kind of response that is being invited, it treats apparent oppression as no worse than a failed but honest attempt at comprehension, and simply refuses any other possibility—on the grounds that it might well be an honest attempt, and that dialogue otherwise is impossible anyway.

Examples

I would emphasize again that these responses are only schematic forms—in actual use, many different wordings are possible. The following six example messages show this effect. Together they display all of the responses defined. They also show how several responses can be used in one message.

These examples are adapted from conference exchanges in which I have participated, within a course on systems practice—a kind of practice for which the ability to handle multiple perspectives is a key skill.

The six example messages are divided into four sections, as shown in Table 1. The first section contains Message 1, which demonstrates standard stabilization (the shaded columns in the table). This is an example in which I simply listen (L), acknowledge (A), express (E) to add my own view, and then listen again. Since the conferences are asynchronous and I cannot hear anyone’s responses immediately, the second listening is the kind that I use in response to silence—that is, first-degree (L1).

Table 1. Stabilization and restoration responses displayed by each message

		Stabilization / restoration responses											
		L	L1	L2	L3	A	A1	A2	A3	E	E1	E2	E3
Message number													
		Standard stabilization											
	1	x	x			x				x			
		Strong listening to invite thinking self-expression											
	2	x		x	x								
		Strong acknowledgment to invite attentive listening											
	3	x	x			x	x	x		x			
	4	x	x					x	x	x			
		Strong self-expression to invite comprehending acknowledgment											
	5	x	x			x					x	x	
	6	x	x			x				x	x		x

The second section contains Message 2, which embodies second- and third-degree attentive listening (L2, L3), in order to invite thinking self-expression very strongly.

The third section contains Messages 3-4, which embody first-, second-, and third-degree comprehending acknowledgment (A1, A2, A3), in order to invite attentive listening very strongly.

Finally, the fourth section contains Messages 5-6, which embody first-, second-, and third-degree thinking self-expression (E1, E2, E3), in order to invite comprehending acknowledgment very strongly.

Standard Stabilization

Message 1

L: *A participant is quoted as noting that ultimately he can see only from his own perspective, and another is quoted as wondering in response how people then can be expected to handle multiple perspectives.*

Hi S and S,

A: I hear you both as feeling stuck at an apparent contradiction.

E: I find a reconciliation of these two views in a simple but careful use of language:

A report of my own perspective can start with:
I see/hear...

A report of my grasp of *your* perspective can start with:

I see/hear *you* as saying...

In other words, my grasp of your perspective is nested within my own perspective.

Example:

I see the tree as moss-covered.

I hear *you* as seeing the tree as clear. (I am looking at the north side, you are looking at the south side...)

Example:

I perceive this animal as snake-like.

I hear *you* as perceiving this animal as tree-like. (I am perceiving the trunk of the elephant, you are perceiving a leg...)

L1: I hope this helps. Comments welcome.

Strong Listening to Invite Thinking Self-Expression

Message 2

L: *After I have used a Stephen Covey principle (1989) to suggest that all fights are about who gets to feel understood first, a participant is quoted as asking me what I think of this statement in view of Abraham Maslow's (1943) hierarchy of needs. This sets me up to teach rather than to help him learn, so I change the subject back to himself:*

Hi S,

L2: I can't tell from that, what it is that you'd like to explore.

L3: If you tell me what YOU think about those things, and where any puzzle about them arises for you, then perhaps I can tune in.

Strong Acknowledgment to Invite Attentive Listening

Message 3

L: *When criticism (not to be confused with critique) emerges in the conferencing, and I remind people that the conferences are for learning through discussion, a participant is quoted as dogmatizing that the conferences should be for learning through debate.*

Hi S,

A2: I'm not sure if you are agreeing with me here, or disagreeing.

A1: Perhaps you are saying that you see debate as essential for learning.

A: If so, ...

E: I would say the following.

I take care, as does the course, to distinguish between discussion and debate. In my lexicon, debate is something that is won or lost. It is in there with fights and games (Rapoport, 1960). It is for persuading people to agree. It is based on the idea that someone will be proved right about 'what is going on' or about 'what to do', and someone else will be proved wrong. Therefore I

see debate as antithetical to handling of multiple perspectives and therefore as antithetical to learning from other people.

In contrast, I see discussion as putting different views side by side and seeing how they might be combined—that is, as being for shared learning, not for persuading. This means that I see discussion as wholly compatible with handling of multiple perspectives.

So when I said that the conferences are for learning through discussion, I was being precise. I did not mean debate. I did mean discussion.

L1: I hope that this clarification is of help.

Message 4

L: *In the same context, a participant then is quoted as dogmatizing that feedback must be expected. This confuses feedback with criticism—a distinction that the course makes at length (Zimmer, 2004c).*

Hi S,

A2: I'm not sure what it is that you're countering here—I don't hear disagreement with what I was saying.

E: Reports of people's experiences of the course are very welcome. This means reports of what they've noticed, what they imagine about it, and how they feel about that because of what they need—and perhaps what they'd like to do about it and would like help to do.

That is feedback, as defined in the course—in short, what they liked, what they did not like, and what they would change. I find that feedback, unlike criticism, can be learned from and makes improvement possible.

A3: What I was referring to did not sound to me like feedback. I could find no information in it that could guide improvement—which involves saying what's been got right.

L1: I hope that you find this clarification of use.

Strong Self-Expression to Invite Comprehending Acknowledgment

Message 5

L: *A participant is quoted as owning to a personal hatred of consultants—and then is quoted suggesting in a later message that a reply from me to someone else sounded like a consultant speaking.*

Hi S,

A: From those responses,

E2: I can't tell what I've got across to you.

E1: I'd welcome your sense of what I was seeking to convey in each case—in particular, any way of putting it ...

L1: ... that you think you might have found easier to take in.

Message 6

L: *The same participant is quoted as saying that he believes that he understands—then shows that he does not. He characterizes the IALC as 'being civil' and 'touchy-feely' and suggests that it cannot be used when something really needs to be done.*

Hi S,

A: I have great sympathy with that position. I think that it often can seem that the more urgent things are, then the more control must be imposed and the more that people must be told what to do.

E: At the same time, it is my own experience that people's resistance tends to dissolve when they feel understood. This is certainly the case with myself. I also find that their resulting increased co-operation can save a lot of time.

So more and more, I try to remember to start if at all possible by offering my comprehension of their concerns.

E3: This strategy to me is not 'touchy-feely'.

E: It's a recognition of my own and other people's informational needs.

I think that people listen a lot more easily when they hear comprehension of their concerns. I also think that they understand more easily when they hear a personal perspective rather than something

purporting to be 'what is'. In addition, I think that they are more likely to give a personal perspective themselves than to try to tell people 'what is', when they feel safe because of good listening. And that is the whole IALC right there.

E3: So it's not really about being 'civil', as you suggest—

E: it's an information-processing thing.

E1: As usual, I'd welcome your sense of what I'm saying,

L1: and any reflections that you might have on it.

The last two lines above have come to represent for me what is most important about use of the IALC. It invites not just thought, but further thought—so that a learning dialogue can grow.

FUTURE TRENDS: IMPLICATIONS OF THE IALC FOR COURSE DESIGN AND ASSESSMENT

I believe that routine use of the IALC can have profound implications for teaching and instruction, collaborative learning, assessment, course evaluation, and professional development.

Teaching and Instruction

Most traditional teaching and instruction that I have seen consists of dogmatizing—that is, teachers apparently believing that they possess objective knowledge and believing that teaching consists of imparting this knowledge to course participants. From my point of view, this amounts to telling participants what to think.

I see this even in professional conferences. These often begin with 'keynote addresses' that effectively tell paying participants what to think about, instead of polling the participants to find out what they would most like to learn about in the context of the conference title.

Worse, as paying participants increasingly come to see themselves as consumers, it appears

to me that they expect to have knowledge delivered to them in this way. That is, they expect to be taught rather than helped to learn—an expectation reinforced by prevailing practice.

I believe that use of the IALC can reverse this trend. It begins with listening for desires instead of talking. And it ends with listening for feedback or further reflections. In so doing, it engenders collaborative learning.

For example, this chapter has been designed to do exactly that. It begins with listening, where the six questions that are asked invite the same thinking reflection that the chapter itself describes:

- What you notice and what you imagine about it
- How you feel about that because of what you need
- What you would like to do about it and to ask others to do

The chapter then describes what I think that your answers will have centered on, and only in that context does it then express what I myself think. Finally, in the Conclusion section, it will end by listening again—it will invite your reflections on what I have said and how I have said it.

Collaborative Learning

The IALC invites itself in return, so its use facilitates collaborative learning between teacher and course participants. In my experience, this engenders a sense of safety for participants.

I have found that when such a sense of safety has been established, mutually supportive learning can emerge (Zimmer & Alexander, 2000), and collaborative discussions then can take off in a very learningful way.

Such discussions often include challenge of ideas. Because the IALC puts support in before challenge (i.e., comprehending acknowledgment before thinking self-expression), personal safety is maintained.

All that I have ever known to stop this process is the tradition of competitive debate—that is, a win-lose situation develops in which people get dismissed along with their ideas. But I have also seen an antidote arise to this loss of collaboration, when course participants themselves understand the IALC well enough to use it consciously themselves. At this point, I find that a learning community can begin to emerge (Zimmer, Harris, & Muirhead, 2000).

If and when knowledge of the IALC—by whatever name—becomes widespread amongst course participants, then I predict that collaborative learning through discussion will become the norm.

Assessment

I know of two main kinds of assessment. The first is teacher-centered, in which the teacher wants to get something about a topic across. The assessment score then measures how well the teacher feels understood. Multiple-choice questions generally are suitable.

The second kind is participant-centered, in which the participant is given space to explore a topic and to put together a case about it. The assessment score then measures how well the participant presents his/her own thinking. Multiple-choice questions generally are *not* suitable.

In my experience, much of traditional assessment confuses these two. It is teacher-centered, in that the teacher wants to get something about a topic across and to be accurately understood about it. So whatever the topic might be, the teacher is the subject. But then the teacher acts as if the course participant were the subject, and turns the assessment score into a performance rating that bestows praise (or blame) on the participant, for the participant's acquisition (or not) of the teacher's knowledge.

So far as I can see, this is simply dogmatic judgmentalism and does not help either the teacher or the participant to learn.

Use of the IALC undoes this confusion, by always making clear who the subject is—teacher or participant—whatever the topic of conversation. In Figures 6-8, this distinction is represented in each diagram by the difference between the right-hand and left-hand sides.

This puts participant-centered and teacher-centered assessment alongside each other, showing that they are not in conflict with each other. If this realization spreads, I predict that participant-centered and teacher-centered assessment will be used increasingly to complement each other.

I see another benefit as well, in use of the IALC for assessment. It suggests low-maintenance versions of participant-centered assessment.

In particular, since participant-centered assessment is about how well the participant can present his/her own thinking, then in each participant's responses there always will be a personal aspect that is uniquely identifiable to a teacher who knows him/her—meaning that the assessment questions need not be changed from year to year.

So if and when knowledge of the IALC becomes widespread amongst teachers, I predict that the workload involved in assessment will decrease.

Course Evaluation

Traditional course evaluation, so far as I can see, suffers from the same confusion as does traditional assessment. The course participant is invited to lay judgments of praise or blame onto the course or the teacher—that is, 'Rate this course/teacher for...'.

I have never known such judgmentalism to provide information that a teacher can use to improve what he/she does.

In contrast, by maintaining clearly the distinction between what is about the teacher and what is about the participant, the IALC invites a report of the participant's experience of the course and its teaching—that is, what the participant liked, did not like, and would change.

In my experience, such feedback does provide information that the teacher can use to improve what he/she does.

So if and when knowledge of the IALC becomes widespread amongst teachers, I predict that the rate of improvement of course material and of teaching will increase.

Professional Development

My own experience of professional development for teachers has included being presented with vast quantities of material that amounted, metaphorically, to a lot of trees but no forest—that is, a lot of detail with no overall pattern.

I have found that to look at such mountains of material in terms of the IALC can be a great aid for making rapid sense of it all. It enables me to see rapidly what supports development of the learning dialogue and what does not.

So I predict that if and when knowledge of the IALC becomes widespread amongst teachers, professional development material will become considerably simplified.

CONCLUSION

I find that cultural and linguistic traditions often favor competition for dominance over mutual support. That is, they substitute dogmatic, judgmental oppression for thinking, attentive comprehension. In so doing, they can play havoc with collaborative learning, both online and face-to-face.

I also find that conscious use of the interpersonal action-learning cycle (IALC) offers a solution. This chapter shows how.

Further ideas about use of the IALC—including its use in this chapter itself—are invited.

FUTURE RESEARCH DIRECTIONS

Figure 9 summarizes the five areas of application of the IALC to instructional design that are discussed in the ‘Future Trends’ section. The areas of application are on the left and the effects are on the right. The arrows show the main directions of influence, as I see them.

Figure 10 shows five wider areas of application for future research that I also see. As in Figure 9, the areas of application are on the left, the effects

as I see them are on the right, and the arrows show the main directions of influence that I see.

General references for these wider areas of application appear in the ‘Additional Reading’ section.

In addition to these five wider areas of potential application, I see six main areas of systemic thinking in which the IALC itself has its roots. These are shown in Figure 11. As in Figures 9 and 10, the arrows show the main directions of influence that I see.

Figure 9. Instructional applications of the IALC, discussed in this chapter

Figure 10. Wider areas of potential application of the IALC, for future research

Figure 11. Areas of systemic thinking in which the IALC has its roots

Investigation of these roots can lead in principle to deeper versions of the IALC, with correspondingly wider domains of application.

General references for these roots also appear in the ‘Additional Reading’ section.

Chapter 6.6

Synergy: Service Learning in Undergraduate Instructional Technology Courses

Jacqueline M. Mumford
Walsh University, USA

Elizabeth Juelich-Velotta
Walsh University, USA

ABSTRACT

Synergy describes a situation where the combined efforts are greater than individual parts. Service learning ties together academic content, in this case instructional technology, while providing service. This chapter offers an orientation to an exceptionally rewarding service learning activity in an instructional technology course. Based upon a case study and extensive literature review, this chapter provides best practices for fostering the synergy between service learning and instructional technology courses. This approach increased teacher candidates' exposure to diversity, served community needs, and facilitated candidate practice of skills from instructional technology class.

DOI: 10.4018/978-1-60960-503-2.ch606

INTRODUCTION

In instructional technology courses, teacher candidates are taught to use a variety of tools for instruction. Some instructional technology courses require field experience where pre-service teacher candidates observe and interact with in-service teachers and students in schools. A service learning model provides candidates with an opportunity to put the theory they are learning in the classroom into practice while serving the community. Service learning sites provide unique field opportunities for teacher candidates to work with diverse student populations. The resulting experience can be both rich and rewarding.

Service learning is an activity that meets identified community needs and connects course content with real life experiences. By exposing

instructional technology undergraduate teacher candidates to service learning, significant benefits are possible. Howard (1998) also indicated that academic service learning is a synergistic model where the students' experiences in community settings are just as valuable to the students' learning experience as any other element within the course. Citing a reciprocal relationship between service and learning, he posited that the service experiences of his students both "inform and transform the academic learning and the academic learning informs and transforms the service experience" (p.22). This chapter will explore the benefits of this approach to instructional technology courses through literature review and a case study.

This chapter will:

- Explain the synergistic relationship between instructional technology and service learning in undergraduate teacher preparation.
- Define service learning through both a historical and teacher preparation lens.
- Investigate stakeholder responsibilities and benefits of service learning.
- Detail a case study from a small, private, Midwestern university.
- Discuss best practices, documentation, and integration of experiences.
- Provide recommended readings.
- Establish an agenda for future research.

THE NECESSITY AND COMPLEXITY OF FIELD EXPERIENCES

The National Council for Accreditation of Teacher Education (NCATE) defines field experience as "A variety of early ongoing field-based opportunities in which candidates may observe, assist, tutor, instruct, and/or conduct research. Field experiences may occur in off-campus settings such as schools, community centers, or homeless shelters" (2008, p. 86). Field experiences are considered critical to

teacher preparation programs (McIntyre, Byrd, & Foxx, 1997). This experiential work provides an opportunity for teacher candidates to interact in an authentic instructional setting. Candidates teach, facilitate learning, and connect theory from classes to actual practice in their field placements. Such field experiences promote increased emotional involvement and intrinsic motivation for candidate success (Casey & Howson, 1993). By integrating field experience partnerships between K-12 schools and universities, positive results have been reported (Clark, Foster & Mantle-Bromley, 2005).

Although field experience has been a long-standing hallmark of teacher education, integrating field experience into educational technology was a relatively new concept just a decade ago. Many reports surfaced in the late 1990s indicating that a restructuring of technology preparation toward integrative models (theory and practice) was necessary in order to prepare teachers for the digital age (Larson & Clift, 1996). According to one report from Willis and Mehlinger, 1996:

Most pre-service teachers know very little about effective use of technology in education and leaders believe there is a pressing need to increase substantially the amount and quality of instruction teachers receive about technology... [T]he virtual universal conclusion is that teacher education, particularly pre-service, is not preparing educators to work in a technology-enriched classroom. (p. 978).

Field experiences integrating technology were recognized as solutions to the deficits in teacher technology skills (Brush, Igoe, Glazewski, Ku, & Smith, 2001). In a 1999 paper, Strudler and Wetzel detailed programs that provided pre-service teachers with technology experiences in the field prior to student teaching. In reaction to the reports and recommended solutions, models were developed that provided teacher candidates with authentic experiences focusing on effective use of instructional media (Dexter & Reidel, 2003;

National Council for the Accreditation of Teacher Education [NCATE], 2008).

More recently, teacher preparation programs began confronting another issue: preparing teacher candidates to teach in diverse settings. Public schools are becoming more diverse, while the teachers remain predominantly White, female, and middle-class (Swartz, 2003). There is a certain “cultural discontinuity” (Irvine, 2003) that may produce negative interactions and reinforce teacher candidate stereotypes. This cultural discontinuity creates a divide between the teachers and the students they are teaching. The literature indicates that teachers need to have more field experiences with diverse student populations in order to understand students and offer better instructional experiences (Graybill, 1997; Pransky & Bailey, 2002/2003). Research indicates that field experiences in culturally diverse urban settings encourage teacher candidates to teach in culturally responsive ways (Barnes, 2006; Gay, 2000).

MAKING THE CASE: A CASE STUDY ON INTEGRATING SERVICE LEARNING

In an effort to address the technology deficit, as well as the need for diverse experiences, a program was developed and implemented in the undergraduate teacher preparation program at a small, private, Midwestern university. Service learning is a general education requirement for all undergraduate students at this institution. Instructional Technology is a required core course for all teacher candidates.

Since fall 2006, every teacher candidate in Instructional Technology has been required to complete a minimum of ten hours of structured service learning field experience. This service learning field experience for instructional technology was piloted in three phases. In every phase, teacher candidates completed structured pre-service reflections, kept reflective logs, and

participated in service share sessions in class. Service shares will be discussed further in the case study narrative. These experiences tied the theory of instructional technology and pedagogy to the practice of working in a diverse setting with students via service learning.

There was a distinct lack of substantive research and literature on integrating service learning with instructional technology courses. In the literature review process, no research on this specific connection with undergraduate students was located. However, significant information on service learning was available. With a goal of investigating the synergy of service learning and instructional technology, the guiding question for this process was: “How can service learning be integrated effectively into undergraduate teacher preparation through instructional technology coursework?”

SERVICE LEARNING FUNDAMENTALS: A REVIEW OF THE LITERATURE

Prior to implementing the case study, a thorough investigation into service learning was completed. This included reviewing the history, definitions, concepts, models, and best practices of service learning. It was essential to have a clear understanding of this method in order to design an integrated service learning experience in educational technology. The following section highlights critical aspects of service learning pedagogy.

Establishing a Working Definition of Service Learning

The term service learning has infiltrated the vocabulary of most college campuses today. As a result of the desire to improve the scholarship of teaching and learning and to produce educated citizens who can think critically and solve problems, service learning programs and courses have developed and expanded over the last few

decades. But just what does the term service learning mean and how is it different from other forms of experiential education and service?

Many definitions and methods of service learning exist in the literature base from the field, but commonalities exist amongst them. For the purpose of this chapter, the NCATE definition will be used. Service learning is defined as:

A teaching/learning method that integrates community service into academic courses, using structured reflective thinking to enhance learning of course content. Through meaningful service, candidates are engaged in problem solving to create improved schools and communities while developing their academic skills, their sense of civic responsibility, and their understanding of social problems affecting children and families. When used as a pedagogical strategy, service learning can help candidates understand the culture, community, and families of students, as well as the connections between the school and the community (2008, p.91).

Service Learning Foundations

The term service learning first surfaced in the 1960s. During that time period, Robert Sigmon emerged as a leader within service learning and coined three principles that would serve as the foundation for future service learning work (Mintz & Hesser, 1996). Sigmon's (1979) principles were:

1. Those being served control the service(s) provided.
2. Those being served become better able to serve and be served by their own actions.
3. Those who serve also are learners and have significant control over what is expected to be learned (p. 10).

Sigmon's principles highlight the centrality of reciprocity, capacity building, and community-

defined need. Reciprocity exists due to the symbiotic relationship between the server and the served. As the expert on the community needs, the community should be the ones to define the 'what' and 'how' of the service. Additionally, the service is not meant to perpetuate the dependency on the servers, rather the service should help build capacity for the served to better help themselves (Council for the Advancement of Standards in Higher Education, 2006).

The 1980s were marked with increased growth in the national service movement as the Campus Outreach Opportunity League (1984) and Campus Compact (1985) were formed (National Service Learning Clearinghouse, n.d., History). With a desire to create high quality service programs and to aid in institutionalization of service learning, the National Society for Experiential Education (NSEE) collaborated with seventy organizations and the Johnson Foundation to convene a group at Wingspread (Mintz & Hesser, 1996). The result of this group was the *Principles of Good Practice for Combining Service and Learning*, or otherwise called the Wingspread Principles (Porter Honnet & Poulsen, 1989).

The group outlined the following principles for combining service and learning:

1. Engages people in responsible and challenging action for the common good.
2. Provides structured opportunities for people to reflect critically on their service experience.
3. Articulates clear service and learning goals for everyone involved.
4. Allows for those with needs to define those needs.
5. Clarifies the responsibilities of each person and organization involved.
6. Matches service providers and service needs through a process that recognizes changing circumstances.
7. Expects genuine, active, and sustained organizational commitment.

8. Includes training, supervision, monitoring, support, recognition, and evaluation to meet service and learning goals.
 9. Insures that the time commitment for service and learning is flexible, appropriate, and in the best interest of all involved.
 10. Is committed to program participation by and with diverse populations. (8)
9. Be prepared for variation in, and some loss of control with, student learning outcomes.
 10. Maximize the community responsibility orientation of the course (pp. 16-19).

Service Learning Stakeholders

When deciding to integrate service learning, faculty must consider whether service learning will enhance the course learning outcomes. Service learning, as a pedagogical tool, engages students in active learning and allows them to put theory into practice while serving others. The benefits, however, are not exclusive to the students or the community partner. Although there is additional work associated with creating service learning courses, faculty members can also benefit tremendously from the experience. Synthesizing the work of the Morgridge Center for Public Service at the University of Wisconsin – Madison (2008), Table 1 outlines the benefit of service learning for stakeholders: faculty, students, and community partner.

One of the most important components of making good service learning partnerships is effective communication amongst stakeholders. Each entity needs to understand the other stakeholders' needs, expectations, responsibilities, and roles. Faculty members have the pressure of teaching, scholarship, and service within the time context of a semester or quarter. Community partners have the focus of serving clients, staffing,

More than a decade after the Wingspread Principles were drafted, the rapid progression of service learning led to new pedagogical principles that built on the Wingspread Principles. Jeff Howard (2001), Editor of the Michigan Journal of Community Service Learning, outlined ten principles for service learning pedagogy. They are:

1. Academic credit is for learning, not for service.
2. Do not compromise academic rigor.
3. Establish learning objectives.
4. Establish criteria for the selection of service placements.
5. Provide educationally-sound learning strategies to harvest community learning and realize course learning objectives.
6. Prepare students for learning from the community.
7. Minimize the distinction between the students' community learning role and classroom learning role.
8. Rethink the faculty instructional role.

Table 1. Service learning stakeholder benefits

Faculty Benefits	Student Benefits	Community Benefits
Enhances teaching through organization's service learning experience	Provides an opportunity to apply course content	Supplements the human resources to meet the community needs
Strengthens relationships with students	Improves critical thinking	Raises awareness about the organization's mission needs, and population served
Broadens topics for research and publication	Gain valuable work experience	Provides the organization a connection to the community
Demonstrates commitment to university	Explore career interests	Identifies prospective employees and volunteers

funding needs, etc. within the unique timeline specific to the services they provide. Having a conversation prior to entering into a partnership will make the service learning more effective, smooth, and successful. Building off the work of the Council for the Advancement of Standards in Higher Education (2006), Cress, Collier, Reitenauer, and Associates (2005), and Howard (2001), Table 2 outlines each stakeholder's responsibilities.

While considering stakeholder responsibilities, addressing student rights is crucial for higher education institutions. Service learning takes place via the sphere of academics, but the classroom extends beyond the college campus, thus acquiring unique features. As a result, it is important to note that students have "rights" when it comes to service learning courses. Cress, Collier, Reitenauer, & Associates (2005) and Heffernan (2001) note that students have a right to:

- Know what is expected for the service learning and how it will be graded.
- Work with a community partner in a safe environment.
- Have the opportunity to apply knowledge for the benefit of others.

In order to have the most beneficial and educational service learning, it is important not to overlook safety; if the students don't feel safe, they won't be able to learn. Everything from

travel associated with the service to the actual physical environment of the service site needs to be discussed with students to aid in preparation. Some students arrive to college having experienced little exposure to diverse settings or economically depressed communities. While not all service learning takes place in these types of communities, environments in which students work with homeless, tutoring programs, and other social services do frequently have similar characteristics. Discussing what to expect; helping students reflect on their fears, expectations, and prejudices; as well as outlining safety procedures, will help prepare students to gain more from the experience.

PRINCIPLES OF GOOD PRACTICE

There are many aspects to consider when designing a service learning course. Fortunately, abundant resources and research are available to inform practice. To implement service learning into instructional technology courses, components like reflection, learning outcomes, and syllabi require attention.

Reflection

When incorporating service learning within a course, reflection is a critical component. Students will have new, eye-opening, and challenging ex-

Table 2. Service learning stakeholder responsibilities

Faculty Responsibility	Student Responsibility	Community Responsibility
Listen to community partner needs	Understand their role and function within the organization	Create an environment conducive to learning
Develop clear, strong, and course-specific learning objectives	Manage time effectively as to accomplish the goals and/or work	Orientate and train the students
Create meaningful reflection opportunities	Learn by engaging, discussing and reflecting	Serve as partner and co teacher
Know the skill level of the students and inform the community partner	"Do no harm"	Provide honest communication to the faculty member
Ensure academic rigor	Represent the college/university well	Understand the university timeline

periences via service learning; thus, it is important to help them process the experience as it relates to academics, career pursuits, and life. Through their service, students may be confronted with circumstances, behaviors, and human experiences that force them to re-examine previously held ideas or theories. Old frameworks for analyzing experiences may not suffice.

Eyler and Giles found that “the centrality of reflection to the academic enterprise had a significant impact on problem solving and critical thinking and on the complexity of students’ problem analysis and issue understanding” (1999, p.174). In a survey of 22,236 undergraduate students, Astin, Vogelgesang, Ikeda, and Yee (2000) found that class discussion, encouraged by the professor, was “the second most significant factor in a positive service learning experience” (p.iii). Similarly, Mabry found that while there was no difference between groups in her study with different frequency of out of class reflection, there was greater academic benefit for students who reflected at least weekly in class (1998). Some modes of reflection are: writing (journals, reflective papers, directed writings, case studies); activities (role playing, skits, interviewing peers); multimedia (photo or video essay, on-line discussions, wikis or blogs, poster boards); and telling (presentations, class discussions, meetings with faculty). Each of these modes offers a different way for the students to process and learn from their service learning experience.

Syllabus and Learning Outcomes

It is important not to overlook the power of the syllabus and learning outcomes when creating a service learning course. The syllabus is seen as the contract between the students and faculty member and serves to prepare students for the experience that will unfold over the semester. Additionally, students need to see the connection between the service learning and the academic course content or learning outcomes. Faculty can demonstrate

that connection via the course learning objectives and description of the service learning project.

The Council for the Advancement of Standards, in describing the role of the service learning syllabus, recommends that the following components be included in the syllabus:

- Needs that the service will address.
- Desired outcomes of the service and learning for all participants.
- Assignments that link service and academic content.
- Opportunities to reflect on one’s personal reactions to the service and learning experiences.
- Logistics (e.g., time required, transportation, materials required).
- Nature of the service work.
- Roles and responsibilities of students and community members.
- Risk management procedures.
- Evaluation of the service and learning experiences and assessment of the degree to which desired outcomes were achieved (2006, p. 305).

A CASE STUDY ON SPARKING SYNERGY: THE ROAD TO BEST PRACTICES

Based on the benefits of the service learning practices outlined above, three class sections of an initial teacher preparation course were selected to incorporate service learning. The average class size was 17; with two-thirds of the candidates being female and one-third male. Instructional Technology is generally the second course in education for the majority of students; the first course being a survey of school and society that requires several observation hours. None of the students had formal service learning experience at the university prior to taking this course.

The guiding research question was how to incorporate service learning effectively into

undergraduate instructional technology courses. Spanning four semesters, this case study illustrates three separate phases of implementation for all instructional technology students, detailing successes and challenges. The study takes place at a small, private Midwestern university. It is important to note that teacher candidates in this NCATE accredited program may pursue licensure in five different bands including Early Childhood (Pre-K through Grade 3), Middle Childhood (Grades 4-9), Adolescent to Young Adult (Grades 7-12), Multi-Age Physical Education, and Intervention Specialist (special education).

Phase One: Hi-Tech Environment

In fall 2007, undergraduate candidates in the teacher preparation program began their course with an innovative component—ten required hours of service learning. Prior to the semester, arrangements had been made with a local school district to place these candidates in classrooms and labs where they could tie the theory of instructional technology to practice. Placements were also aligned with their intended licensure bands.

According to the Ohio Department of Education (ODE) District Report Card for 2007-2008, the local school district selected for this phase consisted of 4,100 students (ODE, 2008). This school district's enrollment was 1,347 students at the high school, 1,025 students at the middle school, and 1,547 students at the seven elementary schools. The ratio of students to teachers was 17:1. Demographically, the district was 94% Caucasian, 2% Multiracial, 2% Asian, and 2% Black. The district reported 13% of the students had disabilities, and the overall attendance rate was 96%. Only 14% of the students in the district were economically disadvantaged. The district had recently received the second-highest recognition from the state, a designation of "Excellent." The expenditure per pupil was \$7,424. The school district was rich in technology, and all classrooms had at least one networked computer. Most classrooms had a data

projector, and each school had at least one Smart Board™ interactive whiteboard. There were multiple brand-new computing labs in each location.

Prior to the start of classes, the instructor met with the cooperating schools. The instructor and cooperating teachers discussed expectations, curriculum, learning goals/outcomes, and needs. Upon completion of that discussion, the course syllabus was created. Because service learning was integral to the course and a general education requirement at the university, teacher candidates would not be able to pass the course if the service component was not successfully completed. A service learning contract between the teacher candidates, site, and faculty member was implemented. Please note that in subsequent semesters, an additional liability waiver for travel was added, based on administrative policy.

Scheduling teacher candidates for service learning times was challenging. With several different schools comprising this district and each school having its own unique schedule, teacher candidates were challenged to balance service learning hours and their academic schedules. The university schedule for course times as well as academic calendar did not match any schedules at the partner schools. A system of creating sign-up sheets displaying time options was created to address schedule issues, although many candidates expressed stress and frustration because some schools were on block scheduling that conflicted with candidate coursework on campus.

Qualitative data was gathered to analyze candidate expectations and growth. Since service learning literature discussed the emphasis on reflections prior to their first site visit, candidates were asked to do a pre-service reflection. These reflections were brief open-ended essays covering candidate feelings, perceptions, and attitudes regarding service and technology. This first pre-service reflection format was unstructured. Due to the broad scope of responses, in subsequent semesters a more structured format of the pre-service reflection activity was implemented. The

goal was to improve focus and ensure that all teacher candidates addressed specific questions.

Pre-service reflection essays offered insight to inform class discussions, reading materials, and instructor intervention. The themes that emerged were that the candidates:

1. Did not see themselves as technology experts.
2. Had high comfort levels with certain technology applications (Facebook®, MySpace®, Microsoft Word®, PowerPoint®, Internet searches, music, etc.).
3. Felt their high school experiences did not include teachers modeling effective technology.
4. Expressed apprehension regarding interaction with students at the partner site.
5. Believed effective teachers made school fun, and technology was the answer.

As the semester unfolded, the emphasis on reflection continued. Teacher candidates completed a log of activities, accomplishments, epiphanies, or other notable occurrences throughout the service learning experience. The cooperating teacher verified participation and completed an evaluation of each candidate's work. Two of the teacher candidates did not complete their service hours which resulted in a failing grade.

At the conclusion of this service learning experience, teacher candidates wrote extensive reflections based on a departmental service rubric. For assessment of learning outcomes, a rubric was created by a task-force within the Division of Education to evaluate candidate reflections. The five criteria for the teacher candidate final reflection essays included:

1. What happened? (Objective statements without interpretation describing population, setting, demographics, and activities)
2. What was learned about the candidate's licensure area?

3. What are the candidate's reactions, feelings, impressions, and ideas? (An analysis of the experience)
4. What about the future? (Theoretical issues, content knowledge, dispositions that could apply to future teaching)
5. What two Specialized Professional Association (SPA) or State Teacher Standards could be applied to strengthen the service learning experience?

All candidates in the undergraduate instructional technology course were required to create a Microsoft PowerPoint® electronic portfolio that showcased their semester of coursework. A significant portion of this presentation required candidates to detail their experiences, growth, and learning as a result of this service component. This course generated interest from the broader campus community. Administrators and other faculty members attended student presentations to learn more about the synergy.

When the semester concluded, the instructor analyzed student reflections and comments. Each electronic portfolio presentation was reviewed, as well as any notes taken on verbal comments from the candidates' presentations. Five themes emerged. Participants in this service learning course:

1. Developed a sense of efficacy regarding the use of technology.
2. Observed effective use of technology.
3. Benefitted from working with students and technology in an authentic environment.
4. Appreciated exposure to new high-tech equipment (SMART Board™ interactive whiteboards, audience response systems, and specialized software).
5. Established bonds with the students they were tutoring.

In spring 2008, given the same placement, results were parallel. The instructor this time

handed out periodic service share worksheets to candidates for completion in class. Service share sessions were discussion/activity times set aside in specific class sessions where teacher candidates shared information on their experiences in service learning. Candidates completed forms consisting of open-ended questions about what was happening in their service work, how they were connecting class content to their service experience, and any challenges or successes. These worksheets were reviewed by the instructor. Closer attention was paid to each candidate's experience and follow-up calls or instructor visits were made to service sites to facilitate better cooperation and improve experiences. However, at the close of spring 2008, it was apparent that the challenges from fall 2007 remained.

Teacher candidate comments confirmed that appropriate placements were critical to success. Candidates who were matched with cooperating teachers excited and skilled with instructional technology had very positive experiences. The candidates assigned to cooperating teachers who were not confident in their ability to use technology were either given menial tasks (photocopying, lunchroom supervision/tutoring) or given too much responsibility (primary instructor for technology lessons). Additionally, many students jokingly remarked that the service site (school) had better technology than their own university campus. The instructor reviewed data. It was clear that the experience had benefits, but the design of the service component was not the right fit. Two questions arose:

1. How can negative experiences be avoided?
2. Are candidates providing true service in an environment already rich in resources?

After thorough discussion at the university, it was decided that a greater focus on service and diversity would be beneficial to the teacher candidates. Investigation for alternative placements began.

Phase Two: Shifting Focus - Service and Diversity

In fall 2008, the instructional technology course sections partnered with an after-school urban outreach enrichment program sponsored by the university and an urban church for K-4 youth. Candidates with licensure bands addressing early childhood, middle childhood, and intervention specialist participated in that program. Candidates with adolescent to young adult licensure bands assisted with an alternative high school program in the same building. This combination of service learning field placements made it possible for all licensure areas to be accommodated.

According to the Urban Outreach Report (Smith, 2009), the urban outreach site consisted of 32 students in regular attendance. The student to teacher ratio was approximately 5:1. Demographically, data indicated that 47% of the students were White, 34% Hispanic, 16% Black, and 3% did not disclose. Approximately 75% of the students served were economically disadvantaged. Although some students had disabilities, no data was gathered that semester on that topic. Over 90% of the students were at the early childhood licensure band level at this site (grades one through three). Regarding technology, this site offered seven older non-networked computers and 2 non-networked printers.

The adolescent to young adult licensure band service option was at a "last chance" high school in the same building. The mission of this school was to serve at-risk youth including drop-outs, near drop-outs, adjudicated youth or others with low achievement. This charter school did not meet any of the state requirements and was listed at the lowest designation, "academic emergency," on the state report card (ODE, 2008). The high school had approximately 88 students (J. Cole, personal communication, August 27, 2008). The ratio of students to teachers was 10:1. Demographically, the district was 46% Black, 42% Caucasian, and 12% Unspecified. The school reported 46% of the

students had disabilities. The attendance rate was 65%. At least 56% of the students in the district were economically disadvantaged (ODE, 2008). Regarding technology, most classrooms had at least one networked computer, and 2 classrooms had data projection.

In addition to the instructional technology course, several other university courses participated in the after school urban outreach initiative. The location of these facilities was in an economically disadvantaged area, candidate safety was a concern. To prepare the candidates for working with a more diverse population, a mandatory evening orientation session was scheduled and delivered prior to beginning the service hours; an asynchronous version was also available to candidates.

A few schedule concerns arose from the design of this service learning partnership. The enrichment program was an after-school program offered only on Tuesdays, Wednesdays, and Thursdays between the hours of 4:00 and 6:00 PM. Several candidates had evening or afternoon classes at those times. Others candidates were athletes or had employment/activity conflicts. With the program running over a 12 week period, many candidates reported stress based on scheduling issues.

Candidates signed service learning contracts and wrote pre-service reflection essays; however, the reflections were modified to include questions on diversity and poverty. Most answers about technology were parallel to previous semesters. However, the incorporation of diversity and poverty questions into this exercise yielded interesting data. Candidates:

1. Enjoyed community service and helping others.
2. Expressed concern about interactions with poor people.
3. Worried about how low socio-economic status impacted teaching and learning.
4. Lacked prior experience with racially and economically diverse populations.

Throughout the semester, candidates completed a log of their experiences, as well as answered periodic service share worksheets to inform the instructor of their activities and progress. These worksheets helped the instructor adjust lessons to more closely tie the service experience to the theory and objectives of the course. Additionally, based on comments from candidates' reflections, several readings on the culture of poverty were introduced and discussed in class.

Upon analysis of student reflections and comments at the end of the semester, the instructor saw some substantive growth with regard to diversity, empathy, and volunteerism. Seven core candidate observations emerged. The participants:

1. Reported that they felt they had made a difference in students' lives at the service sites.
2. Expressed interest in volunteering more.
3. Witnessed the effects of poverty.
4. Realized trust and respect had to be earned from the students.
5. Adapted activities to meet the needs of their diverse students.
6. Experienced a great deal about different cultures, economic status, and values.
7. Developed bonds with the students they served.

Some shortcomings did appear regarding the limited technology available. Although the initial project at the enrichment site was to set up and install a non-networked computer lab, some candidates raised concerns that there was not much connection to instructional technology thereafter. Additionally, some reported that they felt there were too many university service students for the number of youth participants. Candidates felt that they could not tie classroom theory to practice since there was a lack of opportunity for personal interaction with the partner students.

Upon analysis, the course instructor found the experience extremely rich and positive with respect to diversity, but the candidates' experi-

ences lacked a focus on instructional technology. Experiences under the previous structure (Phase 1) afforded candidates observation of cooperating teachers modeling effective technology use but lacked a true sense of service. Phase 2 offered candidates the opportunity to truly serve others in need, but lacked sufficient technology exposure. It was decided that an alternative site (Phase 3) would be sought to address both concerns.

Phase Three: Merging Service Learning, Diversity, and Instructional Technology

In spring 2009, the instructor and Director of Service Learning contacted a local non-profit organization that worked closely with an urban school district to implement after-school programs. At this location, 95% of the students attending the partner schools were below the poverty level. Further, 100% of the students participating in the non-profit organization's programs were below the poverty level (T. Bigler, personal communication, January 8, 2009). The non-profit also offered several support services (food, clothing, counseling, etc.).

The urban school district directly served by this non-profit consists of almost 11,000 students. Regarding enrollment, there were seventeen elementary schools with a total of 5,090 students, six middle schools totaling 2,528 students, and four high schools totaling 3,361 students. Nine of the schools in the district are listed as charter, alternative, or collaborative locations. The non-profit partner was specifically affiliated with a neighborhood area serving approximately 400 students. The student to teacher ratio was 19:1. Demographically, 54% of the students were Black, 24% White, 20% Multiracial, and 2% did not specify. The combined district reported 19% of the students had disabilities. The attendance rate was 95%. The district expenditure per pupil was \$9,916. The school received a mid-level designation of "Continuous Improvement" from

the state (ODE, 2008). Regarding technology in the non-profit center, there were multiple computers and printers in a networked lab, a digital music lab, library, large art/media classroom, and access to additional resources in the adjacent school building.

Collaboration between the non-profit Education Director and course instructor outlined expectations, needs, schedule options, and responsibilities for participants. Candidates were offered a sign-up sheet of various service times throughout the week between 10am and 5pm. This schedule addressed earlier concerns regarding candidate schedule conflicts mentioned in Phases 1 and 2. The Education Director delivered an orientation that prepared candidates for their work in an impoverished ethnically diverse neighborhood. The orientation included safety, rules, regulations, best practices, and other administrative issues.

Once again, candidates signed a service learning contract and liability waiver. They completed pre-service reflections, kept time logs, and participated in structured in-class service share sessions. Additionally, the final presentation and e-portfolio requirements were continued. Communication between the service partner and instructor was open and regular.

In spring 2009, candidates completed their service learning instructional technology experiences at the third site. Although some candidates felt that they had signed up for dates and times where there was not as much interaction with students, the overall response was very positive. Candidates reported that the activities they completed addressed both traditional and electronic media including:

1. Organizing and evaluating media (books, software, etc.).
2. Developing a cataloging system for media.
3. Tutoring on computers.
4. Working one-on-one with students to create mixed media projects.

5. Creating instructional and tutoring materials (bulletin boards, flashcards, PowerPoint® presentations).
6. Developing thematic units incorporating technology.
7. Supporting instruction with technology.

In previous semesters, service share activities were primarily written and insular. In this phase, four structured service share sessions were conducted verbally in class. Candidates began to build off of each other's experiences and openly discuss theory and practice connections collaboratively. The instructor used a variety of active learning methods to facilitate the reflections.. Active learning is defined by Bonwell and Eison as: "instructional activities involving students in doing things and thinking about what they are doing." (2001, p.2).

One example of active learning was an asynchronous discussion on SAKAI, an Internet-based open-source learning management system. An online discussion was conducted, focusing on "repurposing" equipment/materials as well as critically evaluating such materials. The instructor posted a question asking students to consider their service site and how they could "repurpose" or "re-use" existing equipment in innovative ways to bring media rich experiences to impoverished schools. Several candidates were able to locate and share that they could create a low-cost interactive whiteboard—much like the SMART Board™ interactive whiteboard used in the course, by using an infrared pen (\$8) and a Nintendo Wii™ remote (aka "WiiMote") (\$40). Candidates downloaded free software and tested their idea. Although instructional technology candidates commented that it was not as good as the classroom SMART Board™, they used research from the *WiiMote Project* (<http://www.wiimoteproject.org>) to successfully build and evaluate their own low-cost interactive whiteboard (Chung Lee, 2009).

The service opportunity in Phase 3 demonstrated the synergy between providing true service

and applying instructional technology content. Candidates openly discussed how to work with limited budgets but still bring rich technology options to their students. The candidates connected with the idea of technology being a tool, but recognized that not all schools would have the 'latest and greatest' equipment. Instead, they had learned to find innovative solutions to increase student learning with somewhat non-traditional technology tools.

In final presentations and reflections, candidates expressed high levels of satisfaction and growth as a result of this experience. Several commented that they had found projects that they planned to implement in their own classrooms. They also indicated that they had new appreciation for serving diverse learners. The majority of candidates felt they would continue to volunteer for the facility in the future.

At the conclusion of the semester, candidates' reflections and final presentations offered an interesting combination of the positive outcomes from previous semesters, as well as shed light on some new affordances. Overall, eight specific themes emerged. Candidates reported that they:

1. Saw great benefit from working with students and technology.
2. Developed bonds with the students they were tutoring.
3. Made a difference in students' lives at the service partner sites.
4. Expressed interest in volunteering more.
5. Witnessed the effects of poverty and expressed an increased understanding of the importance of education all children and creative ways of introducing technology.
6. Adapted activities with technology (traditional and electronic) to meet the needs of their diverse students.
7. Learned a great deal about different cultures, economic status, and values.
8. Developed bonds with students.

Beyond Phase Three

The instructor found the format of Phase Three to be the most effective. Plans are to continue to nurture the partnership with the local non-profit organization in order to improve services to all stakeholders. Course activities are being added in order to further strengthen the connections between service learning and instructional technology. Experience from the three phases has led to the continuation of best practices for this course--including pre-service reflections, verbal service shares, clearly stating expectations/outcomes, schedule flexibility, student diversity, and adequate technology. In the spirit of continuous improvement, evaluation will be ongoing.

Recent research offers a great deal of information on the implication of social justice as it ties into this service learning and instructional technology study. Currently social justice is not an explicit part of service learning at the university, though it is part of the underlying foundation. Unfortunately, it was not one of the specific main goals of the experience during the case study period. In the next phase, the instructor will focus more on social justice and its implications by incorporating additional readings and discussion points.

SOLUTIONS AND RECOMMENDATIONS

Based on the literature review and established best practices noted earlier, it is critical for the instructor to focus on the 'how' and 'why' of integrating service learning into instructional technology. At the same time, it is critical to ensure that the design of the service learning course will meet all stakeholder needs. Recommendations for those who wish to pursue service learning in instructional technology are:

- Incorporate meaningful pre-service reflections.

- Prepare students through orientations on the service site as well as safety.
- Select an appropriate site based on course learning objectives.
- Provide an opportunity and environment for meaningful direct service.
- Incorporate frequent and varied reflections with peers and faculty member.
- Maintain flexibility as service learning is not controlled by the instructor but discovered through the journey.
- State requirements and outcomes/objectives for service on the syllabus.
- Require all stakeholders to sign service contracts.
- Communicate effectively with all stakeholders and maintain a dialog.
- Evaluate and revise throughout the process.

FUTURE RESEARCH DIRECTIONS

This initial case study has yielded several agendas for future research topics addressing different stakeholder impacts. A series of potential research questions surfaced, spanning three domains: University Students, Community Partner Site, and Faculty. Although the entire list is not exhaustive, the researcher will work with the Director of Service Learning, community partner(s), and faculty to formulate additional research projects. The following list offers some emergent questions relating to each of the domains.

University Students

- What is the impact of service learning on university students regarding skills, knowledge, and implementation of instructional technology (quantitative and qualitative approaches)?
- How can candidates better understand poverty and its effects?

- Does the synthesis of service learning and instructional technology impact teacher candidates in their first year of practice?
- Does the service learning experience make candidates more comfortable in selecting diverse schools for their first year of practice?
- How does in-class discussion of service learning affect the experience for the service learning students?
- How many hours are optimal to achieve enhancement of course learning objectives via service learning?
- How do educators better prepare students to work in diverse educational environments?

Community Partner Site

- What are the academic, emotional, and social impacts of service learning on the constituents (students) from the community site through which the university students served?
- Are service projects able to meet a need identified by the community partner?
- How can the partnership be improved?
- What time commitment is sufficient to meet service partner needs?

Faculty

- What are the benefits for the faculty member teaching the service learning course?
- Is teaching and learning improved based on the service learning experience?
- Does the faculty member have a stronger relationship with the students?
- What are the incentives for teaching a service learning course?
- How can institutions of higher education better support service learning faculty?
- How can social justice be effectively integrated into an instructional technology course in a service learning format?

CONCLUSION

In conclusion, combining service learning with an undergraduate technology course requires a great deal of preparation and planning but yielded rich results. This chapter provided an overview of critical service learning information, review of current literature, and discussion of best practices. Combining service learning with instructional technology offers teacher candidates valuable experiences while tying the theory from the classroom to practical experience serving others. Effectively implementing service learning can meet the deficit previously found in field experience for instructional technology courses while preparing teacher candidates for diverse educational settings.

Chapter 6.7

Knowledge Transfer in G2G Endeavors

Luiz Antonio Joia

Rio de Janeiro State University, Brazil

INTRODUCTION

Since the beginning of the 1980s, a movement was fomented by academics and executives to use information and communication technology (ICT) not only as a tool for processing data more rapidly, but also as a powerful strategic weapon. The need to use ICT as an enabler for reformulating old processes, rather than simply automating existing practices, was perceived by these academics and executives (see, for instance, Davenport & Short, 1990; Venkatraman, 1994).

As Internet technology became more readily available, the reformulation of productive processes in the public arena became a reality, leading all levels of government to strive for greater efficiency, efficacy and accountability in their relationship with their stakeholders, in what is named e-government.

Besides, the understanding of knowledge as a strategic weapon for a corporation is all but recent. In 1945, Frederick Hayek presented research about the use of knowledge in society. In 1962, in a seminal work, Fritz Machlup from Princeton University produced an eight-volume work under the general title, *Knowledge: Its Creation, Distribution, and Economic Significance*. In this work, it was concluded using 1958 data that 34.5 percent of the gross national product of the United States could be allocated to the information sector. In 1993, Peter Drucker analyzed a new knowledge economy and its consequences. Therefore, increasingly the importance of the intangible assets of a corporation, and even those of both countries and any other organizations—including non-profit entities—has been highlighted by academics, researchers and practitioners.

This article draws on the juncture of these two former main streams, namely e-government and the strategic role of knowledge for corpora-

DOI: 10.4018/978-1-60960-503-2.ch607

tions. It was elaborated in order to present the critical success factors that are able to explain the dynamics of knowledge transfer processes in government-to-government endeavors. In doing that, the article aims to explain how public administration can streamline their workflows, create more transparency between their agencies and deliver knowledge to civil servants more effectively and at reduced cost.

BACKGROUND

E-Government: An Idea Lacking a Clear Definition

E-government is still an exploratory knowledge field and it is consequently difficult to define it precisely. Moreover, it encompasses such a broad spectrum that it is difficult to find one expression that encapsulates accurately what e-government really represents.

According to Zweers and Planqué (2001, p. 92), one can say that:

E-government concerns providing or attainment of information, services or products through electronic means, by and from governmental agencies, at any given moment and place, offering an extra value for all participant parties.

On the other hand, Lenk and Traunmüller (2001, p. 64) choose to see e-government as a collection of four perspectives:

- **Citizen perspective:** Striving to offer public services to citizens;
- **Process perspective:** Seeking to rethink and redesign the *modus operandi* of current productive processes within public administration at its various levels, such as the bidding process to purchase products and services, namely e-procurement.

- **Cooperation perspective:** Aiming to integrate the many public agencies among themselves as well as with business and non-business organisations (NGOs), in order to streamline the decision process without prejudicing quality, as well as avoiding fragmentation, redundancies, and so forth, currently established in the relationships among these various players.
- **Knowledge management perspective:** Enabling the government, at all levels, to create, manage and make available the knowledge both developed and accumulated by its organisations in adequate databases.

Knowledge Transfer in Government-to-Government Initiatives

In the traditional governmental processes between two or more public agencies, it has recently been observed that efficiency, efficacy and effectiveness are substandard and costs are high (Joia, 2004). Faced with this situation one question arises: if private companies have discovered the enormous benefits that the Internet can generate for them through linkages among themselves, why don't public agencies use this technology and the integration it provides in order to become more responsive and at reduced cost? As public budgets have been challenged in many countries around the globe and society is increasingly calling for more accountable public administration, integrated electronic processes between public agencies via the Internet, known as government-to-government (G2G), can be the answer to this dilemma (Joia, 2004).

Government as a collection of public agencies, each of them having their own information and knowledge, needs to ensure that these agencies are linked such that they can share their knowledge. It can be said that government is (or should be) similar to a metabusiness—a quasi-firm, or virtual firm, created via digital links between several

companies—in such a way that it is almost impossible to define its precise boundaries (Keen, 1991).

THE KNOWLEDGE TRANSFER PROCESS IN G2G PROJECTS

In a G2G knowledge transfer process some critical success factors are involved. They are duly listed below.

Technological Infrastructure

In order to deploy a knowledge transfer undertaking, a solid technological infrastructure is needed. This endeavour is based on online linkage of knowledge repositories built on databases through inter-organisational systems (IOS). This linkage is built upon an extranet using either a private leased line or a VPN (virtual private network).

Inter-organisational systems (IOS) are typically defined as automated information systems shared by two or more organisations. The use of IOS thus involves networks that transcend organisation boundaries.

In the knowledge repositories, data, documents, videos, and so forth are all stored together. This poses a great challenge to public agencies, namely that of establishing compatible common technical interfaces to permit interoperability among the agencies. Several e-government interoperability frameworks have been developed, however no *de facto* standard framework has yet been developed. It can be claimed that XML (and its variants) has arisen as a standard for document exchange among public organisations, and the metadata concept has also begun to be applied to link different public agency databases (Augsten et al., 2004). By the same token, where knowledge is stored by the civil servants in their systems, standards like UDDI and SOAP have been used to deploy Web services among public organisations (Klischewski, 2004).

Furthermore, security features need to be adopted in order to grant restricted access to the system by the civil servants. Although risk is not the same as trust (Nissenbaum, 2001), trust building in a digital environment depends heavily on the perception of risk by the users (Jarvenpaa, 1997), in this case the civil servants. Hence, digital certificates in addition to access controlled by password need to be installed by the public agency, in order to reflect the privileged access designated for each user.

Installing an excess of security features usually results in a lack of flexibility in the IOS and user resistance to its use (see, for instance, Joia, 2004). So, there is a trade-off to be negotiated, that is, the inter-organisational system must be perceived as being both safe and flexible by its users.

Organisational Setting

According to Davenport and Prusak (1998), an adequate organisational setting is necessary to enable the transfer of knowledge. In this respect, Pinchot and Pinchot (1993) point out that the Weberian model adopted for use in public administration can hinder the transfer of knowledge. Facets of bureaucratic organisations that hamper the knowledge transfer process include: a hierarchical chain of command, specialisation by function, uniform policies covering rights and duties, standardised procedures for each job, and so forth. Further, wariness, a lack of trust and a non-flexible organisational structure and reward system are at odds with knowledge transfer in an organisation, leading civil servants to hoard their knowledge.

Therefore, the following measures need to be adopted in public organisations in order to promote the knowledge transfer process:

- Creation of set times and places for knowledge transfer
- Creation of a common ground based on mutual trust

- Development of evaluation performance on the basis of transfer and sharing of knowledge
- Encouragement of a non-hierarchical approach to knowledge, where the quality of ideas are considered more important than the status of the owner

An organisational culture oriented to knowledge transfer must therefore be instilled in public administration. As stated by Joia (2004), purely taking the technological facets of the specific enterprise into account in a G2G knowledge transfer project, that is, disregarding the internal culture of the public agency involved, can lead G2G project managers to fail to grasp the specifics of a given endeavour. Although the public realm is governed by the same set of laws, as it has to comply with the same administrative procedures, each public agency has its own identity and specific culture, with its own values, codes, symbols, and so forth. Consequently, preliminary painstaking analysis of the different cultures of the organisations involved in a G2G project is of paramount importance.

Training

Davenport and Prusak (1998, p. 97) stress the fact that knowledge transfer can only be achieved if there is similar common ground between the sender and the receiver. Moreover, the authors point out that lack of absorptive capacity in recipients can hamper the knowledge transfer process. By the same token, Szulanski (1996) points to ignorance, lack of absorptive capacity and lack of interaction as the major hurdles to knowledge transfer.

Glazer (1998) stresses the pressing need to establish a theory of knowledge equity, so as to manage the knowledge transfer process adequately.

Although a G2G knowledge transfer system is usually developed with a user-friendly interface and based on well-known technology, G2G processes demand a new *modus operandi* that most of the staff in public agencies are not acquainted

with. Therefore, training strategies related to the use of the system are also necessary, in order to communicate the benefits of this new workflow. Moreover, specific training events that allow greater interaction among public agencies lead to a better understanding of the system, not to mention the possibility of upgrading it with feedback from the trainees. These training sessions are also important for disseminating and sharing the knowledge associated with processes involving public agencies, so as to make it possible to develop and implement better practices.

FUTURE TRENDS

Naturally, the potential benefits accrued from the implementation and use of G2G knowledge transfer initiatives hinge on the basic presupposition that qualified and skilled public administration personnel are on hand to deal with this new *modus operandi*.

According to Araya Dujisin (2004, p. 28), it is not so much the challenge of having external specialists hired by government, but the need to envisage permanent training policies addressing the different knowledge fields embedded in e-government, as well as ensuring the integration between them.

On the other hand, it is necessary to understand that e-government is far more than mere technology (Lau, 2004, p. 243). According to Biasiotti and Nannucci (2004), a mix of several disciplines must be created, encompassing not only information and communication technology and administrative science, but also social, human and legal sciences, among others.

Several endeavors are underway to train civil servants in e-government (Biasiotti & Nannucci, 2004). However, the training models are very much centered on the content and duration of the courses (Lau, 2004), avoiding classification of the civil servants into specific training groups, according to the current hierarchy, so as to deliver

different skills to different actors within the public administration arena.

Consequently, it becomes clear that there is a pressing need to link all the aspects involved in e-government training efforts into a single integrated framework, so as to allow capacity-building endeavors to achieve the outcomes sought by policy-makers.

Fountain (2001) highlights the importance of training public managers in e-government. Joia (2005), for his part, emphasises the need to train not only the public managers but also the civil servants and the ICT personnel in public administration on e-government issues, so as to avoid failures in e-government endeavours.

CONCLUSION

Responsiveness to G2G knowledge transfer processes can be far greater than that obtained in traditional processes and such agility is, in itself, of paramount importance in deploying more effective and efficient public policies. Clearly these processes represent a valid new tool for public administration, which in many countries is facing the dilemma of cutting back its operational budget to ease control of governmental fiscal deficit and comply with citizen expectations with respect to public agencies.

As demonstrated above, G2G knowledge transfer processes are a form of inter-organisational network. According to Fountain (2001), despite the rationales and determinants of networks it has been seen that relatively few organisational networks have succeeded in the business realm. Assuming this to be the case, one can imagine the hurdles that need to be overcome to deploy an inter-organisational system within the public arena, where the structures of incentives, rewards and risks operate in accordance with the Weberian model.

Undoubtedly, the implementation of a G2G knowledge transfer endeavour must be conducted

by taking the possible sources of user resistance into consideration. Therefore, it is important to survey the precise context in which the system will be implemented, in order to comprehend fully how the system can be perceived as being valid by the users. Powell et al. (1996) state that the perceived usefulness of the network can foster a strong and fundamental interest in access to knowledge rather than simply resource sharing, or transaction cost reduction.

In line with this rationale, users must be given both instrumental and conceptual training in e-government and the inter-organisational system in order to take full advantage of the new workflow.

The security issue in a G2G knowledge transfer process is a critical factor, since any breach of security can be highly prejudicial not only to public agencies but also to society as a whole. Therefore, a healthy balance must be found, as excessive security and preoccupations with redundancy can cause the system to become too inflexible to harmonise with the processes and culture of a public agency.

Furthermore, to fail to take the organisational culture of a public agency into account by concentrating efforts solely on a technological facet of a G2G knowledge transfer project may cause the undertaking to fail. Despite the fact that public administration is ruled by the same legal agenda and must comply with similar procedures and rules, each public agency has its own identity, values and culture, leading it to develop different workflows, sometimes totally at odds with workflows addressing a similar process in another public agency. Analysis of the culture and values of a public agency is of paramount importance to ensure the success of a G2G knowledge transfer undertaking. It is also important to understand the division of labour as well as establish what the main characteristics of power and politics within a public agency are. If this is not comprehended and factored in, a clash between the IOS and the organisation might arise, leading the IOS to be swiftly abandoned by the users.

Finally, in order to take advantage of knowledge repositories in their organisations, public administration will have to tackle the challenge of creating a technical common ground among its public agencies. Most of the problems that have occurred in G2G projects to date arise from a lack of interoperability among the public agencies. If this is already a problem in the business realm, one can imagine the huge obstacles public administration will need to overcome in order to create this common ground, due to several different legacy systems deployed over the course of time in its organisations.

All in all, this is a very recent knowledge field, which is why a great deal more research is needed. This chapter attempts to make a contribution in this very challenging area, in the hope that the results achieved may be of benefit to society worldwide.

KEY TERMS AND DEFINITIONS

E-Government: The various ways government uses information and communication

technologies to remain relevant in the knowledge society.

Government-to-Government (G2G): The digital-enabled collaboration and cooperation perspective among distinct government agencies.

Inter-Organisational Systems (IOS): Automated information systems shared by two or more organisations.

Knowledge Management: Techniques and tools for collecting, managing and disseminating knowledge within an organisation.

Metabusiness: A *quasi*-firm created through digital links among several companies, in such a way that it is almost impossible to know exactly its boundaries.

Metadata: Structured, encoded data that describe characteristics of information-bearing entities to aid in the identification, discovery, assessment, and management of the described entities.

SOAP: A protocol for exchanging XML-based messages over a computer network.

UDDI: An open industry initiative enabling businesses to publish service listings and discover each other and define how the services or software applications interact over the Internet.

Virtual Private Network (VPN): A private communications network usually used within a company, or by several different companies or organizations, to communicate over a public network.

XML: A recommended general-purpose markup language for creating special-purpose markup languages, capable of describing many different kinds of data.

Chapter 6.8

Policy Issues Regarding the Instructional and Educational Use of Videoconferencing

ABSTRACT

The purpose of this chapter is to identify policy issues for videoconferencing at the elementary through college levels. As videoconferencing becomes a part of our educational landscape in schools across the country, it is important to understand what policy implications need to be addressed in regards to this educational resource. Issues such as ownership, content, and access are some of the areas that suggest policy discussion. Federal, state, and international policies that guide the use of videoconferencing will be discussed. In sum, this chapter attempts to investigate policy issues and trends related to videoconferencing that informs the educational (PreK-12), business (training), and academic (higher education) communities that use this resource.

DOI: 10.4018/978-1-60960-503-2.ch608

INTRODUCTION

The use of the Web/Internet in classrooms has quickly evolved from an occasional resource to a mainstay in education. The trend is clearly evident in New York State's mandate that all public schools be equipped with Internet access. It also can be argued that all major universities in the United States now use and rely on Web resources for many of their educational needs (Bruce, Dowd, Eastburn, & D'Arcy, 2005). Web and Internet resources have revitalized interest in distance education in that they provide a cost-effective and rapid way in which to deliver quality education to a broad spectrum of students. In this respect, online education is quickly becoming a central component of higher education; more colleges and universities are now offering courses using this resource (Lewis, Snow, Farris, & Levin, 1999).

The recent explosion of distance learning technologies clearly demands greater attention from educational researchers and policy-makers if we are to develop a complete understanding of the limitations and possibilities of this innovation. If distance learning is to be viewed as a new venue for learning, rather than as a technology or tool, it is important to examine the new and exciting possibilities made available by new communications and computing technologies.

These possibilities include advancements in videoconferencing that allow classrooms to obtain real-time answers to their questions, to have close-up views of marine life hundreds of miles away, to interview authors of their favorite books, and to exchange ideas for a project with students from another country. Unlike other distance learning tools that have been known to lack interpersonal instructional support crucial for reflective learning (Nobel, 1998), videoconferencing allows for face-to-face interactive experiences that are not possible with e-mail, chats, or threaded discussions. Furthermore, current Internet-based connections have given schools a much more cost-efficient method for establishing videoconferencing, while expanding the possibilities for intellectual growth. Schools are able to take advantage of their pre-existing Internet connections, rather than having to purchase and maintain an ISDN telephone line, which can be prohibitively expensive for schools.

As videoconferencing becomes a part of our educational landscape in schools across the country, it is important to understand what policy implications need to be addressed in the implementation of this educational resource. Issues of ownership, content, presentation, and access are some of the areas that suggest policy discussion. Questions arise such as: Are there federal and international policies that guide the use of videoconferencing? Are there state regulations and policies that focus on videoconferencing? What do school district administrators, board members, and teachers need to be aware of when they create videoconferencing environments? This chapter proposes to identify

policy issues of videoconferencing instruction at the Pre-K through college levels.

BACKGROUND

Before our discussion of policy implications, in regards to videoconferencing, it is important to describe what we mean by videoconferencing, what the origins of videoconferencing are, and the history of videoconferencing. The term “videoconferencing” can be traced back to two Latin words, “videre” which means “I see” and “confere” which means to “bring together.”

Videoconferencing, which is a collection of technologies that form the foundation for a wide variety of applications, can be defined as being an exchange of digitized video images and sounds between conference participants at two or more separate sites (Wilcox, 2000). Videoconferencing allows people at two or more locations to see and hear each other at the same time, using a compressed video system to transmit information from one location to another (Packard Bell, 1995).

In the 1930's, Bell Laboratories gave the first public demonstration of two-way videoconferencing, which involved picture and sound between locations in New York City (Montagna & Carlton, 1998; Wilcox, 2000). In the 1930's as well, Europe began experimenting with the technology, but due to World War II, the technology was not further developed for almost two decades. In 1964, Bell Laboratories introduced the first picture phone at the World's Fair in New York City. The first videoconferencing systems developed by Bell Laboratories failed in part because of poor picture quality and the lack of efficient video compression techniques. In 1970, videoconferencing capabilities were offered to consumers for the cost of \$160.00 a month, but the new innovation proved to be too costly for most consumers. Improvement of the technology needed to take place, along with affordability. This led other companies to improve upon the technology in the

1970's (Wilkerson, 2004). After many setbacks of videoconferencing, mainly due to the lack of quality in the technology, the medium finally arrived in the 1980's as a learning tool, particularly in medicine in the form of tele-lectures (Cannavina, Stokes, & Cannavina, 2004).

In general, videoconferencing has three distinct characteristics that separate it from other types of instruction: its capacity to reach large numbers of distant and dispersed learners, the ability for learners and presenters to interact, and its emphasis on the visual components of learning. In common practice, participants on either end need only a camera, a monitor, a microphone, and speakers, equipment to which most schools already have access. Additional requirements may include access to an information technology specialist to troubleshoot any problems that may occur. In addition to the organizational concerns of a normal classroom (such as the topic to be covered, instructional goals, and assessment), videoconferencing requires a specific amount of planning. For example, although it may seem obvious, it is important to schedule when and for how long the videoconference will be, a process that must be confirmed at both ends. If at all possible, test runs should be performed prior to use to ensure a connection, thereby limiting frustration and difficulties during the videoconference.

Overall, videoconferences can have a broad range of benefits. First of all, it is the closest thing to actually being there without leaving the classroom. Videoconferencing allows interaction to occur between students and instructors, and this enhances understanding not capable through e-mail, telephone, or online chats. Other noted benefits include heightened motivation, improved communication and presentation skills, increased connections to the outside world, and an increase in the depth of content knowledge. Clearly, videoconferencing provides a novel approach to instruction that excites students, thereby allowing them to form meaningful relationships with

others, while encouraging them to ask questions and demonstrate more depth of understanding.

Policy-Makers

As policy-makers define issues for videoconferencing and distance learning, it is essential that they understand the elements that are involved in this environment. A key element is the role of the teacher and the impact that they play on policy decisions. Policy-makers must understand the process, pedagogy, and classroom management expectations of teachers (in videoconferencing environments) to insure that they have the breadth of knowledge to make an informed policy decision. Board members will be asked to make decisions about technology, distance learning, or video distance learning, and base their conclusions on old and outdated concepts of instruction, teaching, learning, and integration of technology. Policy-makers must be reeducated to the new standards of teaching and learning in the technological classroom. Our goal in this discussion is to raise the concern and offer suggestions to policy-makers as they prepare to meet the challenge of policy determination for videoconferencing.

Teachers' Roles in Videoconferencing

Teachers also need to understand the person, the spirit of every child, and find a way to nurture that spirit. And they need the skills to construct and manage classroom activities effectively, communicate well, use technology, and reflect on their practice to learn from and improve it continually. The importance of powerful teaching is increasingly important in contemporary society. Standards for learning are now higher than they have ever been before, as citizens and workers need greater knowledge and skill to survive and succeed. Teachers need not only to be able to keep order and provide useful information to students, but also to be increasingly effective in enabling

a diverse group of students to learn ever more complex material (Darling-Hammond, 2006).

For teachers to reach these goals, we need to insure that policies are in place to support the appropriate deployment of videoconferencing in our schools, while recognizing that these policies are shaped at the local, state, national, and global level. The use of this rich media in classrooms is on the edge of a broad-based discussion of who creates, controls, and distributes the content. Educators would be mistaken not to understand the political forces and why it is important to participate in the dialogue on the policies that are being framed as this process evolves.

Policy Trends Facing Videoconferencing

Videoconferencing has been used in the educational arena since the mid 1980's (Smith, 2003). Because of the capabilities of this ever-expanding technology, some educational institutions have implemented policies that govern its use. Most K-12 schools, as well as colleges and universities, have developed policies that are not stand-alone policies, but have been included in computer technology use regulations or guidelines. The policies that most schools have adopted are generic. They usually include information such as: services offered; acceptable/unacceptable use; the person to contact for scheduling; hours of operation; available equipment; set up and technical support for the equipment; rates; terms of use; ramifications for violating the use of the technology; and responsibility of the user.

Specific information regarding videoconferencing policies can be garnered from policies such as the Child Internet Protection Act (CIPA), which was signed into law in 2000. This law required schools and libraries to operate "a technology protection measure with respect to any of its computers with Internet access that protects against access through such computers, visual depictions that are obscene, child pornography,

or any material that is harmful to minors," and that such a technology protection measure be employed "during any use of such computers by minors" (Wikipedia, 2006). CIPA requires filtering on computers that are used by minors. Because some videoconferencing systems use a broadband connection, it is important to make sure that videoconferencing systems are used for connectivity only and are not used for accessing the Internet (North Dakota State Government, 2005).

Whereas some policies specify use and tacit agreements among and between users, most regarding videoconferencing are merely informal agreements regarding the responsibility of those who use the technology (DeFord & Dimock, 2002). Policies are needed in many states and institutions that address the variety of legal and other responsibilities borne by states, regions, districts, and schools when offering videoconferencing opportunities to students. Because most educational institutions have generic and often limited information regarding the use of videoconferencing in the school setting, a national policy or template that schools can follow will be needed, which governs the use of videoconferencing in the educational setting. Additionally, most institutional policies were developed many years ago and need to be revised to reflect the changing conditions (United States Senate, 1999). Whereas videoconferencing is a technology, its uses are much more complex; hence, it requires stand-alone policies. Because this technology is being used in K-12 schools, and colleges and universities at an increasing rate, it is important to develop separate policies that will help to define how the technology is and should be used in the classroom setting.

In an attempt to facilitate this process, we have identified a group of current policy issues that must be addressed by developers, end users, teachers, college faculty, researchers, and content creators. These issues range from very personal concerns to international implications that will impact Internet visions and usage in the future.

In this section, we will move from the personal to the global issues that face videoconferencing.

Intellectual Property: Personal

The World Intellectual Property Organization (WIPO) defines intellectual property as the creations of the mind: inventions, literary and artistic works, and symbols, names, images, and designs used in commerce.

Intellectual property is divided into two categories: industrial property, which includes inventions (patents), trademarks, industrial designs, and geographic indications of source; and copyrights, which includes literary and artistic works such as novels, poems, and plays, films, musical works, artistic works such as drawings, paintings, photographs, and sculptures, and architectural designs. Rights related to copyrights include those of performing artists in their performances, producers of phonograms in their recordings, and those of broadcasters in their radio and television programs (World Intellectual Property Organization, 2006)

Intellectual property and ownership of content material concerns are probably the main issues that must be addressed in developing content for videoconferencing. Issues of intellectual property and ownership will grow in importance, as teachers and educators create more content material with videoconferencing and other resources (Web sites, books, novels, video production, pod-casting, and lesson plans). When teachers create curricula, lesson plans, and content material for videoconferencing courses, workshops, or seminars, intellectual property and ownership have to be taken into consideration. Does a content developer have exclusive rights or ownership over the teacher's material? Does ownership have to be shared with the district, company, or other entities that owns, leases, or represents ownership of the videoconferencing equipment or network that the content is sent or delivered over? What type of contract has to be developed, and how long should it last? Can the developer take their content and use it

with another videoconference network, school, or business situation?

Many educational institutions have developed policies that were designed to recognize a faculty member's intellectual property rights in the courses that they develop and teach. But these institutions have not kept pace with the changing technologies or laws that govern their use. General terms of these agreements typically specify whether or not the university may continue to offer the course if the faculty member who wrote it no longer wishes to teach it, retires, or resigns; the agreement specifies how the net income resulting from sale or license of the course materials will be divided among the owners (United States Senate, 1999).

Copyright ownership is a very complex issue when it comes to videoconferencing and because of this, the educational community believes that a change in the law is required to optimize the quality and forms of distance education that take full advantage of today's technological capabilities (United States Senate, 1999). Discussions with videoconference service providers, schools, businesses, and colleges should be established to identify their policy on these issues. A written agreement that is satisfactory to all parties involved should be developed and signed. Individual knowledge of intellectual property and ownership protects an individual, an individual's work, and the time spent developing content material for videoconferencing.

Accountability: Building/Local Level

The teacher's role in the classroom, as technology is integrated into the classroom setting, is changing from the "sage on the stage" to a "guide on the side." This constructivist notion follows in the development of the "student-centered learning classroom environment" where the focus is on student learning. As the teacher in a videoconferencing classroom or environment starts to plan their instruction, there are many aspects

that have to be considered before actual course implementation can begin.

Teachers are expected to be “content-knowledgeable” and ready to provide information resources that support classroom instruction in their content area. But what content-level knowledge is needed to integrate videoconferencing? Is an information technology specialist degree required? It is suggested that teachers and/or instructors who teach in videoconferencing environments must be knowledgeable and comfortable with their subject area (English, math, science, history, and other content areas). A strong case can be made that teachers should be certified in the subject area that they are videoconferencing. Content material, lesson plans, Web sites, and resource material all exist on the Internet that can supplement and support classroom instruction. Many times, students can locate electronic or digital content quickly, but they do not have the skills to determine if the information is authentic. The teacher provides that support and instructs the student on how to evaluate the information that they gather from the Internet. The teacher must become a “facilitator of information” that can recommend, evaluate, and create content resources for students and other teachers.

Once content issues are defined, accountability concerns on the part of the instructors can be addressed. How do we address accountability concerns when implementing videoconferencing in the classroom? Numerous state education departments have established educational standards, by content areas, for their K-12 students and mandate that teachers incorporate these standards into their curriculum materials and lesson plans. As such, the performance indicators that are associated with each standard should also be integrated with videoconferencing activities to insure that the content supports student learning and achievement.

Educators also should consider student diversity, including ethnicity and gender, when developing curriculum or lesson plans for a

course. In an electronic videoconference environment, it can be a real challenge to get to know the history and culture of the students who may be in your courses. When using constructivist learning techniques, knowledge of your students is an important factor in the developmental process of supporting instruction of all students in your course. Requesting biographic information about students can assist in learning about the background of each student. Learning about a student’s culture also may provide information that will help in adapting course material.

E-Rate: National

The Telecommunications Act of 1996 required that elementary and secondary schools and libraries be offered discounted access to telecommunications for educational purposes (Federal Communications Commission, 1996).

The Schools and Libraries Program of the Universal Service Fund, commonly known as “E-Rate,” is administered by the Universal Service Administrative Company (USAC) under the direction of the Federal Communications Commission (FCC), and provides discounts to assist most schools and libraries in the United States to obtain affordable telecommunications and Internet access. It is one of four support programs funded through a universal service fee charged to companies that provide interstate and/or international telecommunications services (Federal Communications Commission, 2004).

The Schools and Libraries Program supports connectivity, the conduit or pipeline for communications using telecommunications services and/or the Internet. Funding is requested under four categories of service: telecommunications services, Internet access, internal connections, and basic maintenance of internal connections. Discounts for support depend on the level of poverty and the urban/rural status of the population which is served, and range from 20% to 90% of the costs of eligible services. Eligible schools, school

districts, and libraries may apply individually or as part of a consortium. Each year funding is capped at \$2.25 billion and unused fund balances can be rolled over to the following years. Annual requests for E-rate funding far exceed the monies available (Federal Communications Commission, 2004; Federal Legislation and Education in New York State, 2006).

The FCC, in 2004, determined that the E-rate program should be subject to the Anti-Deficiency Act. The Anti-Deficiency Act prohibits committing funds not actually accrued, so E-rate could not make funding commitments to school districts and libraries for the upcoming fiscal year. Late in 2005, Congress temporarily exempted E-rate from the Anti-Deficiency Act until December 31, 2007. Without continued, uninterrupted E-rate funding, schools and libraries, especially in rural and low-income areas, would not be able to install the technology that students, educators, and library users need to access critical information. Without this exemption, the program could once again be unnecessarily disrupted, causing schools and libraries to delay or eliminate education technology needs (The New York State Education Department, 2006). As educators who utilize these funds to support our work in videoconferencing, we must contact district and legislative officials and share our concerns about E-rate.

Universal Service: National

In the Communications Act of 1934, Congress established a national policy of universal service that went beyond merely laying the wires and infrastructure to connect each to all. It included a commitment to making service economically accessible to all Americans.

The Federal Communications Commission (FCC) was created at this time for the purpose of regulating interstate and foreign commerce in communication by wire and radio, so as to make available, so far as possible, to all of the people of the United States, a rapid, efficient, nationwide,

and worldwide wire and radio communications service with adequate facilities at reasonable charges (Thomson/West, 1997). Today, Congress has not only reaffirmed the central importance of universal service in telecommunications, but it has vastly expanded the concept.

Section 254 of the Telecommunications Act of 1996 significantly expands the concept of universal service (Federal Communications Commission, 1996):

1. The FCC is charged with assuring that all rates for universal service are just, reasonable, and affordable, not just the rates for interstate services.
2. The word “affordable” had not been used before this legislation, but the 1996 Act introduces the concept of affordability directly and explicitly into national policy.
3. The 1996 Act expands the services to which the universal service concept applies and institutes a formal process for expanding the definition of universal service over time.
4. Although access to the network for high-cost areas and low-income consumers has been supported for years, the 1996 Act explicitly requires this policy and requires that it be implemented with specific and predictable mechanisms, in the form of contributions from all providers of telecommunications services, to support universal service.
5. A whole new range of institutions has been identified as having a role in universal service policy.
6. Section 255 also adds a commitment to consumers with disabilities.

Cooper (1996) and Mueller (1993) provided the resources for this section, and their work supports the importance of this area. This is important because of the focus on the “last mile” of connectivity, where the homes of the users are reached. We are requesting a move from telephone access and service to the provision of broadband

services to the communities that need services. Regular telephone service that is supported by universal service at this time does not support the new forms of information (digital text, digital audio, digital images, videoconferencing, and interactive video) that is being passed across the present networks and telecommunications infrastructure. Universal service must keep pace with the information resources that are provided to all people presently in the United States and around the world. Currently, universal service continues the digital divide by not providing broadband capability to all users.

Cyber Security: International

We must determine how videoconferencing will impact national issues of cyber security. Are our networks secure, and do we provide information that may put our nation and end users (students and teachers) at risk? How do we protect our K-12 population and teachers from growing concerns about child pornography, identity theft, and plagiarism? The potential uses of videoconferencing can offer other opportunities where cyber security issues become equally important. These issues include: the use of e-mail and instant messaging to communicate off-line when courses or seminars are not in session, and using Web resources (e.g., Web sites, Web quests, wikis, and blogs) to support instruction. The point here is that as content developers use videoconferencing resources, we have to address cyber security issues because we are using one of the most powerful education media tools: interactive television.

Two legislative acts, the Deleting Online Predators Act (DOPA) and the SAFER NET Act have been introduced in the U.S. House of Representatives in 2007.

Deleting the Online Predators Act of 2/16/07 amends the Communications Act of 1934 to require schools and libraries that receive universal service support to enforce a policy that:

- Prohibits access to a commercial social networking website or chat room unless used for an educational purpose with adult supervision
- Protects against access to visual depictions that are obscene, child pornography, or harmful to minors
- Allows an administrator, supervisor, or other authorized person to disable such a technology protection measure during use by an adult, or by minors with adult supervision, to enable access for educational purposes
- Directs the Federal Communications Commission (FCC) to issue a consumer alert regarding the use of the Internet by child predators and potential dangers to children because of such use, including the potential dangers of commercial social networking websites and chat rooms
- Establishes a website resource of information for parents, teachers, school administrators, and others regarding potential dangers posed by the use of the Internet by children.

There is no companion Senate bill at the present time. (Representative Kirk Mark Stevens, [IL-10] 2007).

The Safeguarding America's Families by Enhancing and Reorganizing New and Efficient Technologies Act of 2/13/07 (SAFER NET) requires the Federal Trade Commission (FTC) to establish an office of Internet safety and public awareness, headed by a director. The office will carry out a nationwide program to increase public awareness and education regarding Internet safety, that utilizes existing resources and efforts of all levels of government and other appropriate entities and that includes:

- Evaluating and improving the efficiency of Internet safety efforts provided by such entities

- Identifying and promoting best practices
- Establishing and carrying out a national outreach and education campaign
- Serving as the primary contact in the federal government and as a national clearing-house for Internet safety information
- Facilitating access to, and the exchange of, such information
- Providing expert advice to the FTC
- Providing technical, financial, and other appropriate assistance to such entities

There is no companion bill in the Senate (Representative Melissa L. Bean, [IL-8] 2007).

Reauthorization of the Telecommunications Act of 1996

Our greatest concern at this point is net neutrality. Ben Worthen's (2006) article, *The Net Neutrality Debate: You Pay, You Play?*, provides an excellent backdrop for this discussion. Worthen (2006) provides a scenario and definition that informs the reader about this situation:

Last April, Cisco Systems published a white paper explaining how the companies that own the phone lines and cables that connect homes and businesses to the Internet, the proverbial last mile, could use new routing technology to boost revenue. The technology would allow telephone and cable companies to establish priority lanes for high-bandwidth traffic like video, games, or voice-over-IP (VoIP) calls and then charge the Googles, Yahoos, and Amazons of the world for access to these highway toll roads. Cisco's paper predicted that this new strategy would allow broadband service providers to create new revenue-sharing business models with any company that sells content online. The plan had only one problem: It was illegal.

Worthen continues the discussion by providing background and definition about net neutrality. He

states that the telecommunications laws that have governed the Internet since its inception require network owners to treat all traffic the same. The laws date back to the 1930's, and were put in place to force telephone companies to prevent a scenario where one company could refuse to carry calls placed by a rival's customer. The Internet was designed with the same principle in mind. Routers are programmed to direct each packet of data on a best-effort basis, regardless of file type, video, voice, e-mail, or who the sender and recipient are. The bill was not finalized in the summer of 2006 and is still under review and discussion in both houses of the United States Congress.

Since then, a Supreme Court ruling and a series of Federal Communications Commission (FCC) decisions have eliminated this barrier, prompting Congress to rewrite the nation's telecommunications laws. The result is that the entire Internet is now essentially outside the law. The new bill, which could be finalized as early as the summer of 2006, will in all likelihood officially eliminate net neutrality as the legal principle that governs the Internet. "If net neutrality goes away, it will fundamentally change everything about the Internet," says James Hilton, associate provost for Academic IT Works of the University of Michigan. More bluntly, Steve Effros, former president of the Cable Television Association, says, "This is about who pays." Worthen (2006) observes, "the competition that emerged in the telecommunications industry is between cable and telephone companies, and the service they are vying to provide is not just phone, but high-speed Internet access and television as well—the so-called triple play." This is the most serious event and challenge that we as educators, content providers, and end users are facing today, and will have a direct impact on how our educational information will be used in the future. In the past, our videoconference information was available to everyone who had access to the equipment and enough bandwidth to receive the conference. The potential exists that the telephone and cable companies will regulate

the freedom of access that we currently have and the amount that we will pay to use their networks.

REAUTHORIZATION OF THE NO CHILD LEFT BEHIND ACT OF 2001 (NCLB)

The No Child Left Behind Act of 2001 is being reauthorized and the Achievement through Technology and Innovation (ATTAIN) Act was introduced by a group of bipartisan legislators in the U.S. House of Representatives on May 23, 2007. The ATTAIN Act is designed to make improvements to the Enhancing Education through Technology (EETT) (Title II-D) program. The ATTAIN Act focuses on priority funding for schools in need of improvement, state assessment of technology literacy of students by eighth grade, systemic reform programs with strong technology components, and professional development (Roybal-Allard, 2007). The Act has the support of several education organizations including: Consortium for School Networking (CoSN), International Society for Technology in Education (ITE), State Educational Technology Directors Association (SETDA), National Education Association (NEA), National School Boards Association, American Association of School Administrators, and the Nation Council of La Raza (Jones, 2007). There is hope that similar legislation will be sent to the Senate in the near future. Advocates for the ATTAIN Act are working diligently to have this Act included in the larger NCLB reauthorization bill the House Education and Labor Committee will present later. Overall reauthorization of NCLB is not clear at this time.

FUTURE TRENDS

Videoconferencing has recently gained much wider acceptance as an instructional tool in the academic community (Fels & Weiss, 2001).

Because of its increased use for instruction in the classroom setting, the ways in which to use this technology is increasing as well. The world of videoconferencing is continuously changing everyday to reflect the ever-changing educational landscape in the United States schools, colleges, and universities.

One reason for the change in educational institutions is the increase of students in classrooms, specifically in schools that serve students in grades 9-12. It is expected by 2009 that the United States will graduate its largest high school class, and college enrollment will increase by 16 percent over the next ten years as well (Howell et al., 2003). As the enrollment of students in high schools and colleges expands, the need for video conferencing will increase. As the size of enrollment changes in colleges and universities, the needs of students will change as well. Students today are seeking educational institutions that meet their needs in regards to schedules and circumstances. Videoconferencing and distance learning are helping to meet the needs of those students who need flexibility when it comes to receiving an education.

The future uses of videoconferencing in the educational setting are many. For example, videoconferencing today in the educational arena involves the educator delivering a lecture or presentation to an audience. Videoconferencing in the future will become a full interactive experience, where the audience can play a role in the discussion, be seen, heard, and even share their own documents (Good, 2003). As such, visual and audio cues will help the instructor and students with developing a rapport (Galloway, Boland, & Benesova, 2002).

Furthermore, educational organizations and institutions can, and commonly do, limit access of materials to students enrolled in a particular class or institution. Additional technology and software will be required to address the multitude of intellectual property, ownership, and copyright concerns. The most effective means now available are secure container/proprietary viewer technolo-

gies that allow copyright owners to set rules for the use of their works, which are then attached to all digital copies, and prevent anyone from making a copy that is not in accordance with the rules. For example, students could be allowed to view the work or print a single copy, but not save it to disk or distribute it to others electronically. Streaming formats also will be used because they do not facilitate the making of copies as does the use of low-resolution digital copies (United States Senate, 1999).

The tools for videoconferencing will change as well in the future. Videoconferencing will no longer be stand-alone tools. A person will be able to go to a computer, select who to invite to a meeting, and then start a meeting. There will not be a need to upload materials ahead of time or convert them. Loading the materials onto your screen and sharing them with one click will be all that is needed (Good, 2003).

Another way in which this technology will be used in the future is to support students who will not be able to attend school. For example, students who may be in the hospital for an extended period of time or home convalescing from an illness will be able to participate in a lesson at their school from the hospital or their home. This will enable the student to keep their schoolwork current and not fall behind in their studies (Arnold, Cayley, & Griffith, 2003).

Videoconferencing and other technologies help to enrich distance media and provide many benefits of face-to-face instruction. Technology fluency is becoming a graduation requirement. Many colleges and universities are requiring students to complete at least one online course before graduation. More and more colleges and universities are offering coursework through distance learning (Howell et. al., 2003).

The integration of videoconferencing with other technologies such as video streaming and chat will be used as more schools move to Internet protocol (IP) environment for videoconferencing. The use of IP-based conferencing will increase

the number of systems available in the school setting. Futuristically, every computer will have conferencing capability (Arnold et al., 2003). Videoconferencing also will have the capability to be integrated with content management tools, such as: presentation software, video and audio editing, and interactive white boards. The simultaneous use of these technologies will enable more people to take part in a conference by watching it live and feeding back responses via other media such as e-mail (Arnold et al., 2003; JKC, 2006). New ways in which to use videoconferencing for educational purposes are being developed. A recent development is to incorporate videoconferencing into Web-based systems. Web-based systems using streaming video multicasting are now reaching the educational arena. With these systems, educators can sit in their own office or other location and present a live lecture in front of a camera attached to a Web server. With the use of a simple switching device, the educator can provide remote participants with graphics, whiteboard, flipcharts, and other visual aids as well as alternative views of the classroom or lecture room. Video streaming in this manner also will be used to archive recordings of videoconferences and make these available via the Internet, possibly packaged with other teaching resources (Arnold et al., 2003; JKC, 2006; Plymouth, 2006).

Mobile videoconferencing, which is still in its infancy, will enable a user to conference while on the move using portable devices. Mobile videoconferencing also will help to increase the awareness of and interest in desktop-based videoconferencing. Mobile conferencing has the ability to change the entire landscape of the videoconferencing market, and the prospects for growth is tremendous (JKC, 2006; National Informatics Centre, 2006).

Lastly, technological advances will allow the user to manipulate video images, such as moving one image with another and overlapping different images to provide a continuous picture appearance. Frame-by-frame manipulation also will be avail-

able, and will enable the user to print still pictures, rewind to a particular frame, interleave frames, and synchronize frames. Because videoconferencing systems are becoming less expensive, multiple participants will be able to videoconference with other participants in the conference simultaneously (National Informatics Centre, 2006). The use of videoconferencing in the academic community will soon become a regular part of teaching. This technology will be useful for a variety of activities by teachers and students alike. Videoconferencing is changing the way in which we communicate with each other, much like the telephone did when it was first invented. Videoconferencing is continuously growing and changing the educational arena and, more importantly, videoconferencing is here to stay (JKC, 2006).

CONCLUSION

Our research on policy issues regarding videoconferencing has led us to several issues that we have identified and discussed. The conversation is not over, however; there is a need for more sharing of thoughts on the development and deployment of policy decisions about videoconferencing. The major limitation of the above discussion is the lack of informed data and research focusing specifically on videoconferencing. In most areas, policy research has focused on technology integration in general and is not specifically focused or targeted at videoconferencing. It is our hope that we have provided a strong case to document the importance of further research into videoconferencing-based learning policy issues. There is a need for research regarding policies for videoconferencing that can be shared to inform policy-makers about important issues around this topic. Should our research interest focus on higher education, cultural education (libraries and museums), and pre-K-12 uses of videoconferencing individually? And what collaborations may evolve that relate to policy issues?

The goal of our discussion was to provide policy guidance and leadership for users of videoconferencing. Our findings promote the use of videoconferencing across the Pre-K-16 spectrum to support program development and create a larger research base. This larger base expands the concerns about policy issues for videoconferencing and the discussion about new policies that need to be addressed in the future. Concerns such as cyber security issues, protection of access, and content are critical points that policy-makers must address. Is there a need to monitor, assess, and regulate content? These questions will certainly raise concerns about intellectual property issues for faculty and others that produce videoconferencing course material and teach classes. More importantly, could policy-makers develop policy that protects content development?

Videoconferencing provides great instructional opportunities to students and teachers in urban and rural communities, because it provides access to instructional material that may not be available. Many school districts use videoconferencing to enhance instruction and provide additional shared resources to classes, library, and administrative activities. Having an understanding of the policy issues and concerns associated with videoconferencing strengthens the opportunities and reduces the challenges to provide the best instruction possible in this environment. Whether there is a need for policy or just regulatory statutes to be in place for videoconferencing is an area for further research and discussion. We believe that both should be in place and that policy issues should be discussed, planned, and developed. State education boards, business council organizations, and state offices of technology should be working together at the state level. At the federal level, we should look for collaborative support from the Department of Education, Department of Commerce, and the Federal Communication Commission to manage and monitor videoconferencing policies. Furthermore, we support the call for a national

clearinghouse on videoconferencing that provides information, best practices, and policy decisions.

DEDICATION

The authors of this chapter would like to dedicate it to Mrs. Violetta Bowman, Mr. Joseph Bowman, and Mia Felice Fernandez.

ABSTRACT

Using technology tools in math instruction can help stimulate problem-solving skills and understanding of math concepts. However, teachers need to be confident in their abilities to use technology tools. This study investigated whether or not a four-week in-service professional development institute that addressed the use of technology in

math education helped improved the teachers' attitude and confidence in applying technology. Findings indicated that as the teachers explored and used the available technology tools relevant to math instruction during the institute, the more proactive and motivated they became to continue their professional development in using technology for classroom instruction. They realized that they were able to use technology and desired to continue their education in this area.

DOI: 10.4018/978-1-60960-503-2.ch609

INTRODUCTION

Technology is a tool that could be used in the mathematics classroom to enhance learning (NCTM, 2000). There are many forms of technology that can assist in teaching mathematics, supplement instruction, and remediate mathematical skills that require reinforcement. Tools such as spreadsheets, databases, educational software programs, drill-and-skills programs, scientific calculators, interactive whiteboards, and other applications are appropriate methods to teach mathematical concepts. The problem lies in that some teachers do not know how to use the technology tools or feel that they possess the ability to integrate technology effectively. Hence, teachers need to obtain the knowledge and skills that would help improve their self-confidence in using the technology at hand (ISTE, 2008). Mitchem, Wells, and Wells (2003) state that, "Research on schools and teaching has suggested for decades that student success and achievement are intricately associated with students' interactions with effective teachers" (p. 1). If this is true, then mathematics teachers are the key agents to bringing out reform toward technology integration (Garofalo, Drier, Harper, & Timmerman, 2000). But, the way to effectively prepare teachers to become change agents is another issue. Professional development is a primary factor toward helping teachers become self-adept in learning the knowledge and skills required of them when teaching math content. This study investigates whether professional development could promote math education teachers' self-confidence in using and applying the technology tools learned back to the classroom. In-service teachers participating in a Math Summer Institute are the participants in this particular study, and the researchers explore whether completing a four-week intensive professional development institute has improved the participants' knowledge, skill sets, attitude, and self-confidence in applying what they have learned.

Literature Review

The effective preparation of teachers to teach mathematics in K-12 education is recognized as a vital factor toward students' academic success. In conjunction with the curriculum, teachers are the key in assisting students to learn required information necessary to succeed in the mathematics curriculum (Schmidt et al., 2001). Several professional organizations note the importance of teacher preparation and professional development as a means toward improving the aptitudes of math education teachers, especially in regards to technology integration. The National Council of Teachers of Mathematics (2000) considers technology as being essential "in teaching and learning mathematics; it influences the way mathematics that is taught and enhances students' learning" (p. 2) as one of their six principles of school mathematics. Furthermore, the Association of Mathematics Teacher Educators (2006) goals includes one to promote the recognition of the ever-increasing impact of technology on mathematics teacher education and has made a position statement on the importance of preparing math teachers to meet the current standards of integrating technology. If one reviews the Association of Mathematics Teacher Educators newsletter called *Connections* (2008), the content solely concentrates around technology and why these tools should be utilized in the math classroom. If organizations such as these recognize the importance of technology, then teacher preparation and professional development need to include a demonstration that goes beyond just the "how to use technology," but how to integrate.

Reasons behind using technology in the mathematics curriculum are numerous. Heid (1997) cites that technology when used in conjunction to teaching math could (a) make learning more student-centered, (b) give students the experience of being mathematicians themselves, (c) provide an avenue for reflection, and (d) make available constant access to the instruction, meaning that the instruction is no longer restricted when the

teacher teaches. Contextual learning in constructive environments is critical when applying technology in math education. Students need to apply learning in novel and authentic situations so that they can practice skills, knowledge, and decision-making, while experiencing the implications or repercussions of certain decisions (Dyer, Reed, & Berry, 2006). Constructive or contextual learning environments actively engages the students as they (a) relate learning to one's life experience, (b) experience and learn by doing or through exploration and discovery, (c) applying the concepts to actual scenarios, (d) cooperate with others in terms of sharing, responding, and communicating with others, and (e) transfer the knowledge to a new context or novel situation that has not been covered in the classroom (Crawford, 2001). In short, technology in math education provides students with an opportunity to explore, reflect, and discover the consequences of learning math concepts.

The issue toward successful implementation of technology in math education is professional development. A large body of literature cites that the major obstacle toward teachers using technology in the classroom is the lack of proper teaching training (VanFossen, 1999; Veen, 1993; Whetstone & Carr-Chellman, 2001; Wild, 1996). Teachers today are often behind in meeting current challenges of the rapid expansion of technology in education. Many technology tools are available to teachers, but the application of these tools to teach content areas can be foreboding, especially when training is not present. Other studies on the effectiveness of teaching technology in pre-service and in-service courses reveal some positive results such as the participants improving their likelihood to use technology in the classroom and altering their perspectives toward technology as an obstacle (Lee & Hollebrands, 2008). Although some studies indicated that certain technology tools are more likely to be used than others, an introduction to technology in math education is important (Franz, Pope, & Fredrick, 2005). Thus, professional

development is critical when expecting teachers to use technology in the math classroom. With more practice, teachers' self-assurance increases.

Problem Overview

Educators in math education should integrate technology tools as a means to assist students to learn mathematical concepts and principles. Technology can become an interactive supplement to the standard form of math instruction through paper-and-pencil methods to stimulate higher order problem-solving skills in novel situations. In addition, technology is a tool that could be applied in classrooms to assist students with diverse needs and learning styles to approach math and problem-solving scenarios more effectively (Kurz, Middleton, & Yanik, 2005). Students are not a homogeneous group of individuals in which everyone learns at the same pace and in the same method. Hence, math instruction should be individualized to cater diverse learning styles. One classroom teacher cannot design and develop personalized math curricula for thirty-three distinct students. But, the teacher could use different instructional tools and strategies that could accommodate individual learning characteristics (Cohen, 2001). With the availability of technology in schools, homes, libraries, and other public spaces, using technology as instructional tools to teach mathematical concepts and problem-solving skills seems to be the logical approach. However, the teacher is the central cornerstone toward successful implementation and integration of technology. The teacher is the one who selects and evaluates which technology tool to use at specific times. Without access and knowledge concerning technology hardware and software, successful integration of technology will not occur. In addition, not only do classroom math teachers need constant instruction and assistance in using various hardware and software application tools, personal self-aptitude and esteem are also essential criteria toward effective integration.

The teacher has to know what he/she is doing in the classroom, along with embracing a positive outlook toward using technology as a means to instruct math. Thus, attitude and confidence are key criteria when trying to integrate technology into the mathematics curriculum.

For teachers who are currently in the classroom, in-service professional development conducted during the summer is a way in which they can obtain instruction concerning available technology tools. In addition, these in-service institutes can provide teachers with practice in using and adapting technology into their curriculum. The goal of these in-service institutes is to foster a positive reinforcement on part of the teacher's ability to take the knowledge back to the classroom. The researchers in this study were involved in such an in-service Summer Math Institute to help teachers in the surrounding area to learn, explore, utilize, and practice different technology tools that could be applied to math instruction. The researchers wanted the participating teachers to understand that alternative instructional tools were available that could be successfully utilized in the math curriculum. Improving the participating teachers' self-confidence was a primary objective of the in-service math institute.

This study tried to assess whether participating in a four-week Summer Math Institute concerning the integration of technology into the math curriculum helped improve teachers' skills, knowledge, ability, and willingness to apply what they learned. To examine this research problem, four research questions were investigated:

1. Does participating in an in-service training session concerning technology integration into math instruction help teachers learn how to apply and use their knowledge and skills in the classroom (RQ1)?
2. Does participating in an in-service training session concerning technology integration into math instruction help develop teachers' interest in using technology and self-confidence to apply what has been learned (RQ2)?
3. Do teachers who complete a technology-oriented in-service training session focus more on learning to use the technology during the professional development, as opposed to applying the technology in teaching (RQ3)?
4. Do teachers who complete a technology in-service training session have a more positive attitude and outlook toward technology after completing the professional development (RQ4)?

Methodology

Participants

Participants for the research study involved public school mathematics teachers in grades 5 – 8 from South Mississippi. A total of 75 teachers (24 in 2005, 24 in 2006, and 27 in 2008) participated in the Summer Math Institute. Between five to nine high-needs schools were represented each year (5 of 9 in 2005, 9 of 12 in 2006, and 5 of 12 in 2008). In this case, high-needs schools were those that served not less than 20 percent of the children from families with incomes below the poverty line. The vast majority (80%) of the teachers had more than 3 years of teaching experience; 12% had over 25 years. The Institute provided four-weeks of professional development on the integration of technology into math instruction including: strategies involving the scientific graphing calculator, Microsoft PowerPoint, Microsoft Excel, MS Paint, MathType Equation Editor, and the Internet. Instruction occurred in a computer lab equipped with an interactive whiteboard and enough computers for each teacher to work individually. Each teacher was provided a USB flash drive and TI graphing calculator to use during the institute and for classroom instruction.

Instrumentation

Methods of data collection for this study involved teachers completing a pre- and post-survey and completing a weekly reflection instrument. An instrument for the in-service institute derived from The Concerns-Based Adoption Model was developed by the researchers (Hall & Loucks, 1979). The model describes a hypothesized sequence of seven stages that individuals experience as they adopt a new practice. Professional development strategies may then be tailored for the predominant stage of a group. The Stages of Concern instrument, consisting of 35 items, was developed for assessing concerns of teachers as they adopt new practices (Hall, George, & Rutherford, 1979). Teachers respond using a scale of 0 – 7 with 0, indicating that the concern is irrelevant and 7 indicating that the concern is very true. Bailey and Palsha tested this version with a shorter, 15-item instrument (1992). Using multiple statistical tests, these researchers demonstrated enhanced psychometric properties with the shortened version and made the argument for a five-stage model. The correlation between total concerns on both the long and short versions of the questionnaire was .92. Along with a brief description of each level of concern, the Cronbach's Coefficient Alpha for each factor is provided below.

- Awareness. The individual has little concern or involvement with the innovation, but wants to learn more about it. Cronbach's α long version .74; short version .74.
- Personal. Individuals are concerned with how the innovation will affect them, with a specific focus on required changes in roles and tasks. Cronbach's α long version .76; short version .83.
- Management. Individuals are concerned with time management, organization, and prioritizing responsibilities. Cronbach's α long version .55; short version .60.
- Impact. Individuals focus on the innovation's effects. Cronbach's α long version .73; short version .81.
- Collaboration. Individuals are concerned about working with others to implement the innovation. Cronbach's α long version .78; short version .79.

The survey developed specifically for this institute consisted of 24 items based on a four-point Likert scale: 4=Strongly Agree, 3=Agree, 2=Disagree, and 1=Strongly Disagree (see Appendix). Modifications included changing the statements from generic to more specific terms. For example, the statement "I am concerned about not having enough time to organize each day using this innovation," was changed to "I am concerned about not having enough time to organize each day when it comes to combining math and technology." There were sixteen items (1-16) of this nature. In addition, 8 statements (items 17 – 24) required teachers to indicate their perceived level of proficiencies in specific technologies (e.g., Microsoft PowerPoint, Microsoft Excel, graphing calculators, MathType Equation Editor, the Internet). Following the initial orientation session, the survey was administered during the first day of the 2005, 2006, and 2008 institutes. The questionnaire was administered again four weeks later at the end of the last regularly scheduled working day.

The second method of data collection consisted of prompted responses. The instrument consisted of five prompts on a one-page reflection paper. Each prompt was positioned within a large circle with room provided for teachers to record their responses. Prompts included: (a) I expected, (b) I got, (c) A thing of value, (d) I wish, and (e) Next I will or Next I need. In this regard, Krathwohl's affective domain taxonomy (1964) helped frame the effectiveness of a professional development institute by taking into account prior expectations. If participants' expectations are incongruent with the goals of a professional development program as indicated by responses in the "I expected"

circle, then teachers may be dissatisfied with the experience despite the quality of the program. The prompts served as a means of formative assessment and enabled instructors to make modifications if needed. The prompts also facilitated the process of metacognition. Metacognition is the process of monitoring one's own learning progress and making changes to improve learning strategies (Winn & Snyder, 1998). Ways to facilitate metacognitive approaches to instruction, including the use of prompted responses, have been described in *How People Learn* (NRC, 2000). On the Friday of each week of the Institute, time was set aside at the end of the day for completing the prompted response instrument. Following the Institute, the researchers listed each teacher's responses to each prompt in an Excel document.

Findings

The presentation of findings is organized into one of the four categories developed for this study: (1) technology integration, (2) hardware, (3), software, and (4) confidence. These categories emerged as the researchers reviewed and analyzed the prompted reflections. Initially, the researchers began with six categories, but later immersed two categories into one of the four. The following discussion addresses the results from the survey, supported with responses given by the participants in the prompted reflections.

Survey Instrument

The survey consisted of 24 items (see Appendix). The researchers anticipated that scores for some items would *decrease* from pre to post, because it

was hypothesized that teachers would demonstrate greater concerns about using technology in teaching mathematics at the beginning of the institute than at the end of the institute. Thus, numbers 1, 2, 5, 6, 8, 9, 15, and 16 were coded as negative items. All the negative worded statements were recoded (reversal of responses) during analysis of the survey. The researchers anticipated that scores for other items would *increase* from pre- to post-test, because it was hypothesized that teachers would demonstrate less confidence about using various technology tools at the beginning of the institute and greater confidence at the end. Positive items included numbers 3, 4, 7, 10 - 14, and 17 - 24. Overall, the survey included 16 positive and eight negative statements. The eight negative items are italicized in the Appendix. Two of the positive items overlapped among categories. Item number 7 combined integration, hardware, and software; number 17 combined integration and confidence. All the hardware and software questions were positively worded. While analyzing the overall confidence, the researchers considered all 24 items, including those designated as confidence. As shown in table 1, six positive items (4, 7, 10, 13, 14, and 17) and four negative items (1, 5, 9, and 16) were categorized as *integration*; four positive items for *hardware* (3, 7, 21, and 23), six for *software* (7, 18, 19, 20, 22, and 24); three positive (11, 12, and 17) and four negative (2, 6, 8, and 15) for *confidence*.

Descriptive statistics (means and standard deviations) were used to describe the central tendency and dispersion on all measures. Table 2 provides the minimum and maximum scores for each category. The participant's responses over technology integration, hardware, software and

Table 1. Classification of survey items for data analysis according to category and coding

	Integration	Hardware	Software	Confidence
Positive	4,7,10,13,14,17	3,7,21,23	7,18,19,20,22,24	11,12,17
Negative	1,5,9,16			2,6,8,15

Table 2. Minimum and maximum scores in each category

	Total number of items	Scale	Minimum Score	Maximum Score
Positive integration	6	1-4	6	24
Negative integration	4	1-4	4	16
Hardware	4	1-4	4	16
Software	6	1-4	6	24
Total positive Confidence	16	1-4	16	64
Total Negative Confidence	8	1-4	8	32

confidence at the beginning and end of the program were compared by using two-tailed paired sample t-test. The 0.05 level of significance was set for the rejection of all null hypotheses.

Technology Integration

The first category to be discussed is technology integration. Participants were asked to rate their capabilities and knowledge for incorporating technology into math instruction. Results from this particular area helped answer the research questions RQ2 and RQ4. The analysis revealed that teachers' concerns decreased over the course of the institute each year. The analysis revealed significant changes in participants' attitudes toward the integration of technology in math instruction in 2005 and 2008, positive changes though not significant in 2006 (see Table 3). These results indicated teachers' confidence levels in using technology in their math instruction increased as well as their knowledge about the use of technology. They had more confidence in both their

capabilities and knowledge needed for integrating technology into math instruction.

Participants' improved attitude toward technology integration also emerged in the prompted reflections. The following statements demonstrate how the institutes altered teachers' attitudes toward the use of technology in teaching mathematics.

As a result of this workshop, I expect to become a more efficient user of technology and use calculators and computers in my classroom.

A thing of value from this experience is the benefit of being able to learn to use a variety of strategies for various technologies in mathematics instruction for the classroom.

Next I need to go observe a computer discovery class (7th grade) in my school to learn more about how technology can be used.

Next I will take back to my classroom all the information that I have learned in this workshop. I

Table 3. Attitude toward integration of technology in mathematics instruction

Year	Pre-Survey		Post-Survey		Change of Score		t	p ¹
	N	(Mean±SD)	N	(Mean±SD)	N	(Mean±SD)		
2005	18	27.50±2.12	17	30.35±3.52	15	2.20±3.53	2.41	0.0300
2006	16	28.69±2.85	17	30.71±2.93	10	0.40±3.03	0.42	0.6857
2008	22	30.23±2.14	24	32.04±3.91	20	2.30±4.08	2.52	0.0208

want to carry all my skills back to the classroom to help instruct my students.

Hardware

In the hardware items, teachers were asked to rate their proficiency in the use of a graphic calculator (T1-83 or T1-84) and other technology materials. Results from this particular area helped answer the research questions RQ1 and RQ3. Paired t-tests revealed significant and positive changes in self-confidence in the knowledge and use of hardware across the three years (see Table 4). These findings show that participating in the summer mathematics institutes had a positive impact toward the attitudes of using hardware in math instruction. Researchers could also see that the participants obtained greater confidence in using hardware and became more aware of institutional support for hardware. This confidence not only made these teachers believe they were better able to use hardware, but also helped them become future leaders in their schools to advocate technology access and availability.

Participants' attitude toward the utilization of technology hardware to teach math concepts also changed for the better in the prompted reflections. The following statements demonstrate how the institutes improved teachers' attitudes toward the use of related technology hardware in teaching mathematics.

I got a lot of information on the calculator skills this week and how to graph the information in

tables. I am feeling reasonably safe and competent with calculator use.

Wish I can learn more ways of implementing all this into my classroom. I would like to use this and see how the Smart Board and the Smart View software (in conjunction with the graphing calculator) can be used in the classroom.

I wish our district would use the graphing calculator presentation as part of our staff development. This technology can really help us teach math skills.

I expect to continue learning about Excel and the graphing calculator. So far, I have learned many things such as creating graphs and random number generators in the calculator that I had no knowledge of prior to this workshop.

I wish we were reviewed more on using the Smart-Board. We do not know all of its features and what it can do in the classroom

I wish I had a SmartBoard in my classroom. But, now I know how to ask for it (from my principal) because of what it could do for the classroom.

Software

The third category is the application of various software programs in education. Results from this particular area helped answer the research questions RQ1 and RQ3. Teachers' attitudes toward

Table 4. Attitude toward hardware use in mathematics instruction

Year	Pre-Survey		Post-Survey		Change of Score		t	p ¹
	N	(Mean±SD)	N	(Mean±SD)	N	(Mean±SD)		
2005	18	9.50±1.58	21	12.52±1.50	16	3.00±2.22	5.40	<0.0001
2006	21	10.62±1.88	20	12.65±1.93	17	2.12±2.50	3.50	0.0030
2008	24	9.67±1.95	26	12.69±2.43	23	3.00±2.65	5.44	<0.0001

Note: ¹ by paired t test.

related software programs used in mathematics instruction are revealed in Table 5. Teachers were asked to rate their knowledge of software programs that included Excel, PowerPoint, Equation editor, and the Internet. Researchers found significant and positive differences between the pre- and post-surveys in all three years. From these results, researchers believe that teachers became more prepared for using the software programs available, and this increased confidence will have a positive impact on the usage of software programs in their teaching process.

Teachers also changed in their perspective toward using different software application programs to teach math concepts in the prompted reflections. The following statements demonstrate how the institute helped teachers positively perceive the use of software in teaching mathematics.

I want to continue learning various functions in Excel and use special features of PowerPoint so that I can use these programs when creating lesson plans.

A thing of value is learning how to make spreadsheets, creating charts and graphs, and using clipart. I also enjoyed creating PowerPoint for teaching math lessons and using animations.

A thing that I valued the most was using spreadsheets to create gradebooks. Learning how to create a gradebook from scratch and putting formulas into cells to get operations performed was useful. I know how to make the spreadsheet more for "my taste."

Confidence

The fourth category involves an increase in confidence, attitude, and a desire to continue using technology to teach math concepts in math classrooms. Results from this particular area helped answer the research questions RQ1, RQ2, and RQ4. The results revealed significant improvement in their concerns regarding the use of technology across all years (see Table 6). According to these results, the researchers believed that the participants acquired greater confidence regarding technology integration and their knowledge of hardware and software compared to before attending the institutes. The significant changes between the scores of pre- and post-survey also indicate that the teachers were more prepared to utilize the technology available in schools. The institutes not only gave teachers knowledge of hardware and software, but also helped them gain confidence to integrate technology into their curriculum. This confidence would help teachers utilize the available technology in schools and in math classrooms. In turn, the improved confidence would help teachers explore more concepts and applications in this area.

The responses in the prompted reflections also indicate an increase in self-confidence and willingness to learn more about technology integration. The following statements demonstrate how the in-service training led by the Institute's instructors assisted in improving teachers' confidence and continuing their desire to use technology. Most of these comments with reference to confidence emerged in the *Next I will* or *Next I need* prompt.

Table 5. Attitude toward software use in mathematics instruction

2008	21	59.62±6.93	23	71.30±9.23	19	12.05±8.86	5.93	<0.0001

Note: ¹ by paired *t* test.

I will continue to learn all that I can in order to be an asset to my students and my school. I also want to pass this information to my fellow co-workers.

I will continue to practice experimenting and using what I have learned. I want to take these skills into my own classroom.

I will continue to work harder in understanding the various formulas in Excel and work on my own!

I am getting a SmartBoard this coming year. So, I need to go in and play with it. I also need to begin creating PowerPoint's for certain math skills taught this coming school year while this is still fresh on my mind. I would also love to set up a master Excel sheet with formulas already set in it for students to use.

I will try and take time to find places/topics in the curriculum standards to insert Excel and PowerPoint. I also need to continue building my confidence in what I am doing.

I want to take all this information back to my classroom to make it a more exciting and productive environment for learning.

I got 50000000 much more from all this. My brain was exercised greatly with the math concepts to go along with the technology skills.

An interesting finding from the prompted reflections was the issue of time, in addition to

technology access. The teachers wanted to keep learning and using these technology tools in the classrooms. But, time and access were a reoccurring concern as exemplified in these statements, "I wish I had more time with colleagues to develop in-depth math lessons for my class and have more computers in my class to implement the lessons," and "I wish I had more time and access to integrate all of this into my daily schedule."

CONCLUSION AND DISCUSSION

The research questions asked for this particular study have been answered. First, offering an in-service professional development institute concerning technology integration into math instruction can help teachers learn how their knowledge and skills could be used in the classroom. Teachers not only learned about the technology hardware and software per se, but also the practical skills that they could use in instruction. By modeling appropriate uses of technology in the institute, teachers could envision how instruction can be carried out. Second, participating in an in-service professional development institute concerning technology integration into math instruction helped develop teachers' self-confidence to apply what they learn. Many teachers who had never used a computer before voiced their aspirations to continue learning and using technology beyond the institute. Some expressed interest in becoming leaders in their schools to help others learn to use the technology tools. Third, the teachers who

completed this technology-oriented institute not only focused on learning to use the technology, but also on the application of technology in teaching. The questionnaire and prompted reflections indicate that although teachers valued the how-to-use-technology instruction they received, the teachers also began thinking about how they could use the technology in their math lessons and how to make it part of their school culture. This information reveals that the institute was successful in taking teachers from the initial "awareness" level all the way to the final "collaboration" level in Bailey and Palsha's five-stage model of concern (1992). Finally, the teachers who completed this institute developed a more positive attitude and outlook toward technology. Most were excited to continue their exploration of the possibilities that technology tools could provide in the classroom and how to obtain them.

This study does have its limitations. First, the sample population is not representative of teachers in South Mississippi. They were selectively chosen to participate in the Institute through an application process. Second, the administration of the prompted reflection instrument was not always consistent. In some years, the weekly reflections were administered on Thursday rather than Friday and the content schedule fluctuated that affected how the participants responded to the prompts (e.g., for one year the topic of grants was predominant, but not in another). Although this factor did not affect the data findings, not all the participants completed both the pre- and post-surveys. Nonetheless, the findings from this study address the effectiveness of conducting an intensive, four-week professional development institute focused on the integration of technology in teaching mathematics and how this could enhance teachers' attitude, confidence, and skills acquisition.

Teachers' perceptions, attitudes, and concerns should be addressed during any professional development workshop or institute. Simply administering a questionnaire before and after an event

bypasses the rationale for a concerns-based survey, and, other than providing institutional assessment, serves as a fruitless exercise. Feedback from the weekly reflections enabled instructors to address teachers' struggles with certain technologies or mathematical concepts immediately. Instructors provided personal attention and instruction was modified accordingly. As revealed by this study and others (Atkins & Vasu, 2000; Rakes & Casey, 2002), future studies should continue to be performed in the tradition of Hall and Loucks (1978) in order to examine the effectiveness of professional development in improving teachers' confidence and attitude. However, a survey is only useful if the professional development staff uses the initial analysis to design the professional development experiences. That said, however, a survey alone is not sufficient to determine all areas of concerns that teachers may have. Prompted reflections, administered daily during a workshop or weekly during an institute, provide a simple and effective way to obtain additional feedback and take immediate steps to address teachers' concerns. However, an even more thorough qualitative approach could be performed that includes interviews, observations, and document analyses. This type of examination would bring a further in-depth perspective of how professional development sessions can change the environmental culture and people's perspectives.

Professional development helps teachers become the key agents they need to be. If anyone expects change to occur in the classroom, teachers need to be well-informed, skilled, ready, and possess the correct tools for change to take place. Without this help and support, change in the mathematics classroom will not occur. The Summer Math Institute provided teachers with the professional development needed to integrate technology into the math classroom. However, this professional development model is just not limited to mathematics. Schools, colleges, and universities can adopt similar types of extended professional development to help facilitate the acquisition of not only content material (e.g.,

math, science, language arts), but technology skills and pedagogical applications as well. In addition, professional development requires to be delivered over a longer period of time in order to be effective in changing the confidence level of teachers. A one-time, daylong workshop is not sufficient enough to initiate change in terms of attitude and confidence. Participants in such shorter professional development sessions may acquire specific technology skills or content knowledge, but the application of such skills and knowledge may not be fully recognized. A long-term professional development model is required to help stimulate continuing interest among the participants and increase confidence. A final observation that emerged from this study is that time and access to technology must be provided to mathematics teachers. This access to technology needs to be ensured in order for change to occur in instruction. Comments made by the participants in this study emphasized the need for extra time to assimilate all the information and skills learned into their actual teaching. Furthermore, the participants were concerned that the technology used in the professional development workshop may not be available back at their schools. They believed that in order to fully integrate what had been learned from the Summer Math Institute, extra time to practice using the technology tools was required. This is an area in which educational institutions need to consider if change is to occur. In short, effective professional development is one way to stimulate interest that would extend beyond the constraints of the workshop itself and lead toward greater self-confidence in one's ability.

APPENDIX

Survey for (SM)² I Summer Math Institute Participants

The purpose of this questionnaire is to determine your current concerns regarding the integration of mathematics and technology into your classes. The items were developed from typical responses of teachers who ranged from no knowledge at all about the ideas to many years experience in using them. **Therefore, a good part of the items on this questionnaire may appear of little relevance to you at this time.** For completely irrelevant items, please circle “NA” on the scale. Other items will represent those concerns that you *do* have, in varying degrees of intensity, and should be marked higher on the scale. Please respond to the items in terms of your present concerns about your involvement, or how do you feel about your involvement with **integrating mathematics and technology into your classes**. We do not hold to any one definition of this innovation, so please think of it in terms of your own perceptions of what it involves in your teaching situation.

1 = completely disagree 2 = somewhat disagree 3 = somewhat agree 4 = completely agree NA = Irrelevant

- 1 2 3 4 NA 1. *I am concerned about my ability to integrate mathematics with technology.*
- 1 2 3 4 NA 2. *I am concerned about not having enough time to organize each day when it comes to combining math and technology.*
- 1 2 3 4 NA 3. *I am concerned about availability of technology materials at my school.*
- 1 2 3 4 NA 4. *I would like to help other faculty in their attempts to blend technology into their subject areas.*
- 1 2 3 4 NA 5. *I have a very limited knowledge about integrating mathematics and technology.*
- 1 2 3 4 NA 6. *I am concerned about the students' abilities in technologies exceeding my own.*
- 1 2 3 4 NA 7. *I would like to know what resources are available if we decide to integrate mathematics and technology.*
- 1 2 3 4 NA 8. *I am concerned about my inability to manage all that integrating math with technology requires.*
- 1 2 3 4 NA 9. *I would like to know how my teaching or administration is supposed to change when integrating these subjects.*
- 1 2 3 4 NA 10. *I would like to revise the instructional approach for integrating technology into the mathematics classroom.*
- 1 2 3 4 NA 11. *I would like to have more information on time and energy commitments required for integrating these subjects.*
- 1 2 3 4 NA 12. *I would like to know what other faculty are doing in this area.*
- 1 2 3 4 NA 13. *I would like to determine how to supplement, enhance, or replace the mathematics teaching that I use to integrate technology.*

Section VII

Critical Issues

Section 7 details some of the most crucial developments in the critical issues surrounding instructional design. Importantly, this refers to critical thinking or critical theory surrounding the topic, rather than vital affairs or new trends that may be found in section 8. Instead, the section discusses some of the latest developments in cognitive load, social constructivist and pedagogy theories, as well as new approaches in faculty development, learning with visualizations, and implications of anonymity online. This section also asks unique questions about the role of business intelligence in developing countries and in linguistic confusion across cultures. Within the chapters, the reader is presented with an in-depth analysis of the most current and relevant issues within this growing field of study.

Chapter 7.1

Theories and Principles for E-Learning Practices with Instructional Design

Maria Ranieri
University of Florence, Italy

INTRODUCTION

E-learning has become an area of increasing interest for academics, consultants, and practitioners. Notwithstanding, it seems that in current experiences the instructional dimension is often overlooked. Many e-learning courses are content-oriented and the attention is often put on the technological dimension. We believe that a fruitful contribution in order to overcome the gap between technology and pedagogy and promote a more sensible instructional approach to e-learning, can be derived from *instructional design* (ID). ID is an ever growing field of research (Dijkstra, Seel, Schott, & Tennyson, 1997; Gagné & Briggs, 1990; Merrill, 2001; Reigeluth, 1989; Savery & Duffy, 1995; Wilson & Cole, 1991). Its results have a transversal value with respects to the specific delivery supports adopted in the learning

environment. Whether we are dealing with online or face-to-face education, useful criteria from ID can be outlined for designing effective, efficient, and appealing learning experiences.

Therefore, with the aim of suggesting useful criteria and guidelines for e-learning design, this paper focuses on ID and examines some main approaches that currently characterise this field.

HISTORICAL AND THEORETICAL BACKGROUND

The field of ID emerged more than 40 years ago as psychologists and educators searched for effective means of planning and implementing instructional systems. One of the most important work for the growth of this field was Robert Gagné's *The Conditions-of Learning* (Gagné, 1965). According to the American psychologist, there are

DOI: 10.4018/978-1-60960-503-2.ch701

different levels of learning, each of which requires different types of instruction. He distinguished eight types of learning (from signal learning to problem solving) arranged in hierarchical order and proposed nine instructional events as conditions for learning. See Table 1.

These events should provide the basis for designing instruction and selecting appropriate media.

ID from the very start, was configured as a field of research aimed at identifying criteria for the choice of the most appropriate learning methods, taking into consideration the conditions-of-learning and the different learning methodologies. And yet this sector was often confused with other fields, thus generating ambiguity and misunderstanding. Recently, Reigeluth (1999) elaborated a deep study on ID with the purpose to clarify its specific field and focus on the epistemological nature of ID theories. Broadly speaking, an ID theory provides more or less general indications on how to facilitate learning and cognitive, emotional, social and physical development of people. But how should the term “theory” be interpreted, and what does an ID theory consist of, compared to other theoretical fields?

First of all an ID theory is design-oriented, that is, it focuses on how to achieve learning results. It therefore has a prescriptive nature, and does not involve the description of cause-effect

relations between events, but indicates how to obtain specific results. An ID theory is not true or false, but involves a choice between possible preferable ways of intervening, and thus satisfies preferability criteria rather than that of validity.

There is a tendency to identify ID with the area of learning theories. Obviously the relationship between these fields is very close since the learning theories have the fundamental role of explaining why an ID theory works or not. However, an ID theory involves the defining of the methods that facilitate learning and indicates the situations in which their use is preferable.

The methods have a situational nature and not a universal one, meaning that they work in certain situations and not in others. The situation affects the choice of methods and influences their applicability.

An ID theory therefore defines not only the methods, but also the situations, while identifying the aspects of the context that influences the choice of the method. In any learning situation, the most important aspects can be put into two macrocategories which are the learning conditions and the desired results. Among the first to be considered are: the nature of that which must be learnt (e.g., understanding concepts is different from developing abilities), the characteristics of the students (e.g., their previous knowledge, their learning strategies, their motivations), the characteristics of the learning environment (e.g., the activities could be carried out at home, or in a class of 20 students, or in small groups at workplaces, etc.), and the organizational and economic constraints. All these conditions can affect the choice of the most favorable methods for achieving the desired results. They must not be confused, however, with the *conditions-of-learning* of Gagné, even when the internal conditions coincide with the category, “student characteristics”, while the external conditions are methods of learning and not conditions of learning. The desired results are the levels of effectiveness, efficiency (costs/time) and appeal (attraction for the student) with which one hopes to reach learning objectives.

Table 1.

Instructional events	Cognitive Process
Gaining attention	Reception
Informing learners of the objective	Expectancy
Stimulating recall of prior learning	Retrieval
Presenting the stimulus	Selective Perception
Providing learning guidance	Semantic Encoding
Eliciting performance	Responding
Providing feedback	Reinforcement
Assessing performance	Retrieval
Enhancing retention and transfer	Generalization

The situation is therefore defined in a rather complex way and the intervening factors are multiple. This entails another characteristic of the ID methods, that is, they always possess a probabilistic nature. It means that an ID method does not guarantee that the application of an appropriate method in a certain situation will deterministically lead to the desired results, but does indicate a good degree of probability in a given situation, that the method will work.

Briefly, an ID theory identifies the adequate methods, so that, given certain learning conditions, learning results to be effective, efficient and appealing (Figure 1).

Currently there are two main approaches occurring in this field. The first is more traditional and is usually indicated as “instructivist”. The second prefers alternative expressions like “learning communities” rather than “instruction” and leans towards constructivism.

In the second part of the chapter, we shall focus on these two different approaches, examining the ID principles developed in the traditional approach and the most recent evolutions of ID due to constructivism.

DO FIRST PRINCIPLES OF INSTRUCTION EXIST?

Merrill (2001), an advocate of the instructivist approach (Merrill, Drake, Lacy, Pratt, & ID2

Research Group, 1996), claims the right of ID to develop general principles in order to design instruction. According to Merrill, in comparing existing instructional models, it can be gathered that there are five instructional dimensions occurring in a transversal way: problems, activation, demonstration, application, and integration. What do such principles prescribe?

Problem. Learning is facilitated when the students concentrate on the solution of authentic problems. This principle is followed by resulting corollaries, that is, learning is facilitated: (1) when students are shown the task to achieve or the problem to resolve at the end of the course, rather than focusing on abstract learning objectives; (2) if the students are engaged in achieving a task or resolving a problem and not at the level of simple action or application of procedures; and (3) when the student solves more problems arranged in order of growing complexity for the gradual and progressive development of skills.

Activation. Learning is facilitated when pre-existing knowledge is activated as foundation for new knowledge. It is surprising, Merrill observes, how often we pass on immediately to presenting new information in very abstract forms, without first having prepared the ground for them to be understood. Activation implies much more than testing previous knowledge; it is rather the activation of those mental models that can be modified in order to allow students to integrate new knowledge with the existing one.

Figure 1. Elements of ID theory (Reigeluth, 1999)

The best example for activation is that of the advanced organizers of Ausubel (1960, 1963).

Demonstration. Learning is facilitated when, what must be learned is demonstrated instead of just receiving information about it. Knowledge is often represented at a too general level rather than through examples. It would be more opportune instead, if examples and counterexamples were furnished for concepts, demonstrations held for procedures, and visualization done for processes and modelling of behaviour. Demonstrations entail a guide that helps the student to select the relevant information, the offer of the multiple representations of knowledge and also the comparison among multiple examples.

Application. Learning is facilitated when the student is given the opportunity to practise and apply new knowledge or abilities in the solution of a variety of problems. It is necessary obviously to provide adequate support (coaching) and feedback during the performance.

Integration. Learning is facilitated when students are encouraged to apply the new knowledge/abilities in real life, are given the opportunity to demonstrate their own new knowledge/ability, and are able to reflect, discuss and defend their new knowledge. Integration has positive effects on motivation. If the students have the opportunity to demonstrate their own progress, their motivation increases.

INSTRUCTIONAL DESIGN AND CONSTRUCTIVISM

During the last 20 years, studies in cognitive science and psycho-pedagogy have led to a meaningful change in the definition of learning. Three main research paths have been developed which, though similar, emphasize different aspects (Striano, 1999). These main perspectives consist of: (1) a constructivist approach which recovers the piagetian work, and interprets learning as an adaptive process in which the learner plays an active

role of construction/de-construction of structure and knowledge strategies; (2) a historical-cultural approach referring to Vygotskij and interpreting learning as a mediated experience and as a socially shared and culturally constructed process; and (3) a contextual approach which emphasizes the ecological attitude of learning processes (Striano, 1999).

Therefore, new currents have emerged in the ID field as constructivist instructional design (Dick, 1991; Jonassen, 1994; Savery & Duffy, 1995; Wilson, 1996), which share the perspectives developed on the psycho-pedagogical level.

The instructional models which are oriented towards constructivism, put the emphasis on the concept of learning environment. This is defined as “*a place where learners may work together and support each other as they use a variety of tools and information resources in their guided pursuit of learning goals and problem-solving activities*” (Wilson, 1996, p. 5). The idea is to set up around learners, multiple supports and resources available for their cognitive progress. This concept is derived from the Vygotskijian theory of zone of proximal development. The latter indicates a set of potentialities that the individual can develop, if adequately helped. In order to promote learning a varied environment consisting of learning resources, techniques, and interpersonal activities must be constructed around learners, so that each student can find the suitable atmosphere and the most appropriate “strongholds” to make progress.

Other authors provide further interpretations. According to Collins (1996), a learning environment should offer multiple representations of reality, avoid simplifications representing the natural complexity of the real world, focus attention on the building of knowledge and not of its transmission and reproduction, offer opportunities for learning based on real world situations rather than on predefined instructional units, nourish reflective practices, allow the building up of knowledge according to context and favor the cooperative construction of knowledge through social negotia-

tion. Briefly, a constructivist learning environment is characterized by the following aspects:

- Focus on knowledge construction rather than knowledge transmission;
- Focus on context rather than abstraction thus presenting authentic tasks based on real cases;
- Multiple and complex perspectives on reality which stimulate metacognitive attitudes;
- Emphasis on social meaning negotiation and cooperative learning.

We now focus on two models arising from the Vygotskian tradition, that is, the community of learners (Brown & Campione, 1990) and the Community of Practice (Lave & Wenger, 1991). What defines a learning community is the existence of a culture of learning in which each person is committed in a collective effort of meaning comprehension (Collins & Bielaczyc, 1999). The four specific factors that characterize such a culture are:

- The diversity of expertise among the community members
- The shared objective to contribute to the continuous growth of expertise and collective knowledge
- The emphasis on learning how to learn
- The setting-up of methods and tools for sharing what is learned.

A learning community can also be considered as a “social device” oriented towards favoring collaborative learning. It is characterised by members joining spontaneously and deep emotional relationships. A learning community cannot be designed in a strict sense, but is at most, “favored” or “cultivated”. More analytically, according to Collins and Bielaczyc (1999), the issues to be addressed in order to promote a learning community can be analysed within eight dimensions:

1. **The scope of the community:** It is that of promoting a culture of learning, in which both the individuals and the community considered as a whole, learn how to learn. The members of the community share their efforts to reach a deeper understanding of what they are learning. The students learn to consider multiple perspectives to solve problems, and to use each other’s knowledge and expertise as a resource to collaboratively solve problems.
2. **Learning activities:** The activities of a learning community aim at: (a) promoting individual development and collaborative construction of knowledge; (b) favoring the sharing of knowledge and abilities; and (c) making the process of learning visible and well structured.
A learning community is typically involved in learning activities, such as individual and group research, discussions, peer tutoring and learning, collaboration in artefacts production intended to make visible what students learn, and collaborative problem solving based on shared objectives. Brown and Campione (1996) suggest that learning community activities are distinguished by two aspects, that is, interdependent actions and interconnected objectives.
3. **The changing role of the teacher and transformation of the educational relationship:** In a learning community the teacher assumes the role of organiser and facilitator. The student becomes responsible for his/her own learning and that of the others.
4. **Centrality/peripheral and identity:** The member’s identity is defined by the central or peripheral role he plays in the community and by the respect he receives from the other members of the community (Lave & Wenger, 1991). In a learning community the central roles are those that contribute more directly to collective activities and to

community knowledge. There are, however, opportunities for all and the participants who assume peripheral roles are evaluated for their contributions. The centrality and peripheral aspects depend on the context. Individual identity is constructed through participation. Therefore the community identity emerges by working towards a common goal. It makes collective awareness grow, and favours the skipping of peripheral positions to favor centrality.

5. **Resources:** In a learning community the knowledge acquired and the learning processes enriched by external sources are shared between the members and become part of collective knowledge.
6. **Speech:** In learning communities language used to communicate ideas and practices emerge in the community through the interaction with the various sources of knowledge and the cobuilding and negotiation of meaning between the members. The learning communities construct a common language through which they express learning processes, plans, aims and assumptions. Speech assumes the function of a medium for the exchange of ideas; promoting moreover, the motivations of research and reflection, and arousing new questions and hypotheses that give rise to ulterior research. In this process the students help each other.
7. **Expertise:** In learning communities both individual and collective expertise are emphasized. Subjects that focus on principles and ideas that can generate wider and deeper comprehension of the themes themselves, are preferred. A growth in the community knowledge also occurs when the discussions on what the members have learned lead them to seek other knowledge to be shared within the community. Therefore there exists an inter-relationship between personal growth and that of the group.

8. **Products:** In a learning community the members collaborate to produce artefacts that can be used by the community to understand other themes or problems.

As regards communities of practice (CoP), they are defined by Lave and Wenger (1991) as groups of persons sharing an interest and regularly interacting to learn how to perform better. They are distinguished by three crucial features: identity that is defined on the strength of a shared interest, belonging to a community wherein the members help each other, and the sharing of practices. A CoP shares a program of resources, experiences, stories, tools, ways of problem resolutions, and in short, a program of practices.

INSTRUCTIONAL DESIGN AND E-LEARNING PRACTICE

We have just examined the two main current perspectives in ID field. How can they offer methodological insight for e-learning design?

As an example, let us consider the following case, that is, the methodological structure of a master on e-learning designing and managing delivered at the University of Florence since 2001. The master lasts one year (including a period of internship and one month reserved for the final dissertation) and provides blended learning, including f2f meetings and online activities supported by a virtual learning environment.

Briefly, the overall instructional model which characterises the master is based on the following principles inspired by both Merrill's Principles and learning community theory:

- Promoting problem based learning
- Favouring the activation of pre-existing knowledge
- Providing expert modelling through case studies and simulations

- Allowing students to apply knowledge and abilities in different contexts
- Facilitating knowledge integration through project based work
- Favouring the development of a community of practice
- Promoting students awareness on their own performances

How are these general principles concretely implemented? The master starts with a first phase of three months aiming at providing students with the conceptual handholds and expert examples concerning the various subject area. Each week is dedicated to a particular topic and is planned as described in Table 2.

During the following three months, a completely online phase is delivered, which is oriented towards collaborative project work. The purpose of this phase is to enable participants to apply their own knowledge and skills in real life contexts (application and integration). At the same time, the emphasis is put on the formation of collaborative groups and the growth of a community of practice.

The team building process is favored by the sharing of a common interest and supported by the e-tutor. Students can choose among various scenarios referring to different contexts, that is, university, private company, public corporation, and so on. The groups therefore emerge from the interest in a particular scenario and operate within the selected scenario. Participants start to search and exchange information in order to create a common knowledge base and language. Next step is to define the objective to be accomplished and identify the necessary resources. The project work activity engages the students in a continuous problem solving process, asking them to develop different views on the same topic and to evaluate different possible solutions.

In addition, two intensive face-to-face workshops are delivered with the aim of offering more opportunities for demonstration and application.

CONCLUSION

During the last 20 years, Instructional Design has gained its own autonomy as a specific field of research and has developed a theoretical reflection on its own epistemological statute. It is designated to elaborate instructional theories or models, able to indicate the adequate methods so that, given certain educational situations, learning can have greater probabilities of becoming effective, efficient and appealing. At the same time different approaches are emerging. One is more oriented towards the research of transversal fundamental principles applicable to a variety of contexts. The other, inspired by constructivism, is more intent on valorising the social and contextual dimension.

Even if the two approaches are different and in some way hardly reconcilable from a theoretical perspective, we believe that both the traditions provide methods and criteria that should be taken into consideration in e-learning design and practice. As noted, these criteria can be identified either in the Merrill's first principle of instruction or in the guidelines for cultivating learning communities.

In any case, professionals and practitioners in the e-learning field should not overlook the instructional dimension, while paying special attention to the research contribution from instructional design.

Table 2.

PROBLEM	Monday	E-tutor		
		ONLINE WORK The e-tutor presents the subjects and the themes that will be examined and discussed during the week. He also introduces the subject matter experts (SME). At the same time, he provides documents and learning materials on the subject area, and focuses on the fundamental questions that will be addressed in face-to-face event.		
ACTIVATION	Monday		Students	SME
	Tuesday		ONLINE WORK Students achieve their tasks autonomously or in small groups supported by a Web forum. They must identify problems and issues emerging from the provided learning materials and documents. Eventually they realize a concept map or a final report on emerged issues.	ONLINE SUPPORT During this period the SME may interact if needed with students giving support and hints on the subject area. He therefore intervenes in the Web forum collaborating with the e-tutor.
	Wednesday			
	Thursday			
DEMONSTRATION	Fryday (afternoon) and Suterday (morning)	Before the face-to-face event, the e-tutor summarizes students reports and submits the final report to the SME so that he can arrange the face-to-face lecture on the emerged issues.		FACE-TO-FACE WORK* During the face-to-face event, the SME discusses the issues identified by the students giving feedback and adding new information and examples on the subject area.
DEMONSTRATION	Suterday (afternoon)	FACE-TO-FACE WORK * The e-tutor gives ulterior information on the discussed themes, and organises possible in-depth examinations if needed.	FACE-TO-FACE WORK* Students will realize personal works taking into consideration the information and the suggestions provided by the SME and supported by the e-tutor . The personal works will be inserted into the student portfolio.	
* Students who cannot be present to the face-to-face event, may participate and interact with the SME and other students through a videoconferencing system.

KEY TERMS AND DEFINITIONS

Constructivism: Epistemological theory according to which individuals construct knowledge through active experience. It emphasizes that knowledge is a social product, historically and culturally situated, and which is negotiated, constructed and learned by the members of a community.

E-Learning: A Neologism created at the start of the 2000s to indicate a set of methodologies aimed at using the ICTs in order to provide learners with learning resources and interactions free

from temporal and spatial constraints. Three main solutions can be distinguished: content + support, wrap around, and integrated model. These three structures are respectively based on content, teacher's support for activities between peers and the Internet, and the collaborative learning group.

Instructional Design: Is the sector which has to do, on international levels, with the study of criteria and instructional models applicable to diverse contexts, in such a way that learning has a greater possibility of becoming effective, efficient, and appealing.

Learning Community: It is a notion that received a great attention in last years by educational scholars. According to Bielaczyc and Collins (1999) the four essential characteristics to define a learning community are: (1) diversity of expertise among its members, who are valued for their contributions and are given support to develop; (2) a shared objective of continually advancing

collective knowledge and skills; (3) an emphasis on learning how to learn; and 4) mechanisms for sharing what is learned (p. 272).

Learning Environment: A definition currently accepted in literature is "*a place where learners may work together and support each other as they use a variety of tools and information resources in their guided pursuit of learning goals and problem-solving activities*" (Wilson, 1996, p. 5).

Zone of Proximal Development (ZPD): The ZPD theory goes back to the work of social psychologist Vygotskij, according to which social interaction is critical to learning. He considers the learning process as continuously moving from an "actual development level" to a "potential development level". The movement between these two levels, where the ZPD lies, occurs through the interaction of an expert and a novice.

Chapter 7.2

Humanistic Theories that Guide Online Course Design

MarySue Cicciarelli
Duquesne University, USA

INTRODUCTION

Humanism comes from one of three schools of psychology in which theories are categorized. The other two schools are the schools of behaviorism and cognitivism. It is believed that one school of theory is not better than the other, and individuals are encouraged to apply the theory that is the most appropriate for the student. Theories from the school of humanism focus on students' affective needs which means that the theorists center their attention on feelings, emotions, values, and attitudes (Tomei, 2007). Colonel Parker, once deemed the Father of Progressivism of the nineteenth century by John Dewey, promoted creating curriculum with the child at its center. He wanted the school to be a replica of home, an inclusive community, and a budding democracy

for the students. Parker's work and thought on curriculum would eventually be an apparent part of John Dewey's progressive work (Pinar, Reynolds, Slattery, & Taubman, 1996).

Years later, G. Stanley Hall fervently criticized a report created by the Committee of Ten that promoted fitting children in a learning mold that consisted of canned subjects that were meant to be taught to all students in the same way without individualization of any kind. Hall rejected these ideas, because he believed that changes in society evolved slowly and that genetics not surroundings impacted students. Unlike Parker's push for individualization so that every child's needs could be met, Hall believed in individualization so that the gifted child would stand out. Eventually, Hall's critics who saw no need for social reform labeled his laissez-faire ideas as disastrous (Pinar et al., 1996).

DOI: 10.4018/978-1-60960-503-2.ch702

Then, during the 1950s, theorists such as Elliot W. Eisner, Ross Mooney, and Paul Klohr expressed their views concerning curriculum and the need of the educator to design curriculum that focused on self-value. Finally, during the 1960s, humanism began to be thought of as the third psychological orientation that followed theories of behaviorism and cognitivism. At this time, Carl Rogers and Abraham Maslow, respected humanistic psychologists, began to contribute papers on humanism which provided the field with an alternative educational view. The change that began to occur was considered to be a paradigm shift in which theorists moved from an interest in curriculum development to an interest in understanding curriculum. It was antiwar efforts and political unrest that helped drive the interest in a curriculum that focused on the self (Pinar et al., 1996).

Researchers noted that in 1975, McNeil presented four conceptions of curriculum: the humanistic, the social reconstructionist, the technological, and the academic curriculum conception (Pinar et al., 1996). The humanistic view brought back the facet of progressivism that looked to child-centered and individual-focused learning experiences. This came as the social reconstructionists tried to bring about societal reform through school reform.

HUMANISTIC THEORIES AND ONLINE DESIGN

When we look at the past, we see that theorists such as Elliot Eisner and Elizabeth Vallance thought of schooling as a way for individuals to gain personal fulfillment. They thought of it as a means to provide a way for people to discover and create their own identities. Curriculum, at that time, had the responsibility of fostering personal development in many different ways. Theorists began to present their theories through

models of teaching and learning (Pinar, et al., 1996). For example, the phenomenal field theory, self-actualization theory, theory on nondirective teaching, theory of moral development, theory of immediacy and social presence, and cooperative learning theory came about.

Phenomenal Field Theory

A humanistic theorist named Arthur Combs presented his phenomenal field theory with psychologist Donald Snygg. According to this theory, they postulated that to understand human behavior, the time must be taken to consider the point of view of another. They believed that if one wanted to change another person's behavior that he or she must first modify his or her beliefs or perception. One had to "walk in their shoes" if one wanted to understand and guide change. By taking this line of thinking, educators had to recognize that the learner needed to find meaning and understand the learning as opposed to learning and understanding the strategies (Boeree, 2007; Tomei, 2007).

Combs and Snygg felt that if they were to understand and foresee the behavior of another that they had to reach into the person's phenomenal field. Since it was impossible for them to physically look into another person's mind, they had to make inferences from what was observed. When educators utilize this theory, they cannot choose a topic of instruction and a strategy, implement the learning experience, and expect every child to be motivated by what has been placed before them, because the information does not connect to their own lives. Instead, the educators have to get to know the learner's phenomenal self and create learning experiences that have meaning to the learner. Once instructors take this path, the student that was not motivated to learn at one time will become connected to the learning experience (Boeree, 2007; Tomei, 2007).

Self-Actualization Theory

Nearly forty years ago, Abraham Maslow and Carl Rogers presented their ideas about personal growth and performance in connection with individual differences in how individuals respond to their physical and social environment. Other theorists who based their theory in the other schools of psychology focused on ability and development. Maslow and Rogers focused on an individual's view of his or her self. Maslow believed that strong beliefs about one's self was connected to the thought of self-actualization. According to his thinking, individuals with strong self-actualization interacted well with others, and they found ways to develop and contribute to the world around them fairly easily. Those who did not have strong self-actualization choose to live within their environment and accept what comes their way, instead of reaching into their environment and making new opportunities happen for themselves. People of this nature are less secure with themselves in their environment and their ability to succeed. Maslow believed that every individual had a force within that either sought or shunned growth (Joyce, Weil, & Calhoun, 2000; Pinar et al., 1996; Tomei, 2007).

For people to reach the level of self-actualization, they had to be fulfilled at each level of what Maslow referred to as the hierarchy of needs. The first level was the biological level. At this level, an individual's need for food and shelter had to be met before the individual could move to another level. At the next level, the individual would have to feel secure. Level three of the hierarchy of needs demanded that the individual felt as though the individual belonged and was loved. Needs for self-respect, achievement, attention, and recognition needed to be fulfilled if an individual was to move past the esteem level of the hierarchy. When an individual had past each of those levels, the individual had reached the final level, the level of self-actualization. At this point, the individual's ability to reach potential

could take place. While each level had to be fulfilled, they did not have to stand alone and one behavior could satisfy more than one level on the hierarchy. Instructors who utilize this theory when designing and conducting a course look to see if their students' needs have been met to help them understand student behavior (Joyce et al., 2000; Pinar et al., 1996; Tomei, 2007).

Nondirective Teaching Theory

Carl Rogers believed that in order for people to grow, they needed positive relationships with other people. Instructors who have utilized this theory nurtured their students instead of controlling the learning experience. The nondirective procedure required the teacher to guide students to explore new information and experience new occurrences in the world around them. According to this theory, students and their teachers are partners in learning (Joyce, et al., 2000). Rogers believed that all humans had an innate drive to learn. He felt that when a student viewed the learning as valuable that the experience would be valuable to the student. Educators were expected to create a threat free learning environment where students could initiate learning, and they could think metacognitively about their own learning needs. Teachers were seen as facilitators in the nondirective teaching approach (Joyce et al., 2000; Tomei, 2007).

Theory of Moral Development

Lawrence Kohlberg developed the theory of moral development. According to Kohlberg, individuals moved through different stages that defined their own perception of justice. He presented three levels from which he believed morals developed. The first level, the preconventional level, was divided into two stages. At this level, individuals responded to the cultural rules and labels of good and bad or right and wrong. During the first stage of this level, the individual's moral judgment was motivated by a need not to be punished. An individual's

moral judgment was impacted during the second stage by the need to satisfy personal desires. The second level of the moral development theory was the conventional level. At this level, honoring the expectations of one's family, friends, or others in society determined the individual's development. This phase also contained two separate stages. The first stage from the second level held that individual and moral judgment was impacted by the need to avoid rejection, disaffection, and disapproval. The second stage at this level showed moral judgment to be impacted by one's need to not be criticized by others. The third phase of this theory was the postconventional stage. During this stage, individuals tried to describe the morals and values that they felt were valuable. Individuals from this level of moral judgment tend to be influenced by community respect and a need for social order. Those at the second stage from the third level found that their moral judgment was motivated by their own conscience. Instructors who integrated this theory in the curriculum guided the learners to look at their own moral situation, and they lead them to recognize how they justified their moral position. Critics of this theory have indicated that it is difficult for a teacher to apply this theory during instruction because the students were all at different levels of moral development (Joyce et al., 2000; Pinar et al., 1996; Tomei, 2007).

Theory of Immediacy and Social Presence

A model of online learning which presented the significance of social presence during asynchronous computer mediated discussion was presented by Rourke, Anderson, Garison, and Archer (2001). They held that learning took place through the interaction of three core components: cognitive presence, teaching presence, and social presence. A more in-depth look was made by the researchers of the social presence response and was presented as affective responses, interactive responses,

and cohesive responses (Martyn, 2004). These responses were used as indicators by Rourke et al. (2001) when analyzing content during their exploration of computer mediated discussions and affective behaviors among participants. Learners' perceptions were an important factor that instructors kept in mind when designing online courses, because learners' perceptions influenced their behavior. Two behaviors that have had an impact on interaction are immediacy or quick response to an act or question and social presence referred to a learner's skill of visually and affectively interacting in the learning environment whether it be done synchronously or asynchronously.

After administering a questionnaire, researchers found that perceptions of interaction had an influential effect. In the case of this study, the teacher's perceptions of the interaction influenced how the students perceived the actual interaction which in turn influenced the teacher's perceptions of interaction. Based on the results of the study, self-assessment and self-reflection on the part of the teacher for the purpose of modifying the actual interaction was necessary if the teacher wanted to change the perceptions of interaction in the classroom. If perceptions were adjusted for the better then circular communication processes developed so that behaviors were influenced to be more interactive (Fisher, Richards, & Newby, 2001).

Predictors of learner satisfaction were explored by Gunawardena and Duphorne (2000) in a study that focused on the academic computer conference environment. Of the influential factors that they investigated in the study, comfort with participating in discussions, easiness with communicating with text, and assurance with presenting oneself into a computer mediated discussion were some of the variables that significantly impacted learners' perceptions. Results pointed to the understanding that learners' social presence was effected by students' perceptions of preparedness and that course design and immediacy on the part of the instructors attended to familiarize the

learners with online features, computer mediated discussion learning approaches, as well as the tools and abilities that they needed to feel ready to participate in a discussion.

Murphy (2004) presents sharing personal information, recognizing group presence, communication appreciation towards other participants, expressing feelings and emotions, and expressing motivation about a project or participation as indicators of social presence in a computer mediated discussion that promoted collaboration. Social presence existed as a lower level thinking ability on the online asynchronous discussion model that was designed and presented by the researcher. Social presence was a significant engagement that the researcher found to exist during a computer mediated discussion. It was a skill or behavior that learners needed to accomplish before they could move to the higher levels of Murphy's design model.

Cooperative Learning Theory

Five facets of the basic elements of cooperative learning were presented to help others understand how to design learning experiences that utilized cooperative learning theory. Positive interdependence took place when students worked together, and they perceived that they were moving toward the same goal. Direct interaction occurred when students discussed what they planned to do and how to go about it. Individual accountability brought individuals to master learning while sharing and working with others. Attaining collaborative skills involved individuals working together before they could cooperate and learn. Finally, group processing took place when the individuals in the group discussed and evaluated their work. Upon evaluation, the group members found that they worked well together. Instructors who have applied this theory would guide their students through each facet of the model. The more students developed, the better that worked in a cooperative learning situation (Joyce et al., 2000).

Teaching Tips

Instructors who utilized humanistic theory were advised to use developmental psychology as a guide for adjusting instruction so that the students were asked to perform at their own developmental level. Some instructors found that once they had identified their students' developmental level of ability that they should not expose the students to the higher levels of instruction. Other instructors believed in instructing just above the students developmental level because the students were not ready. Joyce et al. (2000) indicate that instructors should not underestimate an individual's mind. They felt instructors should remember that students need hands-on experience to help them understand the concepts.

KEY TERMS AND DEFINITIONS

Behavioral Theory: Behavioral theory comes from one of three schools of psychology in which

theories are categorized. Theories from the school of behaviorism hold that the environment has an impact on learning and that all behavior is learned.

Cognitive Theory: Cognitive theory comes from one of three schools of psychology in which theories are categorized. Theories from the school of cognitivism guide students to process information in ways that are meaningful to the student. These theories are based on declarative and procedural learning tasks that are authentic.

Humanistic Theory: Humanistic theory comes from one of three schools of psychology in which theories are categorized. Theories from the school of humanism focus on learner's affective needs that include their feelings, emotions, values, and attitudes.

Instructional Design Theory: Use of theory by professionals when designing, developing, managing, and evaluating a learning experience.

Online Instructors: Qualified individuals who have had the schooling or training to teach or guide learners to gain new knowledge and abilities in an online learning environment.

Online Learning: A form of learning in which learners interact with each other and the instructor through either asynchronous or synchronous modes of learning.

Chapter 7.3

Commodity, Firmness, and Delight: *Four Modes of Instructional Design Practice*

Brad Hokanson

University of Minnesota, USA

Charles Miller

University of Minnesota, USA

Simon Hooper

Penn State University, USA

This chapter is interactive, with surveys and reflective examinations of the reader's own work in instructional design. It examines instructional design using four professional models: manufacturer, engineer, architect and artist to help develop a broader understanding of the process of design. The values of the instructional design are also challenged, with the chapter examining the balance between utility and aesthetics, function and form. It concludes with a call for the instructional designer to work more as an artist, and offers tactics to encourage that change.

DOI: 10.4018/978-1-60960-503-2.ch703

INTRODUCTION

How do *you* solve an instructional design problem? Do you attempt to craft a solution based on the unique demands of each problem and the application of well researched instructional strategies? Or do you build upon an existing model, one that has worked many times before, selecting from solutions developed for a range of previous projects?

Your work is directly connected to your conceptualization of your role within the field of instructional design. And that conception includes assumptions and biases about processes, theories, and products. In the course of this chapter we

will ask you to re-conceptualize your professional practice as an instructional designer and to recognize the roles of instructional manufacturer, instructional engineer, instructional architect, and instructional artist. We will describe how the working ethos of each shapes their practice.

What then, would happen if you were an *instructional artist*? As an instructional artist, you might be encouraged to create fundamentally different designs and work in a completely different manner. You might begin from an idea, engaging and desirable, but unconnected with learning, only later to apply it to instruction. It might work; it might not; but the application would be entirely different. We can see that the perspective through which we view ourselves biases how we understand and address problems.

Your Balance in Design

The following survey is intended to stimulate personal reflection and discussion of the ideas included in this chapter. Participating in the survey will help you to engage with the article, to stimulate understanding of the concepts presented, and to reflect on your personal practice as an instructional designer. The survey was built from the characteristics which will be explored in this chapter, and will focus on the Vitruvian values of *commodity*, *firmness* and *delight*. We will pose these questions twice in the course of this writing, the second time at the conclusion of the chapter.

To complete each question, select the point on the Likert scale most aligned with your *current* practice. Note that there is no middle point and there are no right or wrong answers. Questions are intended to create difficult choices, encouraging

personal reflection. After completing the survey, score each response according to the directions that follow.

Scoring of Each Item in the Survey

Each question is given two scores which are entered in the boxes to the left and right of the Likert scale. To determine the score for the left box, count the number of blank spaces from the right margin to your entry (each margin is set at 0). For the right box, count the number of blank spaces from the left margin to your entry. In the illustration below (see Figure 1) the sample entry is three steps from the right margin, scoring 3 points for pedagogy. Likewise, the check is two steps from the left margin, scoring 2 points for Innovation. Together, the total points awarded for each question must sum to 5. There are 21 questions, with 105 points in total.

Calculating Your Score

After scoring each item, use the table below to assign points to the three categories (i.e., commodity, firmness, and delight). Each question will produce two scores. The short answers for each question are included in the table to help with proper scoring. For example, in the scoring example above, “pedagogically sound” will be in one box, and “Innovative” in another; the appropriate score should be written in each box. Shaded boxes designate comparisons not included for that question; do not write in scores in those places. Add the points when complete to achieve a total score for commodity, firmness, and delight.

Figure 1. How to calculate the survey score

Scores should be interpreted as follows:

- 0-14 points: low
- 20-50 points: medium
- 51 + points: high

We will help you to analyze and interpret your scores later in the chapter.

INSTRUCTIONAL DESIGN

Instructional design is guided by a range of theories and ideas, beliefs and assumptions, not the least of which is a perception of our own practice. Consequently, if we view the process of instruc-

tional design as one of production (that is, the manufacture of instructional materials) we will create work limited in conception and execution. Similarly, if we go beyond mere production to engage theories of learning and perception, the scientifically based outcomes are engineered, highly efficient, yet may lack the wholeness needed for the development of knowledge (Wilson, 2005). To be complete, we must extend our self-image and think beyond production or engineering. We must seek a balanced model of professional practice, one which expands our understanding of design itself.

Ultimately, in this chapter, we hope to improve educational practice through the design and development of technology based products and methods.

Table 2. Scoring the survey

Q	Commodity		Firmness		Delight	
01CD	Teacher				Artist	
02CF	Functionally useful		Stable			
03CF	Content providers		Tools			
04CD	Pedagogically sound					
05CF	Usability		Utility		Innovate	
06FD			Stability		Visual richness	
07CD	Easy to use				Motivating	
08FD			Functional capability		Motivation	
09CD	People				Design experiences	
10CF	Pedagogical soundness		Efficiency			
11FD			ID products		ID experiences	
12CD	Content				Experience	
13CD	Usability				Aesthetics	
14CF	Teacher		Technician			
15CD	Functionality				Visual richness	
16FD			Tools for learning		Tools for experience	
17FD			Efficiency		Innovation	
18FD			Utility		Aesthetics	
19CF	Ease of use		Functional capability			
20FD			Technician		Artist	
21CF	People		Products			
	Commodity Total		Firmness Total		Delight Total	

Achieving such a goal requires an understanding of the relationship between instructional design practice and product. To clarify this relationship, we examine instructional design through the architectural dictum of Vitruvius: commodity, firmness and delight. We will identify four modes of design practice; instructional manufacturer, instructional engineer, instructional architect, and instructional artist; and examine how the Vitruvian values are employed. Finally, we offer tactics to promote a balanced approach to instructional design.

Methods

Instructional design specifically addresses learning through products and contexts which facilitate the development of knowledge (Parrish, 2005). The traditional methodology of the instructional design field encompasses the analysis, design, development, implementation, and evaluation of instructional processes and products (Reiser, 2001). Other professional fields of design, such as interface design, systems engineering, information sciences, industrial design, technical communications, and new media design have similarly strong understandings in psychology, community context, implementation, and social value (Wilson, 2005).

To orient the field toward design work that engages learners more meaningfully and effectively, instructional designers must begin to focus on creating *experiences*, as opposed to simply developing products or processes. To engage and involve the learner, instructional designers must shift their practice. Substantial innovation in the field will occur only when designers surpass the technical and pedagogical issues in their work. (Innovation is messy and difficult in most situations, particularly including education). Beyond utility is the affective domain, the engagement of the learner, the beauty within the eye of the beholder; not the steak but the sizzle. This is the aesthetics of design.

For thousands of years, philosophers and designers have used the term aesthetics, often interchangeably with the word beauty, to illustrate the sensual relationship and dynamic perception of art to culture (Lavie & Tractinsky, 2004; Parrish, 2005). For example, Leone Battista Alberti, the Italian 15th century architect, painter, and philosopher, defined aesthetics as “a great and holy matter,” essentially the harmony of all design elements in proportional relationship to one another (Johnson, 1994, p. 402).

Formally established as a philosophical means to critique the visual arts, literature, music, performing arts, and even food (Ekuan, 1998), aesthetics is defined by the *American Heritage Dictionary of the English Language* as “an artistically beautiful or pleasing experience” (Tractinsky, 2004, p. 11). However, the influence of aesthetics and its significance to the instructional design community moves beyond illustrating the relationship of art to culture and simply critiquing the surface level elements (e.g., shape, color, texture, etc.) of objects and environments (Parrish, 2005). Parrish (2005) defines aesthetics as “a quality that exists equally in the experiences of everyday life as in the fine arts, and one that certainly applies to the learning experiences we design as instructional designers” (p. 16). Central to human thought and practice (Lavie & Tractinsky, 2004), aesthetic experiences provide a foundation for the intellectual activities associated with learning (Parrish, 2005). For the purposes of this chapter, we define aesthetics as those elements of interactive design which are focused primarily on enhancing and heightening the learner’s experience, as opposed to elements that merely satisfy the pedagogical or technological needs of the instructional objectives. In other words, aesthetics is *design beyond done*, the essence of the design process which continues after the completion of operational and technical requirements.

For the most part, aesthetics has been largely overlooked by instructional designers; only a handful of recent articles address the relationship

between aesthetics and usability (cf. Aspillagae, 1991; Kirschner, Strijbos, Kreijns, & Beers, 2004; Parizotto-Ribeiro & Hammond, 2004). The instructional design community at present is concerned primarily with performance improvement and systematic instructional design procedures (Reiser, 2001). The field's reluctance to acknowledge aesthetics as an integral facet of instructional design curriculum, practice, and research will suppress the development of engaging learning media and, ultimately, the effectiveness of instruction (Parrish, 2005; Wilson, 2005).

Parrish (2005) posits that instructional designers often view aesthetics as a superficial quality which encourages passivity by creating an illusion of learning, sidetracking the chief responsibilities of instruction. Yet others suggest aesthetics should exist at the core of design, intertwined with utility and usability, to provide pleasant experiences that enhance and extend the way people work and learn with technology (Kirschner et al., 2004). Frequently viewed as superficial, aesthetic design gets overlooked in lieu of utility and efficiency (Tractinsky, 2004) and is traditionally delegated to graphic designers late in the design process (Parrish, 2005).

Although instructional designers often neglect the potential impact of aesthetics on learning and view emotional design as a superficial task, many disciplines (e.g., architecture, automotive engineering, interior design, etc.) view aesthetics as a principal design element in the problem-solving process (Parrish, 2005). For example, automotive engineers often place the aesthetics of their vehicles at the core of the design process, playing a vital role alongside utility and usability in the development of the final design. Instructional designers, "beholden to the dry, yeastless qualities of their work" (p. 5) tend to focus on theoretical strategies and levels of efficiency, rather than discussing how their designs emotionally inspire or motivate learners.

Some in the field of instructional design have begun to address a balanced approach which

includes aesthetics in their work. For example, interaction design is a framework anchored in utility, usability, and aesthetics focused on creating pleasurable learning experiences that appeal to and benefit the user (Kirschner et al., 2004). While utility is defined as the array of functionalities and features incorporated by a system (i.e., the tools present in the software that satisfy the outlined pedagogical requirements), usability is concerned with the effectiveness, efficiency, and satisfaction with which learners can accomplish a set of tasks. Together, the utility and usability of a design represent the *usefulness* of the system. For a system to be perceived as useful by its audience, the design of a software environment must balance utility and usability. In addition, interaction design is concerned with aesthetics and emotion, more precisely, how the software may appeal to and benefit learners (Kirschner et al., 2004).

BALANCE

Some design fields have long recognized a value in the balance of the functional, technical, *and* aesthetic aspects of design. It is implicit that no one aspect should dominate, nor should any be neglected. From intercontinental bridges across the Bering strait to the elegant simplicity of an orange juicer (Norman, 2004), delight, beauty, and aesthetics are common in the fields of engineering and product design. Historically, architecture has codified this balance as *commodity, firmness, and delight*.

In the first century B.C., Marcus Vitruvius Pollio, a Roman writer, architect, and engineer, authored a book titled *De architectura*, later known as *The Ten Books of Architecture* (McEwen, 2004). Considered the forefather of systematic architecture theory, Vitruvius advocated that architecture design must satisfy three discrete requirements: *firmitas* (i.e., strength), *utilitas* (i.e., utility), and *venustas* (i.e., beauty) (Tractinsky, 2004). Whereas *firmitas*, or firmness, refers to the construction

and physical soundness of a building, *utilitas*, or commodity, deals with the functional use and appropriateness of a design. The phrase “commodity, firmness, and delight” is partially attributed to Henry Wotton, who translated Vitruvius’ text in 1624.

The third Vitruvian requirement, *venustas*, or delight, refers to the aesthetic or beauty of architecture. Vitruvius believed architecture was an imitation of nature (McEwen, 2004). Humans, mirroring techniques employed by birds and animals, construct their homes as shields against nature’s elements. However, in addition to building strong, durable, and useful homes, Vitruvius believed architects must focus on the aesthetic elements, or beauty, in their designs. Beauty (i.e., delight), is responsible for making design a uniquely human process: “Is it not strange that sheep’s guts should hale souls out of men’s bodies?” (Shakespeare, W., *Much Ado About Nothing*, Act 2)

Vitruvius’ architectural requirements present an illuminating framework for instructional designers to re-align their design methods. The elements of commodity, firmness, and delight can inspire instructional designers to greater innovation and higher quality, and the three aspects of architecture can be used to inform the work of instructional design.

Within instructional design, the Vitruvian ideal of firmness can be used to describe the technical issues of instructional design, specifically how media are used and how technology is applied in a solution. Technical skill is a requisite for success here. For example, software should not crash; it should run well and be delivered on time. This is the production aspect of instructional design.

Commodity refers to the functional use of a design product. Within the field of instructional design, commodity refers to the application of instructional methods, the use of sound instructional theory, and the structuring of the interface design. Scientifically researched and proven, this is the domain of the engineering aspect of instructional design.

Delight encompasses the affective aspects of the design, from the surface aesthetic to the complete experience of the learning adventure. This is the area that is most difficult in which to succeed, and which will prove most effective and rewarding. As a dominant feature, this would describe the realm of the instructional artist, possibly sacrificing utility for aesthetics and experience.

YOUR VALUES IN THE DESIGN PROCESS

We will now revisit the results of the survey completed at the beginning of the chapter. Your scores will reflect your perception of your own work, illuminating those areas most central to your current instructional designs. Any one aspect rating in the high range (i.e., 50 points and above) indicates a predilection for that area to the detriment of others. Each area scoring in the medium range (i.e., from 20 to 50 points) indicates a balanced approach to design.

Some designers focus on a single design aspect, others successfully integrate two in their work, and many have a goal to balance all three. For example, some architects are known to put buildings together well; others understand the social, functional and programmatic aspects of the field; and some, the rare few, concentrate on the aesthetic domain of the field. (From an old anecdote; Frank Lloyd Wright to a patron with a severely leaking roof: “Enjoy. You live in a Frank Lloyd Wright building.”)

Many of the professions that create the designed objects, environments, and experiences we interact with in society can be described through the Vitruvian descriptors of commodity, firmness, and delight. For example, one can imagine the results from various cooks and chefs to the survey. Some would view food as a utilitarian need, as all people need to eat. Sufficient food is provided in many settings. It is warm, it’s cooked, and it’s safe to eat. A better diet can be provided, however, ensuring

some variety and essential nutrients needed for a healthy lifestyle such as fiber, vitamins, and antioxidants. It might not taste great, but it's very good for you. Some meals reach the level, however, of *cuisine* where the taste, the smell, the nutrition, the visual sensation, and the experience of the meal combine to make something exceptional. In that case, the chef may have achieved the Vitruvian charges of commodity, firmness, and delight. And so should we in instructional design.

One way to apply the three Vitruvian aspects to instructional design is to use other design professions as models for our work. Although many definitions of instructional design exist, models for professional orientation can provide a means to advance the field.

INSTRUCTIONAL MODES OF PRACTICE

We have identified four modes representing distinct yet common approaches to instructional design practice: the instructional manufacturer, instructional engineer, instructional architect, and instructional artist. The modes were developed from our observations of design practice, and are used as a sorting mechanism, a 'hat' to help understand what is a continuum of practice with varied characteristics (see, for example, Rowling, 1996). Names were chosen to signify various processes in design. Each mode differs on several dimensions (see Table 1). Most importantly, practitioners in each mode differ in how they go about their work; the difference is reflected in the nature of their products. After reading the modes of practice, we ask the reader to identify their personal primary design approach from within the modes.

The *manufacturer* is a developer of instructional materials. The manufacturer is often a technician who applies a pre-defined design model or template to solve an educational problem and delivers a product as efficiently as possible. To a large extent, the solution to an educational

problem is presented to the manufacturer whose responsibility becomes one of developmental efficiency. Product consistency and stability are of primary importance, leading to results that are predictable and stable.

The *engineer* is an instructional problem solver. The engineer is generally a highly trained professional who ensures a product achieves its educational goal and is usable by the target audience. The engineer can apply contemporary research-based ideas to develop educational materials. Thus, interface design and pedagogical theory are important components of this mode of instructional design. The engineer's principal goal is the functional efficiency of the design.

The *architect* extends the engineer's functional and usable solution and attempts to incorporate aesthetics at the core of the design process. By doing so, the architect explores divergent solutions that extend and cultivate the affordances of a medium. The architect's approach to instructional design attempts to balance utility, usability, and aesthetics.

The *artist* is an instructional explorer. The artist uses instructional problems as stimuli to experiment with media and affordances. The instructional artist may work without client or audience, only later attempting to apply to instructional practice what has been learned through the artistic experience. The artist embraces failure and engages in continuous self-criticism while attempting to understand both the problem and self.

What then is your mode of instructional design practice? One's perception of role indicates one's general orientation; in other words, how you perceive your professional orientation will affect your processes and methods of working. Most designers have one principal orientation for work. In reality of course, most instructional designers operate in different modes at different times, but for our purposes here, understanding your principal mode of operation will provide a basis for understanding this chapter. The results of your survey can help you locate your own profes-

Table 1. Survey

Q1	Are you a teacher or an artist?		Teacher Artist
Q2	Which is more important: a functionally useful product or a stable product?		Functionally useful Stable
Q3	Should media be used as tools or content providers?		Content providers Tools
Q4	Which is more important: pedagogical soundness or innovation?		Pedagogically sound Innovative
Q5	Which is more important: software usability or utility?		Usability Utility
Q6	Which is more important: software stability or visual richness?		Stability Visual richness
Q7	Should designs be easy to use or motivating to the learner?		Easy to use Motivating
Q8	Which is more important: functional capability or learner motivation?		Functional capability Motivation
Q9	Should people or design experiences be more central in ID?		People Design Experiences
Q10	Which is more important: pedagogical soundness or efficiency?		Pedagogical soundness Efficiency
Q11	Should products or experiences be more central in ID?		ID Products ID Experiences
Q12	Which is more important in media use: content or experience?		Content Experience
Q13	Which is more important in media use: usability or aesthetics?		Usability Aesthetics
Q14	Are you a teacher or technician?		Teacher Technician
Q15	Which is more important: product functionality or visual richness?		Functionality Visual Richness
Q16	Do media provide tools for learning or tools to create experiences?		Tools for learning Tools for experience
Q17	Which is more important: efficiency or innovation?		Efficiency Innovation
Q18	Which is more important in media use: utility or aesthetics?		Utility Aesthetics
Q19	Which is more important: ease of use or functional capability?		Ease of use Functional capability
Q20	Are you a technician or an artist?		Technician Artist
Q21	Should products or people be more central in ID?		People Products

sional practice among these four modes. It is hoped by examining beliefs inherent in the survey questions we can stimulate reflection and encourage balance within the field.

We can examine each of the modes by using hypothetical results from our earlier survey (see Figures 1–4). Although we illustrate the performance of each of the four modes across a range

Table 3. Focus of the design process for the artist, architect, engineer, and manufacturer

Focus	Artist	Architect	Engineer	Manufacturer
Audience	Self	End users	End users	Irrelevant: Audience has been predetermined
Usability	Irrelevant beyond the artist	Important, but adaptable	Very important	Irrelevant: Usability has been predetermined
Technical robustness	Will vary according to the problem	Important, but adaptable	Very important	Irrelevant: Structure has been predetermined
Aesthetics	Critical	Important, but adaptable	Low	Irrelevant: Aesthetics has been predetermined
Profit	Irrelevant	Less important than for the engineer	Budget driven	Critical
Solution	Internally driven	Externally driven	Externally driven	Template driven

of factors, the illustrations are not presented as quantitatively precise graphs. Instead, they are intended to illustrate the changing values among different professional modes.

Manufacturers would have high scores in the firmness category, indicating a concentration on production, operation, and utility. Instructional engineers would have a high rating in commodity, with interests in usability, the scientific/research basis of education, and a focus on the human aspects of learning; they would also have a medium rating for firmness. Artists would have a high rating in the aesthetic area, possibly ignoring or viewing as less valuable other aspects of the design endeavor. Instructional architects would have a balance in the three areas with no one area

having dominance in the design process. Actual results would vary among modes and even within individuals on a day-to-day basis. We now ask you to return to your initial survey scores to compare and reflect on the illustrated modes in Figures 2–5.

We can compare how each of the four modes of instructional design is differentiated by the Vitruvian aspects (see Figure 6). We believe it is particularly important to understand how different design aspects vary across each mode. Once this pattern has been recognized, we anticipate readers will quickly understand other relationships presented herein and may generate additional relationships of their own.

Artists generally rank highest for aesthetic issues (i.e., delight), but produce correspond-

Figure 2. Commodity-firmness-delight: Instructional architect

Figure 3. Commodity-firmness-delight: Instructional artist

Figure 4. Commodity-firmness-delight: Instructional engineer

Figure 6. Differences in design approaches for the artist, architect, engineer, and manufacturer

ingly low ratings for firmness and commodity, reflecting the instructional artist's interest in the experimental, experiential, and visual as opposed to the utilitarian aspects of design. Instructional architects' scores generally reflect a balance across the three areas: no single dimension dominates the design process. Instructional engineers score high in commodity, reflecting interests in usability, the scientific/research basis of education, and a focus on the human aspects of learning. Engineers score medium for firmness. Manufacturers are concerned with the utilitarian aspects of design (i.e., efficiency, robustness, and completion) and score high in the firmness category, reflecting an emphasis on production, operation, and utility. However, they score low in commodity and have little interest in aesthetic design.

Figure 5. Commodity-firmness-delight: Instructional manufacturer

These classifications suggest one's attitudes and goals for instructional design. We contend that the field of instructional design emphasizes function and theory, neglecting affective and aesthetic issues to the detriment of education.

INSTRUCTIONAL DESIGN EDUCATION AND INNOVATION

While our observations of the field and subsequent description of modes of practice can shed light on the field of instructional design, comparisons with other aspects of professional practice can also be valuable. In this graph we illustrate two separate areas, innovation and instructional design education. Each is discussed separately, and in combination below.

Within instructional design education, the focus of learning is principally on the manufacturing and engineering modes. Indeed, we suspect many instructional designers would be happy to complete an instructional design program armed with the ability to select and apply one or more of the most frequently used design models and a foundation in using the most visible software applications in the field (Jonassen, 2006). For those most interested in manufacturing approaches, the focus on software tools becomes paramount. Many instructional design students learn how to use software to produce instructional materials,

which are often based on applying existing models of learning.

More advanced students may approach the engineering mode, employing educational and pedagogical theories in their design work. Few students of instructional design reach the level of instructional architect balancing aesthetic concerns with functional and theoretical concerns. Occasionally, students (and practitioners) assume the mantle of instructional artist, but given the radical and experimental nature of their products, their efforts tend not to be well supported.

Innovation, the ability of the field to develop and implement new methods of instructional design, varies greatly across instructional design modes. Innovation is least evident in manufacturing, where accepted production methods are maintained and applied to instructional design problems, but no new directions are used or sought. Change is incremental and craft based; improvements in efficiency are sought, but are generally modest. Instructional engineers are more likely to innovate through research-based concepts and directions, but change remains moderate. Instructional architects specifically seek new directions for their work, and hence, innovation is increased. Instructional artists, perhaps seeking the “shock of the new” (Hughes, 1991), rate highest in innovation and change.

A hypothetical comparison can be made between the educational system for instructional designers and the value placed on innovation in instructional design. While we often contend creativity and diversity are valuable, in our own students, in instructional design education, those qualities are “messy.” Quite often, our goals, like those in mainstream education, are the transmission of content and the development of proper students, graduates, and subsequently instructional designers. We are pleased to produce instructional engineers, and often fail to recognize the value of the instructional artist. A culture of innovation has not developed within instructional design education.

MEDIA FOCUS

Many instructional design students have an intense engagement with technology; many others develop skills in this area as they practice. Media can be the stepchildren of instructional design: a chore to some, but a pleasure to others. How we emphasize or avoid media is an interesting measure of our instructional design practice (see Figure 3).

Media is an important component of instructional design, and our emphasis or lack thereof is instructive in understanding our modes of instructional design practice. As practitioners vary across the landscape of instructional design, there is a close connection between the focus on the media and our component, delight.

As with practice as an artist, increased skill in media increases the potential for innovation and aesthetic reward. This connection follows with electronic media as well; high levels of skill are often more engaging and more enriching. The instructional architect, however, realizes both the value of a focus on the media and a balanced approach to function and utility. The artist may overstate the instructional experience, whereas the engineer or manufacturer may overemphasize production and function and undervalue aesthetics.

INSTRUCTIONAL MODES IN PRACTICE

We anticipate the design approaches for each mode could be examined across diverse instructional design problems. To illustrate, we will explore the use of distance learning and how it is addressed by practitioners of each of the four modes of instructional design. Afterwards, we will ask you, the reader to imagine your own hypothetical instructional design problem and to conceive how you could, as an instructional manufacturer, engineer, architect, and artist, address the problem.

Although each solution approach will embody the designer’s theoretical conjectures about how

people learn and interact with media (i.e. expectations about how designs should function in unique instructional settings) (Sandoval & Bell, 2004), the divergent characteristics of each mode ultimately guide the exploration and solution of the problem.

When asked to develop educational materials for use through distance education, the instructional manufacturer might employ traditional instructional design methods to develop instructional materials emphasizing content presentation and application. Such materials are commonly delivered to learners via the most efficient technologies (e.g., online quizzes, Blackboard/WebCT templates, PowerPoint presentations, etc.). Most of these technologies are stable and, at the core, are based on educational theories such as constructivism, collaboration, or cognitive science, but such theories are remote from the manufacturer. Models for the design process would focus on the functional (i.e. “form follows function”). As with the architecture in the 1960s, an aesthetic could develop based on making the technology work, on utility.

Following a more innovative and media-driven approach than the manufacturer, the instructional engineer could design materials that promote higher-level learning (i.e., both near- and far-transfer) of the content. For example, the engineer could use the linear interactive affordances of a development environment such as Adobe authorware to design animations to highlight key steps in worked examples, simulated models of complex phenomena, and develop interactive exercises adaptive to the prior history of each learner.

The instructional architect, fueled by a balanced approach that includes aesthetics and innovative design, would approach the problem by designing new solutions that promote high-level learning (i.e. generation and challenge), followed by a critical examination of the solution to improve user engagement, motivation, and interaction. By scrutinizing the design and questioning the solution, instructional architects are unique in

that they are not satisfied by simply solving the problem. The architect is motivated by extending the boundaries of the available media affordances to explore solutions that enhance the learner experience, moving beyond the pedagogical and technological specifications of the instructional problem (i.e. design beyond done).

The instructional artist, operating with a high expectation of failure, would approach the scenario with little concern for the problem specifications and simply experiment with the available design media and content. For example, the artist could use the graphical capabilities of Adobe Flash to create interactive visualizations or sonic interpretations. Most importantly, although the initial goal may have been pure experimentation with experience, an instructional artist might discover techniques that promote learning. (Note that the term “might” is critical to the nature of the artist; results that are unsuccessful in generating added learning remain valuable.)

We ask now that you, the reader, imagine an instructional design problem of your own. It might be one of your current practice or one that is imaginary. How would this problem be addressed as a manufacturer, as an architect, as an engineer, and as an artist? Which is closer to your own practice or learning? And from which can you draw further inspiration?

It is important to note that most instructional designers are not purists: They do not restrict themselves to a single design mode. Instead, they often shift between modes, borrowing from each mode’s approaches and processes. For example, an instructional architect may choose to shift responsibilities toward a manufacturer to construct rapid-prototypes for transient use and experimentation with learners early in the development process. Alternatively, an instructional engineer may shift towards an architectural or artistic practice mode to enhance the aesthetic design and user engagement of their solution, essentially working “beyond done.”

The modes are dynamic: any individual designer at times may work in each of the modes. The goal of a balanced approach to instructional design is paramount, encouraging activity across the modes as necessary.

RETAKING THE SURVEY

In reading any article or experiencing any lecture, one measure of success in communication is in changes affected on the reader or audience. We now invite you to revisit the survey from the beginning of the chapter, and this time, answer the questions as to how you would like to perform as an instructional designer. An additional copy is provided after the bibliography.

Reflection on possible changes and alternative directions is valuable for most professionals, including instructional designers. Have your ratings changed? How will this change your outlook on your current position? How should this change the nature of your future design work?

We hope to continue the research surrounding this survey which is available through <http://hokanson.cdes.umn.edu/CFD/>.

MOVING TO THE LEFT: TACTICS TO INFUSE AESTHETICS IN YOUR INSTRUCTIONAL DESIGN

So how should you solve an instructional design problem? We contend that to do it well, you need to step outside of your comfortable answers and ideas. To do it well you need to embrace failure through experimentation. And to do it well, you need to be more of the instructional artist.

How then *will* you become an instructional artist? You might begin by making semantic and conceptual steps, in other words, thinking of yourself *as* an instructional artist and describing your work to others in that way. Extend that to your work procedures: redefine not only your work,

but the next project you begin. Assume that the work has hidden meaning, and that you bring to it a completely new vision.

Much of the work in instructional design is done in modes displayed on the right of Table 1, or Figures 5-7 working as an instructional manufacturer or an instructional engineer. Moving to the left (i.e., becoming more balanced in one's approach to instructional design, and working more like an instructional architect or artist) is a philosophy contingent on how *you* value the aesthetic and effectual components of your designs. A number of tactics can be employed to engage and infuse *Delight* in your practice of instructional design; they follow below. Examples of tactics and strategies are described for individuals, professional firms, and schools of instructional design, each encouraging a "move to the left".

Each of these approaches attempts to develop skills of the architect and artist, to help create work that is more engaging, experiential, and delightful. These approaches may be contrary to many aspects of practice in instructional design, and of course, should not become dominating in one's practice. They are meant to re-orient one's practice. We have based this on a series of observations about those actions which would encourage more innovative and diverse work.

Figure 7. Differences in instructional design education and innovation for the artist, architect, engineer, and manufacturer

Figure 8. Differences in media focus and delight for the artist, architect, engineer, and manufacturer

- **Technological immersion leads to insight.** We believe that the instructional medium drives the selection of the method. Limiting design work to a single medium limits the ability to conceptualize those procedures possible with that medium. Similarly, having a range of different media for use allows for a cross-pollination of ideas; what you learn in Flash can help you understand audio software technology. “Intelligence is skill in multiple media” (Hokanson, 2001).
- **Diversity in background leads to innovative practice.** Expertise in a different field provides inspiration and metaphors for novel and innovative work. Pragmatically, alternative expertise stimulates divergent thought, provides varied examples of work, and attracts a wealth of contacts, discussants, and diverse experts to engage.
- **Understanding how to think, communicate, and behave as one’s audience, clients, and colleagues is valuable to any practice.** Good instructional design cannot be created in a vacuum; it needs engagement before, after, and during the design process. Understanding one’s audience is a constant in the field. We all pay lip service to the idea. However, actively engaging the audience in the design process and seeing their responses is less frequently part of the process.
- **Improve design ideas through learning to criticize and critique the work of others and yourself.** Develop a filtering system that helps you to identify what is valuable, good, and wasteful. Then use it.
- **Finding new ideas and using them is the center of design work.** Develop practices that encourage divergent uses of media. Creativity, application, and innovation are critical to advancing the field. Creativity, as a skill, can be developed through conscious practice.
- **Strive for continuous innovation and advancement in design; nothing is ever perfect.** The instructional designer should develop dissatisfaction with the status quo, striving to be better with a reach exceeding one’s grasp, striving for flow; seeking failure. There needs to be a constant questioning of the ideas, values, assumptions, and procedures of the designer. Self evaluation and critical thinking need to be integrated into the instructional design process.
- **Involvement with others, particularly peers, is valuable to professional work.** Meet, present, publish, engage, and share—discussing and critiquing one’s work in a public setting helps people to think divergently.
- **Delaying functional perfection allows aesthetic aspects to evolve.** It is important to experiment with technology and ask questions such as, “What can be done with this medium?” Relevant instructional applications need not be immediately apparent, as the artist creates learning artifacts without consideration for an intended audience or use. Instructional designers, indeed all creative professionals, would be well served by following the model of the 3M

Table 4. Moving to the left: Steps toward becoming an instructional architect or artist

Tactic	Short-hand strategy	Individual tasks/actions	Firm tasks/actions	Curriculum tasks/actions	Outline your tasks/actions
Technological immersion leads to insight	Get your hands dirty	Develop a strong expertise in at least one ID media or technology	Expand divergent skills; encourage cross-team communication of technological advancement	Provide opportunities for technical skills development: include a studio component as part of ID program	
Diversity of background leads to better practice	Become an expert at something else	Develop skills in another domain; enrich your 'day job' by expanding your skill set	Support professional development and cultural activity among employees	Provide flexibility and encouragement for non-ID course work	
Understand one's audience, colleagues, and clients	Understand people	Ask questions and listen; invite others to use your designs during the design process	Employ active user testing, prototyping, and other public engagement	Include psychology and user-testing courses in curriculum	
Improve design ideas throughout the development process	Learn to criticize and critique	Seek feedback on design work; develop a habit/process of self reflection; put your work on display when possible	Celebrate design work with open critiques; publish work through peer review	Model and include active critiques in courses and studios	
Finding and using new ideas is the essence of design	Learn to be creative	Choose the other path, the one less taken; destroy your routine; be receptive to new inspirations in any environment	Develop as a creative organization; support and develop creative ideas by all	Add creativity courses; require multiple concepts in problem solving across curriculum	
Strive for continuous innovation and advancement in design	Never finish	Integrate self evaluation and critical thinking into the design process; develop dissatisfaction	Always strive for new products; reward exploration and failure; 3M's 15% rule (Kao, 1997)	Develop skills in critical thinking and design critique; encourage and model self-reflection and improvement	
Interaction with peers improves critiquing skills, ideas, and the design process	Connect	Talk to someone else; present at conferences in ID and other fields; become active in the design community	Support employees in attending conferences, courses, and community events	Encourage participation, within ID and with other disciplines; encourage projects with other majors	
Delaying functional perfection allows aesthetic aspects to emerge	Work as an instructional artist	Create experimental instructional projects; build instructional experiences; do something wrong; value failure	Use competitions and 'what-if' sketches to investigate ideas; become less utilitarian	Reorient priorities of the design process; support "way out" projects; embrace the experimental failures of students	

Corporation, where it is expected that 15% of budgets will be used for research and experimental development (Kao, 1997).

Table 4 summarizes these topics, and both the table and the listing above are merely begin-

nings; we ask that you complete the last column in each row, outlining a set of tasks, strategies, or even daily goals to help improve your work as an instructional designer by *moving to the left*.

APPLICATION

How one describes one's work deeply affects the procedures, ideas, and quality of the work itself. We hold that instructional design has long focused on the productive and technical aspects of instructional design, the pedagogical issues or the software delivery system, and has for a long time, ignored the aesthetic and affective domains. Instructional design generally remains a craft based system, with modest theoretical direction. Adherence to traditional procedures, even perfecting the means of production, will continue to produce projects and designs that only have the same capabilities.

Now, as we close, we return to the original questions of the chapter: How *should* you solve an instructional design problem? How could you solve your most common design problem in a different way? How has this changed in reading this chapter?

Instructional designers are not engineers, or artisans, or crafts people, or manufacturers. Their work must go beyond each of these appellations. Instructional design should include all of the aspects reviewed here: commodity, firmness, and delight. Each of these qualities is essential to good design and must be addressed in the design process.

Designers begin each project without knowing the nature or quality of their ultimate solutions. We are not designing if we already know the answer. We are not designing if we follow a cookbook of theories and pedagogy. Yet, we know that the design process, of creating without a net, is engaging, challenging, and leads to superior solutions. To truly design is to extend understanding, to create something new and innovative. To design is a *goal*.

To change education you need to change your perception of your profession. To change your work, you will need to change your mind.

Chapter 7.4

Performance Case Modeling

Ian Douglas

Florida State University, USA

ABSTRACT

This chapter introduces performance case modeling as a means of conducting a performance analysis. It argues that the design of any instruction focused on practical subjects should be preceded by understanding of the performance requirements for graduates of a course of instruction. This understanding is facilitated by the collaborative creation of diagrams that identify the different roles a performer takes and their associated goals, together with documentation of performance measures for the goals. The measures serve as a baseline for the evaluation of instructional effectiveness. Other approaches to visual languages in instructional design have been more focused on modeling the architecture of the instructional system rather than the performance environment

in which its graduates will be expected to perform. The approach described is based on UML use cases and serves to focus thinking on the performance analysis that should occur prior to the design of instruction.

INTRODUCTION

The performance analysis stage of most instructional system design process models has long been seen as one of the most crucial stages (Harless, 1970). If designers do not sufficiently understand the problem they are unlikely to create an optimal solution. In addition to aiding the understanding of the problem, performance analysis is also focused on establishing performance measures and collecting initial data. It is not possible to determine the value of a solution, such as a new course of instruction, without having analysis

DOI: 10.4018/978-1-60960-503-2.ch704

data that would allow one to show improvement over a baseline level of performance (Deming, 1982). This is especially true if designers are aiming to achieve Kirkpatrick's level 3 (on the job application of acquired skills and knowledge) and level 4 (improved organizational outcomes as a result of the acquired skills and knowledge) (Kirkpatrick, 1998). Clark and Estes (2002) present a number of case studies illustrating that data-driven analysis leads to better solutions for performance improvement.

Some terms that are often used interchangeably in performance analysis are: needs assessment (Kaufman, 1988), needs analysis (Mager & Pipe, 1984), performance assessment (Robinson and Robinson, 1995), front-end analysis (FEA) (Harless, 1988), and training needs analysis (Rossett, 1998). In this chapter the term performance analysis is used as a general term for all of these types of analyses.

The majority of attempts to adapt visual languages for instructional design have been focused on designing the solution space (the nature of the instructional system). In this chapter we will consider an approach that is specifically focused on understanding the problem space (the performance requirements for the employers of the instructional system graduates). Understanding the desired performance is an important first step that should occur prior to developing instruction or any other means of improving human performance.

The specific approach is an adaptation of use case modeling, which is part of the unified modeling language (UML). UML is a systems modeling tool which, although developed primarily for computer systems modeling, is adaptable to the modeling of other types of systems. Despite its origins in software engineering, elements of it have been adapted for such diverse purposes as business process modeling (Marshall, 2000; Eriksson and Penker, 2000) and educational modeling (IMS, 2005). Different aspects and applications of UML relative to instructional design are described in a number of chapters in this book. In this chapter

we will focus on one area of UML that has been relatively neglected.

UML is not a single language but rather a collection of diagramming techniques and specification languages that serve different purposes in systems analysis and design. It can be used both to model existing systems and to envisage models of new systems. The nine different diagramming techniques found in UML serve different purposes: describing what the static structure of a system is like (class, object, and component diagrams), describing how a system operates and information flows through the system (activity, collaboration, sequence, and statechart diagrams), describing how a system is deployed (deployment diagram), and describing the functional requirements of the system (use case diagrams). A number of the chapters in this book describe the adaptation of elements of UML for instructional systems architecture design (e.g., Chapter IX). They primarily focus on the use of Structure and Flow diagrams. In this chapter the focus will be exclusively on use case diagrams.

Given that they are concerned with system inputs and outputs rather than the internal technical details, use cases are often seen as a crucial part of UML when used in software development. Use cases aim to establish what an efficient and effective system should achieve. They serve as the starting point and driving force behind all other analysis and design activities (Jacobson, 1992; Rosenberg & Scott, 1999).

This chapter explains the concept of use case modeling, shows how it can be adapted for performance analysis (performance case modeling), discusses software tools for repositories and reuse, and suggests guidelines for applying performance case modeling.

PERFORMANCE ANALYSIS

There are a number of approaches to performance analysis prescribed and studied in the literature

(Rummler & Brache, 1995; Swanson, 1994; Wedman & Graham 1992; Schaffer, 2000).

The major tasks of performance analysis that they tend to share are the following process:

- Identify what people in particular roles are required to achieve.
- Identify gaps between exemplary (or expert) performers and typical performance or novice performers.
- Analyze causes for those gaps.
- Identify and select the solutions (e.g., required instruction) to close the gaps.

Modern approaches to performance analysis move beyond being tied to a single specific solution such as classroom instruction, and often include job support through electronic performance support systems (Raybould, 2000). Managers, supervisors, and executives may be inclined to believe that when performance problems exist it is the individual's knowledge or skills at fault; less frequently do they consider environmental factors. As a result, instruction in a traditional training setting is usually the solution they select. Optimal performance analysis identifies all factors contributing to performance by focusing on a performer and his or her work environment (Wedman & Graham, 1992).

There is evidence that the performance analysis stage of design is sometimes overlooked. Often the reason given for this is lack of time (Swanson, 1994). Rossett and Czech (1995) studied the practices of graduates of San Diego State University's Instructional Systems program and found that professionals are often unable to use their analysis skills because organizational leaders prefer a silver bullet approach to fixing problems. Ideally, performance analysis involves a partnering between the analysis team and stakeholders to define and achieve organizational goals, and it is during this process that some kind of visual modeling is likely to provide assistance in achieving a shared understanding. Performance analysis

is used to describe what is happening, what ought to be happening, and what can be done to improve the current status of the organizational problem (Wedman and Graham, 1992).

USE CASE MODELING

Use cases (Schneider & Winters, 2001) are one of the main modeling approaches that were brought together into the initial version of UML. They were developed by Jacobson (1992) as an improvement over the situation of communicating software system requirements in a purely textual form. Cockburn (1997) notes that despite the formal appearance of use case models, they are usually used informally. This is particularly so in the early stages of development.

There are two parts to creating use cases: diagramming and documentation. Diagram creation is done either on paper or a whiteboard, or using a diagram creating software tool. It is an iterative process and initial diagrams are often discarded. Figure 1 represents an initial use case diagram for a software system to support a travel booking system. The diagram elements are deliberately simple to allow sketching by people with little graphic design skill. The stick figure, referred to as an actor, represents an entity that is external to the system and interacts with it to obtain some service. This entity often represents human end-users, but it can also represent another computer system that exchanges data with the system being designed. The ellipses represent the actual use cases, which are the services provided by the system to the actors to enable them to achieve some goal.

Use case modeling is a useful informal tool for communicating with non-technical stakeholders during the domain analysis and requirements phase of a development project. Use case diagrams can also be used to brainstorm around possible functions of a new system, prior to more formal use cases being created to specify the actual

Figure 1. Use case diagram for a flight booking system

functionality of a system to be built. UML diagrams are often used in an iterative development process, where you start at a high level and go through a process of review and further refinement. The diagrams become increasingly complex as the process continues.

Once the diagrams have become established and the key use cases are identified and named, the next stage is to document them. The documentation of use cases should be done after the informal modeling leads to a stable use case diagram. As with diagramming, this is also likely to go through an iterative process, starting with sketchy and informal narratives and progressing to more detailed formal documentation. For example, Brugge and Dutoit (2000) recommend the process of identifying informal scenarios of

use. These take the form of stories about how the identified people would achieve some goal with the system being modeled. From a collection of these informal stories, a more formal representation of how a goal is achieved in the system is outlined in the use case documentation (see Table 1).

This is not necessarily a finished use case, as a stakeholder may find certain parts need to be clarified (e.g., how the customer selects the preferred trip). Once the use case is refined and in a stable state it becomes a useful resource for software engineers to identify which objects and components will be required for building the system (e.g., an interactive calendar). They would use the items highlighted in bold in the use case narrative as a starting point for UML object, class, and component diagrams which describe the structure of the system and the flow, and Interaction diagrams which show how data flows throughout the system. Many of the software tools that exist for creating UML diagrams allow the interrelating of the different diagram types (see Figure 2).

It should be emphasized that Table 1 illustrates just one example of how a use case can be documented. Practitioners of use case modeling often use variants of this basic model. Cockburn (2001) suggests that different documentation models are

Table 1. Typical documentation for a use case

use case Name	Book Flight
Participating Actor	Initiated by Customer
Entry Condition	1. Customer has logged into the system and has identified a specific travel date and destination
Flow of Events	2. System presents flight booking screen to the customer 3. Customer fills in the form by entering starting and ending point in entry fields , selecting roundtrip or one way button and travel dates from calendar object 4. Customer presses the go button 5. System searches the database using the entered requirements 6. System presents the results to the user in table format 7. Customer selects preferred trip 8. System presents detailed information on itinerary 9. Customer selects purchase or exit button
Exit Condition	10. Customer selects confirm booking or selects exit
Special Requirements	E-mail confirmation is sent within one day of confirmation

Figure 2. Screenshot from a computer-aided software engineering tool that incorporates UML (Reprint Courtesy of International Business Machines Corporation copyright © International Business Machines Corporation)

appropriate depending on the purpose of the modeling. He identifies four basic functions that use case models can perform in an organization:

- Describe a business' work process (domain analysis)
- Focus discussion about new software features (establishing the possibilities)
- Create the functional requirements for a system (determining what will be built)
- Document the design of the system (creating a map for maintenance)

He also notes that the functions might vary depending on whether they are written by a small, close-knit group, or by a large, distributed group. In addition, use cases might be used by documentation and training specialists to identify training and documentation needs of the users. They can also be used as the basis for constructing system functionality and usability tests; with the completed system you should be able to get a test subject to play the role of the actor and, with representative input data, reach the exit condition of the use case. This should be done without en-

countering problems through failure of the system or poor usability (such as not easily being able to identify and use the appropriate controls).

The use case documentation is a resource for analysts and stakeholders, which captures a description of the functionality they wish to achieve in the system (why it is being built). It is also a documentation resource for designers and developers, allowing them to start the process of identifying and connecting the structural components and information flows required within the systems they will design and build (how it should be built). In this sense, use cases drive all other modeling and development.

ADAPTING USE CASE MODELING FOR HUMAN PERFORMANCE

It follows that when adapting a similar modeling approach to UML for instruction, that an equivalent of use cases (to help determine why the system should be built) should be included. Those who have looked to UML to support non-software systems have tended to focus more on adapting

the structural and flow diagram techniques (IMS, 2005). This modeling is focused on describing what will be built, how it is structured and how it works, rather than answering the important question of why the system should be built. That is, why will the system being built result in a better performance from the individuals that use it and the organizations that they participate in? This is as legitimate a question for a learning system as it is for a software system. Creating the equivalent to a use case would help determine the value, in terms of individual performance, that is to be obtained by the creation of a new learning system.

In order to adapt the use case modeling scheme to the task of modeling for learning and performance support systems, we need to re-conceptualize what is meant by the actor, the use case and the system. Actors can be re-characterized as Performance Roles and use cases can be re-characterized as performance cases (Douglas, 2003). Performance Cases are goals that a person attempts to achieve with his or her own skills and knowledge, using the available tools and support available. The system refers to the organizational system of which the individual's role is an integral part. The role does not reside outside the system as the actor does in software use case modeling.

The UML concept of a package is used to collect related performance cases into a meaningful unit and to illustrate the alignment of individual performance goals with organizational goals and processes. The performance cases within packages will usually represent high-level performance goals. A high level performance case can be refined into a more detailed model. For example, Figure 3 shows a package of administrative roles and goals. 'Office Manager' is an organizational role that corresponds to an identified job title within the organization. It includes the two operational roles identified in this diagram as 'New Employee Processor' and 'Travel Administrator.' An operational role is a role someone has to adopt as part of his or her job; a given job title is likely to encompass several operational roles. Operational roles in

Figure 3. Performance case for a company travel administrator

small companies may be primary roles in larger organizations. For example, a large organization may have a job title for travel administrator.

This diagram introduces the 'secondary role' to the interactions needed to achieve the performance goal. Identifying secondary roles is important because when looking at performance in an organization, people tend to focus on the knowledge and skills of the person occupying the primary role and often fail to consider those in the secondary roles. Failures in performance can be due to a lack of knowledge of the person in the secondary role, on whom performance is partially dependent, or poor communication between the two people occupying the roles.

Each of the use cases in Figure 4 is a high level Uses Case that can be refined to a lower level. Figure 5 represents an extended use case model for "Process Travel Request." In this model the person in the traveler role has to submit a travel authorization request (TAR) form, and this is processed by the travel administrator, who will check to see that the organization's travel rules are correctly applied. Already we are starting to identify knowledge needs, in that someone in the traveler role will need to know where to obtain the form, and how and when to fill it out. The travel administrator will have to know what organizational rules apply. In this particular case, the travel administrator is responsible for actually booking the trip and you will note that the use case book flight is contained within a package.

Figure 4. Travel processing performance case diagram

The package here is used to illustrate that the 'Book Flight' performance case is accomplished through a computer system (automated travel system or ATS).

While it is possible to adapt the notation of use case diagrams to learning and performance systems modeling, it is not so simple to apply the documentation schemes. As was noted earlier, practitioners of use case modeling in software engineering often use variants of the basic model presented in Table 1. Cockburn (2001) suggested that different documentation models are appropriate, depending on the purpose of the modeling. Certainly Table 1, which represents a basic task analysis, could be adapted to the needs of performance modeling. Any type of task analysis could be performed and documented in the performance case. Different documentation schemes would be appropriate, depending on the needs of the user and the role that performance case models can serve in an organization. This includes:

- Focusing discussion on the possibilities for improving performance through new instructional systems
- Understanding the environment in which graduates of a course of instruction will be expected to perform
- Focusing discussion on the possibilities for complementing instruction with other performance improving solutions, for example, an EPSS

Figure 5. Extended performance case for a company travel administrator

- Creating the functional requirements for a proposed instructional system
- Creating the functional requirements for solutions that complement instruction (e.g., a quick reference sheet on the company travel rules)

In the above example, the examination of the travel processing would lead to an identification of the performance roles and goals of the various participants in this system. This would serve as a starting point to enable the identification and specification of performance aids and instruction, to help them achieve their individual goals and thus serve the higher-level goal of the organization (having an efficient travel process).

In software systems, use cases not only serve to identify requirements but also, once documented, allow developers to begin to determine the software objects required to build the system and how they will interact. performance cases can serve a similar role in regard to learning systems, which are beginning to utilize an object approach (Wiley, 2000). For example, if a course of instruction for travel administrators contained a set of learning objects (see Figure 6), some of which were of general relevance (e.g., an introduction to company travel rules). These objects could be adapted for the instruction of all the employees who are likely to find themselves in the traveler role in this performance model.

Performance case modeling would best be done in association with a methodology for performance analysis of the kind developed by scholars such as Gilbert (1996) and Robinson and

Figure 6. Performance case with documentation for a company travel administrator

Robinson (1995), and promoted by the International Society for Performance Improvement (ISPI). It should be seen as preceding instructional design and should not specifically presuppose the need for new instruction. Complementary (e.g., electronic performance support systems or EPSS) or alternative solutions (e.g., automating human tasks) should also be considered.

There are several approaches to performance analysis but they all tend to be in agreement on the need for the following:

- Take a systems view of problem solving
- Focus on results that should be achieved rather than tasks under taken
- Identify good measures of performance
- Identify gaps in performance and analyze their causes using evidence rather than opinion
- Consider a full range of potential interventions that can be applied to address the causes and close the gaps

For people trained in the application of a particular solution (instructional design or software design), there is a need to recognize a potential bias towards their method, which may not always be the most appropriate or sole answer to a particular problem. Inadequate performance from individuals in organizations may be due to a lack

of skills and knowledge, but it may also be due to a dearth of good tools or of motivation. Any solution development should be preceded by a careful front-end analysis that looks at the intended goals of performance and the barriers to attaining them.

The following is some important performance-related information that could be included in the documentation of a performance analysis:

- A description of the desired performance result and linkage to desired organizational results
- The interaction of other performance roles
- The requisite knowledge and skills required by the performance roles
- Performance measures that identify standard and exemplary levels of performance

In addition, other information that may be linked to each performance case includes the following:

- Task analyses
- Cognitive models
- Detailed study of exemplary or expert performers

It is up to the community of analysts to decide the optimal documentation approaches to accompany performance diagramming and to work towards creating acceptable standards. The rest of this chapter will define and illustrate one approach that can be used to begin such a process.

PERFORMANCE CASE MODELING

Performance case modeling is a combination of the typical non-visual methods that performance analysts use, and an adaptation of the visual modeling method of the use case. Performance case modeling provides a visual method for identifying and analyzing performance requirements at the operational/individual performer level.

Performance cases represent a performance goal within an organization or process that is the responsibility of one or more people. Performance goals are attained through the effort of people undertaking a performance role. Performance roles have individual responsibilities in relation to a performance case that can be achieved by anyone with the proper knowledge and skills.

Performance case models can provide a framework for examining optimal human performance in an organization and for selecting and specifying the appropriate instruction and performance support. Exemplary performers will provide analysts with a scenario, that is, specific information on how best to achieve the goals of the case. The performance cases documentation will be abstracted from several exemplary scenarios. The documentation for each performance case will provide the foundation for identifying the resources necessary to achieve performance support for those occupying the roles responsible for achieving the performance. The performance case documentation will also enable analysts, in collaboration with stakeholders, to determine the barriers to achieving optimal performance. These barriers help classify the performance problems by causes and potential solutions, which helps analysts develop recommendations to close performance gaps.

In the course of working with specialist performance analysis units in different parts of the U.S. military, Douglas et al. (2003, 2004) examined the methods used, data collected, and knowledge management practices. In the course of this work the concept of the performance analysis object was developed. An analysis object is a proposal for the standard digital capture of a unit of analysis (defined by a specific goal). It separates out the components of an analysis, rather than merging them all into a traditional analysis document. The analysis object distills knowledge into digital objects that can be stored in a searchable database. From the database they can be linked to elements in a diagram or any other digital objects relevant

to a particular performance. Table 2 identifies the key elements of an analysis object, which form a potential standard documentation scheme for a performance case.

The key elements identify what performance is required, who is involved in attaining it, and how to measure it. The measurement indicators are particularly important not only in informing analysis and design, but also in serving as a template for subsequent evaluation efforts. That is, if a course of instruction is created based on the analysis of this performance, once someone graduates from the course you would expect to see an improvement in the identified performance measures in order for the instruction to be declared effective. The metadata requirement for the Analysis Object provides the background data on the object (e.g., what it is and who created it); the Dublin Core Metadata Initiative schema (Dublin Core Metadata Initiative, 2007) is a commonly accepted means of defining this metadata. Metadata is useful for assisting in the search for, and the reuse of, existing information resources.

Figure 7 illustrates a refinement of Figure 6 that demonstrates the interlinking of a performance case diagram, performance analysis objects, and digital solution objects. The performance analysis object will link to digital components and documents that relate to the solutions whether they are learning or non-learning. The solutions could be existing solutions stored in digital libraries and repositories, or solutions designed and developed subsequent to the analysis.

Figure 8 illustrates a performance case diagram from an actual analysis carried out by the Center for Army Lessons Learned, a specialist performance analysis unit in the U.S. army. It illustrates the stepwise nature of constructing such diagrams. The main performer in the system is the fire support officer, the person who is responsible for planning the supporting fire from aircraft and artillery. A performer in this role will have a number of high-level goals to achieve when supporting the planning of missions. Each one of

Table 2. Elements of an analysis object

Data Element	Description	Example Data
Performance Goal	The desired achievement, result, or output that occurs at the individual level	Travel Administrator completes travel requests in a manner that is satisfactory for both the traveler and the organization
Primary Role	The individual performer who is the focus of the performance analysis process	Travel Administrator
Secondary Role	Other roles that interact with the primary role to achieve a performance goal	Traveler
Optimal Performance	Describes the desired performance at the individual level required to reach organizational goals	Process completed No errors in processing Organizational regulations are adhered to The traveler is satisfied Processed within three days
Gap Statement	The difference between desired performance and current performance	30% of travel transactions not meeting optimal performance goal
Indicators	Quantifiable criteria for a performance goal	Time to complete Errors requiring correction during processing Errors identified during auditing Traveler satisfaction survey
Cause	Statement of proposed root cause that is inhibiting optimal performance	The computer system has a difficult-to-use interface Travel requests received with little notice New staff not given enough time to adjust
Recommended Solution	Statement of a proposed instruction, or other intervention, that corrects the root cause	1. Recommend travel training be included in new employee orientation 2. Create computer system job aid 3. Request computer system usability improvements for next release 4. Create incentives for early submission of travel requests
Solution Links	Unique identifiers of any digital solutions that are reused or created subsequent to the analysis	Travel Training PowerPoint http://www.vpfa.fsu.edu/control/training/traveltraining.ppt
Metadata	Additional information provided that complies with established metadata standards	Author of object, date of creation, etc.

Figure 7. Performance case for a company travel administrator with interlinking of performance analysis objects and digital solution objects

these goals will have a number of more detailed sub-goals and the achievement of these goals will involve interaction with one or many (indicated by an asterisk) representatives of other performance roles. Indicating the interacting roles is crucial because any deficiency in performance may not just be due to lack of skills and knowledge of the FSO, it may be due to communication problems between people occupying the different roles. Thus in this example, analysts while looking at instructional requirements for a fire support officer, may in addition discover an instructional need for those who assist him.

Figure 8. Performance case package

Figure 9 represents a more detailed view of the performance goals that contribute to one of the high level goals of the FSO role in the mission planning process. The diagram allows for immediate identification of the roles, goals and interactions involved in creating a fire support plan. The next step would be to create detailed documentation for the problems identified in this process that may require the development of instruction, or some other means of supporting the performer. Table 3 demonstrates how one of these performance cases would be documented. The data would be derived from interviews, surveys, observations, discussions and reviews.

It should be stressed that the creation of the models is an on-going collaborative process. These models are not meant to result in all performance cases being refined and documented to the lowest

level. The identified gaps in performance revealed through interactions with the stakeholders will guide the refinement process for the models.

Given that a great deal of effort is likely to be invested into an analysis process, it is important that the knowledge derived from this effort be archived and reused. If analysts need to reconsider problems or changes in the instruction of those involved in the various roles under consideration in the future, they will have this digital resource as a foundation to build on and modify, rather than having to redo all the analysis from scratch. It would therefore be useful for any large organization to store both completed diagrams and the related analysis objects in a digital repository. The metadata will be particularly important for this in that it will allow easy searching for relevant information in the repository.

There are a number of ways in which this documentation could be extended through the solution links and metadata relations. It has been noted that learning objects can be linked to the performance analysis object. In addition to relevant digital documents, archived interviews, and surveys, online discussions (informal analysis) can be linked into the analysis object. Another important resource that should be linked is any subsequent evaluation study on solutions created,

Figure 9. Refined performance case model for "Create Fire Support plan"

Table 3. An analysis object for the FSO analysis

Data Element	Data
Primary Role	Fire Support Officer
Performance Goal	Verify risk estimate distances & attack criteria (i.e. the risks of landing on your own forces when using long range weapons)
Secondary Role	Mission Commander
Optimal Performance	Correctly identify risks for each weapon system used Develop a comprehensive knowledge of mission plans No errors in processing
Gap Statement	Only 60% of plans after execution meet satisfaction of mission commander
Indicators	Errors identified during peer review of plan No friendly fire incidents during execution of plan Mission commander satisfied with the plan
Cause	FSOs have difficulty finding and retaining knowledge about varying risks involved in the many different weapon systems they have to deal with Calculations difficult to accomplish in available time frame
Recommended Solution	Create job aid for quick look-up of risk data Integrate job-aid into training Create software application to assist in calculation
Solution Links	Fires integration: http://www.globalsecurity.org/military/library/policy/army/fm/3-90-2/appg.htm
Metadata (derived from Dublin Core)	Title: Verify Risk Estimate Distances & Attack criteria Analysis Object Creator: Ian Douglas Subject: Military, Mission Planning Description: Contains information on the analysis of fire support planning. Identifies the roles involved, problem causes, performance indicators, and recommended solutions for achieving an optimal level of performance. which will give an indication of how successful a given solution was at closing the performance gap identified in the analysis.

SOFTWARE TOOLS AND REPOSITORIES AND REUSE

Rather than using a written report at the end of a process of analysis as the main method of communicating knowledge, analysis knowledge can be collected, edited, and communicated on a continuous basis using the power of the Internet.

A digital library can serve as a single point where analysis thinking, in the form of performance case diagrams and associated analysis objects, can be reviewed, commented on, and critiqued by others on a continuous basis. If a written report is still required, it can be generated from the data entered into the objects. Roles and goals provide a useful scheme for organizing this knowledge in a way that is useful to all stakeholders.

In the work of Douglas et al. (2003), prototypes for a Net-centric performance improvement (Net-PI) system that incorporates such digital object management systems are described (see

Figure 10). The prototypes integrated the visual modeling scheme of performance cases, analysis objects, and a cataloguing system that contained records of previous roles and goals analyses. It also integrated a collaborative feature that allowed users to have threaded discussions on objects and diagrams under development. The latter is potentially important for maximizing the number of people that can review analyses and identify errors and misconceptions that would otherwise lead to faulty design and inferior performance support. The analysis is organized in the database according to roles (e.g., radio operator) and goals (e.g., establish communications), and a catalog feature that prevents the same role or goal from being analyzed and reported in two different geographic locations by two different analysts (which is easily the case without a centrally cataloged knowledge store). The analysis object also forms the basis for performance evaluation and performance support delivery. Thus, the basic model for organizing performance analysis knowledge is extended to delivery of performance support and tracking of individual and unit performance.

A standard system for modeling, together with a repository for analysis models and documentation, would mean that over time higher-level models would pre-exist to be reused in analysis.

Comprehensive and evolving performance models for the whole organization would emerge. This would enable the analysis of problems of similar roles and performance goals to be reused both within and across organizations.

GUIDELINES FOR APPLYING PERFORMANCE CASE MODELING

The emphasis of this chapter is that performance case modeling is a potentially useful tool in the analysis that should precede the design of instruction, or any other form of human performance improvement. No matter what modeling tool is being used, it is important not to overemphasize the power of modeling languages. The success of modeling probably has more to do with the person doing it than with the tool itself. It is important to recognize the need to develop the skills of analysis and design rather than look to a specific tool to provide a magic solution. Bell (2005) has written an influential article called *UML Fever: Its Diagnosis and Recovery*. He was motivated to do so by the seemingly blind faith being placed in UML by some advocates in the software engineering community. The critique serves as a precautionary note for those seeking to develop

Figure 10. Modeling performance in Net-PI

and use modeling schemes in instructional systems design. Here are some of the symptoms of UML fever that are also applicable to modeling languages in general:

A UML-Centric Training Curriculum

Many organizations, noting the popularity of UML, have bought tools and training for UML without focusing on the more general skill gaps among their developers. Knowledge of UML diagrams does not substitute for knowledge and experience of analysis and design methods. Without the latter, UML diagrams will be of little use.

Design Brainstorming Degrades into UML Syntax Free-For-All

Bell notes that informal diagramming around a whiteboard is a common activity in the early stages of systems development. In this chapter we have noted that use case diagrams are particularly well suited to this. Their informal use in brainstorming can be disrupted when advocates of the more formal aspects of UML push to formalize the diagramming too early.

Absence of Stakeholder Input in Artifact Development

Whoever creates a diagram should be able to state not only its purpose but also who, other than themselves, will find value in it. Ideally it should serve as a means of shared communication between stakeholders and developers, and not just be an artifact demonstrating the creative skills of a single individual (see Chapter II).

A UML Model has Turned into the Product

The models are a means to an end, creating the most efficient and effective instruction or performance support; they are not the ends in themselves.

There is the danger that if a lot of effort is put into diagram creation a project will be seen as having produced something of substance. Unless a diagram directly leads to system creation or improvement it has no substance. A diagram can even have a negative consequence if time that could be spent on building the system is instead spent on refining a diagram to perfection.

At no time should a design diagram be considered fixed and unalterable. It is also possible to initially draw diagrams only to help you understand the design (rather than document it) and then throw the diagrams away. In a sense, the process of creating the diagrams is more important than the diagrams themselves. Those who see design as a discrete process may be tempted to perfect all the diagrams before allowing any systems development to occur.

A set of guidelines for the use of modeling techniques include the following:

- Have a clear purpose for the diagram.
- Remember that the primary purpose of the diagram is communication—more than one person should be involved in its creation and as many people as possible should be involved in reviewing it.
- Do not feel you have to diagram everything.
- Do not feel you have to document everything you diagram.
- Focus your diagramming and documentation efforts on the most important things—i.e. do not create detailed, highly refined diagrams for areas where there are few performance problems.
- The effort involved in diagram creation should not substitute for system creation. The diagram is useful only if it leads to a solution of proven effectiveness.

CONCLUSION

Use cases form a key role in UML modeling, as they are the starting point for requirements

analysis, understandable by stakeholders and, through identifying objects and interactions within the documentation, an origin for the creation of other diagram types. This chapter has argued for a direct equivalent to use cases for those interested in developing modeling languages for instruction. Performance Cases as described in this chapter are intended to be used at the earliest point in the process to explore the problem, prior to selecting the appropriate solution.

Before planning instruction or any other solution aimed at improving human performance it is necessary to understand the performance environment in which individual performance takes place. It is also necessary to understand the metrics by which performance is evaluated. Performance Case modeling is a tool that can be used to facilitate this approach. It can focus instructional, and other solution designers, on what the solution is required to achieve and how it should be evaluated. It is aimed at understanding and overcoming identified causes for gaps in human performance.

Chapter 7.5

Can Cognitive Style Predict How Individuals Use Web-Based Learning Environments?

Martin Graff
University of Glamorgan, UK

ABSTRACT

This chapter considers the question of whether Web-based learning environments can be employed to effectively facilitate learning. Several questions are considered around this issue, principally whether variations in hypertext architecture, and individual differences in information processing are salient factors for consideration. Furthermore, whether the effectiveness of learning depends precisely upon how learning is defined. Finally, differences in hypertext navigational strategies are assessed in terms of whether these can be predicted by individual differences in cognitive style. The chapter ends by concluding that the research on Web-based instructional systems is to some extent promising, although the field of cognitive style is diverse, and realistic predictions regarding the use of this construct in instructional design is, as yet, tenuous.

DOI: 10.4018/978-1-60960-503-2.ch705

INTRODUCTION

One of the salient features of web-based learning environments is that they can provide an explicit structure to instructional material, which should ultimately facilitate the learning process. For example, such structures can be designed to explicitly indicate the conceptual links between related information. The following chapter assesses the degree to which this theoretical position can be supported by the extant literature. More precisely, this chapter reviews the literature on how web-based or hypertext-learning systems have been employed in an educational context. We will consider issues such as the most facilitative hypertext architecture for assisting the learning process. Later in the chapter the evidence on the extent to which cognitive style mediates the effects of architecture are reviewed. Finally, evidence will be assessed regarding the way in which users navigate hypertext and how this may influence their comprehending of its structure.

BACKGROUND

Web-based learning environments are structured around hypertext systems, which allow conceptually related pieces of information to be connected or linked. Information on one page in the system can be linked to a related piece of information contained in a separate page. Such systems are user driven, in as much as individuals can choose to be 'transported' or moved within the system to pages containing related information. Furthermore, web-based or hypertext systems can be structured in a variety of ways, and the way in which the system is structured is referred to as the system architecture. Typical architectures found in the literature are 'linear', where pages of information are linked sequentially, rather like they are in a book; 'hierarchical' where superordinate information is contained in pages higher up the system, and linked to more detailed information further down in the structure and 'relational', which is similar to the hierarchical architecture, although this structure also contains lateral links between conceptually related information at the more detailed level. This chapter considers the effectiveness of learning from web-based systems, and it is appropriate at this stage to consider the term 'learning', and the way in which it has been applied in the literature. Perhaps one of the most expedient notions of learning to consider in this respect is that offered by Bloom's Taxonomy of levels of learning (Bloom, 1968). In essence, Bloom advocated that learning could be arranged at different levels ranging from basic knowledge or recall, up to a more sophisticated type of learning manifest in evaluation or synthesis of material. The notion that learning can be applied at different levels is important to consider as we review the extent to which learning may be facilitated by web-based learning environments.

WEB-BASED LEARNING AND HYPERTEXT ARCHITECTURE

A useful starting point would be to question whether using different hypertext structures differentially affect learning performance. The earlier studies considering this question seem to suggest that mixed or relational web-based or hypertext systems appear to be the most facilitative. For instance in a study by Mohageg (1982) the issue of whether question answering performance would vary following delivery of learning materials via three different web structures or architectures was considered. The architectures used in this study were hierarchical, where the learning material was constructed such that more general information was contained higher up the structure, and more specific information lower down; network, where the information was structured in a complex system of links; and mixed which was a combination of the other two structures. The findings indicated that learning performance was poorest in the network architecture condition. However, there were no differences in learning performance in the other conditions. The interpretation of this finding was that as the mixed condition featured more links than the other conditions, this may have increased the learners' facility for learning. McDonald and Stevenson (1998) employed 30 undergraduate and postgraduate students in their study of web-based learning. They also used three hypertext architectures, which were hierarchical (as described above), non-linear (in which the information was constructed in a type of network) and mixed (hierarchical with lateral links). After using one of the three systems, participants answered ten questions on information they had read in the learning system. The findings revealed that those student participants who had used the mixed system found information quicker than participants in the other conditions, which is possibly due to the fact that the mixed architecture made it easier for the users to understand the overall structure. The

above studies sought to measure learning using tests of recall, which is synonymous with basic knowledge or recall at the lower level of Bloom's Taxonomy of Learning (Bloom, 1968). However, as outlined earlier, learning also takes place at a deeper level, which could be said to involve an appreciation of the interrelationships between the various concepts and procedures in a particular subject domain. This more sophisticated approach to learning might necessitate comprehending how related concepts within a subject domain, may be arranged or constructed into a unified whole. This issue is considered with respect to web-based learning, in the following section.

Learning at a Deeper Level

In one study, Shapiro (1998) used an essay question to investigate how effectively learners showed an appreciation of the overall structure of the information contained within a web-based learning system. Three different architectures were employed in this study, which were hierarchical with some lateral links, unstructured, which had the same links as the hierarchical, but with no specific information about the structure, and linear where the material was presented sequentially, one step at a time. Seventy-two participants were asked to write an essay which required them to integrate the material they had learned from reading information from one of the web architectures. Essays were rated on four criteria which were integration of material in the essay, how well the participant understood the topic about which they were writing, the clarity of the essay and the overall quality of the essay. On all of these criteria, it was found that participants in the unstructured hypertext condition scored higher than those in the other conditions. The interpretation of this finding was that the lack of any explicit information in this condition required a deeper level of processing of the information in order for participants to understand it, and this resulted in a higher level of performance.

Concept Maps

Concept maps provide a visual representation of the interrelationships among concepts or pieces of knowledge relating to a particular subject domain. This idea was pioneered by Joseph Novak in the 1960s, and it is suggested that the technique may facilitate an individual's learning of how the finer details contributing to a wider body of knowledge are integrated. It is also conceivable that concept maps may also be employed to facilitate a user's understanding of the interrelationships between smaller, more detailed pieces of information presented in web-based learning environments. Shapiro (1998) in the study outlined above, compared also the concept mapping performance of participants, assigned to one of the three hypertext learning environments outlined. Participants were required to recall the structure of the hypertext web by producing drawings, one measure of which was amount of detail present. Participants in the linear condition included less detail in their concept maps than participants in the hierarchical and unstructured conditions. This finding was explained in terms of participants in the hierarchical and unstructured conditions visiting the same pages in the structure more times than the participants in the linear condition, thus the amount of exposure to the information, led to differences in the amount of detail recalled. Shapiro also found that participants in the hierarchical and unstructured conditions produced concept maps which reflected the actual links in these structures, and it therefore seems that the links reflect the participants' internal representations of the hypertext. A slight variation to this finding was reported by McNamara, Hardy and Hirtle (1989). They found that despite using non hierarchical hypertext environments, their participants still produced map representations which tended to be hierarchical. They explain this finding in terms of certain types of information being mentally organised in a hierarchical manner. Such a mental organisation facilitates effective recall

of the information. We now move on to consider the different ways in which individuals navigate or move around hypertext environments, and assess how this may be used to provide information on the affect it has on an individual's ability to apprehend its structure. The reasoning behind this notion is that the route an individual takes through an environment is likely to influence their representation of that space. Indeed Maglio and Matlock (1999) found that the way in which individuals move around in hypertext affects the ways in which they think about it. From their interview data, they suggest that people view hypertext as a type of physical space in which they move around. Their participants remembered landmarks and routes, and also the key information they found while navigating. In addition to this they found that participants relied on personal routines, similar to the types of routines individuals employ when travelling from one point to another. The suggestion is that the way in which an individual navigates will affect their mental representation of the hypertext. In the next section the types of navigational strategies which have been identified in the literature are examined. In the literature, the terms 'navigation' and 'browsing' are sometimes used interchangeably with regard to moving around in hypertext. The broad distinction would appear to be that browsing is considered to be a more casual non-goal related task, whereas navigating is more purposely directed towards some final end. Nevertheless, both terms refer to how we move around a hypertext system.

Navigational Strategies

Batra, Bishu and Donohue (1993) identified differences in navigational behaviour according to the hypertext architecture to which users were assigned. The two architectures they employed in their study were hierarchical and hypertorus (pages arranged in a rectangular pattern). They also looked at the effect of each type of archi-

tecture on participants' ability to answer ten questions, the answers to which could be found in the hypertext. Their results suggested that the hypertorus structure generated more exploratory browsing behaviour, but despite this the hierarchical structure made it easier for participants to locate information. However, it is easy to interpret the findings as being attributable to the number of links in each architecture. In their study Canter, Rivers and Storrs (1985) categorised navigational strategies as being related to the function each strategy serves for the user of the hypertext. These strategies included pathiness, where users follow long linear paths; loopiness, where users navigate around the hypertext in circles; ringiness, which are small loops or circles and spikeiness, where users follow paths to dead ends. The researchers also examined the number of pages within the hypertext users visited, and number of different pages visited, and the ratio of different pages visited to the total number of pages visited. From this information, they devised five distinct navigational strategies, which were scanning (covering a large area without depth), browsing (following a path until a goal is reached), searching (striving to find an explicit goal), exploring (finding out the extent of the information system) and wandering (purposeless and unstructured globe-trotting). The authors also concluded that these navigational strategies apart from wandering, have a function in navigating hypertext. Scanning and exploring are used to get an overview of the hypertext, whereas browsing is following a train of thought through the hypertext. All in all, this study provides a useful way of categorising navigational behaviour. Despite the fact that the above studies provide comprehensive information regarding the relative effectiveness of different hypertext architectures on learning, none of the studies reviewed so far has considered individual differences in the ways in which various users engage with hypertext. Because it specifically refers to individual differences in information processing

the construct of cognitive style is pertinent to consider in assessing how effectively individuals learn from hypertext.

COGNITIVE STYLE, HYPERTEXT AND LEARNING

Cognitive style can be defined as a variation in the ways in which individuals process information, in terms of differences in perceiving, remembering, recalling and applying this information. Various cognitive style constructs have been proposed by various researchers, for example reflective-impulsive (Kagan, Rosman, Day, Albert and Phillips, 1964), convergent-divergent (Guilford, 1959), leveller-sharpener (Holzman and Klein, 1954) and serialist-holist (Pask, 1972). All these style constructs are based on the notion that different style types exist at opposite ends of a continuum. The style type field dependent-independent which developed from the work of Herman Witkin is one of the most extensively used models of cognitive style. Field dependence-independence is defined in terms of whether individuals perceive entities as separate units, (field independent) or as complete wholes (field dependent). There is also evidence to suggest that there are differences in the ways in which field dependent and field independent individuals learn (Witkin, Moore, Goodenough and Cox, 1977). Field independent learners are able to see a degree of structure in what they learn, whereas field dependent learners rely more upon being provided with a structure externally. Theoretically, a highly structured hypertext instructional architecture will be of greater benefit to field dependent learners, because this will provide an organisational aid to their learning. Conversely, a poorly structured learning environment where a degree of organisation would need to be provided by the learner would be less beneficial to field dependent learners, although in such an unstructured environment, field independent learners would suffer no debilitation in learning,

because of their superior capacity for imposing structure on the material they are attempting to learn. However, the empirical evidence reviewed in the following does not necessarily support this reasoning. For example, Lin and Davidson-Shivers (1996) assessed verbal recall in a group of 139 undergraduate students, following a period of time using one of five hypertext architectures. The architectures corresponded to linear, hierarchical, hierarchical-associative, associative and random, and all of the architectures contained the same information. The participants were also assessed using the Group Embedded Figures Test (GEFT) designed to measure field dependence-independence (Witkin, Oltman, Raskin, and Karp, 1971). The results of this study revealed that participants who were more field independent as indicated by their higher GEFT scores, outperformed participants who were assessed by the GEFT as being more field dependent. In addition to this, field independent users displayed more favourable attitudes to using the hypertext than field dependent participants. The researchers explained the results by suggesting that field independent learners are more self motivated and have greater expectations of achievement. Consistent with the previous study, a further investigation assessing the differences between field dependent and field independent learners' ability to answer questions following a period of time browsing a hypertext architecture, again revealed that field dependent participants performed less well than field dependents (Korthauer and Koubek, 1994). In this study the learners were experienced with the hypertext document they used. The findings are explained by the fact that the existing knowledge of the field dependent learners and the way in which these learners attempted to represent the information, conflicted with the more explicitly structured hypertext, thus affecting their learning. However, one possible drawback with the above studies, is that the GEFT has been found to correlate with standard tests of spatial intelligence (McKenna, 1984, 1990). Accordingly, another

possible interpretation of the above studies is that field independent learners possessed greater intelligence, and this accounted for their superior performance rather than any differences in the strategies they employ in organising the information they learn. Accordingly, there is a need to consider potential differences in learning from hypertext employing a cognitive style measure independent of spatial intelligence. Melara (1996) employed forty participants who were students of computer science, maths or engineering and required them to complete Kolb's Learning Style Inventory. This instrument identified participants as possessing either a reflective or active style. Following this participants were assigned to one of two hypertext architecture conditions, which were either hierarchical or network in structure. The design of the network structure was such that it linked together related concepts in order to form a web, and the task of the participants was to answer ten questions on the information featured in the hypertext. The results revealed no differences between the participants of different learning styles in each condition, however the results were approaching significance with superior performance from participants in the hierarchical condition. Furthermore, individuals with active and reflective styles displayed superior performance when using the hierarchical architecture. In essence the results merely show that a difference exists between the two hypertext structures, although style seemed to have no effect. One further difference was that the participants in the hierarchical architecture condition took significantly longer to complete the task, than participants in the network condition, which seems to be a more likely explanation for the superior performance of participants in this condition.

Learning Measured by Essay Questions

In an extension to the studies described above, Graff (2003a) looked at whether the way in which

learning was assessed made a difference to the effect of matching different hypertext architecture conditions to the cognitive style of the learner. This study employed three hypertext architectures, which were linear, hierarchical and relational, with each representing a way in which the information to be learned was arranged. Cognitive style was measured using the Cognitive Styles Analysis (Riding, 1991), which identifies cognitive style in a way similar to the Group Embedded Figures Test (Witkin et al, 1971), but uses the label wholist for field dependent and analytic for field independent. Essay scores were measured by length and amount of detail included. The results indicated that in the relational architecture condition, intermediates (i.e. individuals between wholist and analytic styles) achieved superior scores. The findings reviewed so far appear to indicate that cognitive style does have an impact on the degree to which individuals learn from hypertext, and therefore need to be considered in the design of web-based instructional systems. However, the findings from the above studies are somewhat perplexing as they derive from an array of style measures, and therefore more research is required, with a view to unifying and consolidating different measures of style. We now move on to analyse how the application of style research can be applied to slightly more complex cognitive tasks performed within the parameters of hypertext. Graff (2002a, 2005a) assessed differences in the types of concept maps produced by learners, and whether the types of maps could be predicted from measures of cognitive style. In one study 55 participants were assigned to one of three hypertext architecture conditions which were linear, hierarchical or relational, and were instructed to recall information and produce maps of the hypertext used (Graff, 2005a). In this study cognitive style was measured with the analysis-intuition measure of cognitive style (Allinson and Hayes, 1996), and the results revealed that analysts scored highest in the hierarchical condition, intermediates scored highest in the relational condition and intuitives

scored highest in the linear condition. In terms of assessment of the concept map density (the degree to which users were able to integrate the concepts in the hypertext), participants using the hierarchical condition produced the least dense maps, with little difference between the relational and linear architectures. The higher density scores which users in the relational architecture condition produced was explained by the fact that the intricate relational architecture encouraged participants to produce dense maps purely because of the impression that this architecture gave them. The finding differs from that of Shapiro (1998) as here no differences in density scores were found between participants performing in different architectures. However, in the study by Graff (2005a), no differences in maps were found between individuals possessing different cognitive styles. In terms of assessment of map complexity, (how representative the map was of the architecture) the results revealed that participants performing in the relational architecture condition produced the most complex maps, with participants in the hierarchical condition producing the least complex maps. These results were explained by the fact that there were differences in perceived ease of use by participants in each architecture condition. The rather complex array of findings presented here provide no real evidence that cognitive style is a factor in predicting differences in concept map production.

Hypertext Segmentation and Overview Provision

When considering hypertext design, two further considerations need to be addressed. Firstly, the degree to which the hypertext should be segmented, in other words whether it should be designed with long scrolling pages, or whether the pages should be segmented and topics which are conceptually related be connected via hyperlinks. Secondly, whether the provision of an overview of the hypertext provides any advantage in guiding the user through the structure. Indeed, Dee-Lucas and

Larkin (1995) discovered that the provision of a diagrammatic overview of the hypertext system made it easier for users by directing them to significant information within the system. Similarly, Hsu and Schwen (2003) compared the effects of structural cues derived from single and multiple metaphors in the design of hypermedia documents. Fifty-four undergraduate students were required to perform selected information searching tasks, and the findings indicated that the provision of metaphorical cues helped participants to find a greater number of accurate answers and do so in a shorter period of time. However, it is entirely possible that an individual's cognitive style could influence the degree to which segmentation and provision of an overview is useful. An investigation of this issue, Graff (2003b) employed 50 participants who browsed one of two hypertext architectures containing information on psychological ethics, and also completed the Cognitive Styles Analysis (Riding, 1991). The differences between the architectures was in terms of the degree of segmentation, with one being more segmented (required less scrolling of pages) than the other. Furthermore, half the participants were provided with an overview of the architecture, and the other half received no overview. After spending a period of time browsing one of the two hypertext systems, participants were requested to answer questions regarding their understanding of the material featured in the hypertext. Both cognitive style and degree of segmentation influenced the degree to which participants learned from each architecture. More specifically, analytics displayed superior learning performance in the less segmented architecture, whereas wholists showed superior performance in the more segmented architecture. However, the provision of an overview of the system had no effect here.

Cognitive Style and Hypertext Navigation

The final question to be considered in this chapter is whether cognitive style can predict differences

in the ways in which individuals navigate hypertext, and several studies on this issue are considered here. Firstly, Ellis Ford and Wood (1992) investigated this issue employing postgraduate student participants and who completed a Study Preferences Questionnaire (SPQ) which was a non standardised test developed by the authors of the study, and which measured holist and serialist study strategies, presumably conceptually similar to field dependent and field independent respectively. Participants were provided with navigation tools for using the hypertext, which were: a self-orientating global concept map, keyword index menus and a backtracking facility, and the subject matter of the hypertext was the European Single Market. The 40 participants used the hypertext, and were then required to answer several questions which required both factual recall and also integration of information from different parts of the hypertext. Their findings revealed that participants with a holist approach tended to make more use of the maps provided, whereas participants with a serialist strategy used the index menu. In a further study, Chen and Ford (1998) employed 20 postgraduate students who used a hypertext system in order to attempt to learn about artificial intelligence. Using the Cognitive Styles Analysis to test style they discovered that wholists made greater use of a menu system for navigation, whereas analytics were more likely to use the backward and forward buttons on the browser software they were using. It must be said that the sample size in this study was small, and accordingly, it is unlikely that the results can be generalised from the findings. The above studies however, tell us more about the user's typical selection of hypertext navigational aids, and it is also relevant to examine navigation of hypertext in terms of the routes users take to move through the system. In a study employing 60 participants, who used a structured hypertext and completed the Embedded Figures Test, Stanton and Stammers (1990) found that field dependent participants used bottom-up navigational strate-

gies, progressing from the more basic information upwards, whereas field independent users tended to use top down strategies, which was viewing the most important information first. This finding is rather perplexing and seems contrary to the reasoning that field dependent users would be able to apprehend the structure of the whole hypertext, and therefore use a top-down strategy, whereas the opposite would be the case for field independent users. What was also contrary to what might have been predicted was the fact that field independent individuals viewed fewer pages than field dependent individuals, whereas the more likely finding would have been that as field dependent learners should have been able to gain an overview more easily, they would have viewed fewer pages. Verheiji, Stoutjesdijk and Beishuizen (1996), performed a study where navigation was assessed by requesting participants to search for information in a hypertext. They identified style by using the Dutch Inventory of Learning Styles which identifies individuals as deep or surface processors (Vermunt and Van Rijswijk, 1987). The findings revealed that different strategies were employed by individuals with different styles, more precisely that those identified as deep processors used a more global approach to navigate the text, whereas surface processors adopted a more step by step approach. The final study considered (Graff, 2005b) employed two groups of participants, who were assigned to either a hierarchical or a relational hypertext architecture and allowed ten minutes to read information contained in the hypertext. Participants were told in advance that they would be expected to answer questions on the information they read, and hypertext navigational patterns were measured by using various indices, including the number of pages visited and the proportion of pages visited to pages revisited. Cognitive style was measured using the Cognitive Styles Analysis (Riding, 1991) which also reveals the extent to which individuals display imager or verbaliser styles. Variations were found between imagers and verbalisers, with the latter visiting

more pages in the hierarchical architecture, and the former visiting more pages in the relational architecture. This preliminary evidence is somewhat encouraging in as much as it would appear to suggest that individuals with different cognitive styles do exhibit different navigational strategies.

CONCLUSION

This chapter has examined much of the evidence on the effectiveness of using hypertext or web-based learning systems as a medium of instruction. The general conclusion which can be drawn here is that the most facilitative hypertext architecture for effective learning is hierarchical in structure with lateral links, although to some extent it appears that cognitive style also influences the effectiveness of the hypertext architecture employed, and this is illustrated in the model shown in Figure 1. For example, cognitive style may to some extent determine how effective a particular architecture is to an individual for learning. Furthermore, the manner in which an individual navigates hypertext also influences his/her ability to understand its structure, and this is because the route followed has an effect on the individual's mental representation of the hypertext. It is possible then that the route followed by an individual browsing hypertext could have an influence on the effectiveness with which they learn.

From the literature, it is clear, that numerous research questions regarding use of hypertext and cognitive style remain. More precisely, further research should pursue an attempt to investigate learning at a deeper level. As mentioned learning in many previous studies has been measured in a relatively simplistic way, and studies should now focus on attempts to assess learning in more realistic situations. While a few studies have sought to investigate the navigational strategies of users, further research should attempt to investigate this in relation to users' cognitive style. Finally, in the

Figure 1. Model of performance in using hypertext, determined by cognitive style/cognitive style mediated by architecture design

literature, definitions of the term cognitive style appear fragmented, with little agreement on how the term may be properly operationalised. Accordingly, attempts to consolidate the construct under a single definition are now well overdue. Regardless of the pressing need for further work in the area, the initial conclusion indicates cognitive style to be a pertinent factor for consideration in the design and implementation of instructional systems. The evidence presented here, although mixed and rather unsettled at present, is nevertheless promising, and cognitive style ultimately has implications for the design of hypertext instructional systems.

ABSTRACT

The current emphasis, in education and training, on the use of instructional technology has fostered a shift in focus and renewed interest in integrating human learning and pedagogical research. This shift has involved the technological and pedagogical integration between learner cognition, instructional design, and instructional technology, with much of this integration focusing on the role of working memory and cognitive load in the development of comprehension and performance. Specifically, working memory, dual coding theory, and cognitive load are examined in order to provide the underpinnings of Mayer's (2001) Cognitive Theory of Multimedia Learning.

DOI: 10.4018/978-1-60960-503-2.ch706

The bulk of the chapter then addresses various principles based on Mayer's work and provides well documented web-based examples.

INTRODUCTION

Improving the efficiency and effectiveness of instruction has consistently been a primary goal of education and training. In pursuit of this goal, cognitive psychology has provided considerable insight regarding the processes that underlie efficient and effective instruction. The past 50 years are replete with empirical studies addressing the characteristics inherent in human learning and the influence of these characteristics on instruction. Unfortunately (Anderson, Reder, & Simon, 1998), this "science of human learning has never had a

large influence upon the *practice* of education [or training]” (p. 227; italics added). This gap between research and practice is lamentable and serves to deny learners and teachers access to powerful forms of teaching, training, and learning.

Fortunately, the current emphasis on the use of instructional technology has fostered renewed interest in integrating human learning and pedagogical research (see Abbey, 2000; Rouet, Levonen, & Biarreau 2001). As Doolittle (2001) has stated, “it is time to stop professing technological and pedagogical integration and to start integrating with purpose and forethought” (p. 502). One area within instructional technology that has begun this integration is multimedia. The domain of multimedia has matured beyond technology-driven applications into the realm of cognition and instruction. As stated in Rouet, Levonen, and Biarreau (2001), “There is a subtle shift of attention from what *can* be done with the technology to what *should* be done in order to design meaningful instructional applications” (p. 1). This shift has involved the technological and pedagogical integration between learner cognition, instructional design, and instructional technology, with much of this integration focusing on the role of working memory in the development of comprehension and performance.

Specifically, a focus has developed addressing the limited resource nature of working memory and cognitive load. Cognitive load simply refers to the working memory demands implicitly and explicitly created by instruction and how these demands affect the learning process. Those learning tasks that are poorly designed or involve the complex integration of multiple ideas, skills, or attributes result in increased cognitive load and decreased learning. This relationship between cognitive load, working memory, and instruction/training has proved to be especially significant when the instruction is in the form of multimedia. According to Mayer (2001), “the central work of multimedia learning takes place in working memory” (p. 44).

This chapter focuses on multimedia and the mitigating effects of cognitive load on teaching, training, and learning. A central organizing theme throughout the chapter is the development of theoretically sound pedagogy (see Figure 1). Theoretically sound pedagogy involves instruction that is based on empirical research and sound theory designed to illuminate the nature of human learning and behavior. Such theoretically sound pedagogy may then be molded to fit specific learning environments, learning goals and objectives, and learners.

Figure 1: The development of theoretically sound pedagogy

WORKING MEMORY, DUAL CODING AND COGNITIVE LOAD

When pursuing theoretically sound pedagogy, it is essential to ground one's conclusions in the human memory literature. Unfortunately, while there is a plethora of research findings exemplifying the structure and function of human memory, a singular model of memory to which one can refer has yet to emerge. Currently, the three most prevalent models are Atkinson and Shiffrin's (1968) dual-store model, Baddeley's (Baddeley, 1986; Baddeley & Hitch, 1974) working memory model, and Anderson's (1983, 1990, 1993) functional ACT-R model. Each of these models has roots in the early information-processing work of Broadbent (1958) and Peterson and Peterson (1959).

Memory Models and Working Memory

Atkinson and Shiffrin (1968) emphasized the structural nature of memory, delineating three essential structures, *sensory memory*, *short-term memory*, and *long-term memory*. Atkinson and Shiffrin asserted that individuals experience the world through their senses, momentarily storing these senses in raw sensory formats at their sensory sites. These sensations, if attended, may then be encoded into a mind-friendly format and consciously held in short-term memory, where if the individual rehearses this encoded experience, the experience may be transferred to long-term memory. The *dual-store* of Atkinson and Shiffrin's model refers to the short-term memory store, where a small amount of information or experience may be held temporarily, and the long-term memory store, where an unlimited amount of information or experience may be held indefinitely. This idea that there were two storage components, each with different processing capabilities, was developed from Broadbent in the 1950s through Atkinson and Shiffrin in the 1960s and was well accepted in the early 1970s. Unfortunately, in the 1970s, testing

of the dual-store model revealed inconsistencies in the need for two storage components. By the 1980s, the dual-store model, with its two storage components, was being replaced by a unified working and long-term memory model.

Two separate memory stores were eliminated, and what remained was a single memory store, long-term memory, and a constellation of related processes, termed working memory, responsible for the regulation of reasoning, problem solving, decision making, and language processing (Miyake & Shah, 1999). Working memory is often confused with, or made synonymous with, short-term memory, as working memory has retained certain short-term memory characteristics. For example, a central characteristic of short-term memory was a limited capacity due to a hypothesized small storage space. This limited capacity is also a characteristic of working memory, but the rationale has changed from a limitation based on structure (i.e., space) to a limitation based on function (i.e., processing). Working memory limitations are currently seen as a function of ongoing processing and the nature of the information being processed (see Miyake & Shah, 1999). While working memory and short-term memory share certain similar characteristics, although for differing reasons, they are also significantly different.

Perhaps the most obvious difference between short-term memory and working memory is that short-term memory was construed as a storage location or "box," while working memory is defined as a set of cognitive processes responsible for the support of complex cognition. A second, and related, difference involves purpose. Typically, short-term memory is described as subservient to long-term memory, where long-term memory is responsible for the cognitive processing and short-term memory is merely a workspace for memorization (Baddeley, 1999). Working memory, however, is interpreted as working synergistically with long-term memory, playing a primary role in control and regulation functions (Cowan, 1999). This emphasis on synergy underlies the

third difference, which is related to the influence of long-term memory on short-term and working memory. The traditional relationship between short-term memory and long-term memory is one of *independence*, where short-term and long-term memory communicate, as two individuals talking on the telephone, sharing ideas but each operating in only distantly related realms. The relationship between working memory and long-term memory, however, is one of *interdependence* (Baddeley & Logie, 1999; Ericsson & Kintsch, 1995). The interplay between working memory and long-term memory is integrated to such an extent that any discussion of human cognitive performance in the absence of either working or long-term memory would be incomplete.

Thus, an exploration of human cognitive performance in a multimedia environment would need to address this working and long-term memory interdependence. This interdependence is evident in two theories that are currently guiding the development of multimedia instructional technology—dual-coding theory and cognitive load theory.

Dual-Coding Theory

Building on working and long-term memory interdependence, Paivio (1971, 1990) created a theory of cognition that emphasizes the mind's

processing of two types or codes of information, verbal and nonverbal. Specifically, Paivio (1990) stated that memory and cognition are represented within two functionally independent, but interconnected, processing systems (see Figure 2). One system, the *verbal system*, is specialized for the representation and processing of verbal information (e.g., words, sentences, stories), while the other system, the *nonverbal system*, is specialized for the representation and processing of nonverbal information (e.g., pictures, sounds, smells, tastes). Each system holds and processes representations that are modality-specific (i.e., visual, auditory, tactile, gustatory, olfactory), that is, the representations retain certain properties of the concrete sensorimotor events on which they are based (Clark & Paivio, 1991). It is important to note that these representations are not exact copies of one's experiences, but rather they represent imprecise facsimiles (Paivio, 1990).

The interaction between the verbal/nonverbal processing and modality-specific perceptions can be somewhat confusing. A central point is that regardless of modality, verbal experiences are processed by the verbal system, and nonverbal experiences are processed by the nonverbal system (see Table 1). An everyday example of dual coding would include an individual looking at a weather map on the computer while listening to a weather report (e.g., <http://www.weather.com/>

Figure 2. A schematic representation of Paivio's (1990) dual-coding model, including both verbal/non-verbal channels and representational, associative, and referential processing

Table 1. Examples of verbal/nonverbal cognitive processing based on specific modality experiences

	Cognitive Processing	
Modality	Nonverbal	Verbal

activities/verticalvideo/vdaily/weeklyplanner.html). The words encountered listening to the weather report would be processed by the verbal system, while the visual images encountered looking at the weather map would be processed by the nonverbal system.

Paivio (1990), upon delineating this relationship between verbal/nonverbal processing and modality-specific perceptions, focused primarily on the verbal/nonverbal processing aspects of the dual-coding theory. According to Paivio (1990), three levels of processing enable verbal and nonverbal representations to be accessed and activated during cognitive tasks (see Figure 2). *Representational processing* is characterized by direct activation; that is, a verbal or linguistic sense experience directly activates a verbal representation and a nonverbal or nonlinguistic sense experience directly activates a nonverbal representation. For instance, reading on-screen text (verbal) directly activates the verbal system, while seeing an on-screen image (nonverbal) directly activates the nonverbal system. *Referential processing* refers to the indirect activation of the verbal system through experience with nonverbal information and the indirect activation of the nonverbal system through experience with verbal information. For example, reading on-screen text (verbal) may indirectly activate a mental image (nonverbal) based on the on-screen text; similarly, viewing an on-screen image (nonverbal) may indirectly activate a concept label (verbal) for that image. Consequently, referential processing is indirect in nature, because it requires cross-over activity from one symbolic system to another. Finally, *associative processing* refers to the activation of representations within either system

by other representations within that same system. For example, for a student with an aversion to technology, the word “computer” (verbal) might elicit verbal associations such as “hate” or “stupid” (verbal); conversely, the sight of a computer (nonverbal) might elicit images or visceral responses (nonverbal) reminiscent of unpleasant experiences using the computer.

Studies examining verbal/nonverbal processing have revealed two central findings (Mayer, Heiser, & Lonn, 2001; Sadoski & Paivio, 2001). First, processing experiences verbally and visually lead to greater learning, retention, and transfer than do processing experiences only verbally (Clark & Paivio, 1991; Paivio, 1975). For instance, in studying the process of osmosis, viewing an animation with a text description of the process (see <http://edpsychserver.ed.vt.edu/5114web/modules/slideshows/slideshows.cfm?module=4>) results in better learning, retention, and transfer than simply reading a text description. Second, both verbal and visual channels of information processing are subject to memory limitations such that each channel may be overloaded, reducing processing capacity and speed, and learning, retention, and transfer. For example, a multimedia slide show that includes auditory narration (verbal), subtitles of the auditory narration (verbal), and text within the slides themselves (verbal) is certain to overload an individual’s verbal channel (http://edpsychserver.ed.vt.edu/5114web/modules/memory5_apps1/slideshow1.cfm). These two findings play a central role in multimedia pedagogy (see Mayer & Anderson, 1991; Schnotz, 2001) and are further explored in the next section, which addresses cognitive load theory. The construct of cognitive load is a means for assessing the memory limita-

tions mentioned previously and for understanding the beneficial effects of adding visual information to verbal information.

Cognitive Load Theory

Cognitive load is a multidimensional construct that refers to the memory load that performing a task imposes on the learner (Paas & van Merriënboer, 1994; Sweller, van Merriënboer, & Paas, 1998). Inextricably linked with cognitive load theory is the notion that working memory is a limited resource; therefore, a careful distribution of the cognitive load within working memory is needed to successfully perform a given task (Chandler & Sweller, 1991, 1992). Further, cognitive load theory is based on several assumptions concerning human cognitive architecture (Mousavi, Low, & Sweller, 1995), including the following:

1. People have limited working memory and processing capabilities
2. Long-term memory is virtually unlimited in size
3. Automation of cognitive processes decreases working memory load

Ultimately, the central premise of cognitive load theory is that working memory is limited and, if overloaded, learning, retention, and transfer will be negatively affected.

Cognitive load theory posits that instructional materials impose upon the learner three independent sources of cognitive load—*intrinsic cognitive load*, *extraneous cognitive load*, and *germane cognitive load* (Gerjets & Scheiter, 2003; Paas, Renkl, & Sweller, 2003). Together, intrinsic, extraneous, and germane cognitive load comprise the total working memory load imposed on the learner during instruction (Tindall-Ford, Chandler, & Sweller, 1997) (see Figure 3).

Intrinsic cognitive load represents the inherent working memory load required to complete a task. As an inherent component of a given task, intrinsic cognitive load is beyond the direct control of the instructional designer. Sweller (1994) suggested that the amount of interaction between learning elements, *element interactivity*, is a critical factor influencing intrinsic cognitive load. *Element interactivity* (Tindall-Ford et al., 1997) occurs when the “elements of a task interact in a manner that prevents each element from being understood and from being learned in isolation and, instead, requires all elements to be assimilated simultaneously” (p. 260). For example, learning the syntax of a computer language imposes a heavy intrinsic cognitive load, because to learn word and rule orders, all the words and rules must be held in working memory simultaneously.

What constitutes an element does not depend solely on the nature of the material, but it also depends on the expertise of the learner (Gerjets

Figure 3. Scenarios of the relationship between working memory capacity and the three components of cognitive load (i.e., intrinsic, extraneous, and germane cognitive load)

& Scheiter, 2003; Tindall-Ford et al., 1997). High element interactivity may not result in high cognitive load if expertise has been attained, thus allowing the learner to incorporate multiple elements into a single element, or “chunk,” through schema acquisition or automaticity. This may be evidenced in the use of online simulations. For example, the Neurodegenerative Disease Simulation Model, a Java applet, can be daunting and create significant cognitive load for the novice due to the multiple options available, the complexity of the graphs, and the lack of automated skills related to the operation of the simulation (<http://www.math.ubc.ca/~ais/website/guest00.html>). For the experienced Neurodegenerative Disease Simulation Model user, however, the cognitive load is significantly reduced as the options are incorporated into schemas that act as an independent element, and the actual operation of the simulation is automated. Thus, using the simulation may result in extremely high intrinsic cognitive load for novices while imposing very little cognitive load on experts.

In addition to intrinsic cognitive load, the manner in which information is presented to learners and the activities required of learners can impose additional cognitive load (Paas, Renkl, & Sweller, 2003). While intrinsic cognitive load is determined by the nature of the material, *extraneous cognitive load* reflects the effort required to process instructional materials that do not contribute to learning the material or completing the task. In this sense, extraneous cognitive load can be seen as “error” in the overall instructional process. Fortunately, extraneous cognitive load is, to a large extent, under the control of instructional designers (Sweller et al., 1998). For example, when animation and text are combined, extraneous cognitive load is increased if the animation and text are not presented simultaneously (Moreno & Mayer, 1999). Specifically, imagine a simulation in which the directions are presented first, followed by the simulation (see <http://webphysics.ph.msstate.edu/jc/library/2-6/index.html>). In this case, the learner

must read the directions, maintain the relevant directions in working memory, and then attempt to use the simulation. The simulation has an innate level of cognitive load, intrinsic cognitive load, to which is being added an additional cognitive load, extraneous cognitive load, as the result of having to maintain the directions in working memory. A simple solution to this extraneous cognitive load would be to provide the directions on the same page as the simulation.

The third type of cognitive load is *germane cognitive load*. Germane cognitive load is the cognitive load appropriated when an individual engages in processing that is not designed to complete a given task, but rather, is designed to improve the overall learning process (e.g., elaborating, inferencing, or automating). Engaging in processes that generate germane cognitive load is only possible when the sum of intrinsic and extraneous cognitive load is less than the limits of an individual’s working memory. In addition, like extraneous cognitive load, germane cognitive load is influenced by the instructional designer. The manner in which information is presented to learners and the learning activities are factors relevant to the level of germane cognitive load. However, while extraneous cognitive load interferes with learning, germane cognitive load enhances learning by devoting resources to such tasks as schema acquisition and automation (Paas et al., 2003). For example, a student may engage in solving an historical murder mystery (<http://web.uvic.ca/history-robinson/>), resulting in both intrinsic and extraneous cognitive load. If sufficient working memory capacity remains, the student may also engage in practicing a metacognitive strategy for assessing the primary sources that serve as data for solving the murder mystery. Using a metacognitive strategy is not essential to engaging the murder mystery, however, this use will lead to greater automaticity of the strategy, elaboration on the primary sources, and ultimately, enhanced learning.

Overall, total cognitive load is comprised of the sum of intrinsic, extraneous, and germane cognitive load. This summative nature leads to several interesting scenarios (see Figure 3), all limited or constrained by an individual's working memory capacity (see Figure 3a). These differing scenarios will all be examined using a common example, a Social Justice Resource Center database site (see <http://edpsychserver.ed.vt.edu/diversity/>).

In the first scenario, if the sum of the intrinsic and extraneous cognitive loads exceeds one's working memory capacity, then learning and performance of the given task will be adversely affected (see Figure 3b). In the case of the Social Justice site, the Advanced Search page could easily overwhelm the working memory capacity of a database/search novice (Figure 4). The Advanced Search page contains complex functions for Boolean searches, data restriction, and layout control, all possibly contributing to excessive extraneous cognitive load.

If, however, the sum of intrinsic and extrinsic cognitive load is equal to one's working memory capacity, then one should be able to complete the given task successfully (see Figure 3c). Continuing the Social Justice example, the extraneous cognitive load may be reduced by instructing a student to focus only on understanding and using the Boolean operator search fields and ignoring the data restriction and layout options. Providing or focusing on fewer options is likely to reduce extraneous cognitive load.

While this situation is acceptable, it does not provide any cognitive resources for engaging in additional and beneficial processing beyond the mere completion of the task. If cognitive load is reduced further, such that the sum of intrinsic and extraneous cognitive load is less than one's working memory capacity, then one may engage in additional synergistic processing, yielding germane cognitive load, resulting in increased overall performance (see Figure 3d). For a database/search

Figure 4. The Advanced Search page of the Social Justice Resources Center that when used by novices to search for social justice resources results in high intrinsic and extraneous cognitive load

The screenshot shows a web browser window with the address <http://edpsychserver.ed.vt.edu/diversity/AdvancedSearch.cfm>. The page is titled "Social Justice Resources Center" and features a navigation menu on the left with links to "Basic", "Advanced", "Add a Site", "Library", and "Home". The main content area is titled "Advanced Search:" and includes a "Search for:" field, a "Search" button, and a "Help | Basic Search" link. Below this are three "AND" search fields and three "Common Keywords" dropdown menus. A note states: "These 'Common Keywords' represent the 20 most frequently cited keywords present in the SRC database." Further down, there are sections for "Include Only:" (with checkboxes for Articles, Artifacts, Books, Chapters, Events, Lesson Plans, Media, Websites) and "Display:" (with radio buttons for Short Record and Long Record, and a "10 matches per page" option). At the bottom, there is a "Focus on:" section with checkboxes for various subjects like English/Language Arts, Fine Arts, Foreign Language/ESL, History/Social Studies, Mathematics/Health, Media Literacy, PE/Health, Science, Special Education, Theatre, Vocational Education, College/University, Elementary School, High School, Middle School, Curriculum and Classroom Materials, and Teacher Background Materials.

novice, no use of the Social Justice Advanced Search page is likely to result in germane cognitive load. To facilitate germane cognitive load, a new Web page may need to be developed that simplifies the task at hand, such as a Basic Search page (Figure 5). The Basic Search page has only one field to complete with very simple directions. The use of the Basic Search page would allow the user to engage in secondary processes, generating germane cognitive load, such as generating a schema of database use, elaborating on potential keywords, and combining keywords into more precise search phrases.

Thus, the ultimate goals of instruction are to (a) create tasks that have inherently low to moderate intrinsic cognitive load, (b) develop instructional designs that reduce extraneous cognitive load, and (c) foster engagement in active processing that facilitates germane cognitive load (see Figure 3e). An example that satisfies all three of these criteria would include searching the Social Justice Resources Database using the Basic Search page that combines a manageable task with an efficient environment to produce effective learning and performing.

This effective and efficient learning and performing is shaped by careful attention to the con-

straints and guidelines provided by dual-coding theory and cognitive load theory. And, just as dual-coding theory informs cognitive load theory, cognitive load theory informs the cognitive theory of multimedia (see Mayer, 2001). By considering factors that may place an undue burden on the learner while engaged in multimedia cognition, designers can develop multimedia environments that promote effective and efficient learning.

A COGNITIVE THEORY OF MULTIMEDIA

Creating multimedia that balances the constraints of human memory (e.g., dual coding and cognitive load) with the goals of education and training (e.g., meaningful learning, retention, and transfer) requires a theory of multimedia instruction grounded in the science of human learning. Until recently, multimedia meant multiple media *devices* used in a coordinated fashion (e.g., cassette tape player and a slide show) (Moore, Burton, & Myers, 1996). However, advances in technology have combined these media so that information previously delivered by several devices is now integrated into one device (e.g., computer, kiosk)

Figure 5. The Basic Search page of the Social Justice Resources Center that when used to search for social justice resources results in low intrinsic and extraneous cognitive load

(Kozma, 1994). Thus, multimedia is now typically defined as the integration of more than one medium into a common computer-based communication framework; specifically (von Wodtke, 1993), “multimedia refers to the integration of media such as text, sound, graphics, animation, video, imaging, and spatial modeling into a computer system” (p. 3).

This common computer-based communication framework for multimedia instruction resulted in early research on multimedia focusing on capturing the capabilities of this new framework to deliver instruction (Moore, Burton, & Myers, 1996). However, the current focus of multimedia instruction has shifted away from this technology-centered approach to a more learner-centered approach, where the emphasis is on how to design multimedia frameworks to aid human cognition (see Abbey, 2001).

This learner-centered approach to multimedia instruction focuses on the cognitive processing of multimedia messages and the influence of this processing on learning, retention, and transfer. This processing of multimedia messages within a computer-based instructional environment is typically reduced to two channels of presentation/sensation—auditory and visual. Within this limited two-channel environment, *words* and *pictures* comprise the two main formats available for engaging in multimedia instruction. Words, or verbal information, include primarily auditory speech or printed text, whereas pictures, or visual information, include primarily static graphics (e.g., illustrations and photos) and dynamic graphics (e.g., animation and video). Fortunately, advances in computer technology have resulted in the emergence of numerous ways of presenting these words and pictures. These advances allow designers to combine words and pictures in ways that were not previously possible. As a result, new research has emerged concerning the effectiveness of presenting instruction using both words and pictures.

Research focusing on exploiting the benefits and limitations of the mind’s verbal and visual-processing channels in multimedia instructional environments has been championed by Richard Mayer and his colleagues (see Mayer, 2001). Mayer (2001), in pursuing this dual-channel multimedia research, specifically defines multimedia as “the presentation of material using both words and pictures. . . . I have opted to limit the definition to just two forms—verbal and pictorial—because the research base in cognitive psychology is most relevant to this distinction” (pp. 2–3). This research base to which Mayer refers is centered on Baddeley’s *working memory model* (Baddeley, 1986, 1999), Paivio’s *dual-coding theory* (Clark & Paivio, 1991; Paivio, 1990), and Sweller’s *cognitive load theory* (Chandler & Sweller, 1991; Sweller, 1994). As mentioned previously, these three theories are not independent but rather overlap, creating theoretical interdependencies. This interdependency is evident in Mayer’s construction of the *cognitive theory of multimedia learning* (Mayer, 2001).

Mayer’s (2001) *cognitive theory of multimedia learning* is premised on the following three assumptions: (a) learners process visual and auditory information in different cognitive channels—the dual-channel assumption; (b) each cognitive channel has a limited processing capability—the limited-capacity assumption; and (c) learners actively process this visual and auditory information—the active-learning assumption.

The *dual-channel assumption* holds that individuals have separate cognitive channels for processing auditory and visual information. For example, if a learner is watching a video clip with auditory narration, then the visual channel will process the video images, while the auditory channel will process the narration. This dual-channel assumption is consistent with Baddeley’s (1986) working memory model and Paivio’s dual-coding theory (Paivio, 1990).

The *limited-capacity assumption* builds on the premise that humans are limited in the amount

of information that can be processed in either channel at one time. For instance, if a learner is watching a video clip with subtitled text, the visual channel could easily become overloaded attempting to process both the video images and the subtitled text, because the images and the text are processed visually. This limited-capacity assumption is consistent with Baddeley's (1986) working memory model and Sweller's (1994) cognitive load theory.

The *active-processing assumption* posits that learners actively engage in processing multimedia environments by (a) *selecting* relevant information from the environment, (b) *organizing* the information into coherent representations, and (c) *connecting* both visual and verbal representations (Mayer, 1997). For example, if a learner is watching a video clip with auditory narration, the learner will select relevant pictures from the video and relevant words from the narration, organize the pictures and words into coherent representations, and then combine these coherent representations into an overall conceptual model of the video clip. The active-learning assumption is consistent with Paivio's (1986) dual-coding theory and Baddeley's (1986) working memory model.

These three assumptions combine to create a model of multimedia processing based on a dual-channel, limited-capacity, active-processing learner. It is important to think of these three assumptions as an integrated whole, not as isolated factors, as each affects the other and in turn affects learning within multimedia instructional environments. For example, if too much visual information is presented (e.g., animation and on-screen text; <http://basepair.library.umc.edu/movies/mitosis1.mov>), then the visual channel's capacity will be exceeded, leading to insufficient processing of that visual information (i.e., either the animation or on-screen text will not be attended to in their entirety). This situation could be corrected, however, by either eliminating some of the visual information (e.g., removing the on-screen text) or switching some of the visual information to

an auditory channel (e.g., using audio narration instead of on-screen text (<http://basepair.library.umc.edu/movies/mitosis.mov>)).

Within these three assumptions, Mayer (2001) posited five cognitive processes necessary for the generation of meaningful learning, retention, and transfer. These five processes are evident in the cognitive theory of multimedia and include the following: (a) selecting relevant words from the multimedia environment, (b) selecting relevant images from the multimedia environment, (c) organizing the selected words into a coherent representation, (d) organizing the selected images into a coherent representation, and (e) integrating the word and image representations with prior knowledge into a coherent mental model (Mayer, 2001). A learner watching a narrated slide show demonstrates these five processes (see <http://edpsychserver.ed.vt.edu/5114web/modules/classical/slideshow1.cfm>). The learner selects relevant words from the narration and relevant images from the slide show. The learner then generates meaningful representations of the words and images. Finally, the learner integrates the words, pictures, and relevant prior knowledge into a coherent mental model of the narrated slide show.

These three assumptions and five processes, based on working memory, dual-coding theory, and cognitive load theories, serve as the framework for much of Mayer's work in multimedia learning. Mayer's work addressing multimedia learning has resulted in several principles of multimedia learning. It is important to note that Mayer's research focuses on the derivation of cognitive principles from empirical research, where the principles may then be used to create general pedagogy (see Figure 1). This clarification is important, as Mayer uses short tutorials within his research. However, the principles that are derived are not limited to tutorial-based instructional environments. The benefit of focusing on the derivation of cognitive principles is that these principles have generalizability beyond the contexts in which they are originally demonstrated. In the following section,

several cognitive principles of multimedia are delineated and examples are provided that extend these principles into nontutorial instructional environments.

MULTIMEDIA, PRINCIPLES AND PEDAGOGY

The development of cognitive principles of multimedia is essential in the quest for theoretically sound pedagogy for multimedia instructional environments (see Figure 1). These cognitive principles serve as the bridge between empirical findings and general pedagogical principles. Over the past 15 years, Richard Mayer, Roxana Moreno, and their colleagues have continued in their efforts to generate empirical findings relative to multimedia learning. These empirical findings have coalesced into a series of cognitive and pedagogical principles relevant to learning and instruction within multimedia environments. The following section will introduce seven cognitive principles of multimedia that have emerged from their work. These seven principles include the multimedia principle, the modality principle, the redundancy principle, the coherence principle, the

contiguity principle, the segmentation principle, and the signaling principle (see Table 2).

Multimedia Principle

The multimedia principle simply states that individuals learn, retain, and transfer information better when the instructional environment involves words and pictures, rather than words or pictures alone. Specifically, individuals who experienced a short tutorial explaining how bicycle tire pumps worked, where the instruction was in the form of words and pictures or narration and animation, learned, retained, and transferred the knowledge within the tutorial significantly better than individuals who experienced a tutorial where the instruction was in the form of narration or animation only (Mayer & Anderson, 1991, 1992). Thus, when constructing multimedia instructional environments, learning, retention, and transfer are facilitated by the use of both words and pictures, or narration and animation.

Theoretically, these results and the multimedia principle may be explained based on Paivio's (1990) dual-coding theory. When an individual experiences instruction both verbally and visually, the individual constructs verbal and visual

Table 2. Brief definitions of the cognitive principles of multimedia

Principle	Definition
Multimedia principle	Individuals learn, retain, and transfer information better when the instructional environment involves words and pictures, rather than word or pictures alone.
Modality principle	Individuals learn, retain, and transfer information better when the instructional environment involves auditory narration and animation, rather than on-screen text and animation.
Redundancy principle	Individuals learn, retain, and transfer information better when the instructional environment involves narration and animation, rather than on-screen text, narration, and animation.
Coherence principle	Individuals learn, retain, and transfer information better when the instructional environment is free of extraneous words, pictures, or sounds.
Signaling principle	Individuals learn and transfer information better when the instructional environment involves cues that guide an individual's attention and processing during a multimedia presentation.
Contiguity principle	Individuals learn, retain, and transfer information better in an instructional environment where words or narration and pictures or animation are presented simultaneously in time and space.
Segmentation principle	Individuals learn and transfer information better in an instructional environment where individuals experience concurrent narration and animation in short, usercontrolled segments, rather than as a longer continuous presentation.

representations of the explanations and subsequently integrates the two representations into a coherent model. This dual-channel integration has been demonstrated to provide for increased learning when compared to learning based on a single-channel representation (Clark & Paivio, 1991; Paivio, 1991). Further, these results and the multimedia principle are consistent with Mayer's (2001) cognitive theory of multimedia. Mayer posits that verbal and visual representations are informationally distinct, such that the informational sum of the integration of verbal and visual representations always exceeds the information present in the verbal or visual representations alone. This integration of distinct verbal and visual representations, in turn, leads to greater learning, retention, and transfer. As Mayer (2001) stated, "In short, our results support the thesis that a deeper kind of learning occurs when learners are able to integrate pictorial and verbal representations of the same message" (p. 79).

This integration has ramifications for pedagogy, specifically, that multimedia instructional environments should utilize words or narration and pictures or animation. Combining words or narration and pictures or animation can be as simple as using static images to clarify on-screen text. For example, ACKY.NET provides a wealth of information regarding Web design, including several effective tutorials that consist primarily of static images and text (http://www.acky.net/tutorials/flash/bouncing_ball/). Another basic method of combining words or narration and pictures or animation is the use of streaming video for disseminating lectures (<http://sinapse.arc2.ucla.edu/streaming/cnsi/seminars/spring2003/mceuen-rm8-mbr.ram>). The video lecture scenario may be made more complete through the use of streaming video, with a concurrent slide show and hyperlinks (http://ra.okstate.edu:8080/ramgen/zayed/leadership_skills_a/trainer.smi). The key in these instances is that words or narration and pictures or animation are being combined for the purpose of enhancing instruction.

Modality Principle

The modality principle, which further clarifies the multimedia principle, states that individuals learn, retain, and transfer information better when the instructional environment involves auditory narration and animation, rather than on-screen text and animation. Specifically, individuals who experienced a short tutorial explaining the creation of lightning, where the instruction was in the form of auditory narration and animation, learned, retained, and transferred the knowledge within the tutorial significantly better than individuals who experienced a tutorial where the instruction was in the form of on-screen text and animation (Mayer & Moreno, 1998; Moreno & Mayer, 1999). Thus, when constructing multimedia instructional environments, learning, retention, and transfer are facilitated by the use of auditory narration and animation.

Theoretically, these results and the modality principle may be explained based on Baddeley's (1986) working memory model and Sweller's (1991) cognitive load theory. When on-screen text and animation are presented simultaneously, an individual is confronted with the task of attending to and creating two visual representations, which can easily overload the visual channel. When the visual on-screen text is transformed into auditory narration, the cognitive load of the visual channel is reduced, and the overall cognitive load of the instructional environment is better balanced between the auditory and visual channels. Further, these results and the modality principle are consistent with Mayer's (2001) cognitive theory of multimedia. Mayer supports the limited-capacity, dual-channel structure of memory responsible for the cognitive overload created by the presentation of two visual stimuli: on-screen text and animation. According to Moreno and Mayer (1999), "When learners can concurrently hold words in auditory working memory and pictures in visual working memory, they are better able to devote

attentional resources to building connections between them” (p. 366).

Pedagogically, using both channels to foster connections implies that multimedia instructional environments should utilize narration and animation, as opposed to on-screen text and animation, whenever possible. Integrating audio and video in multimedia environments is reasonably common these days. Stanford University’s Center for Professional Development provides a series of *Online Seminars* that consist of simple streamed lectures, which combine narration and video, on a variety of topics (<http://stanford-online.stanford.edu/murl/cs547/>). Another example that demonstrates the blending of narration and animation is the International Association of Intercultural Education’s *The Big Myth* that provides lessons on creation myths and cultural pantheons from around the world (http://www.mythicjourneys.org/bigmyth/1_webmap.swf). In each of these instances, the multimedia instructional environment is enhanced through the use of concurrent auditory narration and animation.

Redundancy Principle

The redundancy principle, which provides an extension of the multimedia and modality principles, states that individuals learn, retain, and transfer information better when the instructional environment involves narration and animation, rather than on-screen text, narration, and animation. Specifically, individuals who experience a short tutorial explaining the creation of lightning, where the instruction was in the form of auditory narration and animation, learned, retained, and transferred the knowledge within the tutorial significantly better than individuals who experienced a tutorial where the instruction was in the form of on-screen text, auditory narration, and animation (Mayer, Heiser, & Lonn, 2001; Moreno & Mayer, 2002). Thus, when constructing multimedia instructional environments, learning, retention, and transfer are

facilitated by the use of auditory narration and animation, without on-screen text.

Theoretically, these results and the modality principle may be explained based on Baddeley’s (1986) working memory model and Sweller’s (Chandler & Sweller, 1991) cognitive load theory. When on-screen text, auditory narration, and animation are presented simultaneously, an individual is confronted with the task of attending to and creating two visual representations based on the on-screen text and the animation, and attending to and creating an auditory representation based on the auditory narration. The task of attending to and creating two visual representations can easily overload the visual channel and impair the individual’s ability to attend adequately to the auditory channel. When the visual on-screen text is eliminated, the cognitive load of the visual channel is reduced, and the overall cognitive load of the instructional environment is better balanced between the auditory and visual channels. Further, these results and the modality principle are consistent with Mayer’s (2001) cognitive theory of multimedia. Mayer supports the limited-capacity, dual-channel structure of memory responsible for the cognitive overload created by the presentation of two visual stimuli: on-screen text and animation. According to Mayer et al. (2001), “in this case, learners are less likely to be able to carry out the active cognitive processes needed for meaningful learning” (p. 195) (e.g., elaboration, organization, reflection).

While the redundancy principle has significant ramifications for pedagogy, these ramifications will be combined with the recommendations from following principle, the coherence principle, and will be discussed at the end of the next section.

Coherence Principle

The coherence principle, which refines the redundancy principle, states that individuals learn, retain, and transfer information better when the instructional environment is free of extraneous

words, pictures, or sounds. Specifically, individuals who experienced a short tutorial explaining either the creation of lightning or the workings of a hydraulic break, where the instruction was in the form of narration and animation, learned, retained, and transferred the knowledge within the tutorial significantly better than individuals who experienced a tutorial where the instruction was in the form of narration, animation, and interesting, but irrelevant, words, pictures, or sounds (Mayer, Heiser, & Lonn, 2001; Moreno & Mayer, 2000). Thus, when constructing multimedia instructional environments, learning, retention, and transfer are impeded by the inclusion of extraneous, irrelevant materials; therefore, multimedia should be kept simple and include only those attributes necessary for the instruction.

Theoretically, these results and the coherence principle may be explained based on Baddeley's (1986) working memory model and Sweller's (Chandler & Sweller, 1991) cognitive load theory. When extraneous materials are introduced into the multimedia instructional environment, these extraneous materials compete with the instructional materials for the limited resources of the individual's working memory. If these extraneous materials are significant, then cognitive overload can occur, and learning and performance will be negatively affected. According to Moreno and Mayer (2000), "these findings suggest that auditory overload can be created by adding auditory material that does not contribute to making the lesson intelligible" (p. 121).

The redundancy and coherence principles each have a common message for the building of pedagogy, specifically, that multimedia instructional environments should be clear and concise, avoiding the duplication of information and the inclusion of extraneous, noninformative elements. While the tendency in creating multimedia instructional environments is often to add "bells and whistles" (multiple representations of the same content, interesting sounds, or moving text), simple designs that are focused on the learner's attention and

process are more effective. A simple, yet effective multimedia instructional environment is the *Who Killed William Robinson?* Web site at the University of Vancouver, British Columbia Web address (<http://web.uvic.ca/history-robinson/>). This site is composed of primarily static text and pictures, yet the design and implementation of the project is simple and straightforward. There is no redundant or extraneous material. Another that is simple, yet effective is the Advanced Education Psychology site at the Virginia Tech Web address (<http://edpsychserver.ed.vt.edu/5114web/modules/classical/>). These particular sites are prime examples of effective multimedia instructional environments that are not "tech heavy," that is, sites that do not rely on advanced technology but rather on effective multimedia design.

Signaling Principle

The signaling principle, which is related to the coherence principle, states that individuals learn and transfer information better when the instructional environment involves cues, or signals, that guide an individual's attention and processing during a multimedia presentation. Signaling (Meyer, 1975) "serves as guides...by giving emphasis to certain aspects of the semantic content or pointing out aspects of the structure of content so that the [individual] can see the relationships stated in the passage more clearly" (p. 1). Specifically, individuals who experienced a short tutorial explaining the creation of lift in aeronautics, where the instruction was in the form of narration and animation, and included auditory signals (e.g., intonation changes, pausing) and visual signals (e.g., arrows, color emphasis, summary icons), learned and transferred the knowledge within the tutorial significantly better than individuals who experienced a tutorial where the instruction was in the form of narration and animation but did not include signals (Mautone & Mayer, 2001). Thus, when constructing multimedia instructional

environments, learning and transfer are facilitated by the use of auditory and visual cues and signals.

Theoretically, these results and the signaling principle may be explained based on Baddeley's (1986) working memory model and Sweller's (1991) cognitive load theory. When signals or cues are provided that focus an individual's attention on relevant, rather than irrelevant, information, the individual's expenditure of cognitive resources is more efficient, thus reducing cognitive load. In addition, this reduction in cognitive load, when coupled with cues and signals designed to make explicit relational links within the presentation information, results in the increased generation of connections between auditory and visual representations. According to Mautone and Mayer (2001), "signals encourage learners to engage in productive cognitive processing during learning, including selecting relevant steps in the explanation, organizing them into a coherent mental structure, and integrating them with existing knowledge" (p. 387).

Pedagogically, the signaling principle posits that multimedia instructional environments should include cues to assist in focusing learner's attention and fostering appropriate learner processing of the relevant information. Students often find Web pages and online instruction overwhelming, with too much to see and do. Using cues to guide a learner's attention and processing provides the learner with instructional scaffolding and learner support. As part of the online experience in the Department of Entomology, students have the option of participating in an online "course" called *The Whole Student*. This course combines streaming audio with static slides and provides cues for students through the use of effective navigation and by placing on the static slides the main points discussed in the audio (http://www.ento.vt.edu/ihs/distance/lectures/whole_student/). Another site that provides effective cues is Biology in Motion's *Evolution Lab*. This site provides cues through section headers, color, and graphics (<http://biologyinmotion.com/evol/>). The Whole

Student and Evolution Lab sites both provide effective cues through strategic use of text and text attributes (e.g., boldface, color).

Contiguity Principle

The contiguity principle states that individuals learn, retain, and transfer information better in an instructional environment where words or narration and pictures or animation are presented simultaneously in time and space. Specifically, individuals who experienced a short tutorial explaining the creation of lightning, where the instruction was in the form of integrated on-screen text and animation (i.e., the text was presented spatially within the animation), learned, retained, and transferred the knowledge within the tutorial significantly better than individuals who experienced a tutorial where the instruction was in the form of separated on-screen text and animation (i.e., the text was presented spatially separated from the animation) (spatial contiguity effect; Moreno & Mayer, 1999). In addition, individuals who experienced a short tutorial explaining the creation of lightning, where the instruction was in the form of simultaneous narration and animation, learned, retained, and transferred the knowledge within the tutorial significantly better than individuals who experienced a tutorial where the instruction was in the form of narration *followed by* animation (temporal contiguity effect; Moreno & Mayer, 1999). The contiguity principle, as stated here, combines what Mayer and Moreno referred to as the spatial contiguity principle and the temporal contiguity principle (Mayer & Anderson, 1991; Moreno & Mayer, 1999). Thus, when constructing multimedia instructional environments, learning, retention, and transfer are facilitated when text or narration and pictures or animation are concurrent and are not separated in either time or space.

Theoretically, these results and the contiguity principle may be explained based on Baddeley's (1986) working memory model and Sweller's

(Chandler & Sweller, 1991) cognitive load theory. When on-screen text is presented spatially separate from animation, the individual is forced to split attention between the two sources of information (Mayer & Moreno, 1998). This attention split requires extra working memory and processing resources and is more likely to result in cognitive overload than when the on-screen text and animation are integrated. Similarly, when narration is provided *prior to* viewing an animation, the individual must maintain the narration in working memory while viewing the animation if any connections between the narration and animation are to be created. This narration maintenance is cognitive resource intensive and is likely to result in cognitive overload at the onset of the animation. Mayer's (2001) cognitive theory of multimedia is consistent with these findings and rationales: "If we want students to build cognitive connections between corresponding words and pictures it is helpful to present them contiguously in time and space—that is, to present them at the same time or next to each other on the page or screen" (p. 112).

Applying the contiguity principle implies that multimedia instructional environments should be constructed such that words and pictures or narration and animation are displayed simultaneously and close together. Prime examples of this synchronization of time and place include the fusion of audio and video. For example, Brainware.tv's *Boardband Business Videos* (<http://www.brainware.tv/previews/p1harn2.asx>) and the Electronic Scholar's *Study of Teaching Videos* (<http://www.electronic scholar.com/videos.html>). Another example of synchronization includes the synthesizing of text and animation, where the text is integrated into the animation. An example of this type of synchronicity includes the *Projectile Motion* Java applet (http://galileoand einstein.physics.virginia.edu/more_stuff/Applets/ProjectileMotion/jarapplet.html). This applet plots the path of a simulated projectile, given specific parameters (i.e., velocity, angle, mass), and provides integrated feedback on the projectile's maximum

distance, maximum height, end velocity, and time aloft. The previous video examples represent temporal contiguity, where multimedia are experienced simultaneously, while the applet example represents spatial contiguity, where multimedia are experienced close together in space. It is important that multimedia instructional environments be both temporally and spatially contiguous.

Segmentation Principle

The segmentation principle states that individuals learn and transfer information better in an instructional environment, where individuals experience concurrent narration and animation in short, user-controlled segments, rather than as a longer continuous presentation. Specifically, individuals who experienced a short tutorial explaining the creation of lightning, where the instruction was in the form of 16 short, user-controlled segments of concurrent narration and animation, learned and transferred the knowledge within the tutorial significantly better than individuals who experienced the tutorial as a single, continuous narration and animation presentation (Mayer & Chandler, 2001; see also Mayer & Moreno, 2003). Thus, when constructing multimedia instructional environments, learning and transfer are facilitated by the user being able to control the rate of information presentation.

Theoretically, these results and the segmentation principle may be explained based on Baddeley's (1986) working memory model and Sweller's (Chandler & Sweller, 1991) cognitive load theory. When an individual has control over the rate of information presentation, the individual may pace the presentation such that time and cognitive resources are allotted for making connections between verbal and visual representations. Alternatively, during an automatically paced presentation, the individual may lack sufficient time and cognitive resources to make representational connections, resulting in cognitive overload. Mayer and Moreno (2003),

in discussing the segmentation principle in light of the cognitive theory of multimedia, stated that “the learner is able to select words and select images from the segment; the learner also has time and capacity to organize and integrate the selected words and images” (p. 47).

The segmentation principle, pedagogically, supports the position that multimedia instructional environments should be created to allow the user control over the pacing of the environment, if the environment is likely to foster cognitive overload. A well-constructed example of allowing user control includes Virginia Tech’s *Critical Media Literacy in Times of War* site (<http://www.tandl.vt.edu/Foundations/mediaproject/>). This site integrates text, graphics, animation, and audio, while providing the learner with step-by-step navigational control. Similarly, the Joliet Junior College tutorial *Using a Secant Line to Approximate a Tangent Line* provides the learner with the ability to experience the tutorial in small steps (<http://home.attbi.com/~waterhand/tangent.html>). In each of these cases, the user is provided with the ability to slow his or her interaction with the multimedia instructional environment and thus provide added time and resources for active cognitive processing.

Summary

The explanations and examples of pedagogy based on the cognitive principles of multimedia provide an initial framework for creating multimedia instructional environments that are empirically and theoretically well grounded. This grounding is essential, as it has been demonstrated repeatedly that media itself, even multimedia, has little effect on learning unless the pedagogy that drives the media is focused on student learning (see Clark, 1983, 1994).

Collectively, these seven cognitive principles of multimedia provide a grounded framework within which to begin to build this learner-centered pedagogy. The multimedia and modality

principles clearly delineate the benefits of using concurrent narration and animation in multimedia instructional environments. Furthermore, the redundancy principle extends the multimedia and modality principles by demonstrating that providing redundant information in both auditory and visual-processing channels is detrimental when the visual channel also needs to process images. Further, the coherence principle refines the redundancy principle by demonstrating that irrelevant stimuli, as well as redundant stimuli, are detrimental to learning, retention, and transfer. However, the signaling principle may provide a potential solution to the overload caused by irrelevant or redundant stimuli by providing cues that may focus the learner’s attention and processing and thus ameliorate the cognitive overload. While signaling may ameliorate the presence of extraneous stimuli, the coherence principle demonstrates, more generally, that proximity in time and space of narration and animation is beneficial to learning, retention, and transfer. Finally, the segmentation principle demonstrates that when a narration and animation sequence is likely to proceed too quickly for the learner to process information adequately, then allowing the user to control the progress of the narration and animation sequence pace is beneficial.

CONCLUSION

Improving instruction has been a primary goal of education and training. To foster this goal, educators have employed cognitive principles to highlight effective instructional practices. Unfortunately, a disconnect continues to exist between this science of human learning and daily educational practice. This gap denies learners and teachers access to powerful forms of teaching, training, and learning.

Fortunately, the field of instructional technology, generally, and the domain of multimedia learning, specifically, is providing an avenue for

bridging this educational gap. Current research into pedagogical and technological integration within multimedia instructional environments is yielding significant and meaningful findings related to the improvement of learning, retention, and transfer. As discussed previously, the cognitive principles of multimedia, derived from Mayer's (2001) cognitive theory of multimedia, provide a solid foundation upon which to build a theoretically sound pedagogy. This process, however, of creating pedagogy from theory is fraught with difficulty and thus must be undertaken with care and forethought. According to William James (1899-1958):

I say moreover that you make a great, a very great mistake, if you think that psychology, being the science of the mind's laws, is something from which you can deduce definite programmes and schemes and methods of instruction for immediate schoolroom use. Psychology is a science, and teaching is an art; and sciences never generate arts directly out of themselves. An intermediary inventive mind must make the application, by using its originality. (p. 23)

Thus, pedagogy of any type is at least once removed from its theoretical underpinnings. With this caution in mind, it is necessary that we not only apply the pedagogy arising from the cognitive principles of multimedia with due diligence, but that we also continue to further investigate and refine the pedagogy of multimedia.

Chapter 7.7

Instructional Game Design Using Cognitive Load Theory

Wenhao David Huang
University of Illinois, USA

Tristan Johnson
Florida State University, USA

ABSTRACT

This chapter proposes an instructional game design framework based on the 4C/ID-model and cognitive load theory, its associated theoretical foundation. The proposed systematic design framework serves as the processing link to connect games' powerful characteristics in enhancing learning experience with desired learning outcomes. In this chapter we focus on the cognitive aspect of learning outcome: the development of transferable schema. This chapter introduces design guidelines to attain specific game characteristic by prioritizing the design components in 4C/ID-model. Each game characteristic consists of three levels of design emphasis: preliminary, secondary, and tertiary. The ultimate goal of this chapter is to initiate a series of dialogue between cognitive

learning outcome, systematic instructional design, and instructional game design thereby seeking to improve the overall game design and instructional efficiency.

INTRODUCTION

In recent years, the use of games for teaching and learning has grown significantly in the training industry and K-16 educational settings. There is, however, a lack of understanding between what games readily provide (i.e., games' characteristics) and what the learners need from games (i.e., learning outcome). Such deficiency makes it difficult for instructional designers to systematically apply a design framework as well as to justify their decisions in using games to enhance learning. Being equipped by their multi-dimensional characteristics, the instructional potential of games therefore

DOI: 10.4018/978-1-60960-503-2.ch707

cannot be fully utilized until there is substantive evidence linking specific instructional benefits to various game characteristics. Moreover, the lack of systematic instructional game design process supports unnecessarily prolonged, costly, and inefficient game design.

Games today are usually designed and developed based on generic film production procedures as well as filmmakers' mental models. Entertaining is the key design *objective*. All actions taken in game design are focused on one reason: to entertain the players. But what happens if we are to design instructional games? Does the entertainment element still override everything? While this key objective works for game developers, if games are to become a viable tool with instructional value, games need to more than entertain, they need to facilitate learning. This chapter believes that the design focus should be shifted to enhancing learning experience while still utilizes entertainment to support learner engagement. The ultimate goal of designing instructional games is to preserve the complex nature of games in order to optimize their impact on learning. The lack of a systematic design framework, however, often leaves some games' learning-enhancing features unexplored. As a result, instructional games' capabilities are not fully manifested for the purposes of enhancing learning and learning transfer to performance settings.

The purpose of this chapter is to describe a systematic instructional game design framework to address the issues just presented. We identify the cognitive load theory-based 4C/ID-model as the prototypical model to base the instructional game design framework, emphasizing the 4C/ID-model's focus on schema construction for complex learning and performance transfer. The following sections first discuss games' characteristics based on previous studies. Second, the chapter introduces the 4C/ID-model in the context of cognitive load theory; and third we propose an instructional game design framework based on 4C/ID-model to attain specific game characteristics in support of complex

cognitive learning. Finally, the chapter proposes a design framework for future research with the intention to initiate meaningful dialogue on how we can empirically investigate the learning impact of instructional games.

Background

What Are Games

A game is a context in which individual and teamed players, bounded by rules and principles, compete in attaining identified game objectives. There is a series of decision-making processes are required by the game players. Elliot Avedon and Brian Sutton-Smith (1971) explained that game playing is a voluntary exercise of controlling a system (i.e., the game) intended for a state of disequilibrium. In other words, game players continuously try out new methodologies and strategies during the game-playing process based on the system's feedback until they achieve the game objectives or the equilibrium state. The following section explains several game components that include:

- Games create experiences
- Rules and interactions in games
- Games are complex
- Games are models

Games Create Experiences

Games are known for their capabilities to promote collaborative and active learning (Downes, 2004; Klabbers, 2006; Vygotsky, 1978). Game players learn from their success and mistakes in order to improve their gaming skills and playing strategies. Players learn about the games and how to win the games from playing games and reflecting on the game interactions. The process begins with concrete playing experience. Players observe how the system responds to their actions in the form of scoring. Players then revise their playing strategies and try them out at similar situations.

A player can play the game many times and never quite get the gist of the game (experience alone is not sufficient). At some point, however, a player who thinks about what they are trying to learn (reflection and self feedback) can begin to master the game.

Rules and Interactions in Games

Games requiring individual participation offer a rich environment for players to be interactive with the game system (UNIGAME, 2002). Games comprise a system that consists of rules, process, and interactions that players must experience in order to attain desired outcome. Game rules help players connect the game contexts with players' existing schema; they also impose limits and guidelines on actions and to ensure that all players are seeking to achieve the game goals. Rules represent the criteria for evaluation of the player performance in the form of scoring, as well as to acknowledge players' performance during the game-playing process. Rules further enable players to analyze the interrelationships between different rules to generate feasible and "winning" strategies (Bennett & Warnock, 2007; Björk & Holopainen, 2003; Garris, Ahlers, & Driskell, 2002; Hays, 2005; Leemkuil, de Jong, & Ootes, 2000). Interactions in games are considered as structural components allowing players to interface with other players, game context, and the system. It is the interaction component that makes the game rules and the playing process meaningful (Asgari, 2005; Crawford, 1982; de Felix & Johnson, 1993; Kirriemuir & McFarlane, 2006; McGrenery, 1996; Myers, 1990; Thornton & Cleveland, 1990; Waal, 1995). The interactions within a game allow players to directly acquire first-hand experience thereby helping them to learn about the system presented in the game.

Games Are Complex

An engaging game can be more complex than a boring game. Players must consider multiple

factors before finalizing a winning decision. Sim City™, for example, players are responsible for planning, developing, and sustaining a prospering city. Building a new hospital is usually an effective strategy to attract new residents to move to the "simulated" city. The decision-making process for players is everything but simple and straightforward. One game play or action could impact the overall outcome since all pieces are causally connected by the game rules and system. Games are capable of linking critical elements together and hence can create a complex learning environment, that helps learners see the complex nature of a given model and also can help to develop transferable and predictive problem-solving strategies (Björk & Holopainen, 2003).

Games Are Representations Models

Games can embody abstract concepts and rules. The winning game play or game strategy is the translation of problem-solving strategies intended by the game model. The game adds contextual information to the model as to how to apply the information in different situations. This contextual information is often represented by a story line which implicitly or explicitly guides the players throughout the process. Simulation games, for example, are powerful in creating authentic situations for players to experience realistic and immediate performance feedback. Learners playing simulation games can directly interfacing with the intended model in a tangible way (Bennett & Warnock, 2007; Björk & Holopainen, 2003; Garris et al., 2002; Hays, 2005; Leemkuil et al., 2000).

Gaming Characteristics

An exhaustive literature review has identified 11 prominent and yet interrelated characteristics found in games regardless of their delivery formats. Each game characteristic is described in Table 1.

Table 1. Game characteristics

1.	Challenge	7.	Engagement and Curiosity
2.	Competition	8.	Role-Playing
3.	Rules	9.	Control
4.	Goals	10.	Multimodal Presentation
5.	Fantasy and Changed Reality	11.	Task
6	Story or Representation		

Challenge

A challenging activity provides an achievable level of difficulty for game players that consists of clearly identified task goals, unpredictability, immediate performance feedback, and a sense of accomplishment and conquering after completing the activities (Baranauskas, Neto, & Borges, 2001; Belanich, Sibley, & Orvis, 2004; Bennett & Warnock, 2007; Csikszentmihalyi, 1990; Garris et al., 2002; Malone, 1981; Malone & Lepper, 1987; McGrenery, 1996; Rieber & Matzko, 2001).

Competition

Competition stimulates players to take risk-taking actions in a consequence-free environment enriched with social interactions. Players develop their skills during the game-playing process by matching and exceeding the opponents' skill levels. The competition can be implemented between individual players, among teams, and even between players and the system (Baranauskas et al., 2001; Crawford, 1982; Csikszentmihalyi, 1990; Leemkuil et al., 2000; Rieber & Matzko, 2001; Vockell, 2004).

Rules

Rules of games serve as the guidelines for players' actions. Fair play is also sustained by the enforcement of game rules. Players need to learn about the game rules either by designated training or via the actual playing experience. In the context of

games for learning, game rules could be the direct or indirect translations of intended instructional materials such as scientific concepts of economic principles (Bennett & Warnock, 2007; Björk & Holopainen, 2003; Garris et al., 2002; Hays, 2005).

Goals

Goals in games clearly state the final status for players to attain via a series of planned tasks and actions by following the game rules. Sub-goals in games are often presented to present various stages of accomplishment for motivational and evaluation purposes. The presence of goals is also the major difference between games and simulations (i.e., simulations could be goal-less) (Bennett & Warnock, 2007; Björk & Holopainen, 2003; Csikszentmihalyi, 1990; de Felix & Johnson, 1993; Gredler, 1996; Hays, 2005; Hirumi, 2006; Leemkuil et al., 2000; Malone, 1980).

Fantasy and Changed Reality

Fantasy creates entirely unreal situations and environments for game players. This characteristic encourages players to take risks in a safe environment. Fantasy also motivates players to follow the story line to achieve desired game goals (Bennett & Warnock, 2007; Garris et al., 2002; Kirriemuir & McFarlane, 2006; Malone, 1981; Malone & Lepper, 1987; McGrenery, 1996). Changed reality in games allows players to have exaggerated experiences in a specific context, which must reflect a certain degree of reality, but not entirely.

Usually changed reality separates itself from reality by altering time, space, role-playing, and the complexity of situations (e.g., simplified reality) (Belanich et al., 2004; Björk & Holopainen, 2003; Crawford, 1982; Csikszentmihalyi, 1990).

Story or Representation

Story line or representation in games provides paths for players to interact, react, and progress. It summarizes the game goals, rules, constraints, role playing, and contexts for players in a seamlessly interconnected and embedded fashion (Hirumi, 2006; Rieber & Matzko, 2001). Players usually favor the representation of game rules in stories since it not only informs them the game guidelines, but also provides a holistic view of the entire game context.

Engagement and Curiosity

Engagement created by games allows players to become deeply involved in the game where players lose their sense of realistic self. In other words, players perceive themselves as part of the game and enjoy the intrinsically motivating game-playing experiences. Playing the game itself is rewarding enough without extrinsic motivators. Implementing elements of mystery and curiosity is also considered effective in creating engaging game experiences (Asgari, 2005; Bennett & Warnock, 2007; Csikszentmihalyi, 1990; Leemkuil et al., 2000; Malone, 1980; Malone & Lepper, 1987; McGrenery, 1996).

Control

Control in games enables players to determine and predict the outcome of actions or events. Providing options or choices to players, for example, is an effective approach to allow players to exercise control over the game progression (Belanich et al., 2004; Bennett & Warnock, 2007; Csikszentmihalyi, 1990; Garris et al., 2002; Gredler, 1996;

Malone, 1981; Malone & Lepper, 1987; McGrenery, 1996; Waal, 1995).

Role Playing

Role playing in the game involves the player becoming a character embedded in the story line of the game. Usually the player's role is pre-identified with specific position, access to resource and control, dominance over the progression of the game, functionality (if within a team), and behavioral patterns. Role playing helps players establish connection with the fantasy world of the game in order to better engage players with the game-playing experience (Björk & Holopainen, 2003; Gredler, 1996).

Multimodal Presentation

Games usually utilize multimodal presentation to effectively enhance the interest and instructional effect. This is particularly true in video games. Aural, visual, and textual presentations are combined in order to enrich the experience. Animations, for example, are popular as a major game component since they seamlessly integrate multimodal presentations and can be easily modified for different game contexts (Bennett & Warnock, 2007; Björk & Holopainen, 2003; de Felix & Johnson, 1993; McGrenery, 1996).

Task

Within the game mission, there are several tasks that comprise the building block of a game's goal. Players often are required to take on sequences of tasks in order to achieve the game's final goals. Task feedback or performance scores serve as player assessment of accomplished tasks that help players improve their playing strategies (Björk & Holopainen, 2003; Gredler, 1996). Games tasks can be derived from a learning task analysis and can be used to help players reach of intended learning goals.

Problem

In addition to the aforementioned finding on game characteristics, the literature review (Johnson, Spector, Huang, & Novak, 2007) did not reveal a systematic nor pedagogically sound design model available for optimizing games' effects on learning. Further, there was no evidence that suggested that a specific gaming characteristic or gaming strategy was linked to a specific learning goal. Given the multi-dimensional and multi-layered characteristics of games, the lack of practical design model diminishes the power of the game design to supporting complex learning and also prolongs the design cycle.

The absence of empirical design model for instructional game also poses an immediate concern to the evaluation of games' pedagogical impact. A majority of studies on games and their impact on learning are conducted as post-hoc analyses (O'Neil, Wainess, & Baker, 2005). Without a validated design model to purposefully control the inclusion and exclusion of design elements based on intended learning outcome, it is only possible to speculate the linkage between game characteristics and desired learning outcomes (O'Neil et al., 2005).

Solution

In order to enhance the decision-making associated with game design, we propose that game designers use the underlying principles found in the 4C/ID-model (van Merriënboer, & Sweller, 2005). This model is based on cognitive load theory (Chandler & Sweller, 1991; van Merriënboer & Paas, 1998), to address several of the concerns presented. The 4C/ID-model is suitable for designing and researching instructional games due to the model characteristics that include:

- Affordability to design complex learning environments;

- Flexibility to be applied for non-linear and compact design sequence;
- Scalability for design projects in various scopes;
- Validity and reliability of measuring learning outcome; and
- Emphasis on performance transfer.

Cognitive Load Theory

Cognitive load theory (CLT) (Chandler & Sweller, 1991; van Merriënboer & Paas, 1998) has established a sound theoretical foundation to connect cognitive research on human learning with instructional design and development (van Merriënboer, Clark, & de Croock, 2002). The purpose of CLT is to bridge the gap between information structures presented in the instructional material and human cognitive architecture so learners can use their working memory more efficiently (Paas, Renkl, & Sweller, 2003). "Learning," in the context of CLT, is thought to involve acquisition and automation of schema. Acquisition of schema is the process of how learners construct schema and store them in long-term memory, whereas automation is how learners perform certain tasks without accessing working memory. Information required for the performance of a task is retrieved directly from the long-term memory (Paas et al., 2003). Successful construction and automation of schema will lead to a more efficient use of working memory for desired performance since both attributes require little working memory capacity and yet are critical to meaningful learning (Mayer, 2001).

Three types of cognitive load are suggested by CLT to construct cognitive load: intrinsic cognitive load, extraneous cognitive load, and germane cognitive load. When combined, the three types of cognitive loads compose the total cognitive load, which can never exceed learner's working memory capacity for learning to occur. The total of extraneous cognitive load and germane cognitive load is assumed to be equal to the overall cognitive load minus the intrinsic cognitive load. Since

the intrinsic cognitive load is fixed (i.e., the load cannot be manipulated by instructional design), instructional design's main purpose is to reduce the extraneous cognitive load while increasing the germane cognitive load (van Gerven, Paas, van Merriënboer, & Schmidt, 2003).

Intrinsic cognitive load is associated with the element interactivity inherent to the instructional material itself. Element interactivity is described as the degree to which information can be understood alone without other elements' involvement (Paas et al., 2003). As suggested by Paas et al. (2003), information with high element-interactivity is hard to understand because it usually depends on the involvement of other information units in order to see the full interaction. Therefore, instructional material with high element interactivity is assumed to induce a higher intrinsic cognitive load since the instruction requires more working memory for information processing (Paas et al., 2003). The intrinsic cognitive load is also considered to be independent of instructional manipulations because the manipulation only involves the amount of information a learner needs to hold in working memory without decreasing the inherent element interactivity (Pollock, Chandler, & Sweller, 2002). The extraneous cognitive load and germane cognitive load, in contrast, can be manipulated by instructional design (Brünken, Plass, & Leutner, 2003).

Extraneous cognitive load is also known as *ineffective cognitive load* as it only involves the process of searching for information within working memory as opposed to the process of constructing schemas in long-term memory (Paas et al., 2003). This type of cognitive load can be influenced by the way information is presented and the amount of working memory required for given learning tasks. The extraneous cognitive load is considered as the necessary cost of processing information that is not related to the understanding of information. Instructional design's purpose therefore is to reduce the ineffective (i.e., extraneous) cognitive load (Brünken et al.,

2003). Well-designed instructional multimedia components have been found to be effective in reducing the extraneous cognitive load (Khalil, Paas, Johnson, & Payer, 2005a, 2005b; Mayer & Moreno, 2003). Cobb (1997) suggested similar multimedia application in designing instructional materials to increase "cognitive efficiency, where he used multimedia component (non-verbal and non-textual components) as cognitive capacity external to learners' working memory, to facilitate cognitive information processing. Consequently learners should spend less cognitive effort in understanding given information.

In contrast to the desired low degree of the extraneous cognitive load, instructional materials should be designed to increase the germane cognitive load. The germane cognitive load, also known as *effective cognitive load*, is described as the effort learners invest in order to facilitate the process of constructing schema and automation (Paas et al., 2003). Higher germane cognitive load is suggested to lead to a deeper learning since learners are compelled by the design of the instructional material to reexamine every new piece of information (de Crook, van Merriënboer, & Paas, 1998).

In summarizing CLT, the overall goal of manipulating cognitive load with instructional design is to decrease the level of ineffective cognitive load (i.e., extraneous cognitive load) and to increase the effective cognitive load that promotes deeper learning (i.e., germane cognitive load) (Paas et al., 2003). The CLT further suggests that the combination of extraneous and germane cognitive load should remain relatively constant after removing the fixed intrinsic cognitive load (Paas et al., 2003). The decrease of extraneous cognitive load should lead to the increase of germane cognitive load, or vice versa (Paas et al., 2003; van Gerven et al., 2003).

In order to better apply CLT in practical instructional design, van Merriënboer, Clark, and de Croock (2002) proposed the four-component instructional design system (4C/ID-model) for

designing complex learning environments (van Merriënboer & Sweller, 2005). The following section will discuss the 4C/ID model in detail and its applicability in designing complex game-based learning environments.

4C/ID-model (Four Components/ Instructional Design Model)

4C/ID-model is a non-linear, systematic, integrated, and performance transfer-oriented instructional design model intending to reduce extraneous cognitive load while increasing germane cognitive load during the learning process in complex learning environments. The model includes four non-linear, interrelated design components: *learning tasks*, *supportive information*, *just-in-time (JIT) information*, and *part-task practice*. All design actions center around the learning tasks component.

Learning tasks are concrete, authentic, whole-task experiences that are provided to learners to promote schema construction for non-recurring aspects and, to a certain degree, rule automation. Learning tasks must be complex and require the coordination and integration of all constituent skills. Task classes are used to define simple-to-complex categories of learning tasks and to steer the process of selection and development of suitable learning tasks. Learning tasks within a particular task class are equivalent in the sense that the tasks can be performed on the basis of the same body of knowledge (i.e., mental models and cognitive strategies). Learners are required to elaborate upon their existing knowledge base when given a higher task class. Various supports are also provided with learning tasks. Learner support informs learners about the problem in hand and guidance for generating effective solutions; product-support provided solution models in terms of worked-out examples and case studies; process-oriented support explains performance requirement and criterion reference for learners. The design should primarily aim at the induction process. That is, the design should focus on con-

structing schemata through attentive abstraction from the concrete.

Supportive information mainly supports the learning and performance of non-recurring aspects of intended tasks. Theories and models are often included in supportive information since learners can apply them universally for problem-solving in the same task class. The design of learning environments aims at the construction of meaningful relationships between learners' prior experiences and the learning tasks with experiential approach. More importantly the design should promote the elaboration process with cognitive feedback (Reigeluth, 1999) thus to enable learners to develop complex schemata.

JIT information facilitates learners' development in generating automated responses. Rules and principles are embedded in this design component and applied with the part-task practice. This design component uses demonstrations and instances to effectively explain the rules for all classes of learning tasks.

Part-task practice promotes rule automation for selected recurrent aspects of the intended complex task. The design approach aims to gradually develop learners' ability to automate the performance of recurrent skills via small task building blocks.

In addition to help learners develop desired skill levels separately, the 4C/ID-model stresses the integration and coordination of different levels of skills with intentional design, which traditional ISD models seem to lack. The main design goal of 4C/ID-model is to situate learners in authentic, complex learning environments with realistic contexts. The attainment of desired performance is more than just "assembling parts" together. Efforts also should go into the identification, evaluation, selection, combination of learned separated skills (constituent skills), to solve complex problems. 4C/ID-model suggests the necessity to purposefully design the relationships among different constituent skills (i.e., the outcome of task analysis) in complex learning environments. The

relationships could be temporal as desired tasks need to be performed step-by-step; it is also possible that learners need to demonstrate proficient performance on different task procedures simultaneously (e.g., air traffic controllers must monitor multiple aircrafts at the same time).

The model operates under these assumptions: (1) an upper level learning skill can be attained by assembling sets of simplified task procedure; and (2) performance transfer can be easily achieved after completing simplified learning tasks (van Merriënboer & Sweller, 2005). It further divides constituent skills in general into two categories: non-recurrent skills and recurrent skills. Non-recurrent skills morph themselves from problem to problem. As a result they require learners' cognitive reasoning since every situation is different from their previous experiences. Cognitive strategies are applied to extract existing schema in order to facilitate the problem-solving process in a novel context. Recurrent skills, on the other hand, are less effortful for learners to process and perform. Problem-solving process, in the case of recurrent skills, is very close to what learners have experienced before.

The design of the learning environment should focus on the abstraction of effective problem-solving process for non-recurrent skills since the goal is to enable learners to redevelop their own schema under various scenarios. In other words, the abstraction helps learners transfer the desired performance from context to context. The design approach proposed by this model is to provide concrete cases for learners to fully experience the cycle of abstraction and schema redevelopment. Additionally supportive information is utilized as one of the design component, to facilitate the development of non-recurrent skills, which will be discussed later in this section. When designing for recurrent skills, authentic and full application of rules and principles is crucial. The goal is to help learners automate the desired performance procedures with the least effort. This model proposes a layer-by-layer approach to compile

rules and procedures in the form of part-task practices. The entire task is dissected into inter-related part-task practices and learners are only asked to finish one of them at a time. The repetitive application of rules in order to accomplish all the part-task practices strengthens learners' automated responses toward similar problems. Moreover learners should have spontaneous access to rules and principles while accomplishing part-task practices. The just-in-time (JIT) information thus is proposed in the design model to facilitate the automation development process. By addressing both aspects of skill sets with 4C/ID-model's design approaches, learners will be able to transfer the desired performance efficiently into different contexts.

See Figure 1 for the visual presentation of the 4C/ID-model (van Merriënboer et al., 2002).

USING 4C/ID FRAMEWORK FOR GAMING DESIGN

In this section we describe use of the 4C/ID-model as the framework to compare the design components with games' characteristics in order to answer following questions:

Figure 1. Visual presentation of the 4C/ID-model (in van Merriënboer, Clark, & de Croock, 2002, p. 44)

- What game characteristics, based on previous literature reviews, should be able to directly support cognitive learning?
- How are design components of 4C/ID-model capable of informing the design of specific game characteristic?

Game Characteristics and Cognitive Learning

Cognitive learning, as described in the context of cognitive load theory as well as the 4C/ID-model, mainly focuses on the construction of transferable schema (van Merriënboer & Sweller, 2005). Such construction requires integrations of interrelated knowledge units and problem-solving processes. Learners should be able to understand the relationship among them and be able to apply them effectively in different and most of the time, new, problem-solving situations. Learners not only construct new schema as the result of the learning process, but also relate, flex, and expand existing schema to make the learning experience more meaningful. The instructional information should be delivered as the building blocks for developing learners' cognitive structures in the forms of solved and unsolved cases, worked examples, process-explicit solutions, and so forth. Each building block is self-contained and yet interconnected with other pieces. The learning environment (i.e., instructional games) must help learners acquire what is included in each building block as well as how to assemble all building blocks together. Below is the list of game characteristics that can potentially support the schema construction process:

Challenge: To encourage learners explore and experiment new processes, in other words, to flex their existing schema.

Competition: Learners strive to facilitate the problem-solving process with effective solutions, in order to defeat the opponent(s), be it the game system, or competing units.

Rules: Rules in instructional games provide learners with information that guide the problem-solving process. They also can be composed in a way that requires learners to abstract and modify their existing schema.

Goals: Goals of instructional games oftentimes are not explicitly related to the cognitive tasks intended in the game. But they provide specific performance objectives for learners to pursue in the forms of scores, accomplished missions, and conquered territories. In another words, goals are the performance criteria of assessing learners' newly developed schema.

Fantasy and Changed Reality: This is where instructional games can flex learners' existing cognitive structure. Fantasy enables learners' imaginations based on their experiences. Learners voluntarily extract existing schema that might be useful to accomplish given tasks in the fantasized context. The difference between fantasy and changed reality is manipulated by the foreignness of the gaming context perceived by learners. Learner's prior experience plays a critical role in designing meaningful fantasy or changed reality in instructional games.

Story and Representation: This characteristic in games illustrates operational schema for learners. Ideally, a story contains a problem to be solved, resources required to solve a problem, conditions necessary to implement the solution, and the outcome of applying such solutions. In instructional games the story should be incorporated as the contextual information for learners to see the big picture of the game. Rules of the game can also be implicit in the storylines to guide the learners' actions.

Engagement and Curiosity: Engagement sustains learners' attention during the learning process while curiosity drives learners to explore and experiment. This set of game characteristic enables learners persistently expand their existing cognitive structure.

Role Playing: Role playing does not necessarily have to be in a fantasized context. Learners

can be assigned with a completely different set of skills and environmental and situational characteristics to experience the instructional game. This game feature could enable learners to transfer problem-solving principles from role to role. It also familiarizes learners with various bodies of knowledge given different roles' diverse expertise.

Control: Learners prefer to control their own schema development processes. Self-pacing is one popular mechanism in playing games. Learners are able to monitor their progress in the process of achieving game goals with accumulated scores and number of mission accomplished.

Multimodal Presentation: This is an important game characteristic that affords effective manipulations of cognitive load during the learning process. Application and variation of multimodal presentation aims to reduce unnecessary usage of learners' cognitive capacity therefore facilitating schema development.

Task: Tasks represent a structure on which to construct schema for learners in instructional games. They are the building blocks of a game. Learners are required to accomplish sequenced or classed tasks in order to attain the final game goal. Each task encompasses all the aforementioned game characteristics in an operational form.

4C/ID-Model Design Components and Game Characteristics

This section focuses on the process of using 4C/ID-model design components to create the instructional game environment, which bears the aforementioned game characteristics that are capable of facilitating cognitive learning process. Each game characteristic is paired with a primary component (denoted as 3 for highest priority), a secondary (denoted as 2) component, and tertiary design components (denoted as 1) from 4C/ID-model based on each component's definition to attain corresponding game characteristics. The radar graph in each game characteristic visually depicts the design priority we suggest. The combi-

nation of all components (learning tasks, part-task, supportive information, and just in time) aims to optimize the design outcome.

Challenge

Primary Design Component

Learning task is the main design focus to create a challenging game-based learning environment. Tasks are designed with various difficulty levels of attainable task objectives. Task variability also allows designers to manipulate the challenge levels of the learning environment. (Figure 2)

Secondary Design Component

Supportive information needs to be carefully designed in order to create a challenging instructional game. The amount of supportive information available to learners in the game should be determined by learners' performance in prior tasks. Providing all supportive information to learners without performance analysis might reduce the level of challenge perceived by learners.

Tertiary Design Component

Part-task practice and JIT information are suggested to the tertiary design components.

Figure 2. Design emphasis for challenge

Game Design Guideline for Challenge Characteristic

When creating learning games, designers need to focus on using varying levels of the learning task as the primary focus for creating a challenging game. If game challenge is based on other non-task factors, players will not spend the resources engaging in the critical tasks to be learned. Games need to engage and provide experiences related to the key learning tasks. Challenge can be presented in the form of a score or winning, but the score or success determinant needs to be directly related to the learning task. When designing game challenge, supportive information and part-task practice need to be aligned with learning tasks, thereby strengthening the learning focus of the game. The degree that these design features are present determines the degree of challenge. For example, if supportive information is present then the degree of challenge is less than when the supportive information is absent.

Competition

Primary Design Component

Competition requires immediate feedback on learners' performance as well as information regarding model performance or peer performance. Therefore the primary design components for this game characteristic include supportive information, that provides cognitive feedback, and JIT information that provides corrective feedback. (Figure 3)

Secondary Design Component

Competition loses its attraction while every participant has similar skill level or resources as the result of practicing. Designers need to be cautious about not providing excessive part-task practices thus the competition feature can be fully demonstrated.

Tertiary Design Component

Learning tasks is the tertiary design component for this characteristic.

Game Design Guideline for Competition Characteristic

To facilitate game competition, players need to get immediate feedback on their performance. This feedback is presented primarily in the form of supportive information as well as JIT information. The learning tasks and the part-task practice are related to the game play, but not fundamental to enhancing the competition aspects of games. Competition is based on one player's interest compared to another player or a specified performance standard. The comparison information is either a score or performance feedback for both the player and the competition. This would be considered primarily supportive information. This information can be used as feedback to help the player regulate their level of game involvement.

Rules

Primary Design Component

Rule acquisition is best instilled via repetitive practice. In most cases game rules are translated from intended instructional information. Learners need to be able to automate the use of rules into recurrent aspects of problem-solving tasks. Both

Figure 3. Design emphasis for competition

Figure 4. Design emphasis for rules

supportive information and part-task practices are cable of achieving this game characteristic. (Figure 4)

Secondary Design Component

Designers need to be cautious about inserting too much information about intended rules with the JIT information component. Although it is important to support learners' performance with the recurrent aspect of task by providing learners with JIT information such as rules, the instructional game should aim to develop learners' automation without any support external to learners' cognitive structures.

Tertiary Design Component

Learning task is the tertiary design component for this characteristic.

Game Design Guideline for Rules Characteristic

One of the first tasks in game playing is learning the rules. Once the rules are acquired, players are able to formulate appropriate decision making to compete successfully. Facilitating players' development of games rules is important. Providing supportive information as well as part-task practice can facilitate rule acquisition. Supportive information is direct and can quickly support rule acquisition. Practice allows players to test out

their understanding and revise their rule models. Rules as part of JIT information does not give learners the information at the decision making and strategic point. Plus the use of the rules needs to become automatic for the learners. Optimal task performance occurs as part of the players having a fluent understanding of the game rules.

Goals

Primary Design Component

Goals should be identified in the learning task. The game goals should directly connect to the learning goals with explicit rationales. (Figure 5)

Secondary Design Component

Supportive information and JIT information need to provide cognitive as well as corrective feedback to ensure learners are staying on the right track to attain the game goal.

Tertiary Design Component

Part-task practice is the tertiary design component for this characteristic.

Game Design Guideline for Goals Characteristic

Of the various components of the 4C/ID model, learning tasks need to be aligned with the game

Figure 5. Design emphasis for goals

goals. If the game goals and the learning tasks are not parallel, then the game goals that drive the game play will be more deliberate thereby diminishing the learning tasks.

Fantasy, Changed Reality, and Role Playing

Primary Design Component

The design of learning task is the key component for this characteristic. Contextual information in each learning task enables learners to situate themselves into the specific game setting. (Figure 6)

Secondary Design Component

Designers need to make sure that supportive information can provide additional support for learners to be able to operate effectively in the fantasy world. Common senses or general knowledge might not be sufficient to accomplish given tasks in an unrealistic context.

Tertiary Design Component

Part-task practice and JIT information are the tertiary design components for this characteristic.

Figure 6. Design emphasis for fantasy, changed reality, and role-playing

Game Design Guideline for Fantasy, Changed Reality, and Role-Playing Characteristic

Learning task and to a lesser extent supportive information are important in the development of these game characteristics. The context of the learning tasks will support or weaken the intended setup for fantasy, reality, or role play. The critical element in making the set-up believable is that both the task and supportive information are aligned with the intended environmental setup.

Story and Representation

Primary Design Component

Designers should focus on the learning task for this characteristic. In addition to emphasize individual tasks' function to contain necessary elements in order to complete certain pieces of the story, this part of the design also needs to focus on the connectivity between tasks. Thus learners are able to assemble all pieces together and finish the story. (Figure 7)

Secondary Design Component

Similar to the design of fantasy or changed reality, designers should to provide sufficient background information for learners to see the whole story line as soon as possible. Supportive information

Figure 7. Design emphasis for story or representation

should be designed closely with the background story of learning task.

Tertiary Design Component

Part-task practice and JIT information are the tertiary components.

Game Design Guideline for Story and Representation Characteristic

Similar to fantasy, reality, or role play, the contextual setting for the learning task needs to be primarily considered in the creation of the story or game representation. Aligning the game design with the learning task will impact the quality of the overall game story and representation.

Engagement and Curiosity

Primary Design Component

The design focus should aim to maintain learners' interests in continuing participating in the game-playing process. From the viewpoint of cognitive learning, the learning environment needs to be relevant to learners' prior experience and be able to attract learners' attention in the initial stage of the learning process. Therefore the JIT information needs to be emphasized since it provides learners with support on prerequisite information, which must closely aligned with the learning task. (Figure 8)

Secondary Design Component

Given the complexity involved in creating an engaging instructional game, designers should focus on the learning task and supportive information to continuously guide learners to explore new ways of processing information as well as to stretch their existing cognitive structure.

Tertiary Design Component

Part-task practice is the tertiary design component for this characteristic.

Game Design Guideline for Engagement and Curiosity Characteristic

Engagement and curiosity can be support with JIT information. This type of information can provide players with assistance to decrease frustration levels as well as prompt players with hints about the specific game play. By providing JIT information, players are given information to string them along the game and facilitate their personal interest and curiosity.

Control

Primary Design Component

In order to perceive their full control in a game, learners want to have options in actions taken in a game. Players also need consistent and meaningful feedback from the system and other game participants to support decision-making to best help maintain control. The emphasis of design lies with supportive information for its cognitive feedback and JIT information for its corrective feedback. (Figure 9)

Figure 8. Design emphasis for engagement and curiosity

Figure 9. Design emphasis for control

Secondary Design Component

Learning task should be designed to offer learners multiple paths to solve one problem. Clear performance indicator during the game playing process also needs to be included (e.g., performance scores, enemies defeated, etc.).

Tertiary Design Component

Part-task practice is the tertiary design component for this characteristic.

Game Design Guideline for Control Characteristic

The learning task is predefined and offers little control for the player outside of the standard learning task steps. However the JIT information as well as the supportive information provide players with information about how they can better control the game play as well as giving them information about the game options thereby allowing them to control the decision-making tasks, thereby ultimately giving them control over the game. This is akin to the saying, “knowledge is power.”

Multimodal Presentation

This design principle can effectively reduce the overall cognitive load induced by the game-based learning environment. Designers need to be extremely cautious about not overloading learners’

cognitive load with abundance of multimedia stimuli. Rather, multimedia components should be utilized in a way to serve as the peripheral cognitive capacity for learners to process information. (Figure 10)

Game Design Guideline for Multimodal Presentation Characteristic

While multimodal refers to varying types of media, the 4C/ID-model automatically considers multimodal strategies: learning tasks, supportive information, JIT information, and part-task practice. These four components are collectively considered multimodal. Each one is unique, yet they all are focusing on different aspects of the game environment. In considering the components, this will allow the player game support from multiple directions.

Task

Primary Design Component

Similar to what 4C/ID-model suggested, tasks are the central piece of the design for most of the games. Game task is the embodiment of schema that learners must develop as the result of the learning process. The interconnection between game tasks is equally important as the content within each game task. Designers should focus on the learning task component for this characteris-

Figure 10. Design emphasis for multimodal presentation

tic. Additionally the supportive information and JIT information must be sufficient to provide the connection between all tasks, to develop learners' fluidity in applying intended skill sets to different contexts. (Figure 11)

Secondary Design Component

Part-task practice can be inserted between main game tasks to reinforce the automation of intended skills.

Game Design Guideline for Tasks Characteristic

This game characteristic focuses on the game task. As mentioned earlier, the learning task ideally needs to be aligned with the game task. In as much as these two are similar, the game design will enable players to simultaneously engage in learning during the game-play periods.

CONCLUSION

This chapter, based on cognitive load theory and the 4C/ID-model, proposes a systematic design framework for designing pedagogically sound instructional games. The ultimate goal is to initiate series of empirical inquiries on how designers can link game characteristics with intended learning outcome via systematic design processes.

Figure 11. Design emphasis for tasks

IMPLICATIONS

The adoption of 4C/ID-model not only presents viable opportunities for designing pedagogically sound games, but also reminds us the need for rigorous design research to continuously examine existing instructional design models for instructional game design and more importantly, to identify innovative design models and theories across disciplines. For example, Johnson (2001) proposed the “emergence perspective” to advocate a decentralized and multi-lateral system design approach based on his observations on ant colonies and human cities, which is considered an efficient design approach for video games (Irlbeck, Kays, Jones, & Sims, 2006). The feedback generated by the interactions between existing design model components, intended learning outcome, and preferred game characteristics should guide the overall design process, as opposed to following rigid and linear steps seen in conventional instructional design approach.

FUTURE TRENDS

In terms of systematic design process for developing instructional games, it is likely to see more streamlined process emerging from the field. We also anticipate more joint effort between computer science, learning technologies, and the game industry. The key is to connect theories of learning with design practices that are feasible by current industry standards for many reasons. First and foremost is to promote instructional games as efficient tools to enhance learning experience and to sustain improved performance. Second, designers want to be able to make design decisions with strong empirical support on the pedagogical effect of instructional games. Third, industry wants to be able to manage the design and development process with more efficiency and confidence.

On the research front of investigating instructional games' impact on learning and performance, we foresee research frameworks consist of all

aspects of learning (behavioral, cognitive, and attitudinal), blended methodologies (quantitative, qualitative, and physiological measurement), and human performance improvement. The outcome of such eclectic research undertaking will not only inform all stakeholders about the effect of instructional games, but also will provide concurrent evidence, from various disciplines, to further our understanding on human learning.

KEY TERMS AND DEFINITIONS

4C/ID-Model: 4C/ID-model is a non-linear and systematic processing model for designing complex learning environment based on cognitive load theory. The model consists of learning tasks, supportive information, part-task practices, and just-in-time information. The design focus of this model is on the integration and coordination of various levels of intended problem-solving skills. As a result, learners are able to transfer desired performance to various contexts with efficiency.

Cognitive Load: The amount of mental effort learners invest during the learning process. Which is also closely associated with learner's working memory capacity. The purpose of instructional design is to optimize the allocation of cognitive load to induce the deep learning process.

Extraneous Cognitive Load: This type of cognitive load only associates with the searching and organization of information, which should occupy the least amount of working memory. Instructional designers should utilize multimedia and other cognitive-oriented design to reduce the extraneous cognitive load.

Game: A game is a context in which individual or teamed players, bounded by rules, compete in attaining identified game objectives.

Germane Cognitive Load: This type of cognitive load is directly associated with the construction of schema. Instructional designers should aim

to increase the level of germane cognitive load, induced by the instruction, as much as possible.

Intrinsic Cognitive Load: This cognitive load is inherent with the difficulty of the subject matter (e.g., organic chemistry versus multiplication). The cognitive load level cannot be manipulated by instructional design.

Schema: A schema is a memory unit stored in learners' long-term memory. Schema consists of mental models for reasoning and cognitive strategies for problem-solving.

Chapter 7.8

Faculty Development in Instructional Technology in the Context of Learning Styles and Institutional Barriers

Robson Marinho
Andrews University, USA

ABSTRACT

This chapter describes the within-case analysis of ten faculty members who agreed to share their learning experience and struggles in learning instructional technology. The case focuses on the in-depth description of each participant stressing their unique personal approach and learning styles, describing the main steps experienced and resources utilized by the participants during the learning process. It also highlights one dominant learning characteristic of each participant, which is compared with the participant's result in the Index of Learning Styles Questionnaire of North Carolina State University, with potential implications for academic administrators in promoting the use of instructional technology by faculty members of diverse profiles. The case also discusses the

institutional barriers faced by faculty members while learning how to use instructional technology at a public university in the United States. Three institutional barriers were a major concern for the participants: Time, rewards, and cost. One hundred percent of the participants agreed that providing more time—along with financial and academic rewards—is critical to supporting the learning and implementation of instructional technology.

CASE BACKGROUND

Objectives

The purpose of this study was to collect and analyze information about the personal experiences of faculty members in learning to use instructional technology and to analyze how their learning experience was impacted by one professional

DOI: 10.4018/978-1-60960-503-2.ch708

development intervention. The main objectives of this study were:

1. Analyze the unique journey of individual faculty members in learning instructional technology and how their personal profiles and learning styles impacted their learning approach.
 2. Learn the story of faculty members describing their struggles, failures, achievements and successes in learning instructional technology.
 3. Discuss the major difficulties and institutional barriers that prevent faculty from learning and using instructional technology.
 4. Analyze which aspects of a technology workshop series the participants consider successful in promoting and facilitating learning in instructional technology.
 5. Address possible suggestions of faculty for policy-makers on ways to overcome institutional barriers and increase the positive impact of professional development programs in technology.
2. How do learning styles and personal experiences influence faculty learning experience?
 3. What are the major difficulties and institutional barriers that prevent faculty from learning and using instructional technology on a regular basis?
 4. How do professional development interventions impact faculty experiences in learning instructional

Theoretical Framework

Three major areas of literature are particularly useful in informing how the process of learning instructional technology is influenced by faculty personal styles in professional development programs: (1) Faculty attitudes towards change in technology, (2) learning styles models, and (3) Faculty Development Approaches. These areas are briefly addressed below.

Faculty Attitudes towards Change and Technology

Literature on faculty attitudes towards change and technology has direct implications for faculty development, because research suggests that the use of instructional technology by faculty members is intrinsically related to their attitudes and beliefs regarding the role of technology in education (Race, 2001; Mishra, Koehler & Zhao, 2007). The obvious implication for faculty development programs is that developmental interventions need to consider faculty attitudes and beliefs regarding instructional technology.

The adoption of instructional technology always involves a change process, and people will not always accept a change simply because others tell them of its practical advantages over an existing practice. In fact, the adoption process depends on a set of perceptions toward the change by the people involved in the desired change (Lee and Lawson, 2002), and this set of perceptions has been defined as the process by which people

Problem Statement

Many faculty members participate in professional development programs in instructional technology, but they may feel intimidated by the challenge of mastering the use of technological resources, and there is little information about the many factors influencing the way in which they learn about instructional technology. An in-depth look at how faculty approach this learning situation and the ways in which their learning can be successfully facilitated is an area that needs additional research.

Research Questions

The following research questions guided the study:

1. How do faculty cope with the fear and threat of failure in using instructional technology?

attach meaning to their experience (Eggan and Kauchak, 2004). In other words, without seeing real advantages to instructional technology, no one will actually change their teaching style to adopt technology in the classroom.

Like any other change process, the adoption of instructional technology faces different types of barriers and obstacles. Ertmer (1999) refers to two kinds of barriers: First-order barriers refer to extrinsic obstacles, which are factors external to the individual who are implementing the change, such as lack of equipment, time, training, or technical support; second-order barriers refer to intrinsic obstacles, which are related to the attitudes and beliefs of those involved in the change process, such as the challenge of traditional practices. According to her, “traditional approaches to change have focused on helping those involved in a change to overcome first-order barriers” (p. 151). However, as she says, the most effective approach to change is to focus on people’s belief systems, and not only on the extrinsic obstacles.

Analyzing the intrinsic factors of a change process in the adoption of instructional technology, Lee and Lawson (2002) developed what they call a Concerns Matrix addressing two major dimensions of change: The degree to which change is compatible with the values and beliefs of the target audience, and the levels of the institution affected by the change process. They found that some faculty members who were skeptical of technology were not persuaded to use computers even five years after being exposed to a faculty development intervention. They concluded that a concern analysis must be conducted before any change is introduced.

This discussion about the effects of personal beliefs on a change process is supported by Rogers’ (1995) Diffusion of Innovation Theory, according to which a technological innovation passes through four consecutive stages described as follows: (a) innovation, meaning the stage at which an idea is perceived as new, (b) diffusion or communication through channels within the social

system, (c) time for adoption of the innovation, and (d) integration within the social system, a set of interrelated units sharing a common goal and including potential adopters. Innovation diffusion research explains how and why users adopt a new information medium, such as the Internet.

Rogers’ theory also makes a distinction between different adopter categories, in which adopters are classified on the basis of their speed of adoption. Applying Rogers’ description to faculty members, the categories can be identified as (a) innovators, characterized as venturesome faculty; (b) early adopters, described as those having more years of education and higher social status; (c) early majority, the deliberate ones; (d) late majority, the skeptical faculty; and (e) laggards, who are the most traditional and change resistant faculty members (Clarke, 1999).

The basic characteristics of each group of adopters can be described as follows:

1. Innovators: The risk takers willing to take the initiative and time to try something new and different.
2. Early adopters: People who tend to be respected group leaders, the individuals essential to adoption by the whole group.
3. Early majority: People who are careful, safe, deliberate individuals who do not want to risk time or other resources.
4. Late majority: People suspicious of innovations and resistant to change. They are hard to move without significant influence.
5. Laggards: These are people who are consistent and sometimes inflexible in resisting change. They only change under some kind of pressure (Rogers, 1995; Pacific University, 2002).

Learning Styles

The importance of considering learning styles in professional development programs in instructional technology is supported by current research

that shows an increasing investment in innovative developmental interventions in instructional technology (Carliner & Shank, 2008; Garrison & Vaughan, 2008; Kidd and Song, 2007).

Research literature says that personal learning styles have an influence on the learning experience. Learning style is a generic term as an umbrella concept for recognizing individual learning differences. From different psychological and philosophical beliefs, a variety of authors have proposed different learning style models, and no one has a monopoly on the term or can claim to represent learning style in its entirety (Butler, 1987). In fact Dunn and Griggs (1998) explain that, despite differences in terminology, the models themselves overlap as they address different aspects of learning. Some researchers, for example, have focused on motivation and sociological traits, as well as on the structure of learning (Canfield and Lafferty, 1976; Dunn and Griggs, 1998; Gregorc, 1985; Hill, 1971; Ramirez and Castenada, 1974). Most of these researchers and Kolb (1984) have focused on the way learners perceive the world as a basis for developing their model, and all of them with the addition of Herrmann (1988) have addressed the way the human brain behaves and processes information. Listing all the learning styles models would be a very extensive task, therefore, this section briefly addresses a few models that focus on different learning dimensions and approaches.

Kolb's theory: Based primarily on Dewey (1938), Lewin (1951), and Piaget (1977), Kolb (1984) developed a model called experiential learning as a four-step process, starting with immediate *concrete experience* with people or the environment, and then thinking about this experience through *reflective observations* looking to the meaning of things, from which learners engage in *abstract conceptualization* by analyzing ideas to understand a situation. In the final step, learners apply this analysis in *active experimentation*, getting things done and acting in new and more

complex situations (Claxton and Murrell, 1987; Kolb 2000).

Gregorc's theory: The theory developed by Gregorc (1985; 1998) is similar to Kolb's dimensions, but identifies style in terms of the labels Concrete, Abstract, Sequential, and Random (Sarasin, 1998). Each combination of style describes a different type of learner and the way individuals relate to the world. In short, Gregorc proposes four types of mind styles: (1) concrete sequential, (2) concrete random, (3) abstract sequential, and (4) abstract random (Gregorc, 1998).

Felder-Silverman Learning Style Model: Synthesizing findings from Kolb (1984) and Gardner (1993), Felder and Silverman (1988) developed a learning style model at North Carolina State University, usually referred to as Index of Learning Styles Questionnaire developed (ILS). This model is based on four double dimensions: Sensing and intuitive, visual and verbal, active and reflective, sequential and global (Felder (1993).

Herrmann Brain Dominance Instrument (HBDI): This model of brain dominance combines Sperry's (1975) split-brain concept with MacLean's (1978) triune brain concept to explain the thinking process by the right and left-brain hemispheres, as well as cerebral and limbic sections. The theory is based on the assumption that, wherever there are two of anything in the body, one is naturally dominant over the other, such as being right or left handed. It classifies learners according to their preferences for thinking and mode of knowing as a metaphorical interpretation based on the functions of different hemispheres of the brain. Nasmith, Schultz, and Williams (2003) summarize the four quadrants as distinct groups of activities as follows:

1. Quadrant A (left cerebral): Logic, analysis, mathematical, problem solving.
2. Quadrant B (left limbic): Organizing, planning, control, sequential.
3. Quadrant C (right limbic): Interpersonal, emotional, musical, spiritual.

4. Quadrant D (right cerebral): Imaginative, holistic, intuitive, and conceptual.

The application of the instrument associated with the theory (HBDI) indicates the degree of preference or lack of preference for the type of thinking represented by each quadrant by generating a score for each quadrant (Herrmann, 1988). As Nasmith et al. (2003) explain, “a primary preference for a quadrant indicates the greatest preference for its characteristic process” (p. 4).

The Myers-Briggs Type Indicator (MBTI):

This instrument was designed to apply Carl Jung’s theory in counseling, education, and business (Myers, 1976; Claxton and Murrell, 1987). According to the Jung’s theory, the world can be perceived in two distinct ways, which are sensing and intuition. The theory also states that people use either thinking or feeling to come to conclusions and make judgments, employing two contrasting attitudes toward life, which is either a judging or a perceptive attitude, and using two contrasting preferences to deal with life: Extraversion and introversion. The main characteristics of each personality type can be described as follows:

1. Extraversion (E) versus Introversion (I): “This preference tells us how people ‘charge their batteries’” (Brightman, 1998, p. 1). *Extraverts* focus on the outer world of people and find energy in things and people, while *Introverts* find energy in the inner world of ideas, concepts, and abstractions. They are motivated internally, and their minds are sometimes so active that they are “closed” to the outside world (Personality Pathways, 2003).
2. Sensing (S) versus Intuition (N): Sensing people are detail oriented and focus on facts and practical solutions, while Intuitive people seek out patterns and relationships among the facts they have gathered (Brightman, 1998; Personality Pathways, 2003).

3. Thinking (T) versus Feeling (F): Thinking students value analysis, logic, honesty, and principle. They focus on tasks and on the work to be accomplished and are most convinced by rational arguments. Feeling learners are diplomatic and tactful and make decisions by focusing on human values and needs. They appear warm and friendly and tend to be good at persuasion and facilitating differences among group members. They avoid arguments and conflicts and value harmony by seeking consensus and popular opinion (Brightman, 1998; Personality Pathways, 2003).
4. Judging (J) versus Perceptive (P): Judging people are decisive and like to plan the details in advance before moving into action. They focus on completing the task, like to act quickly, and prefer working with deadlines and schedules. Perceptive people are curious, adaptable, and spontaneous, but may have difficulty making decisions. They start many tasks, want to know everything about each task, and often find it difficult to complete a task. They are naturally tolerant of time pressure and work best as the deadlines approaches. They usually question the need for many rules and feel comfortable in extending deadlines (Brightman, 1998; Personality Pathways, 2003).

Dunn and Dunn model: This model is based on the theory that each person “has biologically and developmentally imposed characteristics that respond either positively or negatively to a variety of environmental, emotional, sociological, physiological, cognitive and instructional variables” (Dunn and Griggs, 1998). Here is how Dunn (2000) summarizes the individual’s reaction to learning in different instructional settings:

1. Environmental preference: Learner’s reaction to sound, light, temperature, and class design.

2. Emotional preferences: Influenced by motivation, persistence, responsibility and structure.
3. Sociological preferences: Learning alone or in group, working with peers or with either a collegial or authoritative adult. Includes a variety of approaches as opposed to patterns and routines.
4. Physiological preferences: Related to perception such as auditory, visual, tactual, or kinesthetic inclination. This level also includes time-of-day energy levels, such as the preference for studying early in the morning or late in the night, and food intake (eating or not while studying), as well as mobility such as sitting still or moving around).
5. Psychological preferences: Related to global versus analytic processing, brain hemispheres, impulsive or reflective action.
4. Visual-Spatial Intelligence: Capacity to think in images and pictures, to visualize accurately and abstractly.
5. Bodily-Kinesthetic Intelligence: Ability to control one's body movements and to handle objects skillfully.
6. Interpersonal Intelligence: Capacity to detect and respond appropriately to the moods, motivations and desires of others.
7. Intrapersonal Intelligence: Capacity to be self-aware and in tune with inner feelings, values, beliefs and thinking processes.
8. Naturalist Intelligence: Ability to recognize and categorize plants, animals and other objects in nature.
9. Existential Intelligence: Sensitivity and capacity to tackle deep questions about human existence, such as the meaning of life, why do we die, and how did we get here.

Theory of multiple intelligences: Gardner (1993) took a more holistic approach in describing cognitive profiles by developing the theory of multiple intelligences. He performed interviews with hundreds of people and defined the first seven intelligences in 1983, adding the last two in 1999. According to Gardner, all human beings possess all nine intelligences in varying amounts, and each person has a different intellectual composition. Below are the nine intelligences proposed by Gardner (2000), as outlined by Disney Learning Partnership (n.d):

1. Verbal-Linguistic Intelligence: Well-developed verbal skills and sensitivity to the sounds, meanings and rhythms of words.
2. Mathematical-Logical Intelligence: Ability to think conceptually and abstractly, and capacity to discern logical or numerical patterns.
3. Musical Intelligence: Ability to produce and appreciate rhythm, pitch and timber.

Despite the popularity of the learning styles theories, it is important to mention that there is still a significant debate regarding the consistency of those theories. The strongest view against the existence of learning styles comes from Human Information Processing (HIP) theorists, who argue that learning style perspectives ignore the critical role that prior knowledge plays in a learning situation. Although agreeing with the importance of recognizing individual differences and providing students with personalized instruction, HIP theorists have the following disagreement with the learning styles theories: (a) confusion in the definition of the term "styles," (b) different learning style theories and instruments use different style categories to define learning style continuums, (c) weakness in reliability and validity of measurement instruments, and (d) identification of relevant characteristics in learners and instructional settings. According to those theorists, learners may react differently in different learning situations, and people have different ways of learning for particular tasks and for different contexts, so they recommend that teachers focus on the role that

encoding, attention, motivation, and metacognition factors play in all learning situations. (Curry, 1990; Denzine, n.d.).

Faculty Development Approaches

Interrelated to faculty development theories, another segment of literature relevant to this study provides a consistent theoretical basis for general approaches to faculty development programs and interventions. Davis and Davis (1998) developed a model for professional development based on learning theories. As they say, “a training strategy is a theory-based effort to maximize a particular kind of learning” (p. 98). Table 1 summarizes what they call “the seven training strategies.” The authors point out that each training strategy has its own strengths and weaknesses. Although it is tempting to select a training strategy that feels comfortable for the facilitator or is the preference of the participant, a trainer should make a rational choice of the strategy that best fits the desired learning outcomes.

These training strategies provide a framework for different faculty development interventions,

which are intended to address both faculty beliefs and skills development. Based on different theoretical models, several experts propose a variety of approaches to faculty development programs and activities, but exploring those models is beyond the scope of this study. As a general concept, however, it is important to understand that there is a distinction between professional development and training. As Chism (1998) explains:

One reason for resistance to teaching preparation is the belief that such preparation will consist of skills training, which seems trivial. Formal attention to teaching preparation involves cultivating habits of reflection and developing conceptualizations and frameworks for practice to organize and evaluate skills and experiential knowledge gained prior to employment or on the job (p. 8).

This distinction makes professional development programs much more complex than a simple training session. This is the assumption underlining the faculty development intervention described in this study.

Table 1. The seven training strategies – side-by-side comparison

Strategy	Best Use	Facilitator
1. Behavioral	Skill development	Setting objectives Performing task analysis Providing feedback
2. Cognitive	Presentations and explanations	Selecting and presenting information
3. Inquiry	Critical, creative and dialogical thinking	Establishing climate Asking questions
4. Mental Models	Problem solving Decision making	Providing information Guiding discussion
5. Group Dynamics	Collaboration and working in teams	Composing groups Developing and using instruments
6. Virtual Reality	Dependence on competence and confidence in a simulated environment	Role playing Setting the scene Designing scripts and scenarios
7. Holistic	Personal learning and self discovery through experience	Identifying and matching experiences to participants Providing useful mechanisms for reflection

Note. From: Davis & Davis, 1998, 404-405.

Methodology

As a multiple-case study, this research employed a qualitative approach, with an in-depth look at the many factors influencing the way faculty approach instructional technology and the ways in which their learning can be successfully facilitated.

Using a purposeful sample (Patton, 1990), ten participants were selected among faculty who attended a series of workshops and seminars in instructional technology, offered by the teaching center at a public university in the United States. In order to obtain a larger variety of data, the sampling strategy employed a maximum variation approach, including faculty from different disciplines and academic areas, and also from different levels of tenure and academic appointment.

Several different data collection methods were employed. The basic method consisted of in-depth face-to-face semi-structured interviews with the participants, supported by follow-up email interviews (Flick, 1998). The data included results of a learning style assessment obtained through participants' completion of the Index of Learning Styles Questionnaire developed at North Carolina State University. This inventory is easily accessible on the web and provides immediate automatic results without requiring any registration or fee payment. As far as validation, Zywno (2003) collected 557 valid questionnaires for a psychosomatic analysis and found that the ILS instrument has relatively high test-retest reliability in repeated measurements over time, and concluded that the ILS is an appropriate and statistically acceptable for characterizing learning preferences (Zywno, 2003).

In addition, samples of handouts, descriptions of content, and copies of the actual agenda of the workshops were gathered for document analysis. Finally, the data collection included non-participant observations of the environment during one offering of the technology workshop (Marshall & Rossman, 1995).

After transcribing the interviews, the data was stored and classified into different categories. This categorical aggregation was the first one of a four-step process (Creswell, 1998) in which a collection of statements was put together, along with ideas, and examples by the participants about their experience in learning and interacting with instructional technology. The participants' statements were classified to find relevant and meaningful points common to different cases.

The second step was developing direct interpretations of specific statements by the participants to draw meaning from the participants' experiences. The following step established patterns and looked for a correspondence between the different categories, in order to find common topics across cases. Finally, the written report put together several conclusions based on the major themes of the study.

SETTING THE STAGE

The Organization

This case study describes the experience of 10 highly motivated faculty members who participated in a technology workshop series at a large public university in the United States. Offering more than 200 degree programs, this university enrolls around 30,000 students with a high representation of international students from over 100 countries. The institution has a faculty development center that offers continuous support for faculty in developing instructional technology skills. All the faculty members participating in this case study agreed to share their learning experiences, motivation, and personal struggles in the journey to learn instructional technology. Each participant was assigned a pseudonym in order to maintain confidentiality.

Case Players

Carol has a Ph.D. in Theater, with a master's degree in Reading and English Language Studies. She has been teaching in higher education for 25 years and is still in love with her career choice.

Diana is an assistant medical physiologist and has practiced as a medical technologist. She graduated from the School of Medicine with a Ph.D. in Physiology and Biophysics and did her postdoctoral work in Pediatric Immunology and Oncology. Her background includes 25 years of teaching in the medical school.

Jennifer has a Bachelor's degree in Nursing and a doctorate in Nursing Science. She has specializations in Nursing Administration and Operating Room Nursing, and has taught nursing education for more than 35 years.

Ellen has a Ph.D. in Musicology and Music History, and began teaching at the college level in 1990. She is passionate about online teaching.

Karen worked in art museum administration for about ten years, and moved to an academic career after earning her Ph.D. in American Civilization. She has taught Art History for more than a decade.

Roy earned his Ph.D. in Urban Technological Environmental Planning and has worked in Social Work Policy and Technology. His career includes

over 22 years teaching and researching social work at three different universities.

Steve has a Master's degree in Physical Education and got his Ed.D. in Higher Education Administration, with a concentration in Human Performance (Physical Education). He has taught sports management courses over the last 30 years.

Nicole earned her Ph.D. in Anthropology and has been teaching this subject for over 12 years. Lately, she has been working in both teaching and faculty development.

Lisa has a background in Occupational Therapy and a master's degree in Applied Gerontology. She is finishing her doctorate in Education and has had a teaching career for more than eight years.

Bryan has a Ph.D. in Sociology and teaches courses in the sociology of religion, sociology of work, sociology of education and methodology. His research area is the scholarship of teaching and learning, but he also does some research on the intersection of religion and pop culture. He has taught Sociology for more than 13 years.

Table 2 shows the basic profile of each participant.

Table 2. Profile of participants

Pseudonym	Degree	Academic Discipline	Status	Teaching Experience
Carol	Ph.D.	Theater	Non Tenure	25 years
Diana	Ph.D.	Medical Physiology	Tenure	25 years
Jennifer	D.N.S.	Nursing Science	Tenure	30 years
Ellen	Ph.D.	Music History	Tenure	11 years
Karen	Ph.D.	Art History	Tenure	8 years
Roy	Ph.D.	Social Work	Tenure	19 years
Steve	Ed.D.	Physical Education	Tenure	29 years
Nicole	Ph.D.	Anthropology	Non Tenure	12 years
Lisa	M.A.	Applied Gerontology	Non Tenure	8 years
Bryan	Ph.D.	Sociology	Tenure	13 years

CASE DESCRIPTION

Introduction

With a clear sense of frustration, you may have had sometimes the same feeling expressed by a faculty member who said:

I find that the people who teach technology generally are good people, but I think they are really bored in teaching somebody like me . . . it is really painful for them to go at the speed that I catch things. They are repeating, but at the time they get to step four, I forgot what I did, and when they say, do it again, I may not remember anymore . . . Some of them are very patient, but I just sense in their spirit that they are kind of thinking that I am dumb, or that I am taking too much of their time.

Like this person admitted, many faculty members with high levels of expertise in different areas may feel intimidated when challenged to learn and use instructional technology. This multiple case study describes different learning stories emphasizing personal characteristics of the participants, their personal learning styles, and their struggles facing personal and institutional barriers.

Case 1: Carol, the Emotional Learner

The Journey to Technology

To sum up her experience with technology, Carol says: “Technology did not crush in on me.” All the schools she has worked at were Historically Black Colleges and Universities, which had no money. She recalls that her first experience with technology was when she received a National Endowment for the Humanities summer research grant on oral literature in Missouri in 1991. This is how she describes her emotions in her first encounter with technology:

There was a lady in the course who kept saying every day, “I got to go and check my email.” I had never heard of it. And she was so excited, and in every break we had, she would go and check her email. Then when I came here, I was working for a top administrator, who kept sending me messages by email, and I was not getting them because I didn’t want to. So he said, “You just have to learn this, because I am not going to send you messages in any other way! So, I learned enough to do email.”

But this was just the beginning for Carol. As she was still struggling to use email in an effective way, her boss sent her to a workshop off campus to learn enough to get his messages. And as the campus became more and more involved in the on-line revolution, Carol could not avoid it anymore.

Learning Styles Analysis

Carol is a very unique type of technology learner. Her emotional way of doing things became clear as she told her story. In fact, her scores in the learning styles inventory reflect her emotional approach to learning, as she scored very high as an intuitive learner (9 points on an 11-point scale) as opposed to being a sensor or concrete learner. She also scored high (9 points) as a global/random learner as opposed to sequential learner. Carol scores are shown on Table 3.

Both the intuitive and the global learning characteristics have more to do with emotions than with logical reasoning: in fact, intuitive learners are described in the literature as people

Table 3. ILS scores for Carol

Carol scores (11-point scale)			
Active	3		Reflective
Sensing		9	Intuitive
Visual	5		Verbal
Sequential		9	Global

who like creativity and dislike repetition (Felder, 1996; Kolb, 2000; Kolb, 2007). They also “don’t like ‘plug-and-chug’ courses that involve a lot of memorization and routine calculations” (Felder, 1996, p. 2), and usually prefer discovering possibilities and relationships, which describes how Carol described her learning experience with technology. The fact that Carol is also a global/random learner helps explain her struggles with technology, as Gregorc (1985) describes abstract-random learners as people who globally evaluate the learning experience atmosphere. They are attracted to nuances of mood and atmosphere, and tend to associate the medium with the message and relate the presenter’s personality with the content of the presentation. They have preference for unstructured information and multisensory activities with no rules or guidelines.

Discussing her experience with technology, Carol does not disguise the force of her negative feelings towards technology, as in this example:

Sometimes I was typing up a newsletter for the community organization I was working for, and I would spend hours and hours typing the newsletter and I would hit a button and it would all be gone, and I wanted to die because I didn’t save it. So it was an awful, awful, awful experience for me. I hated technology, and I hated anybody who used technology, and anybody who talked about it.

In spite of this negative feeling toward technology itself, Carol has a very positive attitude toward her technology instructors in the workshop setting: “What I liked the most was the attitude of the teachers. It was not in any way insulting. They never ever made me feel inadequate, which I knew I was.”

Asked to relate her learning style with the technology experience, Carol proposes a formula for an ideal learning situation:

For me it is hands-on. I think that for my learning style the critical thing is the teacher-student

ratio, and it almost will be like one-to-two or one-to-three. With any more than that, like 12 or 17 students, or whatever, instructors will be too busy with the other 12 and I am going to get lost.

A comparison of Carol’s experience in learning technology with her natural learning style seems to imply the Carol’s emotional nature has a direct impact on her learning process, thus explaining at least in part some of the difficulties that she has faced in her experience of learning technology. Her strong emotional reactions tend to make her more vulnerable to feelings of inadequacy for being slower than others, which results in anxiety and impatience with herself. In fact, she says she feels upset when she cannot perform as well as she would like, and she explains her disappointment: “If I press the wrong key I am upset because I didn’t get it right. So it is frustrating for the instructors and it is frustrating for me, because I want it, but I just cannot.” In other words, Carol’s emotions and variations of mood and sentiments affect her learning performance.

Case 2: Diana, the Risk-taker

Diana’s story is marked by a sequence of challenges and risks. Many episodes in her life stress how challenge and risk played an active role in her experience of learning instructional technology.

The Technology Challenge

Diana summarizes her story of learning instructional technology in a very short statement: “I am a risk taker, but I don’t approach suicidal.” She explains, for instance, that she did take some precautions to protect herself in the very first online class that she taught when she was still learning how to teach online courses. She decided to be part of a teaching team, with another instructor who was eager to learn and use technology, so, as she says, “we helped each other.”

But her journey to technology began many years before. Referring to her very first experiences with instructional technology, Diana still remembers spending an entire week to prepare for a one-hour lecture using slides, tapes and handouts. Years later, Diana challenged herself to attend an intensive program in faculty development including interactive video and computer-based teaching. At the beginning, she went just to try it out, but in the next year she went with the express purpose of teaching an interactive video course, which she did, starting with a few students in the freshman level. Now she talks about the success of this course with a bit of unabashed pride: “This last fall when I taught the course, I had 229 students on seven sites of classrooms. So that tells you how little by little I expanded the course. I still use the statewide system.”

Learning Styles Analysis

Diana admits that learning technology took a lot of hard work and persistence. Usually someone would show her how to do something and then she would go and do it, and when she got stuck, she would call a consultant to help her. Diana explains that her achievements with technology are due mostly to her willingness to take risks:

I was able to do that only because I used to try difficult things, even having minimal computer and technical knowledge. I think a lot of people get into it because they really love to work with computers, and computers are not a challenge for them. I have said more than once, if I can learn this technology, anybody else can.

Diana’s scores on the Index of learning styles inventory show a high level of an intuitive/abstract learner (9 points on an 11-point scale) as opposed to being a sensor or concrete learner. She also scored high (9 points) as a global/random learner as opposed to sequential learners. She does admit that her favorite learning style is that of the

Table 4. ILS scores for Diana

Diana scores (11-point scale)			
Active		3	Reflective
Sensing		9	Intuitive
Visual		5	Verbal
Sequential		9	Global

abstract learner. Table 4 shows the Diana scores on the ILS inventory.

Diana does not see the learning styles theory as playing a direct role in her experience of learning technology. In fact her major characteristic as “risk-taker” does not fit well in any of the main theories of learning styles discussed in this study. On the contrary, Kolb (1993) refers to risk-takers as an example of learners who are in the concrete-active quadrant of his diagram, which is not the case with Diana. This discrepancy in itself seems to imply that, in some cases, other characteristics may be more relevant to the experience of learning technology than those assessed through learning styles inventories. Although this particular case does not necessarily contradict the learning styles theory, it does not support it either. As a result, it seems more appropriate to look at Diana’s experience of learning technology as requiring a major characteristic or attitude of her personality, which is not necessarily her personal learning style in other areas. In other words, while the experience of learning technology sometimes may be explained by someone’s learning style, in some other cases it may be better explained by another major personality characteristic.

Case 3: Jennifer, the Visionary Learner

Envisioning Technology

A visionary of instructional technology, Jennifer started using glass slides 30 years ago, and has had all her lectures on overheads for more than 10

years. Although there was no technology department as she began, she took as much advantage as possible of the medical education resources group at her institution, which then was the department responsible for providing instructional resources for faculty members. Back in the 70s, Jennifer envisioned teaching some components of nursing skills in a video format, and started developing videotapes to be presented in the classroom. With little support, it was very difficult at the beginning, but in 1980, thanks to a research grant, she developed a series of teaching modules using video for classroom presentations.

The process of production, image-taking, editing, and selection of “actors and actresses” for her instructional “movies” was something totally unconventional and may resemble the early ages of the Hollywood industry. As unusual as it may seem, Jennifer was at the same time the producer, director, cameraperson, editor, and distributor of the movies. In addition, the site for recording her pictures was something much more “real” than any scene produced by Hollywood. This is how she describes the adventure of producing those videotapes:

We actually videotaped live surgery in the Emergency Room, and I did most of the editing in a very primitive way. We used to go at midnight to the Emergency Room (ER). We had one student as a cameraman on the ladder to shoot inside, and I also had a camera as I was standing down to shoot when the patient was coming. We didn't put over any sound track, so we had the actual sound of the patient and nurses' activities, and we really saw a lot of real blood!

Even using these primitive methods, Jennifer was always very careful with ethical concerns—asking permission before releasing a film. It was not easy, but she did respect the patient's privacy. She says, “We didn't really release it until after the patient was treated, and we would contact the family for release only for teaching purposes.”

The times have changed and Jennifer no longer produces instructional materials in the same way. One of the reasons is because the grant elapsed. Another major reason is that the curriculum has changed, and the school does not have the Emergency Nursing module anymore. She feels that she does not need those materials as much as she did in the past. She actually gave the tapes to a hospital, and they are using them for teaching purposes as well.

Today, Jennifer does not use the old movies, overheads, or 35 mm pictures anymore. She says that now everything is in the PowerPoint format. She is now equipped with a digital camera, which she bought with grant funds, and takes advantage of digital pictures for her presentations. And she is always looking for new advancements in instructional technology.

Learning Style Analysis

Jennifer was a visionary of technology more than 30 years ago, a time when most faculty and institutions had no concern at all with instructional technology. It seems that a visionary personality goes along with a visual style in Jennifer's case. Even at a moderate level, her higher scores were as a visual learner (5 out of 11) and also as a sequential learner (5 out of 11). Table 5 shows how Jennifer scored on the ILS inventory.

The sequential aspect does not appear to be much applicable in Jennifer's story, but commenting on her favorite learning style in technology, Jennifer refers to the multiple intelligences theory in the following words:

Table 5. ILS scores for Jennifer

Jennifer scores (11-point scale)			
Active		1	Reflective
Sensing	1		Intuitive
Visual	5		Verbal
Sequential	5		Global

The visual style appears to be most applicable as I reflect on my experiences and the learning path I took related to technology. I think the visual-spatial intelligence is my strongest intelligence related to instructional technology, especially in the development of course materials.

Jennifer's comments support the theoretical description of Gardner (2000), according to whom such learners develop the capacity to think in images and pictures, to visualize accurately and abstractly. Her comments also support Felder and Silverman (1988), as they state that visual learners get different information from visual images (pictures, diagrams, graphs, schematics, demonstrations) than from verbal material, which was very much the case in Jennifer's experience producing videotapes and pictures for her class presentations.

Case 4: Ellen, the Hard-working Learner

From the very beginning of her academic career, Ellen had to face a lot of hard work, as she began teaching a class with about 70 students, and had only one week for preparation after she knew she would teach that class. This is how she recalls the beginning of her teaching career:

I was a little bit intimidated, but I also had an extensive performance background, so I called on some of that performance background to help me at least get through the first two days, until the students realized that I was the teacher!

Hard Work in Technology

Before starting a new teaching assignment at another university, Ellen had a part-time job where she was asked to help maintain the company's website. She explains that she had no knowledge of HTML code at all, so she had three classes that lasted eight hours each, which was the full extent

of her knowledge of computers, other than using word processors and everyday software. At the university, her new boss found out that she had the 24-hour HTML training from the previous job, and he challenged her to be in charge of the Internet distance-based classroom for Music Appreciation. Not very much aware of the enormity and urgency of the task, Ellen agreed to teach the class, only to realize later that she was facing a huge problem. This is how she narrates the conversation with her boss:

The way this class started was somewhat humorous. The head of the School of Music came to me and said, "We think you can have an online Music Appreciation class." Then I said, all right. It was the end of June and beginning of July, and I was thinking that I would have the summer and at least a year to do it, but he said: "Oh no, we have offered it for starting this August, so you have until August to have it up and running. So I had about a month and a half to prepare.

Ellen had to work very hard to accomplish the task. She describes herself as typically a traditional in-front-of-the-classroom type of lecturer at that point in time, and the idea that she would not even see the students scared her, and she was not sure of what really she was going to do. So, she learned to use the course management system on the web, and had to handle all of this new technology plus teach four other classes at the same time. She says that the staff in the teaching center was very instrumental in supporting and helping her not to panic when something went wrong.

Recalling her experience, Ellen summarizes the hard work she had to face to learn and make progress in technology with a sense of pride, as follows:

I started with minimal knowledge, no confidence at all, and a feeling that the computer was a tool of terror. Now I realize it is simply a tool like a

pencil or a pen, the programs can or cannot work, depends on what I input.

Learning Styles Analysis

Ellen's scores on the learning styles test reflect her systematic way of doing things. She scored 9 out of 11 as a sequential learner, and 7 out of 11 as a sensing or concrete learner. Table 6 displays Ellen scores on the ILS inventory.

According to Gregorc (1985) this combination makes concrete-sequential learners prefer direct and hands-on experience. They like concrete and touchable tasks and step-by-step directions to follow. Felder (1993) refers to sensing learners as being very practical persons who don't mind detailed work and prefer to solve problems using well-established procedures. Supporting the same idea, Myers (1976) and Brightman (1998) describe sensing people as detail-oriented learners who focus on facts and practical solutions and prefer specific and orderly instructions.

Ellen's reflections about her personal style match the results of the learning styles inventory. This is how she describes herself:

I tend to learn more as a concrete, active, and reflective learner. I combine all these learning styles in my own approach to education, particularly instructional technology. I have used a hands-on approach with looking at a variety of possibilities and attempt to solve problems on my own.

This combination of learning styles supported by Ellen's self-analysis may explain her major

Table 6. ILS scores for Ellen

Ellen scores (11-point scale)			
Active		3	Reflective
Sensing	7		Intuitive
Visual		1	Verbal
Sequential	9		Global

characteristic of "hard work" when learning technology. As she says, she didn't mind staying long hours in the teaching center to learn how to set up an online class with just a month and a half of preparation. She had the task with a deadline, and she worked hard through all the steps to accomplish the task. And she did succeed in completing the work, which is very typical of a concrete-sequential learner.

Case 5: Karen, the Dependent Learner

As it seems natural and usual for someone in the areas of history and museums, Karen has a very conservative teaching background. The irony of this area though, is that history and technology are mixed together as part of the teaching style of Art History, although in a conservative way. This is how Karen explains the marriage between technology and Art History:

I just don't know how otherwise I would teach Art History without a visual image. It is just the standard in the discipline, so everybody does that, and I learned Art History with slides.

From Conventional to Digital Imagery

Willing to enter the digital era, Karen went to a technology workshop on PowerPoint in order to learn the basics. She says she can see that the future is going to be digital, so she decided to learn at any cost. But it was not easy. Although the instructors in the workshop did a great job trying to make it user-friendly, she felt overwhelmed as it just seemed like such a huge task for her. But Karen did not give up and found her own way to learn by hiring somebody else on whom she could depend while learning. She says: "I am not sure I would have gone any farther without having a teaching assistant who is pretty knowledgeable." Taking advantage of this new alternative, Karen

has regular appointments with her teaching assistant once a week to learn how to do PowerPoint.

Besides PowerPoint, Karen is also exploring the resources of the web and is now regularly using the course management system on the web, which she had never used before. At first she was simply posting pictures online. Now she has posted the syllabus, the study terms, and also study guides for tests. But again, she counts on her teaching assistant to scan the slides and post them on the web, so students can study for tests.

Learning Styles Analysis

Describing her personal approach to learning technology, Karen sees herself as dependent on someone else's help and support all the time. This major characteristic as a dependent learner makes all the difference for Karen. She says:

My feeling about the whole technology is that having one person sitting down just with me, so that whatever particular problem or questions I have, that person can be right there at my elbow to help me immediately.

Based on the learning styles inventory, Karen has a well balanced combination of learning styles, as she did not score high in any of the styles. In fact, she scored only 3 points out of 11 in three different styles: Active, sensing/concrete, and sequential, which is not enough to characterize one dominant style of learning. Table 7 shows Karen scores on the ILS inventory.

Table 7. ILS scores for Karen

Karen scores (11-point scale)			
Active		3	Reflective
Sensing		3	Intuitive
Visual		1	Verbal
Sequential	3		Global

According to Kolb (1993) and his theory, the concrete-active combination may explain her major characteristic as dependent on somebody else for learning technology, as this type of learner tends to rely on other people's analysis rather than on their own, and enjoy applying learning in real life situations. Also, they are primarily the "hands-on" type of learner (Algonquin, 1996). Karen's assessment of her own style of learning technology seems to agree with this explanation:

I learn the computer best by the hands-on use of it, even though this is not a kind of learning that comes easily to me. Besides, I learn instructional technology quite well if I have someone by my side who is articulate and knows the programs, who is willing to verbally walk me through it, and assist if I get stuck.

In other words, the inventory did not show a dominant learning style for Karen, therefore the connection between her personal characteristic and learning style offers little evidence to support the theory. Based on her own reflection, however, it seems that she has explored her personal learning characteristic as a dependent learner to learn what she needs in instructional technology.

Case 6: Roy, the Pragmatic Learner

Technology Expertise

Roy has had an easy time with technology since he has been a user. Even when using different technology applications, he didn't have problems, as he states: "I didn't have any difficult time actually. I am probably very technologically-minded, so I really didn't have major problems to do what I needed."

"Technologically-minded" is an apt self-description of Roy's experience using technology, since he started using web pages very extensively in 1994 and wrote a book on how to use the web

in practical social work. He also wrote a tool-book and designed a series of exercises on developing websites.

Learning instructional applications of technology was not hard for Roy either, as he has been basically self-taught. In summarizing his journey, Roy describes his attachment to technology as a lifelong experience in the following terms:

I have been interested forever. Actually I have been interested for fun. It was interesting and cutting edge, so I enjoyed it very much. There is the recreational dimension to it. Part of that too is that, in terms of Social Work, it is very easy to get behind the cutting edge, because Social Work is very reluctant to use technology.

Learning Styles Analysis

On the Learning Styles test, Roy had his higher scores both as a visual and as an intuitive/abstract learner (7 out of 11), and also scored 5 as an active learner. Table 8 presents the scores of Roy on the ILS inventory.

Roy does agree with the visual aspect of his style, and says that he has “the ability to grasp and understand very complex systems easily and visualize them in an effective way.” In addition, Kolb’s theory describes the abstract-active learners as people who like solving problems and finding practical solutions and uses for learning (Algonquin, 1996; Kolb, 2000; Kolb, 2007), which matches the pragmatic aspect of Roy’s personality. One difference, however, is that Roy thinks of himself as a concrete learner instead of the

intuitive one shown in the test result, but he admits that his combination of styles has some differences from the pattern stated by some theorists. This is how he analyzes his personal style:

I tend to be a concrete-active and reflective learner. The difference is that I usually take the hands-on approach when learning instructional technology and am prone to trust my own analysis rather than someone else’s.

In summary, although Roy’s combination of styles somewhat differs from the standard of the theories, which makes it difficult to establish a relationship between his personal characteristics and learning style, his major characteristic of being pragmatic and utilitarian in part supports the description of Kolb’s theory as addressed above (Algonquin, 1996).

Case 7: Steve, the Social Learner.

The Social Adventure of Learning Technology

Steve got involved in instructional technology early on, when he chaired a symposium on teaching excellence back in the 70s and 80s, and technology was one of the teaching strategies discussed in the symposium. Inspired by the idea of technology as a teaching strategy, Steve wrote a grant and got enough money to buy technology equipment for the Physical Education Performance Lab. Such technology would allow instructors to put markers on people and videotape them, so the software would track the markers and do all the compilation of the movements. This is how Steve describes his excitement with the new equipment:

When we got the equipment, and I could take my class and show them a device that would draw a picture to show the movement, store the data, measure the strength, resistance, and speed of

Table 8. ILS scores for Roy

Roy scores (11-point scale)			
Active	5		Reflective
Sensing		7	Intuitive
Visual	7		Verbal
Sequential		1	Global

movement, this suggested to me that there is a lot more about technology that we can use.

Steve always found encouragement in other people and their experiences. For instance, he refers to a book on successful stories of faculty members using technology, where people discuss methods and programs they are using in their classes. Steve also recalls that he had good mentorship from a very trusted colleague who was a role model for him and helped him understand more about technology in the classroom. As he says, “I am not as technologically savvy as some, so I like to hang around with people who are.”

Learning Style Analysis

On the learning styles inventory, Steve scored the maximum as an active learner (11 out of 11), and very high as a visual learner (9 out of 11). Table 9 displays the scores of Steve on the ILS inventory.

The visual aspect does not appear much when analyzing his style of learning technology, but the active component sounds like the perfect description of his style. According to Kolb’s theory, a high score in the active category indicates individuals who have an orientation to experimentation and who learn best when they can engage in such things as projects, group discussions, and peer feedback. Usually they tend to be extroverts. They are also described as “hands-on” learners who tend to rely on other people’s analysis rather than on their own and enjoy applying learning in real life situations (Algonquin, 1996;

Claxton and Murrell, 1987; Kolb, 2007). Steve says he has no doubt that this is his style:

Clearly this is how I learn. From an IT standpoint, I’ve spent too little time reading the manual and probably too much time with trial and error. I’ve enjoyed all that I’ve learned from my IT colleagues because I could let them do the analysis and then I could do the application.

In addition, Felder (1993) states that active learners tend to learn while doing something active, like trying things out, sharing ideas and working in groups, which may explain Steve’s major characteristic as a social learner. In fact, Steve agrees that his interpersonal intelligence plays a major role in his learning experience: “This is also something I’m good at. The IT application is that, when I’m really stuck on a problem, I can easily tap into the available human resources because I understand their motivations and desires.”

His active learning style makes Steve interact with many people and learn from his colleagues, which determines his major characteristic as a social learner.

Case 8: Nicole, the Skeptical Learner

Slow Involvement with Technology

Nicole started using technology in the classroom when she was teaching as a graduate student. She showed videos and used the overhead projector.

She recalls that one of her classrooms once had a multimedia tower with a VCR, a DVD, a computer, a cassette player, a CD player, and internet access. By having that in the classroom, she could easily do anything by just hitting a button and playing a CD, a DVD, or showing a video on the screen, and then turning it off. But, what really made a difference for her was that she could still use all her transparencies accumulated over the years, but instead of using the overhead projector, she used the document reader. Actually,

Table 9. ILS scores for Steve

Steve scores (11-point scale)			
Active	11		Reflective
Sensing	1		Intuitive
Visual	9		Verbal
Sequential	5		Global

she could bring in a book and just put the book on the document reader, or she could show a graph, a picture, or even an artifact.”

Most of the times, however, Nicole would prefer using real objects to illustrate her classes, rather than using technology devices. Usually she would try technology when artifacts were not available.

Nicole recognizes that her weak relationship with technology has been affected by her skepticism towards it. As she admits, she is not quite convinced about online education and of all its benefits. In addition, she says she is not sure if her students will have the equipment that will make it look great and work well, or if they will hate it like she did as a student, because students don’t have the access to the same level of technology as the faculty members do on campus. So she confesses being still a little bit hesitant and willing to let other people forge the pathway, and “when it becomes much smoother,” she says, “then I will go.”

In summary, Nicole can see the benefits and the potential, but technology has not attached itself to her in a way that she would go out and seek to learn and use it all the time.

Learning Styles Analysis

Nicole describes her experience of learning technology as a trial-and-error process, like setting up the computer and playing around. Except for one technology workshop, she had no other classes and no consultation at all. This is how she evaluates her learning process: “It was me sitting there by myself, trying something, and trying again, and when it didn’t work I would get frustrated and say, “What the hell is that?” So it was trial and error, very much. No textbooks, no how-to books, no *PowerPoint for Dummies*.”

Nicole’s selfanalysis totally matches the results of her learning styles test, as she scored higher both as an active and as a visual learner (7 out of

Table 10. ILS scores for Nicole

Nicole scores (11-point scale)			
Active	7		Reflective
Sensing		5	Intuitive
Visual	7		Verbal
Sequential		5	Global

11 in both styles). Table 10 shows the scores of Nicole on the ILS inventory.

Kolb (1993) states that active learners rely heavily on experimentation, and are primarily “hands-on” people who tend to rely on the ability to get things done, and usually use trial and error to solve problems (Algonquin, 1996; Claxton and Murrell, 1987), very much like Nicole described above. On the other hand, Felder (1993) refers to visual learners as people who get more information from visual images than from verbal material, while Gardner (1993) describes the visual-spatial intelligence as the capacity to think in images and pictures, and the ability to visualize accurately and abstractly. Referring to her experience in learning technology, that is precisely how Nicole describes the visual side of her learning style:

I am thinking that my experience with technology tends to be not so much text-based. I have to see it, I have to feel it, I have to feel what the key strokes are, and visualize what I have to do, where I have to click, where the button was, and in which side of the screen the menu was.

In short, while she is not very excited about technology, Nicole has a learning style that works best by visualizing things and doing something through a long trial and error process.

Case 9: Lisa, the “Watching” Learner

Enjoying Technology

Usually suspicious of technology, Lisa tended to always be afraid that things that she fears will not work. Therefore, when doing something on the laptop, for example, she would bring the laptop to project on the screen, but she would also make overheads too, just in case the projection would not work. She recalls that her first experiences with technology had to do with using an overhead projector and trying to figure it out how to turn it on and off.

Lisa describes her experience with technology as “exciting.” The more she found out about the variety of technology applications, the more she wanted to implement those different things in the classroom. As she says, “When I was able to take that technology and get the students excited, that made sense to me. I was dealing with this MTV generation and was able to make connections with them. That was when I got excited and when the big connection was for me.”

Lisa learned the very basics from her fellow faculty members. Usually she had someone in the department set up a manual that would explain step by step how to use a specific technology application. She also had other training opportunities such as classes or technology workshops taken through the teaching center. Other than that, she just experimented on her own and played around with different media.

Learning Style Analysis

Describing her learning process as a journey full of excitement and frustrations, Lisa stresses her preferred learning characteristic:

Watching other people use the technology was my favorite way of learning, and then seeing my instructors in the graduate school use the technology made me excited about it. Usually I had an

instructor who would demonstrate it first, but until I actually tried it on my own, at times frustrating, I would not feel safe using it.

The preference of Lisa to learn technology by watching other people may be explained by her results in the learning styles inventory, as her dominant learning preference is the visual style. In fact she scored very high in only this category (9 points out of 11), showing a low and balanced combination of all other categories. Table 11 presents Lisa scores on the ILS inventory.

Taking Gardner’s (1993) theory of visual-spatial intelligence as the capacity to think in images and pictures, and the ability to visualize accurately and abstractly, plus Felder’s (1993) concept that visual learners get more information from visual images, we would have a framework to understand Lisa’s learning preference. Commenting on her experience with technology, Lisa says that more than simply watching other people, she likes to visualize ideas:

The visual style relates to my learning experiences in IT in that I was able to picture and understand the overall process schemes and ideas, play with them mentally and apply them to the task. I like visualizing the background technical stuff as it helps me understand how the program works, and then manipulate it to meet my needs.

In addition, she says her visual style works best when assisted by continuous technical support, to deal with trouble and difficulties.

Table 11. ILS scores for Lisa

Lisa scores (11-point scale)			
Active		1	Reflective
Sensing		5	Intuitive
Visual	9		Verbal
Sequential		5	Global

Case 10: Bryan, the Self-Taught Learner

Teaching Himself

During his 13-year teaching career, Bryan had used overheads and video occasionally, but most of his teaching was the traditional “chalk on the chalkboard.” It was the use of a course management system on the web that really got him started with technology.

Bryan came up with the brilliant idea of putting partial notes online to be completed by students. He found that students responded very favorably to it, and they really appreciated having those online notes. So he got pretty positive feedback from students, both on the midterm and on the final course evaluation.

After one semester with this new experience, Bryan realized that he still had to write on the chalkboard a whole lot to help students get everything plugged in there. So in the next semester, Bryan came up with his brilliant solution number 2: He decided to convert his lectures into PowerPoint presentations. But not everything was in PowerPoint. Here is how Bryan describes the solution he found: “Sometimes I put questions and force them as a class to offer some examples.”

Gradually, Bryan kept adding new features every semester, such as putting up practice exams on the web, as well as students’ own notes on the web. As he explains, “students email their notes to me and I put it on the web. When the exam time goes around, every student should have their own notes from the discussion, but they also have their classmate’s notes.”

To make sure his methodology is effective, Bryan surveyed all his students at the end of the semester and found that 95% of the students strongly or greatly appreciated having the lecture notes available.

Learning Styles Analysis

It was hard to classify Bryan’s learning style, especially because the result of his Learning Styles test was a well-balanced combination of styles, with only a slight predominance of the intuitive/abstract style (5 out of 11, as compared to 3 points for the active and global/random categories). Table 12 presents Bryan scores on the ILS inventory.

Based on Bryan’s learning experience, however, it does make sense to apply the intuitive style to him. Kolb (1984) describes intuitive and abstract learners as concise and logical people, for whom abstract ideas and concepts are more important than people issues. They like to assimilate diverse data into an integrated whole, and they focus not so much on the practical application of ideas but on the soundness of ideas, and a good logical explanation is more important than practicality (Claxton and Murrell, 1987; Kolb, 2007). According to Myers (1976), intuitive people seek out patterns and relationships among the facts they have gathered. They trust their intuition and look for the big picture. They feel comfortable with ambiguous and imprecise data and with guessing their meaning (Brightman, 1998; Personality Pathways, 2003).

The experience of Bryan in surveying the students to gather facts and data, then his successive application of different teaching ideas, all reflect his concern with logical ideas and sound solutions for his teaching problems. In fact he sees himself related to this category, according to his self-analysis:

Table 12. ILS scores for Bryan

Bryan scores (11-point scale)			
Active	3		Reflective
Sensing		5	Intuitive
Visual	1		Verbal
Sequential		3	Global

I'm probably closest to the abstract-reflective learner. I don't know how this learning style impacted my use of learning technology. I had to stretch myself a bit to figure out how to use course management on the web, and I tried to think conceptually about how it might be used in my courses without creating too much work for myself.

Bryan also describes his learning process as being mostly a case of self-teaching with trial and error. This may relate to both the active and the random aspects of his learning style, although in low scale. According to Kolb (2000), active learners like experimentation, and Gregorc (1985) describes random learners as having an experimental trial and error attitude, as they like to find their own way in intuitive leaps and avoid step-by-step procedures. This description is close to the way Bryan analyzes his experience: "I taught myself to use PowerPoint and course management on the web. I had attended a couple of demonstrations of PowerPoint, but that was about it. It was a slow learning process of trial and error."

According to his comments, Bryan is always trying to find his own way of improving teaching and learning by testing different ideas and logical reasoning, which is typical of an intuitive learner, who tends to trust his intuition by teaching himself.

Faculty Struggles and Institutional Barriers

Most participants in this case felt that learning instructional technology has two opposite dimensions: the sense of accomplishment, and the sense of struggle and fear of failure. In fact, technology itself poses a lot of challenges for faculty who are not familiar with the technical details of computers and software. However, even worse than facing their own limitations is the frustration of missing the necessary support from the very institution they are willing to serve. Focusing on their personal learning experience with technology, participants

in this case describe their major struggles and difficulties with institutional barriers such as system failure, lack of technical structure, and lack of academic and administrative support.

Equipment and System Failure

Most participants pointed to equipment and system failure as their main source of trouble and fear when using instructional technology. Seven out of ten participants have had negative experiences and feel that failure seems to be usual when dealing with technology. Nicole says:

It breaks down, it fails. And then, what do we do? When we go to a committee and have to use a PowerPoint, it is always wise to bring transparencies as a backup. Or if we have transparencies, bring handouts as a backup. Any kind of technology and machinery is going to break down.

According to Nicole, even a small failure of the technology is enough to make people hate it. In her opinion, everybody knows technology will, at some point, break down and fail. As a result, technology can very easily get a bad reputation, and she thinks it is very hard to overcome that reputation once it is there.

Karen has the same struggle in her classes and feels like failure with equipment is pretty normal. This is how she describes her troubles when using slides projectors in her classes of Art History:

I am always afraid of technology. Even with the slide projector, like if the bulb burns out in the middle of a test, then we have to go back and change it, but we can't because it is too hot. Or when the slides get stuck in the projector, or things like that.

It took time for Karen to overcome the fear of failure, since she was always scared with the risk of failure. However, one positive thing about Karen's experience is that the equipment failure

does not decrease her willingness to use it. As she says, she never thinks of giving up.

Lisa feels frustrated when she has problems getting an image to show up on the screen, and setting up the hardware. And she remembers one of the most embarrassing situations in her technology adventure:

I had a guest speaker who came into my classroom, and I felt responsible because the equipment didn't work. Then I said to myself, let me go back to overheads and something like that.

Because she was afraid that things would not work, she always had an alternative, like bringing the laptop and also the overhead projector, in case something did not work.

The experience of Diana is a little different. In fact, teaching with technology does not bother her at all. She says that she likes to teach and she does it well. Although technology is challenging, she knows she has help available in the teaching center. One problem, though, does bother her. She says

The huge problem of failure, the things that terrify me more than even the technology, is having students not be able to access the medical library because the password does not work. They are registered for the course, but sometimes their password is not activated at a distance. I have been dealing with the registrar and the admissions office, and those are the tough parts, those are the things that keep me awake at night.

Those are the most difficult aspects of online education, from Diana's perspective. She thinks this is the real issue faculty have to be worried about. The technical support is no big deal, she says, because there is help available in the support center, and students are prepared to deal with that.

Bryan has had similar disappointments. He says that one thing that is really frustrating is when he goes to the classroom and the system is not working. This is his frustration: "When I try

to login and I cannot access the server on campus. It really annoys me."

Another frustration that Bryan mentions is that sometimes things are out of control. There have been semesters when the demands on the course management on the web overwhelmed the system, so students could not get on the system to print out lecture notes, and they were coming to class aggravated, and Bryan was annoyed as well. Bryan feels that when technology is not reliable and consistent, when it does not work well, it tends to make everybody bothered.

Roy stresses the fact that technology is never one hundred percent reliable, because something always goes wrong. And like Nicole and Lisa, he usually prevents himself from being stopped by those failures, as he says: "I always have a plan B. When I get students taking quizzes online, I always know that a small percentage of them will be shut out or drop out of the system. Anyway, it is getting more reliable."

In other words, system failure is a permanent threat to technology users. In fact, Ellen says that struggles and fears are a continuous source of worries for her. She thinks sometimes the problem may be beyond the local network system. There are problems with the web system as well, and she reports a frustrating example:

Couple of weeks ago, when a virus attacked the internet, I had an online test going, and we lost all of our sound and real media files that had all of our musical examples that were on the test.

There are moments when Ellen feels it is total failure, and sometimes she thinks she will never have another student in this class again. But she feels encouraged when she gets emails back from students saying things like, "I know you didn't cause it, as you are doing the best job you could." In other words, it seems that no faculty member is free of equipment or system failure, and if they want to keep using the resources of technology

they must be willing to deal with failures and frustrations.

Lack of Technical Support

But equipment or system failure is far from being the only source of disappointment when dealing with technology. For Roy, the problem was the lack of institutional interest and support. He says he had political struggles in his career because one institution where he worked did not want to invest in technology at all, so he could not do much at that time. Jennifer also reports her struggles because of the lack of equipment and support in her department. She says, "In my own unit in the school of Nursing, I did fear to fail, because we didn't have equipment and technology. We didn't have support for that, and it was very discouraging."

But Jennifer says it became very easy after she found support from the teaching center. She purchased a notebook with money from a grant, and used it in her school along with the few computers available there. However, she worried that after she discovered advanced ways of doing things in the teaching center, she would be unable to use the same methods in her department because of lack of support.

But this specific struggle is in the past already, as there is now equipment and support available. Jennifer explains that five years ago the department did not have any kind of help, not even a scanner to scan pictures for the web. She remembers that to get the school equipped was very hard. However, through this entire struggle, she says she never thought of giving up, because she was working in an area that she really likes.

Jennifer thinks that faculty in her institution now have reasons to celebrate, because everybody is encouraged to use technology throughout the campus system, and part of the excellence in teaching component for tenure and promotion is explaining how faculty incorporate technology in

their teaching. She says, "It is very new and has been done in the last two or three years."

Time Commitment

If there is any issue in which all the participants agreed one hundred percent it is that the time commitment is a major barrier that interferes in their process of learning instructional technology. In other words, ten out of ten participants unanimously said that this is a big issue for them. Bryan says there is a lot of frustration when he looks at how much time he needs to perform some basic tasks. For example, he reports:

It takes a lot of time to convert lectures to Power-Point, for example, particularly because I want to use some visual images. So we got to go hunting through the clipboard and on the web to find a picture of something. It is a time-consuming task.

Spending that much time with technology makes some faculty members worry about other roles they are neglecting in their career because of technology. Bryan says there were times when he was shaking his head thinking that he would not get any research done because he was spending so much time dealing with technology. He was worried that in some ways he would be penalized for doing it, because it was a time that he was not spending doing research. He thinks one reason is that he is not technologically savvy, as he does not know too much about computers and web pages. However, he says he is making progress, and eventually playing with PowerPoint gets easier the more he uses it. But using instructional technology has been very time-consuming because he had to figure out many things on his own.

Ellen has the same struggle with the time issue. She explains that there were brief moments when she thought the online class was not worth the amount of time it was taking, so she felt overwhelmed, as she describes:

I felt that was a failure on my part that I couldn't pick it up fast enough to know how to keep up with what I needed to do, because I have a lot of different ideas in my head, but I didn't know how to make them come to completion on a timely basis.

Sometimes Ellen wondered if she would even benefit the students enough to make it worth the effort. After a lot of frustration, however, she says she talked to the students, and they made her change her mind. As she says, suddenly she sees the light go on, as students get excited and involved in the learning process. Jennifer also struggles with the time issue. She says that sometimes she is scared because it takes a lot of time to learn something new, and she feels she does not have that much time available.

In turn, Nicole says she has a different problem about spending time. Because there were some students who refused to use the web to access course materials, she ended up having a two-way status among the students in class, those who used the web to a full degree, and those who refused to use it. That is how she describes her struggle:

I felt that I was doing double the work, because I had to do things on the web, but I still had to go back and do all the old way things on top of that to reach those students who didn't do it. And that is my hesitancy about technology.

Besides, Nicole thinks that for any faculty member it is going to be a matter of how many classes they teach and how much service they do. And she is very honest in addressing this issue:

Unless there is some reason why I have to know and do this, otherwise I would lose my job, so to speak, I would not spend much of my time on this. If I was a tenure track person, and my department chair told me that I should be spending my time on my research, and not playing around and putting up a nice website for my students, I

mean, the dilemma research versus teaching, I would not do it.

So, for Nicole, it is either a matter of being forced into it in some way or just a matter of personal interest. And as she says, it is not a personal interest for her. So she thinks it is easy to find an excuse not to do it because of the time commitment it requires.

Bryan thinks the time commitment is an issue not only in the creation of online materials, as there is also an ongoing time commitment. As he reports: "After every class, somebody is emailing me stuff that I have to take the time to put it on the web. So the time I spend on my teaching has increased with the use of instructional technology."

Ellen is convinced that learning technology is a matter of time management, and she says she has spent long hours and days to do what she has done with technology so far. This is the way she sees this issue:

I have found myself waking up in the middle of the night, thinking of new ideas, but I don't have time for doing that. So, the biggest barrier is time. There is never enough for me to either teach, to continue my own learning, to do my research, which is necessary, or to sit on the committees and do the committee work.

Ellen thinks faculty members willing to learn about technology have to face the dilemma of taking time from other activities and still keep up with all their responsibilities, which is not easy, she says.

In her experience, Lisa felt how hard this time management issue is, and she describes how she faced the time dilemma to produce only small pieces of course materials:

When I think about creating activities and including that technology in the classroom, I feel big time constraints. When I know it took me a long

time to edit a video and burn it on to a DVD, and produce only ten minutes of information . . .

Because it takes too much time, and it is not an essential responsibility, Karen says it is easy to keep doing things that are more “urgent,” thus relegating technology as a secondary task. Referring to the time required preparing PowerPoint presentations, this is what Karen says:

In my case I have to get the slides scanned and digitized, and it is either my time or somebody else's time. . . If it is my time, I always tend to give my time for things that are due tomorrow or the next day.

As the preparation of her classes is a top priority in her job, Karen says that the PowerPoint stuff becomes an extra task, therefore, secondary.

Diana has her own conclusion about why many faculty members never get involved with technology. She thinks the time commitment is the main reason why technology is not a priority for faculty. This is her opinion:

Most faculty resist because it is time consuming, and faculty time is precious. The institution loves technology and supports it, but time is still an issue. But personally, I don't let barriers get on my way. If I really want to do something, I just go ahead.

The attitude of Diana seems to be typical of those who are successful in using instructional technology. Like Diana, people willing to teach with technology do not let barriers get on their way. That is how Steve thinks about time commitment as well. He sees the barriers and time requirements, but he says everything depends upon the willingness of faculty, even if the schedule is tight.”

Jennifer and Roy agree with the others and refer to time as a big constraint. Jennifer mentions one example of how technology takes time from faculty and students: “Some students didn't have the latest version of the Real Player software to

play a video clip that I posted on the web. I had the same problem on my laptop, and I had to spend 45 minutes to download it from the web. It is free, but there is also the time constraint.”

Examples like this show that faculty must make it a priority in order to incorporate technology in their teaching routine. And that is exactly Carol's problem, as technology is not her high priority. In fact, she associates the time issue with her own reluctance to use technology. This is how she combines both things:

Time is the main thing. And so is my basic resistance to technology. I think that it slows down. If the time were available, I don't think I would pick it up as fast as I would like to believe I am capable of picking it up, because of this little resistance.

Despite her natural resistance, Carol wants to learn about technology, and she compensates her resistance by exploring an alternative learning method, which is having regular consultations in the teaching center. In short, she thinks that anybody who wants to use technology must be willing to spend enough time with it, as this is the only way to get proficiency and prepare consistent material.

The Rewards Issue

Another barrier addressed by the participants is the lack of rewards for faculty who spend time and effort dealing with instructional technology. Five participants mentioned that if institutions want faculty to use technology, they have to be rewarded in the promotion and tenure system. For Bryan, this is a basic concern, and this is his point of view:

I think many faculty worry that, if they spend a lot of time doing this, they will actually be punished for it, or that it may work against them when it comes to promotion and tenure, or when it comes to the annual review. And maybe the colleagues

in the department or the university will look at this and say that they should have done more in publishing articles. So there is a concern that this sort of effort is not rewarded within the system.

For Carol, this is a matter of institutional priority. She thinks that, if the university really believes that instruction can be improved by technology, the institution should encourage faculty members to use technology in their work by including this issue as a part of the annual review for promotion.

Nicole thinks time and rewards are related issues. She guesses that at least three quarters of all faculty would say that they don't have the time to learn and use instructional technology. Nicole thinks faculty should be guaranteed not only the time, but also the support, like not teaching a class for one semester but getting paid for that time, in order to develop new online courses or strategies.

Commenting on her experience, Jennifer feels lucky that her institution encourages the use of technology throughout the whole campus. She explains that part of the "excellence in teaching" component for tenure and promotion is achieved by reporting how faculty members incorporate technology in their teaching. As she clarifies, this is something very new that has been done in the last two or three years. Steve also refers to his experience to stress the fact that technology did help him to be rewarded with promotion and tenure. He thinks institutions should make it official to all faculty members.

The Cost Issue

Three participants referred to cost as another barrier for implementing instructional technology. Jennifer says that cost is a big institutional barrier. She points to the fact that some students do not have computers at home. And even when they do, they may not have the appropriate software. For Karen, the problem of cost has to do with paying additional people like her teaching assistant. Whenever she needs somebody else's

time, she has to pay the person. This of course is an institutional resources problem, but she has no choice but to hire knowledgeable people to help her continue using instructional technology.

Nicole also sees cost as a barrier, and she says that sometimes students complain about their computer at home, or they didn't have a computer at home, and this problem compromises student's access to the online environment. She thinks this will always be a problem in classes with diverse students, as some students will benefit from online materials while others will not. She thinks it gives an unfair advantage to some students over others who do not have a computer, or do not have the right program, or the right memory, or just are not familiar with the web environment.

The Technology Workshop Series

Willing to deal with their personal struggles and to develop their technology skills, all the participants in this case accepted the invitation to participate in a very innovative technology workshop series, as an initiative intended to foster faculty development in instructional technology and strengthen their motivation and technical skills. The workshop series called "Tech Camp," was designed in a creative way as intensive immersion experience to provide faculty with a rich technology environment supported by full technical and pedagogical assistance provided by faculty developers and technology expert. After the technology workshop series, participants were asked to share the impact of their learning experience described below.

More specifically, Tech Camp is a faculty development workshop series offered by the teaching center of a public university in the US and includes four different levels of seminars offered annually, ranging from basic to advanced content. Each level of seminar consists of a three-day workshop, in which the participants alternate training sessions in a computer lab with personal project presentations, exchange of personal experiences in using technology, and social interactions, including

having breakfast and lunch together every day. The first three levels of workshop are taught every year during the summer, and the fourth level is taught the following spring. In order to make them more attractive and enjoyable, each workshop is structured under an illustrative theme related to sports or adventure. The basic content and features of the workshop are summarized below.

Level 1: The Summer Scout Camp

The first level of the technology workshop series is structured under the theme of a summer camp, with the classroom decorated with trees, tents, and a campfire. The participants, called campers, are invited to spend time around the campfire while learning instructional technology techniques and resources to be used in the classroom. Each camper receives a “Camper Survival Kit,” which is the workshop handbook with printouts of all the lessons. This workshop is designed for faculty who are just beginning to work with online tools, have basic word processing skills, and are familiar with Internet browsing. The content of this workshop includes: Using course management system on the web and creating basic course materials online; creating basic PowerPoint slide shows; transferring files into an Internet server and linking them to a course environment; effective use of email, chat, and conferencing tools; linking electronic library resources; constructing an online quiz; and using the online grade book feature of the course management system.

Level 2: The Chateau Techneau Lodge

This level focuses on web page design, including planning and layout, along with basic creation, conversion, and enhancement of digital images for the web. The theme of this workshop is a winter ski resort called Chateau Techneau Lodge, where a series of exercises is designed to help participants to conquer the technology “slopes.” Every day, participants enjoy lunch and sip hot chocolate by

the “lodge” fire, and are challenged to experience the thrill of designing their very own course on the web. This workshop is designed for faculty members with intermediate technology skills.

Level 3: The Technology Cruise

Under the theme of a cruise, participants of this workshop “embark” as passengers aboard the S.S. Digital Divide with the mission of calming the stormy seas of technology by developing multimedia skills and navigating the basic technology tools for constructing online course materials. This level is designed to teach participants how to incorporate audio and video source material into web-based courses, which includes shooting, digitizing and editing audio and video media. Participants also get notions about the appropriate length of clips and on how to optimize media for better images.

Level 4: The Tech Olympics

Using the theme of the Olympic Games, campers are transformed into Olympians as they compete with themselves to achieve gold, silver, and bronze medals by finishing successive personal projects. In this workshop, the participants learn the basics of Web, CD-Rom authoring, DVD burning, and Flash web animation, using common authoring programs for each form of content distribution. This level is designed to build confidence in technological proficiency in an extremely hands-on learning environment.

General Workshop Structure

The workshop structure can be exemplified by the *Tech Olympics*, program. At the first day, participants entered the site to find a large painting of an Olympic stadium full of people on the front wall, while both an American flag and the five-intersecting-rings Olympic symbol were hanging from the ceiling. A table on the left-hand

side of the room displayed all sorts of balls and sporting gear for tennis, baseball, golf, basketball, volleyball, football, soccer, and so on. Numbered sprint tracks were designed on the floor, and another table at the back of the room covered with breakfast foods, such as fruit salad, orange juice, toast, cookies, coffee, milk, banana nut muffins, and chocolate chip muffins. Participants were sitting in groups around five tables dispersed in the middle of the room.

At the opening ceremony, after welcoming the participants, the coordinator of the workshop lighted an electronic simulation of the Olympic torch, thus officially starting the workshop. The coordinator introduced the “team” of instructors, dressed in athletic clothes, and made jokes with each of them. Then he asked the participants to introduce themselves in a very informal atmosphere. All participants received a folder with the schedule of activities and the workshop material, plus a badge on which they were to write their names using colorful markers. After receiving the instructions for the day, participants recited the tech pledge in unison. It reads as follows:

On my honor, I will try to incorporate technology wherever appropriate into my teaching, my presentations, and classroom discussions. I will post my syllabus online and will develop interactive strategies for my students as I pursue excellence while exploring technology resources.

After the pledge, participants went downstairs to the computer lab for technology exercises. In the lab, every participant sat in front of a computer previously set up with the required software, while one instructor walked the participants through the content in a step by step presentation. While one instructor was presenting, another three or four instructors were circulating the room to answer questions and help the participants.

Theme Strategy

The reaction of almost all participants to the technology workshop was highly positive. Six out of the ten participants referred to the workshop strategy as “relaxing,” and four of them found it “fun” and very attractive. Expressions like, “they made it very relaxing,” or “I knew soon it would be fun,” were repeated quite a few times by the participants during the interview. In fact, nine out of ten participants said they found the theme strategy a very powerful resource to make the workshop interesting and more attractive. Most of them said they enjoyed the different themes, which helped enhance their learning experience.

Some participants went to the workshop fearing that it would be very difficult, but the theme strategy made them feel comfortable at the very beginning. Jennifer says she was afraid: “I was pretty apprehensive that it would be so advanced. But in the first day, they made it very relaxing.” Lisa described her feelings like this: “No way will I be able to do this! I said, Oh my gosh, this is never going to make sense! So it was a little intimidating at first, but it was fun.”

A few comments by the participants are typical of their reaction to the theme strategy. Talking about their first impression of the workshop, some participants related the theme strategy to their learning experience. This is how Ellen reacted:

Oh my gosh! Things like fire and trees within this air conditioned environment, I think these people have lost their mind! But it added to the atmosphere and added relaxation because the first thing we all did was introducing ourselves and laughing.

After being afraid at the beginning, Lisa says the themes enhanced the peer interaction. She described her experience as a learning trip in the following words:

To me the cruise theme made all the difference. Each day we had a different work and a differ-

ent place to sail, and when I came back from the workshop, I asked the faculty member I worked with: Where did you cruise to today?

Nicole also felt that the relaxing sense of vacation was helpful to her learning process:

Even though we were still on campus, we had a sense of being removed on retreat, so we were not on campus because we were in Cancun, or in the Olympics, or in the forest, so themes helped us feel like we were on vacation. So it was relaxed, and not do or die, or so serious like another workshop might be.

Attitude of the Instructors

Eight out of ten participants referred to the attitude of the instructors as one of the most positive aspects of the workshop. Bryan has his own explanation for why the attitude of the instructors is crucial for the success of the workshop. This is his opinion:

I think faculty come to the workshop a little worried that they are going to feel stupid, as they don't know how to do things and the technology people will look down their noses at them because they are not as well versed in using this technology as they are, but I found that not be the case at all.

According to Bryan, the fact that faculty have prestige and expertise in many different areas makes them very sensitive, as they don't like feeling disadvantaged in a learning situation. That is why the role of the instructors is decisive in making faculty feel comfortable. Diana thinks the environment was comfortable and encouraging because the instructors were willing to help with deference and respect. This is how she addressed this point:

The instructors are wonderful and have a respect for faculty and faculty expertise. They also know that faculty who come for help are very vulner-

able, and they are supportive without being condescending and such. I think that the personnel are probably the strongest part of the workshop.

Impact on Learning

The impact of the workshop on the process of learning technology was different for each participant. They were asked to estimate which percentage of their learning of technology could be attributed to the workshop itself, and they came up with different levels of learning impact. Four out of ten participants estimated that 50% or more of their learning of technology could be attributed to the workshop, which means a very strong impact on their learning process. Three participants estimated that the impact on their learning of technology was between 25% and 50%, which could be considered a medium impact. Three other participants estimated the impact was less than 25%, meaning a low impact on their learning of technology.

Karen sounded very realistic describing how she felt about the impact of the workshop on her learning of technology, and this is her explanation:

For me it was a huge part. I would say that maybe 50% of my learning so far is due to the workshop, but I have a teaching assistant, and she may represent 40%, and I am only 10% of my improvement in technology.

Only Roy says the impact was as low as five percent. He is very experienced in technology, so the workshop was only an additional resource. But overall, the majority of the participants were very satisfied with their gains in learning technology through the workshop experience.

Regarding the way the workshop best facilitated their learning, six participants referred to the "hands-on" approach to learning as the most helpful methodology, as they appreciated the opportunity to watch the instructors and practice at the same time. To say that in the words of Roy, "the organizational pattern was pretty busy, transpar-

ent, so I understood what was going to happen. Methodology was good, mostly hands-on, quite professional.”

Both the hands-on approach and the time available to work on their personal projects helped the participants develop technical skills and produce useful material for their classes.

Impact on Teaching

Commenting on their teaching experience with technology as a result of the workshop, six out of ten participants stressed that the workshop had a strong positive impact on their teaching routine. They referred to this impact with expressions such as, “I had never used course management on the web before,” or “I had never done a full PowerPoint presentation before.” Some said things like, “it helped me a lot to use technology,” or “there was an immediate change when I took the workshop.” These participants sounded excited in describing some of their new experiences with technology.

Four participants said they didn’t use the technology applications that they learned about at the workshop much. Bryan says that he used very little of what he learned because he was already using it. The other three participants said that the workshop did not make any impact on their teaching as they didn’t change anything in the classroom. They have different reasons for that. Carol says she did not do anything different in part because of her subject area, which is Theater, and she feels that she does not have much to apply. Roy says he did not have time to produce the material he needs. This is how he analyzed it:

No changes. I haven’t produced any streaming video for teaching yet. As far as the use of Flash and animations, I have one animation distributed on the web, and that is probably the only one I generated so far. The same with Dreamweaver, as I am probably using only 15 percent of it.

In other words, the majority of the participants did feel a strong impact of the workshop on their teaching and applied a great deal, but some others did not make any significant change in implementing instructional technology after the workshop participation.

Overview of Findings and Conclusions

Based on the participants’ descriptions of their learning experiences with instructional technology, one major characteristic of each participant was identified and helped understand better how the learning process worked for each faculty member. In most cases, this dominant personal characteristic of the participants seemed to be consistent with the theoretical description of their learning styles, but in one specific case it was not consistent with the theory, and in three other cases there was little evidence to support the learning styles theories. Table 13 displays a comparison between the descriptions of the participants’ dominant characteristics and their learning styles, as well as the theoretical support found for each dominant characteristic. Columns two and three of the table describe the relationship found between the dominant characteristic of each participant and their personal learning style as assessed by the ILS instrument, and column four presents the learning style theory that offered support for such relationship.

The last column of Table 13 applies the adoption categories of Rogers’ (1995) diffusion of innovation theory to the participants in this study. Diana, Roy and Jennifer were classified as innovators, given their experience as risk takers willing to take the initiative and time to try something new and different. Ellen and Steve can be classified as early adopters since, to certain extent, they served as role models for their peers by being channels to help others to adopt innovations in instructional technology. Lisa and Karen fit in the early majority category, as they are careful, safe, deliberate, and do not want to risk much on

Table 13. A comparison of personal characteristics and learning styles

Participant	Dominant Characteristic	ILS Learning Style	Theoretical Support	Adoption Category
Carol	Emotional	Intuitive, Random	Gregorc, Felder	Late majority
Diana	Risk-Taker	Intuitive, Random	No theoretical support	Innovator
Jennifer	Visionary	Visual, Sequential	Gardner, Felder	Innovator
Ellen	Hard-worker	Concrete, Sequential	Gregorc, Myers, Brightman	Early adopter
Karen	Dependent	Concrete, Active, Sequential (low scores)	Kolb (little support)	Early majority
Roy	Pragmatic	Visual, Intuitive, Active	Kolb (little support)	Innovator
Steve	Social	Active (maximum score), Visual	Kolb	Early adopter
Nicole	Skeptical/Trial-and-Error	Visual, Active	Kolb, Gardner (little support)	Laggard
Lisa	Watching	Visual	Gardner, Felder	Early majority
Bryan	Self-taught	Intuitive	Kolb, Myers	Early adopter

the innovation process. Carol fits in the late majority because, even being suspicious of innovation and resistant to change, she keeps moving slowly influenced by peers and the environment. Nicole describes her experience as a laggard, since her skeptical attitude keeps her somewhat inflexible in resisting innovations in instructional technology.

From the data analysis, another theme that emerged was the positive impact of the technology workshop in the format it was presented. Faculty in this study identified seven major features of the workshop format that made a strong impact on their process of learning technology. These key features of the workshop were: (1) the theme strategy of illustrating the workshop as a sportive adventure; (2) the respectful and caring attitude of the instructors in making participants feel comfortable; (3) the “hands-on” approach in using a computer lab for the participants to apply the content of the workshop; (4) the peer interaction in the classroom and also in social opportunities; (5) the time available for practice after each lesson and presentation by the instructors; (6) the opportunity to develop their own projects during

the workshop; and (7) the continued assistance available to them as they worked for three days surrounded by instructors.

The way in which the technology workshop series was designed seems to include the concepts underlying the above approaches and strategies. Some functions such as modeling, skill training, intensive help, and a user-friendly environment, were mentioned by the participants as an effective part of the workshop format. In summary, participants approved the workshop format and they think faculty development programs should explore more the strategies used in this technology workshop series.

Based on the above discussion, the following conclusions seem to be evident:

1. In order to attract faculty members with different backgrounds, beliefs, and motivations, technology workshops need to be creative, dynamic, and involve participants in a presentation style that includes active learning strategies and a hands-on approach.
2. The theme strategy of illustrating the workshop as an adventure was found to be

a powerful resource to break the natural fear many faculty members feel towards technology, and made them feel comfortable and relaxed enough to enjoy a real learning experience.

3. A prolonged immersion approach is crucial to make participants “live” in a technology environment with full support and tutoring available, so no participant will get stuck without solving the common problems technology presents for beginners.
4. A friendly, respectful, and patient attitude on the part of the instructors is essential for making faculty feel encouraged to participate. Being experts in many different areas, faculty do not feel comfortable being treated as inferior for not knowing the basics of some programs or software.
5. The social interactions promoted by sharing food and participating in group discussion, as well as the peer teaching opportunities, are a powerful learning resource that make faculty encourage each other and exchange learning experiences.

The experience of the participants in this study provided helpful information on different aspects of the process of learning to use instructional technology. Putting together the relationship between the several different factors, the following findings and conclusions seem to be evident from this study:

1. From a practical perspective, this study found that the lack of time and rewards made it harder and more difficult for faculty to learn and use instructional technology. In other words, most faculty claim that they need more time and rewards from the institution.
2. From an institutional perspective, the study found that all the participants felt under stress because of the time commitment, since instructional technology was an addition to their already busy schedules. Therefore, most

participants claim that the preparation of instructional technology materials should be included and rewarded as part of the regular work load. Faculty also fear compromising the promotion and tenure process by spending time with IT.

3. The participation of these faculty in professional development interventions such as the technology workshop series was very helpful to equip and develop faculty skills in instructional technology, thus enhancing the participants’ learning experience.

According to this study, the learning process in instructional technology works as a cycle in two opposite directions. Faculty who have high levels of motivation, positive beliefs, and some background in technology take the most advantage of professional development programs in instructional technology, have a growing learning experience, and are successful in developing teaching strategies that involve students in an active learning experience. The cycle is repeated as the more they learn, the more they increase the background, motivation, and positive beliefs. In the opposite direction, faculty who have low levels of motivation, negative attitudes, and no background in technology take less advantage of professional development programs, have a slow learning experience, and do not use much instructional technology in the classroom. Figure 1 displays this double cycle describing the relationship between the different factors influencing the learning process of faculty members in instructional technology based on the experiences of the participants in this study.

Practical Implications and Recommendations

The findings of this study present practical implications for faculty development in instructional technology, both from an institutional perspective related to policy issues and from the personal

Figure 1. Cycle of faculty learning experience in instructional technology

perspective of individual faculty members who want to learn from the experience of fellows who have struggled and walked the journey of learning instructional technology. Based on these findings, the following recommendations seem relevant to address the needs of the participants from an institutional perspective:

1. Institutions and departments should restructure their academic reward system to compensate faculty members who develop successful teaching activities and strategies using instructional technology and the online environment. The promotion and tenure process should include and consider instructional technology as a relevant part of the teaching excellence component of promotion and tenure.
2. Institutions and departments should restructure their financial reward system to

accommodate different criteria for assessing teaching load and instructional costs. The traditional model of measuring instructional costs based mostly on student/faculty ratio, average faculty salary, and student credit hours (Paulsen and Smart, 2001), must be reviewed to allow room for the time-consuming task of producing online courses and materials, thus providing a fair reward for faculty involved with instructional technology.

3. Institutions and departments should design both a short-term and a long-term pilot-plan for the implementation of faculty development programs in instructional technology, with a wide range of developmental interventions to reach faculty members at different levels of motivation and attitudes, as well as technology expertise and experience.

4. Based on the participants' descriptions of their dominant learning styles and characteristics, faculty development programs should address the needs of different types of learners and focus on different target audiences to reach faculty members with different profiles by promoting workshops with a wide variety of learning approaches including creative strategies like online games, instructional video clips, group discussions, and online case studies of pedagogical experiences using technology.

CONCLUSION

In summary, whether teaching instructional technology to an emotional learner, to a risk-taker or to a skeptical learner, it is always challenging to meet the needs and expectations of faculty with different learning styles, different technology backgrounds, different pedagogical beliefs, different attitudes towards technology, and who have their own pace and their own preferences in dealing with teaching and instruction.

Regarding the faculty development intervention, overall this innovative workshop series seems to have made a positive impact on the learning experience of most faculty members in instructional technology. However, even acknowledging the support of the institution in terms of providing faculty development opportunities, technical assistance and equipment available, one hundred percent of the participants agreed that institutional barriers such as time commitment and the lack of rewards are major barriers in terms of learning instructional technology. As a result, most participants tend to be under stress to accommodate all the demands of their professional appointment, such as teaching, research, service and participation in committees, and still be able to get involved with instructional technology. Many participants felt that instructional technology is an addition to their already heavy workload.

KEY TERMS AND DEFINITIONS

Faculty Development: A wide range of interventions, programs and resources intended to support faculty in developing expertise in specific subject-areas, such as mastering technologies for learning.

Faculty Rewards: Academic and financial recognition of faculty work with technology for learning, including the promotion and tenure process.

Institutional Barriers: Lack of institutional support, resources or academic and financial rewards, thus discouraging faculty of learning and using instructional technology.

Instructional Technology: The art and science of designing, producing, and using solutions to instructional problems, using different media and systems that facilitate learning efficiently (Heinich, Molenda, Russell, and Smaldino, S., 2002)

Learning Styles: A generic term as an umbrella concept for recognizing individual learning differences and preferred ways of interacting or processing new information. No one has a monopoly on the term or can claim to represent learning style in its entirety (Butler, 1987; Kolb, 2000).

Pedagogical Attitudes: Faculty positive or negative reaction, including beliefs or disbeliefs regarding the benefits of technology applications for teaching and learning.

Teaching Strategies: A broad concept referring to the planning, implementation, assessment and management of educational activities, with the goal of producing learning.

Chapter 7.9

On the Role of Learning Theories in Furthering Software Engineering Education

Emily Oh Navarro

University of California, Irvine, USA

André van der Hoek

University of California, Irvine, USA

ABSTRACT

Learning theories describe how people learn. There is a large body of work concerning learning theories on which to draw, a valuable resource of which the domain of software engineering educational research has thus far not taken full advantage. In this chapter, we explore what role learning theories could play in software engineering education. We propose that learning theories can move the field of software engineering education forward by helping us to categorize, design, evaluate, and communicate about software engineering educational approaches. We demonstrate this by: (1) surveying a set of relevant learning theories, (2) presenting a categorization of common software engineering educational approaches in terms of learning theories, and (3) using one such

approach (SimSE) as a case study to explore how learning theories can be used to improve existing approaches, design new approaches, and structure and guide the evaluation of an approach.

INTRODUCTION

Learning theories are attempts to describe and understand the various ways in which people learn. They are an important resource for educational research, as they can both guide us in creating new educational approaches, and help us analyze and improve existing approaches.

In this chapter, we propose that learning theories, which have thus far been explicitly leveraged in software engineering education in only a minimal way, can actually play quite a significant role in this domain. Specifically, we believe that learning theories can serve to move the field of

DOI: 10.4018/978-1-60960-503-2.ch709

software engineering education forward by helping us to categorize, design, evaluate, and communicate about software engineering educational approaches. Categorizing approaches in terms of learning theories can help us to understand the approaches in relation to each other, understand how they fit together, and point out areas of untapped potential. New approaches can be designed to leverage certain theories whose potential is unfulfilled or known to be especially valuable in our domain. Learning theories can be used to evaluate approaches by helping structure experiments to look for the presence of these and other theories in the processes of learners. And, we can use our newfound knowledge to communicate in a common language—that of learning theories—about different approaches and our experience with them.

This chapter details this vision of principally using learning theories in the domain of software engineering education. We first briefly present a set of well-known (mainly constructivist) learning theories that are especially applicable. We then introduce a categorization of the major software engineering educational approaches to date in terms of the learning theories that they appear to have been designed around. Following this, we discuss the role learning theories can play in analyzing and improving the design of a software engineering educational approach (and designing new approaches), and focus on the analysis of one such approach (SimSE) as a case study. We then discuss how software engineering educational approaches can be evaluated in terms of learning theories, again using SimSE as a case study. We conclude with a summary in the final section.

BACKGROUND: LEARNING THEORIES

To provide some background for our discussion on the role of learning theories in software engineering education, in this section we will briefly introduce the set of learning theories that we

surveyed for the purposes of our analysis. We do not include here an exhaustive list of all learning theories with significant detail. Instead, the purpose of this section is to simply introduce some of the ones we have seen software engineering educational approaches centered around most frequently, and provide pointers to where more information about each one can be found. In addition, we will also briefly touch on implications and typical or possible applications of each theory for software engineering education.

We chose the particular set of learning theories discussed here because of two criteria: relevancy to software engineering and orthogonality among the factors defining the theory. In other words, these theories are the ones we have seen to be most clearly and/or frequently embodied in the software engineering educational approaches that we surveyed. Furthermore, there exists a great deal of overlap among learning theories, and there are several learning theories that encompass a number of others. In these cases, we either group theories that have the same basic idea, and omit those that simply combine a number of theories.

We acknowledge that these theories fall mainly into the constructivist paradigm (rather than the behaviorist or cognitive categories), however, given that constructivism is the most recently-developed paradigm, and software engineering is a relatively new discipline, this is not surprising (it has been argued elsewhere, in fact, that the evolution of computer science education in the past decade or so has been significantly influenced by constructivism (Kolikant, 2001)). While it is certainly true that most delivery methods generally contain a mix of various theories that fall into each of the three camps (constructivist, behaviorist, and cognitive), because the constructivist aspects are the most focused on, we have chosen to scope this survey and analysis to focus primarily on these theories. Surely similar surveys and analyses could be done with cognitive and behaviorist theories that would yield interesting results, however, such exercises are outside the scope of the one presented here.

Nevertheless, some of the theories surveyed in this chapter do have elements of cognitive and/or behaviorist principles. For example, Learning through Failure involves a form of “punishment” (failure) meant to “extinguish” a certain behavior.

An additional issue that should be noted is the distinction between learning “theories,” learning “models,” and learning “methods,” as well as their counterparts in the domain of instructional design (instructional design theories, models, and methods). Because the lines between these are blurred and often used interchangeably, it should be noted that in this chapter several of the “learning theories” we refer to can also be called by some of these other terms. When this is the case, we will point it out in our discussion of those theories. However, as is frequently done in the literature, we use the term “learning theory” broadly, as a term that covers all of these categories.

One of best-known learning theories is *Learning by Doing*, a theory based upon the premise that people learn a task best not by hearing about it, but by actually *doing* it (Dewey, 1916). The implication of this theory for instructional design is the following: the learner should be provided with ample opportunity to actually perform the activities they are meant to learn, rather than using passive mediums such as lectures and readings. In software engineering education, this translates to going beyond just lectures and reading assignments (although, for most any domain, a certain amount of such scaffolding is necessary to provide the learner with the required background knowledge to effectively participate in the Learning by Doing). Software engineering educators have recognized this, and now a standard component of nearly all software engineering courses is the class project—a small software engineering project that students must develop using some of the techniques learned in class.

Situated Learning (Lave, 1988) is an educational theory that builds upon the Learning by Doing approach. While Learning by Doing focuses on the specific learning activities that the

student performs, the Situated Learning theory is concerned with the environment in which the Learning by Doing takes place. In particular, Situated Learning is based on the belief that knowledge is situated, being in large part a product of the activity, context, and culture in which it is developed and used. Therefore, the environment in which the student practices their newly learned knowledge should be “authentic”, resembling, as closely as possible, the environment in which the knowledge will be used in real life. A popular application of this theory in software engineering education focuses on incorporating aspects of realism (or “authenticity”) into the class project, such as using an industrial participant to play the role of the customer (Hayes, 2002), using maintenance- or evolution-based projects (McKim & Ellis, 2004), or using large teams of people that are distributed across geographical locations (Favela & Pena-Mora, 2001).

Like Situated Learning, *Keller’s ARCS Motivation Theory* (Keller, 1983) also focuses on motivating students to learn. However, rather than focusing on the physical environment in which they learn, Keller’s ARCS Motivation Theory concerns itself with producing certain feelings in the learner that are believed to promote learning. In particular, these feelings are attention, relevance, confidence, and satisfaction.

- **Attention:** The attention and interest of the learner must be engaged. Proposed methods for doing so are: introducing unique and unexpected events; varying aspects of instruction; and arousing information-seeking behavior by having the learner solve or generate questions or problems.
- **Relevance:** Learners must feel that the knowledge is relevant to their lives. The theory suggests that knowledge be presented and practiced using examples and concepts that are relevant to learners’ past, present, and future experiences.

- **Confidence:** Learners need to feel personal confidence in the learning material. This should be done by presenting a non-trivial challenge and enabling them to succeed at it, communicating positive expectations, and providing constructive feedback.
- **Satisfaction:** A feeling of satisfaction must be promoted in the learning experience. This can be done by providing students with opportunities to practice their newly learned knowledge or skills in a real or simulated setting, and providing positive reinforcements for success.

Keller's ARCS is technically considered an instructional design model that is rooted in various learning theories. Two of the most directly contributing theories are Andragogy (Knowles, 1984) and Expectancy-Value Theory (Fishbein & Ajzen, 1975). Andragogy concerns adult learners in particular, and focuses on their need for self-directed, relevant, hands-on learning. Expectancy-value theory states that in order for a learner to put forth the effort required to learn, they must both value the knowledge/task/exercise and expect that they can succeed at it. Because Keller's ARCS combines these theories and provides more hands-on applicability than either theory alone, we have chosen to include it (rather than the theories it is based on) in our survey and analysis.

While Keller's ARCS could be applied in a number of different ways in software engineering education, in general it entails providing the students with attention-grabbing, realistic, hands-on assignments that pose a significant, yet doable challenge. One class of approaches that explicitly sets out to accomplish such goals is that in which the class project is made purposely open-ended and/or vague. This is done in two main ways: either by allowing the students to define their own requirements (giving students the pseudo-experience of new product development based on market research) (Navarro & van der Hoek, 2005b), or by allowing them to define their own

process (giving students experience in not only following a process, but in designing the process that they follow) (Groth & Robertson, 2001). The stated purpose of these open-ended approaches is to mimic common, less-structured (authentic) real-world software engineering situations, giving the students more ownership of the project and therefore more interest in it, as well as a greater feeling of confidence and satisfaction when the project is completed.

Model-Centered Instruction (Gibbons, 2001) (which is also considered an instructional design theory) says educators should center all learning activities around models of three types: models of environments, models of cause-effect systems, and models of human performance. Presentation of general concepts and theories should be kept to a minimum. Instead, Model-Centered Instruction believes that knowledge is best learned by exploration of these models. In software engineering education, this translates to simulating realistic situations, presenting case studies, and assigning realistic problems for the students to solve. One software engineering educational approach that embodies this theory is the practice-driven one, in which the curriculum is largely lab- and project-based, and lectures are used only as supporting activities (Ohlsson & Johansson, 1995).

The Discovery Learning theory (Bruner, 1967) takes a similar approach to model-centered instruction in that it believes that an exploratory style of learning is best. Discovery Learning is based on the idea that an individual learns a piece of knowledge most effectively if they discover it on their own, rather than having it explicitly told to them. This theory encourages educational approaches that are rich in exploring, experimenting, doing research, asking questions, and seeking answers. Educational software engineering simulation approaches (Drappa & Ludewig, 2000; Navarro & van der Hoek, 2005a) are specifically designed to facilitate this type of learning—no knowledge is made explicit in the simulation, as it is rather discovered by students experimenting with dif-

ferent approaches and seeing the effects of their decisions on the outcome of the simulation. These types of approaches are generally given as structured exercises and combined with other teaching methods (such as lectures, readings, and projects). Including this type of scaffolding has been found to be crucial in making Discovery Learning maximally effective (Kirschner *et al.*, 2006; Roblyer, 2005).

Along the same lines as the Discovery Learning theory is the *Learning Through Failure* theory (Schank, 1997). This theory is based on the assumption that the most memorable lessons are those that are learned as a result of failure. The theory argues that: (1) Learning through failure provides more motivation for students to learn, so as to avoid the adverse consequences that they experience firsthand when they do not perform as taught, and (2) Failure engages students, as they are motivated to try again in order to succeed. Proponents of the theory argue that students should be allowed to (and even set up to) fail to encourage maximal learning. Although Learning through Failure is usually applied to the realm of e-learning, there have also been some non-e-learning software engineering educational approaches in which the main avenue of learning is through failure. In these “sabotage” approaches, the instructor purposely sets the students up for failure by introducing common real-world complications into projects (e.g., crashing hardware just before a deadline), the rationale being that students will then be prepared when these situations occur in their future careers (Dawson, 2000).

The theory of *Learning through Reflection* is primarily based on Donald Schön’s work suggesting the importance of reflection activities in the learning process (Schön, 1987). In particular, Learning through Reflection emphasizes the need for students to reflect on their learning experience in order to make the learning material more explicit, concrete, and memorable. Some common reflection activities include discussions, journaling, or dialogue with an instructor (Kolb, 1984).

One example of this in software engineering is (Tomayko, 1996), a practice-driven industrial partnership approach that incorporates weekly one-on-one mentoring sessions with a “coach” to discuss each student’s performance and help them reflect on their experience. The game-based simulation described in (Drappa & Ludewig, 2000) and the industrial simulation described in (Nulden & Scheepers, 2000) also incorporate dialogue and reflection as post-simulation activities in which students analyze and discuss their simulation experience with a tutor or instructor, and reflect on what they have learned.

Finally, the theory of *Elaboration* (Reigeluth & Rodgers, 1980) states that, for optimal learning, instruction should be organized in order of complexity, from least complex to most complex. Simplest versions of tasks should be taught first, followed by more complicated versions. This is a theory that is generally inherent to most curricula (as well as most other learning theories), as courses and topics are usually introduced in order of increasing complexity. In software engineering educational approaches, applying this theory can sometimes be difficult, as there is oftentimes no natural way to organize the information in terms of complexity (e.g., how can one do this for a class project?). One approach that has been able to do this is the industrial simulation approach described in (Collofello, 2000). In this approach, students are assigned very simple simulations to begin with, and the complexity of the simulations is incrementally increased as the students progress in their knowledge.

As mentioned previously, what has been presented in this section is only a brief introduction to the relevant learning theories. There is much more detail to these theories than what we have discussed, detail which must be looked into further before one can effectively apply these theories to their educational approaches. Typically, subtleties are involved in each one, and care must be taken to pay attention to these details.

LEARNING THEORY-BASED CATEGORIZATION OF EXISTING APPROACHES

One of the main ways that learning theories can be used in software engineering educational research is to provide the field with a way to analyze and categorize existing approaches, both independently and in relation to each other. Such a categorization can serve to help us understand how the different approaches fit together and create a picture of the field as a whole, so that areas of strengths, weaknesses, and untapped potentials can be unearthed. We have done such a categorization, which we will present in this section.

Before creating this categorization, in order to organize our analysis we first surveyed the major software engineering educational approaches published in the past several years and found that they can be lumped into three broad groupings: *realism*, *topical*, and *simulation* (these groupings can be broken down further into sub-groupings, as shown in Table 1). Realism approaches are those that focus on making various aspects of the students' project experience more closely resemble one they would encounter in the real world. Some of these have included industry participation (Beckman *et al.*, 1997; Kornecki *et al.*, 2003; Wohlin & Regnell, 1999), emphasizing non-technical skills such as marketing and project management (Gnatz *et al.*, 2003; Goold & Horan, 2002), and focusing on making the nature and composition of the student teams that work on the project more realistic (e.g., making them very large (Blake, 2003) or composed of several sub-teams (Navarro & van der Hoek, 2005b)). Topical approaches aim to educate students in detail about a topic generally not covered in depth in mainstream textbooks and lectures. These approaches do not focus on specific delivery methods, but instead focus on the mere addition of the topic as a crucial component of an effective and complete education in software engineering. Some examples of such topics are formal methods (Abernethy & Kelly,

2000), real-time software engineering (Kornecki, 2000), and specific software processes such as the Personal Software Process (Hilburn, 1999) or the Rational Unified Process (Halling *et al.*, 2002). Finally, simulation approaches are those that have students practice software engineering processes in a (usually) computer-based simulated environment. Within the realm of software engineering simulations, there are three main types: industrial simulations brought to the classroom (Collofello, 2000; Pfahl *et al.*, 2000), game-based simulations (Drappa & Ludewig, 2000; Navarro & van der Hoek, 2005a), and group process simulations (Nulden & Scheepers, 2000; Stevens, 1989).

To categorize these approaches in terms of learning theories, we carefully studied each one to determine which learning theories appear to have been applied (whether intentionally or unintentionally), and which learning theories have clear potential to be employed. The resulting categorization is presented in Table 2 as a matrix of approaches and the learning theories that they leverage. (For a complete discussion of this categorization, see (Navarro, 2005)—here we present only the highlights.) The presence of three stars in the table indicates that the approach embodies the particular theory, or is centered around it. The presence of two stars represents that the theory appears to be involved in the design of that type of approach, but is perhaps not an intrinsic part of it, and may not be involved in all approaches that fall within that type. The presence of one star indicates that there is an obvious potential for that particular type of approach to employ that learning theory, but there have been very few, or no known cases of it.

Example: Simulation and Learning Theories

As an example of how we analyzed each approach in terms of learning theories, in this section we will focus on the simulation category and walk through how we determined the applicability of each

Table 1. Grouping of software engineering educational approaches

learning theory for these approaches. First of all, all aforementioned educational software engineering simulations allow students to learn software processes by participating in them (Learning by Doing), albeit virtually. This theory is central to the paradigm of educational simulations (hence, the three stars in the table). These simulations also employ Situated Learning by adding realism to the learning environment, although in different ways: Industrial simulations add realistic factors in the form of real project data in the simulation model; Game-based simulations add realism by immersing the student in the role of a participant in a realistic game scenario; Group process simulations inject realism through the simulated characters that behave similarly to real-world participants. Because these realistic factors are artificial in that they are virtual (rather than in a real-life setting), we put two stars in the table for this theory.

Simulation approaches strongly fit with the Keller's ARCS model of learning. In particular, they are specifically designed to promote attention, relevance, confidence, and satisfaction (and have been shown to do so in some cases) in the following ways:

- **Attention:** A number of studies done with educational software engineering simulations have repeatedly shown that students find these simulations enjoyable, engaging, and an interesting challenge they are happy to take on (Baker *et al.*, 2003; Dantas *et al.*, 2004; Navarro & van der Hoek, 2005a; Sharp & Hall, 2000; Stevens, 1989). This is particularly true for game-based simulations. Clearly this is the result of the elements of surprise, humor, challenge, and fun that are integral to many game-based simulations.
- **Relevance:** Because learners can experience firsthand how the knowledge they are learning is relevant in a real-world situation (the one that is portrayed in the simu-

lation), simulation promotes a feeling of relevance to students' future careers. This relevance can be enhanced by the usage of real-world data in the model to make the simulation more realistic. Furthermore, as the theory suggests, relevance is enhanced even further if the educational approach builds on previous and present knowledge. Simulations that are used to demonstrate concepts that have already been communicated to the students in another form (e.g., lecture or text) directly address this.

- **Confidence:** Simulations provide a non-trivial challenge that is also doable. As students are given the opportunity to succeed at a simulation, they will feel a sense of personal confidence in the learning material. This is especially true in game-based simulations, in which students have the additional benefit of feeling they have "won the game."
- **Satisfaction:** As students are able to practice their knowledge and skills in a realistic (yet simulated) setting, seeing the positive consequences of applying their knowledge correctly promotes a true feeling of satisfaction. Again, game-based simulations add to this if the student is also rewarded with a high score or some other game-relevant measure of success.

Model-based instruction has not been utilized at all in simulation, but has obvious potential to be. In particular, simulations could be used as the model (realistic situation, case study, *and* problem, simultaneously) that instruction is centered around. In such a case, students would practice a simulation (or series of simulations) for each concept (or set of concepts) being taught. Simulations would allow for ample exploration—one of the basic tenets of model-based instruction—as students could practice the same simulation multiple times, using a different approach each time, learning the consequences of various actions, and,

as a result, learning a great deal about the process and concepts being simulated.

The exploratory quality of simulation in and of itself directly implements the Discovery Learning theory. The nature of simulation is highly conducive to allowing students to discover knowledge on their own, as they see phenomena played out in a simulation, and are encouraged to explore, experiment, do research, ask questions, and seek answers.

This type of exploratory learning is also inherently related to the Learning through Failure theory. As students explore the simulation and try different approaches, they are likely to fail at least a few times. In fact, one of the basic purposes of simulations is to allow students to “push boundaries”, try different approaches, and fail without fear of the drastic and severe consequences that would occur in a real-world setting. For example, a student who fails in a simulated software project would only have to worry about getting a low game score or seeing an unhappy simulated customer, while in the real world such a failure could cost millions of dollars or have even more serious consequences.

Learning through Reflection has also been incorporated into simulation approach, although only limitedly: with the game-based simulation SESAM (Drappa & Ludewig, 2000), and the industrial simulation described in (Nulden & Scheepers, 2000). As mentioned previously, dialogue and reflection sessions have been incorporated into these learning processes as post-simulation activities. Some dialogue activity is also an inherent part of Problems and Programmers (Baker et al., 2003), the educational software engineering card game simulation. The face-to-face, competitive nature of this physical card game has been shown to promote rich and useful discussion between student opponents, regarding such topics as why they took the approach they did, the reasons behind one person’s win and another’s loss, and their reactions to unexpected events.

Finally, the Elaboration theory has also been only limitedly incorporated into simulation-based software engineering educational approaches. In particular, Elaboration has only been leveraged in the process used with the industrial simulation described in (Collofello, 2000). This process consists of assigning students very simple simulations to begin with, and incrementally increasing the complexity of the simulations as the students progress in their knowledge.

Categorization Highlights

The first thing to notice in general from Table 2 is that, although learning theories are not often explicitly discussed in software engineering education research, they are indeed applicable in our domain. Whether consciously or unconsciously, people have been building approaches toward them in various ways. If we look at how the different learning theories fare with respect to the number of approaches that incorporate them, we can clearly see that our domain has focused the most on Learning by Doing and Situated Learning. This is not a surprise, given the strong emphasis on preparing students for the “real world” that is intrinsic to the field. In contrast, Learning through Reflection is the most under-explored theory, but also has the most potential for greater use—every category of approach has the potential to leverage (or better leverage) this theory.

If we then look at each approach with respect to the learning theories they incorporate, we can see that most of them apply multiple theories at once. The “topical” category has one star for each theory because, since these approaches focus on the topic rather than on delivery methods, they theoretically have the potential to apply all of the theories, depending on the way that topic is taught. Simulation, on the other hand, directly incorporates, or has the potential to directly incorporate all of the theories considered in some way or another. While it certainly is not the case that any teaching method that addresses more learning theories than

another is better than that other method (consider a combination of strategies put together haphazardly in some teaching method versus one well-thought-out and tightly-focused method cleverly leveraging one very good strategy), an approach that naturally addresses factors and considerations of multiple learning theories is one that is most definitely worth exploring. Simulation is such an approach, but one that has been significantly underexplored in software engineering education (Navarro, 2005)—something that we are attempting to address with the approach described in the following section.

DETAILED ANALYSIS/DESIGN/DEVELOPMENT OF AN APPROACH IN TERMS OF LEARNING THEORIES

In addition to providing the field with a way to categorize and analyze existing software engineering educational approaches, learning theories can also help in developing new approaches and modifying existing approaches to be more effective. Categorizations such as the one presented in the previous section can help guide the design (or re-design) of such approaches, as areas for potential are highlighted.

Case Study: The Design of SimSE

In this section, we present a case study of a software engineering educational approach that was actually not explicitly designed with learning theories in mind. In looking back at our approach in light of learning theories, however, we can see that several of our key decisions made in its design are highly relevant to some of these theories. We can also see missed opportunities of ways we could have leveraged additional learning theories to make it more effective.

The approach is SimSE, an educational game-based software engineering simulation environment. SimSE is a computer-based environment that

facilitates the creation and simulation of realistic software process simulation models—models that involve real-world components not present in typical class projects, such as large teams of people, large-scale projects, critical decision-making, personnel issues, multiple stakeholders, budgets, planning, and random, unexpected events. In so doing, it aims to provide students with a platform through which they can experience many different aspects of the software process in a practical manner without the overarching emphasis on creating deliverables that is inherent in actual software development.

The graphical user interface of SimSE is shown in Figure 1. SimSE is a single-player game in which the player takes on the role of project manager and must manage a team of developers in order to successfully complete an assigned software engineering project or task. The player drives the process by, among other things, hiring and firing employees, assigning tasks, monitoring progress, and purchasing tools. At the end of the game, the player receives a score indicating how well they performed, and an explanatory tool provides them with a visual analysis of their game, including which rules were triggered when, a trace of events, and the “health” of various attributes (e.g., correctness of the code) over time (see Figure 2).

To date, six SimSE game models exist: a waterfall model, an inspection model, an incremental model, an Extreme Programming model, a rapid prototyping model, and a Rational Unified Process model. For more information on SimSE, including its design, game play, and simulation models, see (Navarro, 2006).

The idea of SimSE was originally motivated by the hypothesis that simulation can bring to software engineering education many of the same benefits it has brought to other educational domains. Specifically, we believed that software engineering *process* education could be improved by using simulation to allow students to practice managing different kinds of “realistic” software

Figure 1. SimSE graphical user interface

Figure 2. Graphical representation of a SimSE Game, generated by the explanatory tool

engineering processes. The constraints of the academic environment prevent students from having the opportunity to practice many issues surrounding the software engineering process in their course projects. Our approach therefore focused on providing this opportunity through the use of simulation.

To guide us in the design of SimSE, we performed two activities: (1) a study of the domain of software engineering education to discover what its unique needs are, and (2) a survey of well-known principles for successful educational simulations from the research literature. The result of this was a specific set of key decisions that are listed here and discussed in light of the learning theory (or theories) that we later discovered related directly to them:

1. **Use of the game paradigm.** We could have chosen to base our simulation approach on the industrial simulation or group process simulation paradigms mentioned previously, but instead we chose the game paradigm. It has been shown that game-like features such as graphics, interactivity, surprising random events, and interesting, life-like challenges are known to hold a student's attention and promote a feeling of confidence and satisfaction as they succeed in the game (Ferrari *et al.*, 1999). This directly corresponds to the Keller's ARCS theory, which suggests that such qualities promote a highly effective learning experience.
2. **A fully-graphical user interface.** To make SimSE maximally engaging and visually realistic, we chose to design a fully graphical, rather than textual interface. As was shown in Figure 1, the focal point of this interface is a typical office layout in which the simulated process is "taking place", including cubicles, desks, chairs, computers, and employees who "talk" to the player through pop-up speech bubbles over their heads. In addition, graphical representations of all artifacts,

tools, customers, and projects along with the status of each of these objects are visible. This decision to graphically portray simulated software engineering situations turned out to be strongly in line with the theory of Situated Learning—the learner is provided with a visual context that corresponds to the real world situations in which the learned knowledge would typically be used.

3. **A high level of interactivity.** Keeping the attention of the learner engaged is not only done by making a user interface visually appealing, but also by continuously involving the learner. Thus, rather than designing SimSE as a continuous simulation that simply takes an initial set of inputs and produces some predictive results, we designed it in such a way that the player must make decisions and steer the simulation accordingly throughout the entire process. SimSE operates on a step-by-step, clock tick basis, and every clock tick the player has the opportunity to perform actions that affect the simulation. Keeping the learner continuously engaged and giving them ample opportunity to practice their skills and tackle challenges are tactics suggested by the Keller's ARCS theory for promoting attention, relevance, confidence, and satisfaction.
4. **Customizable simulation models.** SimSE includes a model builder tool and associated modeling approach that allow an instructor to build simulation models and generate customized games based on these models. This feature adds the (unanticipated) potential for using SimSE in a way that follows the theory of Elaboration—instructors could build models of varying complexity and use them in order of increasing complexity with students. Although we have not yet built such models with SimSE, it is in our future plans to do so, as we now know that this potential for greater effectiveness is there.

5. **An explanatory tool.** An integral part of SimSE is its novel explanatory tool that provides players with a visual representation of how the simulated process progressed over time and explanations of the rules underlying the game. This feature promotes Learning through Reflection as it allows players to look back on their game and analyze their decisions and how those decisions affected the outcome. The explanatory tool output could also potentially be used as the focal point of a dialogue session between student and tutor/instructor.
6. **Complementary usage of SimSE.** Rather than design SimSE to be a standalone tool meant to replace standard course components such as lectures, readings, and projects, we instead designed it to be used complementary to them, and have used it in such a setting. The simulation models we have built require a basic set of knowledge and skills in order to play and learn from them effectively, knowledge that students conceivably obtain in lectures and readings. Thus, in essence, SimSE allows them to “Learn by Doing” by learning through experience the lessons communicated through reading and lectures, as well as other lessons that are simply not adequately teachable through passive means. Linking the knowledge learned in SimSE to existing knowledge also promotes the feeling that what a student is learning is of relevance to them, a major tenet of Keller’s ARCS.
7. **Simulation models that provide a clear goal.** SimSE allows the modeler to compose a “starting narrative” for the player that appears at the start of a game, and to which the player can refer back at any time during a game. In the models we have built, we have used this starting narrative to provide the player with the exact goals of the simulation, criteria for completion of these goals, and any hints or special notes that might

help them along the way. Precisely defined objectives not only guide students through a simulation, but also pose a challenge that many students find hard to resist. Achieving the goal becomes a priority and Discovery Learning is employed as creative thinking is sparked in coming to an approach that eventually achieves that goal.

8. **Simulation models that are adequately challenging.** We have built into our simulation models interesting situations that are adequately challenging (engaging students’ attention and making it likely that they learn through failure at times) but not impossible, promoting eventual success that leads to confidence in the learning material and satisfaction in the experience (central principles to Keller’s ARCS).

Looking back on the design of SimSE in light of learning theories served to link some of our intuition in the design of SimSE to these theories, thereby increasing our confidence of being on the right path with our approach. In addition to this, it also revealed some missed opportunities that we could have taken advantage of, had we originally designed SimSE with learning theories in mind. For example, we could have better taken advantage of the Elaboration theory by designing our models in incrementally complex versions, and introducing them to students in order of increasing complexity. In our usage of SimSE in courses and in out-of-class studies, we also could have made reflection a more central and structured part of the approach by providing the student with explicit explanatory tool exercises to complete, exercises that would encourage the type of reflection that would help solidify the lessons learned in the simulation (currently, the student is simply given the explanatory tool, and decisions about how to use it are left up to them). As another example, we could have better incorporated aspects of authenticity (promoting Situated Learning) by including more random events (a characterizing

feature of the real world) in our models. These types of events are only used sparingly in many of our models.

Like most software engineering educational approaches, SimSE was not designed with learning theories in mind. However, by looking back on its design in light of learning theories, we have learned a great deal about how SimSE promotes learning and how it can be improved to foster greater learning, as we have seen in this section.

LEARNING THEORY-CENTRIC EVALUATION

Although we did not explicitly use learning theories in SimSE's initial design, we did use them as a central guiding factor in designing a major part of its evaluation. Validating that the theories an approach was designed to employ (or appear to employ) are *actually* employed, as well as discovering if an approach incorporates aspects of any additional theories, can be highly useful exercises—such data can be used to make that and other similar approaches more effective as they are tailored to exploit the characteristics known to promote each theory (van Eck, 2006). Thus, as part of SimSE's evaluation, we performed an in-depth observational study that focused on investigating the learning processes of SimSE players to determine whether they exhibited behaviors indicative of various learning theories.

Case Study: SimSE Evaluation Setup

For this study, we used as subjects 11 undergraduate students who had passed the introductory software engineering course at the University of California, Irvine. This requirement was put in place so that they would have at least the basic understanding of software engineering concepts required to play SimSE. The study occurred in a one-on-one setting—one subject and one observer. Each subject was first given instruction on how

to play SimSE, and was then observed playing SimSE for about 2.5 hours. In order to evaluate how well the explanatory tool achieves its goal of aiding Learning through Reflection, we had eight students play SimSE with the explanatory tool and three without. (Differences in the behavior, attitudes, and opinions of each group could then be compared, though clearly, not to the extent of being statistically significant.) While subjects were playing, their game play and behavior were observed and noted. Following this, the subject was interviewed about their experience for about 30 minutes. In addition to any spontaneous questions the observer formulated based on a particular subject's actions or behavior during game play, all subjects were asked a set of standard questions. Several of these questions were designed to specifically detect the presence of one or more learning theories in the subject's learning process. Some questions did not target a particular theory or set of theories, but were instead meant to evoke insightful comments from the subject from which various learning theories could be inferred, and from which general insights into the learning process could be discovered. Some samples from the standard set of questions are listed here, with the targeted learning theory (or theories) listed in parentheses afterwards when applicable.

- *To what do you attribute the change (or lack of) (improvement, worsening, fluctuation, steady state) of your score with each game?* (Discovery Learning, Learning through Failure)
- *Do you feel you learned more when you “won” or when you “lost”? Why? What did you learn from each “win” or “loss”?* (Discovery Learning, Learning through Failure)
- *When you lost, did you feel motivated to try again or not? Why?* (Learning through Failure)

- *On a scale of 1 to 5, how much did playing SimSE engage your attention? Why? (Keller's ARCS)*
- *How much has your level of confidence changed in the learning material since completing this exercise? (Keller's ARCS)*
- *Did you feel that you learned any new software process concepts from playing SimSE that you did not know before? If so, which ones? (answer could be indicative of multiple theories)*
- *If you feel you learned from SimSE, what do you believe it is about SimSE that facilitated your learning? (answer could be indicative of multiple theories)*

There were also some questions primarily designed for comparison between the subjects who used the explanatory tool and those who did not. These questions were aimed at discovering how the player went about figuring out the reasoning behind their scores, as well as how well they understood this reasoning.

- *Where do you think you went wrong in game 1/2/x? (Learning through Reflection)*
- *Please describe the process that you followed to figure out the reasoning behind your score, or where you went wrong/right. (Learning through Reflection)*

Following the experiment, the interviewer's observations and interview notes were analyzed to try to discover which behaviors and comments were indicative of the various learning theories, and how, as well as to discover any other insights about SimSE as a teaching tool that could be gained from this data.

Evaluation Results

The learning theory that was most clearly involved in every subject's learning process was Discovery Learning. All subjects were able to recount at least

a few lessons they learned from SimSE, and none of these lessons were ever told to them explicitly during their experience. Rather, they discovered them independently through exploration and experimentation within the game. Interestingly, although all subjects that played a model seemed to discover the same lessons (for the most part), no two subjects discovered them in the same way. Every subject approached the game with a different strategy, but came away with similar new knowledge, suggesting that SimSE can be applicable to a wide range of students that come from different backgrounds with different ideas and possibly, different learning styles. This is a central aspect of a student-centered theory like Discovery Learning. Since learning depends primarily on the learner and not the instructor, the learner is free to use their own style and ideas in discovering the knowledge, rather than being forced to adhere to a rigid style of instruction.

Learning through Failure also seemed to be widely evident. Every subject seemed to take a "divide and conquer" approach to playing SimSE, isolating aspects of the model and tackling them individually (or a few at a time). When subjects described the progression of their games in the interviews, it was clear that the way they conquered each aspect was by going through at least one or two rounds of failure in which they discovered what *not* to do, and from this discovering a correct approach that lead to success. When asked explicitly about learning through failure, every subject stated that they learned when they failed, but the amount of learning they reported varied. Five subjects said they learned more from failure than success, two subjects said they learned more when they succeeded, and four subjects said they learned equally as much from failure and success. All but one subject said that they were motivated to try again after they failed. This motivation was also evident in the behavior of several subjects, as some, after the completion of one failed game, hurriedly and eagerly started a new one. One subject even tried to start a new game when the

time for the game play portion of the experiment was up and he was already informed that it would be the last game.

The Learning by Doing theory seemed to be involved in most of the subjects' learning experience. Eight out of the 11 subjects made comments about their experience playing SimSE that hinted at aspects of Learning by Doing. Some of their comments included:

- “[SimSE helped me learn because it] *puts you in charge of things. It's a good way of applying your knowledge.*”
- “[SimSE helped me learn because it is] *interactive, not just sitting down and listening to something.*”

Comments indicative of Situated Learning were also rather frequent, mentioned by seven out of the 11 subjects. Some of these included:

- “[SimSE helped me learn because] *it was very realistic and helped me learn a lot of realistic elements of software engineering, such as employees, budget, time, and surprising events.*”
- “[One of the learning-facilitating characteristics of SimSE was] *seeing a real-life project in action with realistic factors like employee backgrounds and dialogues.*”

Behaviors and comments suggestive of Keller's ARCS Motivation Theory were also evident, although certain aspects of the theory came out stronger than others. To explain, let us look at the four aspects of the theory (attention, relevance, confidence, and satisfaction) individually.

First, the attention of the subjects seemed to be quite engaged with SimSE. This was evident in their body language, the comments made both during game play and the interview, and their ratings of SimSE's level of engagement. Many of them spent the majority of their time during game play sitting on the edge of their seats, leaning forward

and fixing their eyes on the screen. There were head nods, chuckles in response to random events and character descriptions, shouts of “Woo hoo!” after achieving a high score in a game, shaking of the head when things were not going so well for a player, and requests of, “Can I try this one more time?” when the experiment's allotted time for game play was coming to an end. Words some subjects used to describe SimSE in the interview were “challenging”, “fun”, “interesting”, “addictive”, and “amusing.” When explicitly asked how much SimSE engaged their attention, the students rated it quite high—4.1 on average out of five.

Second, relevance was rated moderately high, but not as high as level of engagement. Five of the subjects rated SimSE's relevance to their future experiences as “pretty relevant” or “very relevant”, five described it as “somewhat” or “partially” relevant and one said it was not relevant at all. Although not explicitly asked about SimSE's relevance to their past experiences, nearly all of the subjects mentioned that they used some of the knowledge they had learned in software engineering courses to come up with their strategies for playing the game, suggesting that there is also a relevance between their past experiences (learning the concepts in class) and their learning experience with SimSE.

Third, most subjects felt their level of confidence in the learning material (the software process model simulated and software process in general) had increased at least somewhat since playing SimSE. Four subjects reported their level of confidence had changed “a lot” or “very much”, five said it had changed “somewhat”, and two said it had not changed at all.

Fourth, satisfaction was rated quite high by the subjects. Nine out of the 11 subjects reported that they were “quite satisfied”, “very satisfied”, “fully satisfied”, or “pretty satisfied”, and three subjects stated they were “somewhat satisfied.” Most of the reported factors that contributed to a feeling of satisfaction pertained to a subject's increasing success from game to game, although some also

mentioned that the sheer fun and challenge of SimSE contributed to their satisfaction as well.

The explanatory tool did seem to promote Learning through Reflection, to some extent. Most of the subjects that had access to the explanatory tool did make use of it, the duration of its use after most games ranging from five to 25 minutes. It was obvious that the subjects who did not have the explanatory tool (to whom we will henceforth refer as “non-explanatory subjects”) were significantly more confused and less confident about the reasoning behind their scores and how to improve than those who did have the explanatory tool (to whom we will henceforth refer as “explanatory subjects”). All of the non-explanatory subjects expressed this, while only one explanatory subject stated such an opinion. The following are some of the comments made by the non-explanatory subjects:

- *“I was trying to guess what I was doing wrong, so I probably chose the wrong areas that I was doing wrong, and then I tried to switch back to my original way and then I kind of forgot what that was and once I started trying to improve it, all of my little details started changing and I didn’t know what parts were causing my score to go lower.”*
- *“I felt like I knew, oh, that’s where I went wrong sometimes, like I should spend a little less time there, but a lot of times I was wrong about where it was I went wrong.”*

On the other hand, most of the explanatory subjects’ comments expressed that the explanatory tool did, indeed facilitate their learning:

- *“[The explanatory tool] showed me why I was doing poorly—because of certain events that were happening.”*
- *“The rules [described in the explanatory tool] are really helpful—even if someone doesn’t know anything about software en-*

gineering I think the rules can teach you how to play the game.”

Implications of Evaluation Results

Evaluating SimSE in terms of learning theories provided us with several valuable insights into how SimSE helps students learn. In addition, it also helped us to discover ways to potentially make SimSE more effective. In this subsection, we describe how focusing on some of the theories in our evaluation provided us with knowledge that will help us maximize SimSE’s effectiveness.

Learning through failure: Overall, the challenge of receiving a “failing” score and trying to improve it seemed to be a significant avenue of learning and a strong motivating factor of SimSE. This reinforced our notion that simulation models should be made challenging enough that students are set up to fail at times. It is these failures that provide some of the greatest opportunities for learning. By focusing on this aspect in our observations, we also discovered that one of our models (Rapid Prototyping) was not quite challenging enough, and students could sometimes get a good score without really learning the lessons. Thus, we have since added more challenges to this model, and will continue to build simulation models in the future that have an adequate level of challenge.

Learning by doing: Several of the subjects’ comments mentioned the ability to put previously learned knowledge into practice as a learning-facilitating characteristic of SimSE. This validates our choice to use SimSE complementary to other teaching methods, so that it can fulfill this important role of being an avenue through which students can employ Learning by Doing as they do the things they only heard about in class.

Situated learning: The realistic elements in SimSE seem to add significantly to its educational effectiveness. Thus, it is important that we continue to include elements of the real world in our models, in order to situate students’ knowledge in a realistic environment.

Elaboration: It became clear from our observations that one of our models (waterfall) is much too large and complex for a “SimSE beginner.” (Although the waterfall process is a simple one, the corresponding SimSE model is quite complicated, incorporating several non-technical, managerial aspects.) By giving such a complex model to a student who has never played SimSE before, we were clearly violating the principles of the elaboration theory. Thus, viewing this result in light of that theory taught us that such a model should not be introduced until the student has played other, simpler models first.

Keller’s ARCS: Through this study we were able to discover what elements of SimSE and its models best hold students’ attention by noting when students appeared to be most engaged, and what kinds of things they commented about favorably in the interviews. For example, several students mentioned that the random events in the models (e.g., the customer changing their mind and requiring the team to rework part of the code) added an element of surprise and realism that kept things entertaining. Thus, we will continue to build these elements into our future models, as well as try to maximize them in our current models. We also discovered which elements students found un-engaging. For instance, several subjects thought the inspection model was boring and repetitive. Through the interviews, we were able to detect exactly what it was about the inspection model that made it this way, and have recently implemented changes that we anticipate will make it more interesting for future SimSE players.

Learning through reflection: The explanatory tool partially fulfills its goal of facilitating reflection, but it is clear that it needs to be improved. In particular, more help needs to be given to the user in generating meaningful, useful graphs, and the rule descriptions need to be more easily accessible. We have recently addressed these issues in our development by adding attributes to each model that are meant specifically for explanatory

graphing purposes and by making the rule descriptions more accessible through the user interface.

Learning theories can help structure evaluations by providing ideas about what the researcher should be looking for in the learning processes of students. As we have seen with SimSE, this can be done even if the approach was not designed with learning theories in mind. A careful retro-analysis of the approach’s design in terms of learning theories can reveal the aspects that a learning theory-centric evaluation should focus on. Conducting such an evaluation has the potential to both reveal the effectiveness of an approach, as well as guide future work in the area.

Certainly, not every aspect of an approach can be evaluated this way—an evaluation focused on learning theories should only be one part of an evaluation plan. In addition to the evaluation described here, SimSE’s evaluation plan also included a pilot study, a comparative study, and in-class studies, each of which was designed to evaluate different aspects of SimSE to form a comprehensive picture of its ability as a teaching tool (see (Navarro & van der Hoek, 2007) for more information about these studies).

SUMMARY

Learning theories are an important educational resource of which the software engineering educational community has not yet taken full advantage. Learning theories can be used to categorize, design, evaluate, and communicate about software engineering educational approaches, providing a structured and informed way to move our domain forward with approaches that are effective and well-understood. We have shown one example of applying learning theories to software engineering education in our analysis and evaluation of SimSE. It is our hope that educators can take this example and apply it to other approaches and areas of software engineering education to create

more effective teaching strategies that are rooted in educational theory.

MORE INFORMATION

More information about SimSE, including downloads, evaluations, and publications, are available at <http://www.ics.uci.edu/~emilyo/SimSE/>.

ABSTRACT

Multimedia environments consist of verbal and visual representations that, if appropriately processed, allow for the construction of an integrated mental model of the content. Whereas much is known on how students learn from verbal representations, there are fewer insights regarding the processing of visual information, alone or in conjunction with text. This chapter uses a semiotics approach to provide a definition of visualizations as a specific form of external representation, and then discusses the differences between verbal and visual representations in how they represent information. Finally, it discusses how meaning is achieved when learning with them. The next section discusses basic perceptual and cognitive

processes relevant to learning with visualizations. This background is used to specify the instructional functions that visualizations have either as self-contained instructional messages or as text adjuncts. Moreover, the role of individual differences in processing visualizations is highlighted. The chapter ends with methodological suggestions concerning the important role of interdisciplinary research and assessment methods in this area.

INTRODUCTION

Visualizations constitute a key component in multimedia-based instruction, which can be defined as learning from text and pictures (e.g., Mayer, 2005). Despite the fact that visualizations are used more and more frequently in informal and formal educational settings, not much is

DOI: 10.4018/978-1-60960-503-2.ch710

understood about their semiotic properties, how humans process them, and how they can be best designed to learn from. In educational research, visualizations are often treated in a uniform manner, despite the fact that the visualizations might serve vastly different functions depending on the audience and goals. Just as bad, visualizations are treated as functionally equivalent to text. As a consequence, reviews on learning with visualizations are equivocal, with studies showing widely varying effects (negative to positive) on learning. In the current chapter, we will try to provide a more differentiated view by first reviewing the literature from different disciplinary perspectives (education, semiotics, perception, and cognition) to characterize different types of visualizations, to distinguish them from verbal representations, and to describe how information is derived from them. This approach will attempt to provide a unique approach to addressing the question of when and why visualizations are effective for learning. After some summarizing remarks, directions for future research will be outlined in the final section of this chapter. It is important to note, however, that we will not review the more mainstream literature on the effectiveness of learning with visualizations, as comprehensive reviews can be found elsewhere (e.g., Anglin, Vaez, & Cunningham, 2004; Rieber, 1994).

BACKGROUND

What are Visualizations?

Visualizations are a specific form of external representation that are intended to communicate information by using a visuo-spatial layout of this information and that are processed in the visual sensory system. According to Rieber (1990, p. 45) “visualization is defined as representations of information consisting of spatial, nonarbitrary (i.e. “picture-like” qualities resembling actual objects or events), and continuous (i.e., an “all-in-

oneness” quality) characteristics”. Visualizations are often best understood through the context of their use (MacEachren & Kraak, 1997). In as much as visualizations are created to communicate in a learning or problem-solving context, these visualizations are typically based on models and leverage human perceptual and cognitive abilities to efficiently and effectively convey information (Gilbert, 2005). The model and its use in the context of the visualization then drive particulars of the visualization—from the visual metaphors employed to the dynamic characteristics of elements (Bertoline & Wiebe, 2003).

External representations such as visualizations are defined with regard to their relation to the real world. “The nature of representation is that there exists a correspondence (mapping) from objects in the represented world to objects in the representing world such that at least some relations in the represented world are structurally preserved in the representing world” (Palmer, 1978, p. 266). Thus, a representation is defined through its structural correspondence to what it stands for (i.e., the referent) and is hence analogical to the referent. By means of this analogy, representations can act as a substitute for the referent and evoke similar responses as the real-world referent. Semiotics is an approach that can be used to more rigorously analyze the relationship between the signs that make up a visualization, the underlying intended instructional message of the visualization, and the learning task context in which the visualizations are being employed.

Using semiotics as a methodology, visualizations can be understood and organized in ways that better guides their creation and intended use. Peirce (1960) identified three forms of relations between the representation and the represented object: an *icon* resembles the object it depicts in terms of its criterial attributes in a given context. Criterial attributes are properties of the object that “act as discriminanda for sorting and resorting the objects in the perceptual world” (Knowlton, 1966, p. 162). An *index* refers to its object by

means of a physical connection to it (e.g., a footprint as a representation of a bear). A *symbol* (or digital sign, according to Knowlton, 1966) bears no resemblance to what it stands for and is thus arbitrary (e.g., words, numbers). Knowlton (1966) further distinguishes between realistic pictures, analogical pictures, and logical pictures.

Realistic pictures resemble their referents by means of physical similarity (e.g., a picture of a tree looks like a tree we see with our eyes). This similarity is achieved by copying the real-world referent with respect to shape, details, color, or motion. From a semiotics perspective, there are at least three problems associated with the labeling of this category of visualizations. First, constructivists like Gombrich (1969) have proposed that what people perceive as being realistic in a picture is strongly affected by their preconceptions of how a representation of the real-world object should look like. Second, realistic pictures may vary largely with regard to the level of realistic detail, which is why Alessandrini (1987) suggested calling this type of pictures ‘representational’ rather than ‘realistic’. The third problem with this labeling is that it does not help distinguishing the first from the second visualization category, namely analogical pictures.

Analogical pictures may seem realistic in the sense that the depicted objects look alike to something known from the phenomenal world. However, analogical pictures “make reference to something else – something that is in some way analogous to the portrayed object or to its manner of functioning” (Knowlton, 1966, p. 176). Thus, the objects depicted in the visualization refer to entities that are different from entities that they resemble (e.g., two lumberjacks moving a felled tree as an analogous picture for muscles moving a bone). Resemblance to the referent is established solely through functional similarity or structural correspondence. Whereas realistic pictures can be used to represent the phenomenal world only, “analogical pictures can represent either the phenomenal or nonphenomenal world.

In both cases, this is done through the bridge of the ‘visual’ phenomenal world” (Knowlton, 1966, p. 177). Accordingly, these pictures can represent abstract concepts, albeit not directly; rather, “they can be illustrated indirectly by showing their effects on visible objects, tangible results, specific instances, or concrete exemplars” (Alessandrini, 1987, p. 176).

Logical pictures can be thought of as highly schematized pictures, where the elements of the picture do not bear any physical resemblance to objects in the phenomenal world and are thus arbitrary (*cf.* arbitrary pictures, Alessandrini, 1987; Rieber, 1994). Accordingly, one might argue that logical pictures are symbols rather than icons. On the other hand, logical pictures, like analogical pictures, preserve the structural interrelations between these referents. Examples of logical pictures are depictions of things that are potentially visible, but where we do not know how they look like (e.g., atoms) or of things that do not exist in any tangible way (e.g., a mathematical proof). Moreover, the term logical (or arbitrary) picture is used to describe charts, diagrams, and graphs, because here the spatial layout is used to convey information on conceptual relationships. Logical may be the better term in this case since conventions for the design and layout of charts, diagrams, and graphs are often far from what would typically be considered arbitrary (Bertin, 1983).

Semiotic taxonomies like the one by Knowlton (1966) have been largely neglected in educational research (Anglin et al., 2004), although they may be very relevant to the research and development of visualizations. Research on learning with visualizations has often made generalizations across a wide range of types, which have led to the misuse of multimedia principles (Mayer, 2005). Moreover, visualizations have been incorporated in instruction with the assumption that they behave the same as verbal representations. While both text and graphics can be scrutinized through semiotic analysis, they are truly unique sign systems with

differing strengths and weaknesses in communicating referents.

How Do Visual Representations Differ from Verbal Representations?

The properties that make visualizations different from verbal representations have been discussed in various disciplines. Differences between the two representational formats pertain to three aspects: (1) the features of the external representation, (2) the external representation's relation to the represented world, and (3) the relation between the external and the internal representation (i.e., the representation's meaning).

Features of the Representational Formats

Modularity. Kosslyn (1994) has suggested that verbal and pictorial representations differ with regard to their modularity. Verbal representations can be broken down in small, discrete symbols (i.e., letters), however breaking down letters into even smaller parts will not yield meaningful pieces. On the other hand, there is no discrete unit for visualizations, because they can be arbitrarily broken down in multiple ways and still yield potentially meaningful patterns.

Sequentiality. Visualizations comprise spatial relations to represent information in a two- or three-dimensional structure. Linguistic information, on the other hand, is presented in a purely sequential manner (Larkin & Simon, 1987).

Modality. Verbal representations are amodal, in that information extraction is not linked to a specific perceptual modality. That is, verbal information can be processed by the auditory system, the visual system, or even by the haptic system. On the other hand, the processing of visual representations is strongly associated with the visual modality.

The Relation between the External Representation and the Represented World

Arbitrariness. Verbal representations are said to be arbitrary in the sense that there is no inherent reason for why the word “house” denotes the thing we live in, for instance. Rather, the object could be represented by any given arrangement of letters or phonemes if a culture agreed on this. On the other hand, most visualizations are non-arbitrary in that the representation and the represented world are linked to each other by means of inherent structural correspondences or even by physical resemblance.

Notationality. In verbal representations, distinct elements are linked to real-world elements in an unambiguous and explicit way, thereby determining the semantics of the representational elements (Goodman, 1976). Moreover, for every language there are explicit rules telling us how to combine words to sentences or how to express temporal relationships, thereby determining the syntax of the representation. Goodman calls this the notationality of a representational system, which denotes the “degree to which the elements of a symbol system are distinct and are combined according to precise rules” (Anglin et al., 2004, p. 870). Visual representations are far less explicit in terms of their semantics, whereby these elements can be represented in many different ways and still be recognized, as long as the structural relations are preserved. Nevertheless, in semiotic theory there have been attempts to determine the regularities of visualizations and, therefore, to identify their underlying syntax (Kress & van Leeuwen, 1996). Logical pictures may lend themselves best to this approach since they are often notational in that there are distinct elements arranged according to specific rules or conventions (Tversky, 2003).

Parsimony. The famous saying “a picture may be sometimes worth 10,000 words” suggests that it sometimes takes 10,000 words to express

what can be depicted in a picture with markedly fewer symbols. One reason for this parsimony is that spatial relations of objects are automatically implied in a picture and thus do not require any additional symbols, whereas in verbal representations spatial arrangements need to be made explicit (e.g., x is positioned above and to the right of y). According to Kosslyn (1994) visualizations are more complete than verbal representations in that they deliver information on all possible details of the object (e.g., its shape, size etc.) that is being represented through them.

Expressiveness. Contrary to verbal expressions, visualizations have limited power for expressing logical and temporal relations as well as abstractions (Maybury, 1995). For instance, to represent the concept “animal” it would not be very helpful to show a dog or a cat, as these would be interpreted as standing for the concrete animal, but not for the superordinate category. Knowlton (1966), however, notes “that it may be possible to suggest a concept with an iconic sign, depending, in part, on its level of realism” (p. 167). Accordingly, Schwartz (1995) demonstrated that realistic visualizations made people think more about the concrete referent of the depiction. On the other hand, schematized visualizations facilitated abstract reasoning and symbolic interpretations of the represented objects (DeLoache, 1995; Goldstone & Son, 2005; Schwartz, 1995).

Specificity. According to Stenning and Oberlander (1994) and Bernsen (1994), visualizations can be characterized by their higher specificity compared to verbal representations. That is, while language can be interpreted in multiple ways, thereby corresponding to multiple possible represented worlds, visualizations are often more constrained in that respect and reduce the number of possible worlds that can be represented through them (*cf.* graphical constraining, Scaife & Rogers, 1996).

The Relationship between Internal and External Representations

Conventionalism. The meaning of a verbal representation (i.e., what it stands for or what it signifies) is established through convention or cultural agreement. This is why Palmer (1978) referred to verbal representations as extrinsic representations, where meaning is imposed onto the representation from the outside. The meaning of the visualization is intrinsic to the representation as it is constructed based on the properties of the objects that it represents; thus, its meaning is derived from these inherent characteristics. Whereas these structural correspondences can potentially be expressed in very many ways, for some visualization forms there are established cultural rules as to how to represent the structural features of the real world, thereby constraining the multitude of options (*cf.* Gombrich, 1969; Kosslyn, 1994). As outlined before, this is particularly true for logical pictures (Tversky, 2003).

Interpretation and Reasoning. When being confronted with a verbal expression for the first time (e.g., as a child or as a second-language learner) we will not understand this expression unless we are explicitly told its meaning. Realistic visualizations, on the other hand, can be intuitively understood without making the link to the real-world referent explicit. This is even true for babies who lack experience with external representations (DeLoache, 1995; Hochberg & Brooks, 1962). Gibson (1979) has argued that this is because realistic visualizations result in optical arrays similar to those when looking at their real-world referents. Hence, information “can be directly picked up without the mediation of memory, inference, deliberation, or any other mental processes that involve internal representation” (Zhang, 1997, p. 181). Similarly, other researchers have suggested that visualizations may support inference and reasoning processes grounded in perception (Goldstone & Son, 2005;

Schwartz, 1995; Stenning & Oberlander, 1994), allowing perceptual judgments to substitute for more demanding logical inferences. While these arguments are evident for realistic or representational visualizations (Alessandrini, 1987; Knowlton, 1966), logical pictures may also have specific cognitive processing benefits compared to verbal representations. Larkin and Simon (1987) have suggested that diagrammatic visualizations are often more computationally efficient for accomplishing tasks that require the processing of visuo-spatial properties (*cf.* cognitive offloading, Scaife & Rogers, 1996). In particular, visualizations reduce the need of searching for multiple information elements related to a single idea because this information is grouped (chunked) in visualizations. Thus, in visualizations related information can be processed in parallel (to a certain extent), rather than sequentially.

Internal representation. Verbal and visual representations differ in their dominant internal representation formed in long-term memory. Whereas verbal descriptions are associated with the construction of a propositional representation, non-verbal formats like visualizations are more likely to be encoded and stored as analogical representations (Kosslyn, 1994; Paivio, 1991). According to Paivio, these two internal representations are interconnected by referential links so that they can activate each other (e.g., the word “apple” activating the mental image of an apple tree). It is important to note that words and visualizations may, in principle, both yield a propositional representation as well as an analogical representation (e.g., through construction of a mental image for concrete words). The so called picture-superiority effect (i.e., better recall for pictorial than verbal information) is explained by assuming that this dual coding of information based on a single input representation is more likely to occur for pictures than for words. The picture-superiority effect can also be explained by Baggett’s *bushiness hypothesis* (e.g., Baggett, 1984). It states that knowledge acquired from

visual rather than verbal external representations will be better accessible in memory because the respective nodes in memory share more associations with other nodes in the semantic network. Thus, visual concepts are assumed to be “bushier” than verbal concepts and, therefore, more salient in memory.

Bernsen (1994) mentions a number of mechanisms that help to overcome inherent weaknesses of the two representational formats, such as *focusing mechanisms* in graphics and *specificity mechanisms* in language. Thanks to focusing mechanisms (e.g., selective removal of specificity, highlighting, selective enlargement), analogous visualizations come closer to the strengths of a natural language. Thanks to specificity mechanisms in language (summaries, key points, usage of metaphor and analogy), language comes closer to the strengths of an analogous representation. Even with these mechanisms being present, visual and verbal representations will differ on a variety of dimensions, which naturally affects the way they are processed during multimedia learning. While there are elaborated models of text comprehension, no comprehensive models exist for the processing of complex visual information. In the following section, some pivotal concepts of visual perception are described as they are relevant to multimedia instruction.

Processing of Visualizations

While the research traditions in understanding text and graphic representations are equally rich, visual perception has been less well represented in educational research. Understanding the perceptual and cognitive processing of graphics is crucial to understanding the differences between text and graphic representations and how to most effectively design visualizations.

The processing of visualizations for learning and problem-solving can be understood in the context of information processing theory and, more specifically, multiple resource theory (Wickens,

2002). Using this approach, the processing of visual images contains both perceptual and cognitive elements, each of which require their own resources. In addition, there will also be resources dedicated to overarching, executive functions, guided by both short-term and long-term goals (i.e., the task). While earlier information processing models were often depicted as consisting of a number of distinct stages and functions, multiple resource theory recognizes that mental functions differ both in terms of the amount of resources required and the degree of resource overlap with other functions. Common to information processing theory, resources related to both sensory buffers and short term memory are finite while long term memory resources can be considered essentially infinite. It is the resource-limiting nature of sensory and short term memory and the ability (or lack thereof) to access relevant long term memory resources that informs much of the research in multimedia instructional design (Mayer, 2005; Sweller, van Merriënboer, & Paas, 1998).

It is useful to think of perception unique from cognition (Hochberg, 1978; Zhang, 1997). Perception can be operationally defined as those (visual) mental functions that do not require access to long-term memory. These, then, are abilities common to the normal adult and adolescent population and can be assumed when designing visual representations. Perception, therefore, involves basic processes such as discrimination based on visual properties of color, shape, texture, and orientation, form recognition and spatial arrangement.

Within perception, there is both ambient and focal vision, with the difference largely based on attention (Wickens, 2002). In terms of resources, attention is an executive function that allocates resources to processing information received by the sensory buffers. Some perceptual functions—including peripheral vision—make use of low-level processing capabilities in the brain that require little or no resources (i.e., pre-attentive or automatic processes). These ambient perceptual capabilities include supporting much of everyday

functions such as basic hand-eye motor skills or locomotion through space. All perceptual processes are actively involved in sense-making. These low level ambient functions will attempt to organize a scene as three-dimensional space, segregating foreground and background elements and determining whether these elements lie in discrete locations in depth (e.g., a planar surface) or as a continuous three-dimensional form. Elements will be grouped based on visual properties and their spatial relation to each other. While some of these properties, such as color, are pre-attentive, others (e.g., shape) may require additional attentive processing (Treisman & Gelade, 1980). The Gestalt principles of configuration are some the best known examples of active perceptual organization of a scene (Rock & Palmer, 1990). These ambient processes can be seen at work initially organizing visual information used in multimedia instruction.

Focal vision requires attention and thus more resources than ambient vision. Focal vision will make use of both bottom-up information gathered from ambient vision and top-down information provided by both ongoing focal viewing and higher level cognitive processing. Ambient visual function may provide the “gist” of a scene whereby focal vision then attends to elements initially deemed as interesting, unusual or important. Ongoing processing of this scene then guides focused vision. In addition to information being passed from ambient vision to focused vision functions, information processed at this next level may be processed further and passed to long term memory. Eye movement research informs our understanding of this ongoing process (*cf.* Henderson, 1992). While our conscious perception of a scene is of a single, unified, stable image, the underlying eye movements reveal constant saccadic movement, sampling various portions of the scene to varying degrees. The brain, employing both ambient and focal vision, engages in both real-time, transient and longer-term meaning making of what is re-

ceived in the sensory buffers and creates the sense of a stable, meaningful scene.

Cognition, in this context, can be thought of those resource-driven processes that require long-term memory. For example, viewing a photograph of a lion, perception would be able to separate the lion from the surrounding background, use shading and perspective convergence to mentally orient it's three-dimensional shape in space. Prior knowledge would, however, be needed to know that this form was a lion. Further knowledge would be needed to know whether this lion was male or female, and still further specialized knowledge might allow you to use visual cues to discern the approximate age of the lion. In the context of learning, the difference between perceptual and cognitive functions becomes very important. While most perceptual capabilities can be assumed to be universally present in a population, cognitive capabilities may be much more varied (Mayer & Massa, 2003; Siegler & Alibali, 2005). While all of the students in a sixth grade classroom may know that the photograph is of a lion, they may not all know its sex or approximate age. What is important is which of these elements of prior knowledge is important for the learning task and/or whether these elements are what you hope the student will learn about. Prior knowledge is equally important with analogical or logical images, where the visual sign element must be mapped to its referent in memory. Improper scaffolding may leave a student at a lower level of processing, where the image seen is just a "red triangle" and not, say, a representation of a key biological molecule used in DNA replication (Patrick, Carter, & Wiebe, 2006).

The movement of visual information from sensory buffers to short term memory and then possibly to long term memory establishes a number of points of possible failure to encode into schemas information necessary for a learning task. Low level visual information that cannot be apprehended because it is too small or does not possess enough contrast to be segregated

from surrounding elements cannot be used as part of higher level visual processing. Similarly, elements that meet the requirements of low level apprehension may still not be further processed because attention has not directed the necessary resources to this visual information; the information is not rehearsed in short term memory and not integrated into long-term memory. Finally, visual information in long term memory may not be retrieved because it is not recognized as related to the current visual processing task.

It is important not to think of these processes as rigid and linear, as there is an ongoing flow of information between all levels in both directions, with some of it happening in parallel while other elements happening in a more serial fashion. In addition, it is equally important to not make assumptions about the structure of visual information as it is stored or processed. There is no reason to believe that there is a direct, homologous relationship between the distal visualization (whether it be a physical three-dimensional object, printed graphic, or computer display) and the internally coded visual information (Scaife & Rogers, 1996). That is, that one's internal mental images, no matter how they might "look" like their corresponding real world objects, can be composed of information from multiple sources, including both real-time sensory streams and long-term memory traces of previous experiences. Ongoing cognitive and neuroscience research is continuing to unravel both the physiological and psychological basis for visual information processing and storage.

LEARNING WITH VISUALIZATIONS

If visualizations are going to be optimally deployed in instructional materials, their semiotic, perceptual, and cognitive characteristics and their relationship to textual elements need to be synthesized and operationalized. In the following sections, two issues will be addressed that are relevant to learning with visualizations. The first

section aims at specifying the conditions under which visualizations will contribute to learning. The second section addresses the role of learner characteristics in visualization research.

When Do Visualizations Aid Learning?

A main issue in designing instructional materials pertains to the questions of when and how to use visualizations for conveying knowledge in a particular domain. To find an answer to these questions, one has to ask what information is to be conveyed, what the users' physical and cognitive abilities, preferences, and intentions are, and what the communicative situation is where the instruction will be used (Maybury, 1995). In the following section, we will highlight the function a visualization may have for learning and whether this function is relevant to achieving a particular learning objective. Hence, visualizations are supposed to be effective for learning only if they fulfill functions relevant to achieving a particular learning objective. In the following, we will distinguish instructional functions that visualizations may have if presented as self-contained messages (i.e., regardless of verbal information) or if they accompany verbal explanations. We will end this section with a discussion on whether visualizations can aid learning even if they are redundant to other representations.

Instructional Functions of Visualizations as Self-Contained Messages

The design of the visualization, of course, has to take the instructional context into consideration. There are several instructional functions that visualizations may have—irrespective of whether they are accompanied by verbal explanations or not.

Affect. Visualizations are often said to be motivating for students, because they can make a subject matter more interesting and appealing to students. Moreover, they can trigger specific

emotions or lead to a change in learners' attitudes (Levie & Lentz, 1982). However, there is a danger that visualizations that do not convey any information relevant to the learning objective will distract learners (*cf.* seductive details effect, Harp & Mayer, 1998).

Replace and augment real-world experience. Visualizations as instructional materials can act as a substitute to direct experience by offering highly realistic impressions of real-world objects and events, which might otherwise be too small, too large, too fast, too far away, or too dangerous to observe in reality. In that respect, visualizations do not replace real-world experience, but they may even improve this experience by providing information that would not have been accessible in the real world (i.e., 'better than reality').

Visuo-spatial reasoning. As has been outlined in the section on differences between verbal and visual representations the latter provide direct and parsimonious access to visuo-spatial information and, in case of dynamic visualizations, temporal properties of objects and events (Larkin & Simon, 1987; Rieber, 1990; Tversky, Bauer Morrison, & Betrancourt, 2002). This visuo-spatial information can also be directly used for inferences and reasoning (Goldstone & Son, 2005; Schwartz, 1995). With verbal representations, the sequential information would not only require cognitively demanding processes of searching related information, but also it would need to be internally transformed into a form more appropriate for spatial reasoning. Thus, for visuo-spatial reasoning tasks visualizations are more computationally efficient and allow for cognitive offloading (Larkin & Simon, 1987; Scaife & Rogers, 1996). This function is important in that it does not limit a visualization's capabilities to act as a memory aid; rather, it suggests that reasoning based on visualizations is a way of extending the boundaries of cognition to external representations (Zhang, 1997). External visualizations enable cognitive operations that would otherwise have to be conducted internally (e.g., mental imagery)

and thereby require more cognitive effort (*cf.* supplantation, Salomon, 1979).

Instructional Functions of Visualizations as Text Adjuncts

Most often, visualizations are used in conjunction with verbal instructional materials rather than acting as self-contained messages. Analyzing the combination of text and pictures has a long tradition within semiotics and sociosemiotics (Eco, 1976; Kress & van Leeuwen, 1996), in interface design (Bernsen, 1994; Mullet & Sano, 1995) and in human–computer interaction (Maybury, 1995) and textlinguistics. The perspectives in these works differ; while some stress the differences between text and pictures with regard to their suitability for expressing specific information (Bernsen, 1994; Mullet & Sano 1995), others are more interested in the interplay between them. The latter perspective is also taken here in this section, where it is emphasized that when visualizations accompany text they have functions in addition to those mentioned before, because they interact with the verbal information in specific ways. The most prominent analysis of the instructional functions associated with such a use of visualizations as text-adjuncts in the education literature has been conducted by Levin, Anglin, and Carney (1987). In their review, the authors described five functions of visualizations as text adjuncts: decorative, representation, organization, interpretation, and transformation.

Visualizations with a *decoration function* are not related to the verbal information and are introduced only to make a text more appealing and interesting for learners. However, while they are supposed to motivate learners, the meta-analysis by Levin et al. (1987) actually revealed a negative effect of decorative visualizations (*cf.* seductive details effect, Harp & Mayer, 1998). Presenting irrelevant additional information may distract learners from processing the pivotal learning contents or it may trigger inappropriate schemas for encoding the relevant content.

Visualizations in their *representational function* depict objects and relations mentioned in a text in a way that the meaning of the text more accessible for learners by making a text more concrete. Visualizations with an *organization function* provide an organizational framework for a text (e.g., how-to-do-it diagrams) and thereby make the content more coherent by highlighting the argumentative or organizational structure of the text (Verdi, Kulhavy, Stock, Rittschof, & Johnson, 1996). According to Levin et al. (1987) this function refers to comprehensible texts, whereas the *interpretation function* of visualizations is to make texts understandable for learners that would otherwise be incomprehensible. Accordingly, these visualizations are often introduced in textbooks and multimedia instructions to clarify difficult-to-understand passages and abstract concepts within passages (e.g., pictorial analogies).

The rarest function that visualizations are used for pertains to the *transformation function*. Visualizations that follow this function are designed to improve memory performance directly “by targeting the critical information to be learned, and then (a) *recoding* it into a more concrete and memorable form, (b) *relating* in a well-organized content the separate pieces for that information and (c) providing the student with a systematic means of *retrieving* the critical information when later asked for it.” (Levin et al., 1987, p. 61). Visualizations with a transformation function showed the strongest positive effects on learning outcomes in the meta-analysis conducted by the authors.

It is important to note that Levin’s review is limited to prose learning, whereas most multimedia materials are concerned with a broader and deeper understanding that can be transferred to novel situations. It is thus questionable whether these recommendations can be simply applied to the design of multimedia materials. There is at least one recommendation where research seems to disagree: informational equivalence of verbal and visual representations. According to Levin et al. (1987), students who use redundant informa-

tion to acquire content knowledge benefit from visualizations if these show a large information overlap with the verbally presented information. In fact, the representational, organizational, and interpretational function of visualizations presuppose that text and picture are at least partially redundant. On the other hand, multimedia learning research, has suggested to not present redundant information to learners, because this may require additional cognitive resources for comparing and integrating the information, which are then no longer available for learning (redundancy effect; e.g., Bobis, Sweller, & Cooper, 1993).

There are at least three things that are usually ignored in this discussion in the literature on multimedia learning: First, a certain degree of overlap is necessary to allow for a coherent mental representation, where learners can draw connections between the two sources of information. Second, what is redundant information is often impossible to say. Even when deliberately trying to construct informationally equivalent (and thus fully redundant) representations, it is almost impossible to counteract the fact that visualizations often “unintentionally” convey more, albeit potentially irrelevant information than do verbal descriptions due to their higher specificity or completeness (Kosslyn, 1994; Stenning & Oberlander, 1994). Third, as has been emphasized by Ainsworth (1999, 2006) in her functional taxonomy of multiple external representations (MERs), even informationally equivalent representations may have different functional roles for learning and thus support knowledge acquisition differently. She categorizes these roles into three groups: First, visual and verbal representations may fulfill *complementary roles* in instruction by facilitating different cognitive processes, serving different learning objectives, or addressing the individual representational preferences of different learners. Second, they can *constrain interpretation* and guide learners’ reasoning about a domain. Third, visual and verbal representations together might be suited to foster a *deeper understanding* than could

be achieved by using just one representational format. Thus, whenever any of these functional roles can contribute to learning, representing redundant information visually as well as verbally may be advised according to Ainsworth’s taxonomy. On the other hand, if one of the representations does not contribute to learning on a functional level, it should be deleted from the instruction.

Hence, when designing multimedia materials special attention has to be paid to how to distribute information across text and graphic representations by maximizing the representations’ strengths and reducing their potential weaknesses for delivering specific information aspects. This pertains to the notion of Palmer (1978) that the represented world can be depicted in many different ways and the decision about which constitutes the most appropriate representation depends on the operations that need to be performed with it and the questions that should be answered with it.

The Role of Individual Learner Characteristics in Learning with Visualizations

In order to be effective for learning, visualizations need to be designed in a way that they can be “readily and accurately perceived and comprehended” (Tversky et al., 2002, p. 258). Moreover, the effectiveness of visualizations is affected by what the learner brings to the learning task as another crucial component of the instructional context. Visualization design needs to recognize that there is no homogenous response to graphic or textual representations and how they are, or are not, used in learning. Several learner characteristics have been suggested that may affect learning with visualizations. We will follow a suggestion by Mayer and Massa (2003), who tried to disentangle cognitive abilities, cognitive style, and learning preference along the visualizer-verbalizer dimension. These dimensions account for the fact that “some people are better at processing words and

some people are better at processing pictures” (Mayer & Massa, 2003, p. 833).

Cognitive Abilities

Cognitive abilities related to the processing of visualizations comprise a wide range of constructs that differ not only with regard to their specificity, but also with regard to their empirical foundations. Some constructs like pictorial competence or visual literacy are rather general, whereas the impact of visuo-spatial abilities clearly depends on the type of learning tasks students are confronted with. For the former constructs, to our knowledge, no straightforward measures exist to assess them other than by observing a person performing a task that either requires or does not require this specific ability. On the other hand, there have been many different attempts to assess visuo-spatial abilities, though their literature is still equivocal (see Carroll, 1993; Hegarty & Waller, 2005 for overviews). Thus, at the current moment it is unclear how the concepts are related to each other and how they contribute to learning with visualizations independently as well as in interaction with each other. For these reasons, we will refrain from providing a comprehensive overview and instead sketch some of concepts that are relevant in the current context. The general notion is that learners who lack the abilities to process visualizations will benefit from them to a lesser extent, demonstrated, for example, in a study of science textbook instruction by Hannus and Hyönä (1999).

Pictorial competence. DeLoache, Pierroutsakos, and Uttal (2003) discuss the ability to use pictures from a developmental psychology perspective. According to their view, pictorial competence encompasses “the many factors that are involved in perceiving, interpreting, understanding and using pictures, ranging from the straightforward perception and recognition of simple pictures to the most sophisticated understanding of the conventions and techniques of

highly complex ones” (DeLoache et al., 2003, p. 115). While basic elements of pictorial competence exist already in newborns, more complex skills are characterized by strong developmental shifts. In particular, the ability to understand the relationship between the representation and the referent; that is, to become symbol-minded, is clearly age-dependent (DeLoache, 1995). DeLoache’s research suggests that pictorial competence develops during the daily interactions with pictures and their real-world referents. However, it is unclear whether this kind of familiarity is sufficient to use pictures in academic contexts. According to Pozzer and Roth (2003), “most students are familiar with photographs in general; however, appropriate instructions for how to read and analyze photographs currently are not provided to them.” (p. 1092). While the concept of pictorial competency mostly refers to the interpretation of realistic visualizations, the term visual literacy denotes a more general ability of dealing with visual media of all types (e.g., video, graphics, diagrams, animation, etc.).

Visual literacy. According to Nöth (2003) this concept refers to the “the ability to decode the pictorial repertoire of the media without indexical or iconic support” (p. 186). Messaris (1994) calls it “the familiarity with visual conventions that a person acquires through cumulative exposure to visual media” (p. 3). The “visual literacy” model defined by Messaris (1994) specifies different levels of visual communication that range from simple understanding to aesthetic appreciation of visual media. Despite its popularity in discussions on computer-based instruction, there is no objective assessment tool that would allow measuring the visual literacy of students. While in reading research, illiteracy can be conceptualized as the lack of knowledge on the syntax, semantics, and pragmatics of language, there is nothing comparable in non-notational representational systems, where the interpretation of visualizations is often subjective and context-dependent. Because of this, it has also been suggested to refrain from using

the term literacy and replace it with graphicacy instead (Roth, Pozzer-Ardenghi, & Han, 2005) to get rid of the strong association between literacy and reading. The term literacy may however be adequate for logical pictures, where it can be defined as the knowledge of notational rules, allowing mapping visual features of a representation to an interpretation of the depicted part (Pinker, 1990; Shah & Hoeffner, 2002).

Domain-specific prior knowledge. There is increasing evidence that students' level of domain-specific prior knowledge moderates learning from visualizations. For instance, learners with a high level of prior knowledge are better able to direct their visual attention towards relevant information (Lowe, 2003) and are less affected by a high visual complexity of the display (Lee, Plass, & Homer, 2006). Both findings support the notion that extracting information from a visualization is both a bottom-up as well as a top-down process. In the latter case, existing mental representation guide the lower-level perceptual processes and the interpretation of information acquired through them.

Visuo-spatial abilities. According to Carroll (1993), visuo-spatial ability is not a unitary construct; rather, it comprises five different dimensions that all make up abilities in the perception of visual input: (1) Spatial visualization is "the ability to mentally rotate or fold objects in two or three dimensions and to imagine the changing of configurations of objects that would result from such manipulations" (Mayer & Sims, 1994, p. 392) without referring to one's self, (2) spatial orientation is the ability to imagine an object's appearance from different view points as the observer's body orientation changes, (3) closure speed is the ability to access representations quickly from long-term memory, (4) flexibility of closure, and (5) perceptual speed is involved in the processing of simple visual displays (e.g., quick scanning). Prior findings from other researchers have likewise established evidence for the first two dimensions (spatial visualization and orientation),

while they failed to find consistent evidence for the latter three (Hegarty & Waller, 2005).

Research on spatial visualization suggests that "high- and low-spatial abilities individuals differ in the quality of the spatial representations that they construct and their ability to maintain its quality after transforming the representations in different ways" (Hegarty & Waller, 2005, p. 141). Accordingly, spatial visualization differences have been successfully conceptualized against the background of differences in working memory resources (Shah & Miyake, 1996). The role of visuo-spatial abilities has mostly been investigated in mental animation, where learners have to infer the motion of a mechanical system from a static picture. Here it has been demonstrated that learners with high abilities perform better in this task than low-ability students (e.g., Hegarty & Sims, 1994). It seems very plausible to assume that visuo-spatial abilities will show a strong influence in other tasks involving learning with visualizations. For instance, Plass, Chun, Mayer, and Leutner (2003) demonstrated that either students with low verbal or spatial abilities showed worse performance in multimedia learning than their higher-ability counterparts when receiving visual annotations, whereas abilities played no role when students were given verbal annotations.

Cognitive Styles: Visualizers versus Verbalizers

"A cognitive style is a psychological dimension that represents consistencies in how an individual acquires and processes information" (Kozhevnikov, Kosslyn, & Shepard, 2005, p. 710). The visualizer-verbalizer dimension (Richardson, 1977) characterizes students as verbalizers, if they rely on verbal-analytical strategies when performing a task, whereas visualizers use imagery as a predominant strategy of task accomplishment. Kozhevnikov, Hegarty and Mayer (2002) revised the visualizer-verbalizer dimension and suggest a more fine-grained distinction between spatial and

iconic visualizers (object visualizers according to Kozhevnikov et al., 2005). In a problem-solving task, they collected evidence for these two types of visualizers. Spatial visualizers, in a schematic interpretation, focused on the location of objects and on spatial relations between objects. This group also used “imagery to represent and transform spatial relations” (Kozhevnikov et al., 2005, p. 722), where images were processed analytically to infer their spatial interrelations. Iconic visualizers, on the other hand, in a pictorial interpretation, focused on vivid visual details like shape, size, colour and brightness, thereby processing these objects as a single perceptual unit. Interestingly, this distinction between the two groups fits nicely with research that focuses on dissociating the ways in which visual information is processed. This work shows that there are brain areas that either focus on processing shape and color information to determine an object’s identity (what-system) or on processing spatial and dynamic input (where-system). Moreover, current theories of visuo-spatial working memory (Logie, 1995) make a similar distinction by relating the function of the inner scribe – as one component of visuo-spatial working memory – to the processing of spatial and movement information, whereas the other part is responsible for the processing of color and shape information (i.e., the visual cache). At this moment, however, it is highly speculative if the cognitive styles identified by Kozhevnikov et al. (2002; 2005) could be linked to a different use of these brain areas or working memory systems.

Preferences for Visual versus Verbal Information

Leutner and Plass (1998) developed a method to assess preferences for verbal or visual materials by analyzing the students’ information-selection behavior. The VV-BOS (Visualizer/Verbalizer Choice Behavior Observation Scale) showed very promising psychometric properties as well as a superior validity with regard to the differ-

ential prediction of learning outcomes. Plass, Chun, Mayer, and Leutner (1998) demonstrated that students with visual preferences as assessed by the VV-BOS benefited predominantly from visual annotations, whereas students with verbal preferences gained most from verbal annotations.

Taken together, there is evidence that suggests that when investigating learning with visualizations, the students’ individual differences in terms of cognitive abilities, cognitive styles, and learning preferences need to be considered. With the current state of research, it is impossible to tell their relative influence and direction, but first studies show promising results in this respect.

CONCLUSION

When developing multimedia materials, instructional designers are faced with a multitude of decisions as to which contents should be part of the instruction, which representational format to use for these contents, and how to design these contents. For improving multimedia instructions, two conclusions can be drawn from the current paper.

First, one needs to clearly understand the learning task and relevant individual differences of the learner. From this, the relative strengths and weaknesses of different representational formats can be considered and information visually encoded in accordance with the results of this analysis. Visualizations should be used whenever their instructional functions are assumed to add considerably to the effectiveness of the multimedia instruction.

Second, the use of visualizations often seems to suffer from the *resemblance fallacy* (Scaife & Rogers, 1996). While it is seductive to assume that mental imagery and distal visualizations are homologous and that processing these visualizations only involve low level perceptual processing innate to all humans, this is a grave error in instructional strategy. While perceptual processes are naturally

involved in learning from visualizations, only seldom are the visualizations supposed to be taken literally. Rather, they have to be taken as representations standing for something else than what is being depicted. Identifying what is being represented based on the structural correspondences (rather than physical similarity) may cause severe difficulties for learners when studying visualizations. Thus, it should not be taken for granted that learners will extract the information from a visualization that was intended by an instructor. Rather, students need to be supported in extracting the relevant information from the visualization and guided as to how to best deploy their limited perceptual and cognitive resources. This support can be provided either by guiding learners' attention towards its relevant aspects (e.g., highlighting) or by improving students' competencies in dealing with visualizations. The latter comprises teaching to students existing conventions underlying these (logical) visualizations (e.g., how to read a graph, Pinker, 1990) or training them in developing graphacy (Roth et al., 2005).

FUTURE DIRECTIONS

The final section of this paper is devoted to future directions in research on learning from visualizations. In particular, we wish to emphasize that more in-depth analyses are needed that shed light on the process of perceiving and interpreting instructional visualizations and on the visualization's impact on performance in a variety of tasks. We believe that respective analyses would benefit from an interdisciplinary perspective, where insights from different areas (e.g., cognitive science, education, semiotics, visual perception, human-computer-interaction, human factors) could be united.

Integrating models of visual perception and cognition. Most researchers argue for visualization's instructional effectiveness by referring to its relative ability to support higher-level cognitive

processes. Accordingly, pictorial representations may support a dual coding of the information (Paivio, 1991), the construction of a mental model (e.g., Mayer, 2005), or cognitive offloading (Scaife & Rogers, 1996). These approaches pay considerably less attention to perceptual processes, thereby ignoring that these processes need to take place before higher-level cognitive processes can act upon the information that has been attended to. As a consequence, the vast literature on visual perception is largely neglected in the educational literature, even though it may provide important and novel insights into the design of effective visualizations (e.g., MacEachren, 1995). According to Anglin et al. (2004), "theory-based studies that are informed by both memory research and theories of picture perception are lacking" (p. 876).

Taxonomy research. Currently, visualizations are mostly treated as a unitary construct without taking into account the differences among them. These differences may pertain to their appearance, content, or instructional functions. Future research should attempt to develop taxonomies that will allow classifying visualizations according to these different dimensions. There have been morphological approaches that classify visualizations according to their appearance (e.g., Lohse, Biolsi, Walker, & Rueter, 1994; Twyman, 1985) however, we do not think that these taxonomies will help explaining much of the variance with regard to the instructional effectiveness of visualizations. Rather, content-oriented classifications (Bieger & Glock, 1984) or more systematic approaches to instructional functions like the one by Levin et al. (1987) seem to be more promising in this respect. The availability of such taxonomies would allow greater generalization of findings across studies than what is currently possible.

Analyzing processes and learning outcomes in parallel. While there are some theoretical assumptions on how pictorial representations are processed, most of the existing studies have refrained from empirically investigating these pro-

cesses. Knowledge on how students use pictorial representations is, however, not only necessary for theory development, it is also relevant for practical reasons. For instance, for logical pictures it is often not clear whether these representations sometimes fail to improve learning because they are designed in a bad way or because students did not understand the underlying conventions. Process-oriented data may allow identifying possible misconceptions students have regarding the meaning of the visualizations and assist in developing effective teaching strategies for using them. Despite these promises of analyzing the processes of learning from visualizations, most of the studies until now have only looked at learning outcomes in isolation. Some noteworthy exceptions to this situation come from research that has applied eye tracking methodologies (e.g., Cook, Carter, & Wiebe, 2008; Lowe, 1999). This methodology provides information on the temporal and spatial resolution of visual attention by tracking the location of the eye as a person watches a visual display. It thus offers a good starting point to analyze perceptual and possibly cognitive processes when learning with visualizations. In particular, its combination with think aloud data has been shown to be very informative (van Gog, Paas, & van Merriënboer, 2005). Hence, we suggest combining the predominant outcome-oriented research strategy with a more process-oriented strategy (*cf.* Peeck, 1987).

Assessment of learning outcomes. Despite the fact that core information is often conveyed by means of visualizations in multimedia instruction, most test items are presented in words only. Moreover, in class students are typically required to provide their answers verbally. Thus, most ways of assessing what has been learned from a visualization potentially requires multiple recodings of this information by the learner to accomplish a task. In particular, non-sequential information needs to be transformed into a sequential format to provide a verbal answer (speaker's linearization problem; Levelt, 1981). Moreover, according to the verbal

overshadowing effect (Melcher & Schooler, 1996) it may well be that asking learners to provide verbal answers when assessing their learning outcomes may interfere with the "visual" knowledge stored in memory and make this information less accessible. Hence, verbal tests may inadequately reflect students' acquired knowledge. Moreover, interactions between the instructional format and the learning objective should be considered more thoroughly in future research. A larger variety of test formats might be more apt to account for the complexities underlying learning with visualizations. Accordingly, Joseph and Dwyer (1984) found positive effects for illustrated text compared to text-only versions only in a drawing test, but not in a comprehension test, suggesting that the type of test moderates the effectiveness of instruction. Furthermore, Levie and Lentz (1982) showed in their review on learning with visualizations that visualizations improved recall more in delayed tests than in immediate tests. It might be that the advantages of visualizations relate to dual coding in memory and creating more associations to other long term memory content—a pay off only seen in situations that impose higher demands on memory and understanding.

Chapter 7.11

Teaching Social Skills: Integrating an Online Learning System into Traditional Curriculum

Graham Bodie

Purdue University, USA

Margaret Fitch-Hauser

Auburn University, USA

William Powers

Texas Christian University, USA

ABSTRACT

The ubiquity of instructional technology necessitates a more critical look at the theories that drive adoption and the practical implications of its usage. Blended learning has been offered as one compromise to fully online learning or strict adherence to traditional lecture-based instruction that seems outdated. A particular approach to blended learning is examined in the present chapter through the use of an online learning system. Concept Keys was developed to assist instructors of social skills in breaking down these abstract concepts into manageable units of information appropriate for daily delivery via e-mail. This program is shown to be easily integrated into existing curriculum through two studies. A

concluding section attempts to tie these studies together and suggests potential limitations and avenues for future research.

CHAPTER OBJECTIVES

The reader will be able to:

- Understand the pedagogical goals driving the development of Concept Keys (CK)
- Understand the key elements of the CK system
- Identify two specific ways in which CK can aid in the teaching of specific social skills
- Determine the usefulness of the CK approach to his or her pedagogical needs

DOI: 10.4018/978-1-60960-503-2.ch711

INTRODUCTION

Institutions of higher education continue to face challenges posed by online education and the ubiquitous nature of technology in the classroom. The concept of blended learning—the use of two or more complementary approaches when teaching the same material—has seen heightened attention in literature in the past decade and offers a unique approach to merging the availability of technology with traditional and tested pedagogical approaches. Examples of blended learning include using textbook supplements, peer-to-peer learning, and/or online modules while maintaining aspects of a more traditional, lecture-style format. The purpose of the present chapter is to outline the development, implementation, and effectiveness of one online learning system, Concept Keys (CK), that takes a blended learning approach to teaching social skills (see also Bodie, Powers, & Fitch-Hauser, 2006; Powers, Bodie, & Fitch-Hauser, 2005). In service of these aims, a brief background is offered that situates CK into the larger category of e-learning and examines its core components. Then, two studies are used to illustrate how the system is easily integrated into an existing curriculum and can be custom fit to address specific pedagogical goals. Finally, a concluding section ties these two studies together and offers insights for future research and exploration using the CK system.

BACKGROUND: E-LEARNING, SOCIAL SKILLS, AND CONCEPT KEYS

E-learning can refer to a wide range of online learning protocol. Systems can be created that allow individuals to self-manage their learning or that blend online and face-to-face instruction to greater or lesser degrees. Datamonitor (2004, July 14) predicts the global e-learning market for higher education to grow at a rate of

12% between 2004 and 2008. This growth has necessitated a more critical look at the theories that drive technology adoption and the practical implications of instructional technology usage. Intuitively, technology should not be utilized for its own sake; instead usage should be grounded in specific goals and objectives (see Moore, 2005). This translates to practical considerations of which types, how, and how often specific technologies will be used and in what combinations. Backing such claims, research suggests that, when grounded in pedagogical goals and objectives, technology has the potential to enhance learning outcomes (e.g., Dean, Stahl, Sylwester, & Pear, 2001; DeLacey & Leonard, 2002; Rainbow & Sadler-Smith, 2003). Conversely, using technology can impede the learning process if used poorly (Derntl & Motschnig-Pitrik, 2005; Sellnow, Child, & Ahlfeldt, 2005). Still other studies have found that students have certain expectations of instructor use of technology prior to the first day of class; violating these expectations can have deleterious effects on student learning (e.g., Witt & Schrod, 2006).

Thus, it follows that instructors who teach social skills—communication-related skills such as listening and critical thinking (Leigh, Lee, & Lindquist, 1999)—are likely to benefit from the use of online learning systems; however, the adoption of a given system should be guided by specific curricular goals. Concept Keys (CK) is an online, empty engine approach that allows instructors who teach what are generally categorized as social skills the opportunity to offer students a blended learning approach to obtaining these skills. In other words, CK enables the educator an opportunity to define social skills as broadly or narrowly as needed for a particular application (e.g., how to communicate effectively or how to give meaningful presentations). The system can accommodate educators interested in, for instance, enhancing sales-related communication skills as well as educators interested in teaching engineers how to present complex material or medical

students how to be more patient-centered. Most importantly, the system is customizable based on pedagogical goals and objectives.

The Concept Keys Approach to Blended Learning

The CK system is a focused approach to classroom interaction grounded in educational theory (i.e., chunking, priming, and active learning) that blends Web-based education with face-to-face instructor direction and support. Concept Keys provides students with small bits of information over a long period of time culminating in an integrated store of knowledge about a set of skills and how to perform these skills in specified contexts. Along with daily commentary, or fundamental keys, this method has students rate these keys according to personal relevance. Additional classroom activities are also available, which add to the student-teacher interaction and

increase the chances of information retention and skill acquisition (see Table 1 for a brief overview of program elements). Defining some key terminology within the system will aid in describing its basic components. Once key terms are explained, the CK process will be outlined.

Keys

Keys are very brief statements reflecting small bits of information that make up some larger concept (hence, Concept Keys). This system is based on the notion that the best way to teach complex material is to break it into small, manageable units or bits of information that are systematically delivered over an extended timeframe. This organizational framework mirrors textbook and lecture organization in which students are taught steps, guidelines, and strategies that aid in the successful implementation of a competency (e.g., how to deliver bad news). As noted by Bodie et al.

Table 1. Concept keys online learning system components: Traditional integration options

Each Student in a Concept Keys Certification Achievement Program receives:
• 1 Personal CK website account
• 2 Certification Examination attempts at program conclusion
• 50 Daily “Gentle Reminder” emails
• 50 Daily Keys
• 50 Daily Micro-lessons; each micro-lesson has four paragraphs
• 50 Daily Food For Thought Segments (four questions and responses)
• 10 Weekly quizzes over previous 5 Keys
• 10 Weekly self-selections of the Most Important Key
• 10 Weekly self-determinations of what to do about the Most Important Key
• 70+ Days of availability to download all personal program material
• 70+ Days of Engagement Index Metric (degree of participation in the program)
• 700+ Cognitive engagements in learning and improvement activities
Each Teacher (or designate) in a Certification Achievement Program will receive the following:
• A free copy of the <i>Student Learning Instructor’s Manual</i>
• Daily access to all student’s program activity
• Daily opportunity to obtain detailed metrics for documentation, assessment, and accountability
• Daily option to download metric data for group comparative purposes
• Daily opportunity to provide immediate feedback to students regarding their progress

(2006), “information is more easily remembered (Cowan, Chen, & Rouder, 2004; Miller, 1956) and strategic choices more easily made (Gobet & Simon, 1996, 1998) if small bits of information are built into larger stores or chunks of information that can be recalled in necessary situations” (p. 121).

For example, if you were trying to teach a group of students how to deliver an effective presentation you might start with the necessity of audience analysis followed by appropriate topic selection, writing general and specific purposes and thesis statements, and so forth. These smaller components, if segmented even more, might result in the generation of hundreds or thousands of keys to successful presentational speaking (the concept). One such key might be “Walk a Mile in the Audience’s Shoes.” This key should elicit thoughts concerning the importance of audience characteristics and/or experiences that might differ from one’s own.

Micro-Lessons

A micro-lesson is an extension of the key whereby specific elements of the short statement (e.g., Walk a Mile in the Audience’s Shoes) are elaborated upon. Specifically, each micro-lesson contains 3 elements: the key, three to four bullet points expanding upon the core components of the key, and food-for-thought (FFT) questions (see Figure 1). The paragraphs that follow the key are a combination of explanation and motivation.

Explanation refers to bullet points with the main purpose of explaining what the key means in ordinary language. In the example presented in Figure 1, the first three bullet points explain that “Walking a Mile in the Audience’s Shoes” refers to taking the audience’s perspective into consideration during the speech preparation and presentation process. They also provide specific examples of how to do this (e.g., use words and concepts the audience knows and is concerned

about) in order to give students practical examples of recommended behavior. Motivation refers to the bullet points designed to include both the appropriate behaviors and an example of at least one situation in which the set of behaviors should be used. As seen in Figure 1, each bullet point attempts to provide motivation to utilize the key by suggesting positive outcomes of key use (e.g., increased audience interest) and ramifications for non-use (e.g., not achieving goals, audience not attentive).

In sum, this explanation-motivation sequence provides examples of what can happen when the key is used successfully and the possible negative consequences when the key is misused or not used. These examples are written to resonate with students insofar as they are likely to recall at least one instance in which miscommunication occurred in this particular context; the assumption is that students will connect the mishap with misuse of communication processes thus motivating behavior change. Such suggestions are also likely found in textbook treatments of public speaking; by presenting material in multiple ways and through multiple channels, likelihood of retention is increased (see Bodie et al., 2006).

Each micro-lesson also contains four FFT questions that act to encourage the learner to make a decision about how to increase his or her use of that day’s key. Those questions are also presented in Figure 1. Questions build upon each other allowing the student to reflect on the present use of the key and how this aspect of the social phenomenon might be improved. The final question, especially, places the responsibility for learning on the student.

The Process

Once a student is signed up for a CK program, he or she goes to the CK Website, creates a unique username and password, and submits a working e-mail address.² This e-mail address is used to

Figure 1. An example of a CK micro-lesson

Concept Keys -- Unlocking Knowledge, One Key at a Time
Effective Presentational Speaking
Key #1: Walk a Mile in the Audience's Shoes.

- ☐ Your audience will be better able to comprehend and understand your topic if they are able to relate it to their unique lives and experiences. So to have the attention of your audience, approach your topic from the audience's perspective, not your own. This will assist you in bridging the gap between you and your audience, making your presentation more effective.
- ☐ The audience will trust you more if you show that you can relate to them. This includes using words and concepts the audience knows and is concerned about. This breeds interest and an interested audience will allow for a better presentation.
- ☐ Make sure to incorporate ways in which your audience can benefit from the topic of your presentation. Explain to them how they would benefit if the problem you're addressing in your presentation could benefit them in some way. The audience will have a better understanding of your presentation if it involves something they are concerned about.
- ☐ A presentation that an audience views as not related to them will not succeed in winning attention or achieving its goals. Use words and concepts that your audience will perceive as effective yet understandable and you'll have no choice but to succeed.

Food For Thought!
Now you want to make a decision about how to increase your use of this Key. Answering the following questions should point you in the right direction. Be sure to click on the Finish button below once you have answered all the questions.

1) How would you evaluate your use of this Key in your current work environment?

- A) Not Effective
- B) Slightly Effective
- C) Moderately Effective
- D) Very Effective
- E) Extremely Effective

2) To what extent would increasing your effective use of this Key help you achieve your short-term or your long-term goals?

- A) Not Helpful
- B) Slightly Helpful
- C) Moderately Helpful
- D) Strongly Helpful
- E) Extremely Helpful

3) To what extent do you plan to develop your ability to effectively use this Key?

- A) Not a Priority
- B) Slight Priority
- C) Moderate Priority

send the student daily reminders that a particular key is ready to be viewed (see Figure 2). Once the student clicks on the Web address located in the e-mail, he or she is sent to the login page. Once logged in, the student will be able to access the daily micro-lesson and answer daily FFT questions; past micro-lessons, quizzes, and so forth, not yet completed are also made available.

Summary

CK allows abstract and complex social skills that are otherwise ambiguous, vague, and/or vast in scope to be presented in manageable and meaningful units of information that can be tailored to course goals and individual learners. This information is presented to the learner though daily

Figure 2. An example of a daily reminder e-mail

Greetings, John!

This is your daily reminder that a key is ready for you to read! Today's key is:

Key #1: Take personal responsibility for quality communication!
<http://www.conceptkeys.com/program.php?keyId=1&progId=99>

If the above URL is 'clickable', simply click it to go to the key. You might need to log into your account as well. If you do need to log in, you will be directed to your participant page immediately upon successful log in where you will find the above key in your 'To Do List'.

If the URL is *not* clickable, simply copy and paste it into your web browser.

In addition, the following item has not yet been completed:

Key #1: Food for Thought Questions
<http://www.conceptkeys.com/program.php?progId=99&keyId=1&fft=1>

If you have any questions, comments, or suggestions, please feel free to reply to this message and one of our customer support agents will respond to you shortly.

Sincerely,
 Dr. Will Powers
 CEO Concept Keys, Inc.

micro-lessons over a predetermined period of time. Each micro-lesson consists of (a) the daily key, (b) the cognitive and behavioral components of that key, and (c) "food for thought" questions. CK achieves the objective of breaking down a complex concept like presentational speaking into manageable units of information for increased retention as well as increases the amount of time the student is likely to remain engaged with course material (small bits of information are delivered daily). This is enabled by the empty engine capabilities of the system—individual lessons can be customized as broadly or narrowly as desired. Components of this system, such as FFT questions and motivation-based behavioral examples, aid in student engagement and a sequentially-based learning approach that has been shown to be effective in several classrooms. The next section explores two such applications of the system.

CURRICULUM INTEGRATION

Concept Keys has been successfully implemented in several classrooms at three different universities. Initially, the system was built to provide instructors with 10-week programs that cover a wide variety of areas relevant to social skills. This has been the most widely used component of the system. Study One addresses this traditional integration. In this model teachers serve as *learning system coordinator* to students who are assigned, as one component of a larger class, one of eight e-books each with 50 micro-lessons. Typically, the teacher assigns CK as a supplemental text in a class that is largely focused on some large area of social interaction (e.g., business communication, listening). There are many options available to the teacher, some more appropriate in one level of learning than another (e.g., College students relate to some learning activities differently than would Junior High School students). A complete

Table 2. Two example activities for use with CK modules

Personal Improvement Plan Development Once students identify a particular Key as having some level of special value for themselves as they look at their relationships and career aspirations, the first learning element has to be to get that Key into long-term memory. Thus, the emphasis in so many activities upon repetition leading to enhanced memory. But, memory without use is of value only at some future time—and then, the actual skill may not be as practiced or smooth as one would desire. So, at the same time that memory is being developed, we may wish to ask the students to develop a plan that each student believes will lead to their personal improvement with specific Keys. You could review the plan and have the student implement the final improvement plan and report their progress after a specified time period. You could have Buddies or Teammates select a Key, develop a two-week personal improvement plan for each other, negotiate the plan to each person's satisfaction (you would want to review all plans to assure appropriateness), implement the plan, and have each partner report the progress of the other person. The number of times you use this activity is optional. You could have students develop such a plan for the Most Important Key each week, thus producing 10 personal improvement plans. Or, you could use this activity on the basis of the Most Important Key each 25 Keys leading to two personal improvement plans. Communication Cartoon of the Week Newspapers, magazines and books are filled with cartoons that often have direct relationship to communication or to specific Tips. Students can clip these out and post them on bulletin boards or include them in the newsletter, along with how they relate to Concept Keys content. Or, Teams can present them in class along with their rationale. The best (or most relevant cartoon) can be identified by a vote, and the person/team contributing the cartoon can be recognized. These cartoons can be collected and saved in a photo album with the related Key itself and used later as a resource. A unique twist to this idea could be having a cartoon posted in a central place and having other students figure out which Key(s) it applies to and why. The group or student with the most relevant Keys and explanations can be rewarded. Also, a cartoon can be displayed without the caption, allowing students to write their own caption. Using cartoons allows a humorous look at how things can sometimes occur and also foster some learning.
--

Instructor Manual detailing multiple options is available on the CK Website (see Table 2 for a sample of activities).

Thus, in study one we discuss the ways in which online material was blended into the classroom experience through particular assignments in one classroom; however, it should be noted that this is merely an example of traditional integration (for additional case studies see Bodie et al., 2006; Cook & Powers, in press; Powers et al., 2005). Although the class was small, the results from the study are useful in illustrating points about CK as well as elements of the system that seem to work as they were theoretically grounded.

More recently, the system has been modified to allow students or instructors to author e-books of varying lengths, thus taking full advantage of the empty engine application. Study two describes a student authorship approach that was recently incorporated into an introductory interpersonal communication course. This class was largely focused on theories and approaches to the study of interpersonal communication; therefore, the CK

program was used as a supplement to provide a focus on basic communication skills that students often do not receive when taking such a class. The particular course represented in study two is required or offered as an elective for a wide range of student majors. Since this class is taught in multiple sections each semester, it is necessary to streamline material and textbooks as much as possible. CK offered a non-intrusive supplement that allowed one section to receive CK materials and still be exposed to the same concepts and theories as the other sections of the course. In other words, this context allows for exploring and illustrating a second specific case of integration made possible by the CK learning system.³

Study One: Traditional Integration

The first study looks at the traditional use of a CK e-book and subsequent exercises that are integrated into the requirements of a semester-long course on listening. Eleven students enrolled in a five-week mini-mester at a large southeastern

university during the summer of 2006 subscribed to the *Listening Effectively* e-book which consists of 50 micro-lessons and ten retention quizzes—each quiz tests the retention of five keys. Time constraints of a five-week course altered normal key distribution. Instead of receiving one key per day for 10 weeks, students received three keys each day for three-and-a-half weeks. On day 17, students received the final two keys. Students received retention quizzes at the end of every five keys. These quizzes motivate students to remember each key and to think about the key they find to be most meaningful out of each set by having each student establish his or her most important key (this culminates in each student having ten most important keys with a rationale of why this key is the most important to his or her unique situation). To further motivate students to remember the keys, students were encouraged to take a certification exam at the end of the term that tested overall retention and understanding. Students who correctly answer the questions at a 90% or better accuracy rate are certified at the highest level; those who score in the 80% range receive regular certification. Each student had two opportunities to take the certification test. All 11 students received certification. Two additional assignments designed to integrate the keys into the fabric of the class were used as pedagogical tools.

CK-Related Assignments

The first assignment was used to increase student engagement in classroom discussion by enhancing active learning. This group project had students get into pairs (there was one triad) and write a skit that illustrated two keys which both students agreed were important for social interaction. In addition to writing the skit, the groups had to perform it in front of the class. To increase the number of keys covered, groups were told no keys could be repeated in the class; 10 of the 50 keys to effective listening were represented by this activity.⁴ This activity provides a fun, but challenging op-

portunity for the students to translate the key into an active skill. For example, one skit illustrated the key “stop talking” by featuring an individual missing important instructions for a task because she continued to talk over her supervisor. The skit clearly demonstrated what the key means in a life-like situation and illustrated the importance of the skill. The clarity and creativity of the skits provided useful measures of how students interpreted and integrated the keys into their way of thinking about potential listening situations.

The second assignment required students to turn in, on a weekly basis, a two-page essay focused on how they had incorporated their two favorite keys (out of the previous nine) in their daily lives. The exercise was designed to keep students engaged in the program and provided one more means of getting them to think about the importance of the particular skill or suggestion. By getting them to focus specifically on how they were using a particular key, the students found they either already used a skill or explored how a new approach (as suggested by the key) could help them manage a situation more effectively.

At the end of the semester, the instructor asked volunteers to return copies of their individual CK reports for use in writing the present manuscript. A total of 15 out of a possible 55 reports were returned representing nine out of the 11 enrolled students. Most students returned their last one or two reports. A theme analysis was conducted on the returned essays to determine whether or not they truly integrated the keys into everyday thinking. To show integration, the report should not only discuss the meaningfulness of the key itself, but it should also clearly relate the key to some area of the student’s life. Common themes across essays included relating keys to personal experience, relating keys to relevant prior coursework, and applying the keys. Table 3 provides relevant excerpts for each theme.

Several essays were representative of students focusing on the impact certain keys have on their unique lives and personal experiences when en-

Table 3. Study one: Essay excerpts

<i>Relating Keys to Personal Experience.</i>	
Key(s)	Excerpt
"Take the Time to Respond"	Instead of hollering at one another, [my parents] took their time and came up with a good calm response. This is probably why they have been married so long. So I am going to try to emulate them in my listening behavior and always take my time to respond. From doing so, I can avoid situations where I say something I regret.
"Control Your Feelings About the Task" "Listen with Optimism"	...when it comes to doing certain things [at work], I tend to have a pessimistic attitude. Sometimes, I haven't heard the complete details of the task but I tend to block out the rest of the information being delivered to me. I catch myself doing this at work ... when someone has an idea that I don't particularly like, I tend to focus on how it will not work as opposed to making the idea more effective. ... I think it's important to listen with optimism because if you don't, you may miss details that could lead to mistakes that will be hard to fix. I realize that this pessimism will not get me far, especially when I get a real job and will probably have to work with a group of people for a common goal. I have found that listening with optimism is also a great way to improve relationships among coworkers. . .
<i>Relating Keys to relevant prior course work.</i>	
Key(s)	Excerpt
"Be Aware of Nonverbal Messages while Listening"	Concept Key 48 is something I studied during the last mini-semester in nonverbal communication, Oculistics, or eye behavior, is one of the most important nonverbal behaviors to observe. Deception can be very easily detected by eye behavior. If the speaker avoids eye contact or has trouble maintaining eye contact it could be a sign that the truth is not being told. Kinesics or body language is very important for the listener as well as the speaker.
<i>Applying the Keys</i>	
Key(s)	Excerpt
"Reduce Distractions when Listening,"	I attend a devotional each week ... After the devotional is over, we use the time together to catch up with friends and meet new people. The problem is we are still gathered in a large room with several people. There are a lot of conversations going on.... This is where I have been trying to practice this skill. I have found communication more successful when I try to block out all the noise and everything going on around me.

gaged in interaction with others or when observing good and poor examples of listening behaviors. By personalizing the keys, students took the abstract skill of listening and its component parts, as presented by relevant micro-lessons, and added concrete and applicable dimensions to it. That is, rather than simply drawing general conclusions and applications, which may be equally accomplished by reading a chapter in a textbook, students focused on the actual use or observation of the key and the resulting impact. By ending with a listening lesson, they showed their ability to generalize from their own experience and integrate the concept into their daily behaviors.

Another focus in some reports was to write about how the keys fit with concepts learned in previous communication classes. This provides

support for the notion that chunking helps increase one's knowledge base by allowing individuals to layer relevant information into proper mental category or schema. A core assumption of the CK system is that micro-lessons operate most effectively when students are not only able to relate to presented material but are also able to build mental stores of core concepts that can be recalled when certain aspects of the environment prime relevant information from long-term memory (see Bodie et al., 2006). The more students are able to do this, the more effective learning from such a system should be. This blending and combining of small bits of information is also facilitated by the way in which current e-books are constructed and how authors are encouraged to write new material.

First, programs have been designed to include micro-lessons that are repetitive and cross over potential applications. For instance, the keys “Control Your Feelings about the Task” and “Listen with Optimism” share common aspects (this is also evident in the bullet points following the keys). Thus, the student who wrote about both keys in the same report also illustrated how students are relating previously learned information within the program to build larger stores (chunking) about the core concept (i.e., effective listening). Second, the micro-lessons are designed to reflect an explanation-motivation sequence which should resonate with students. This resonance should call forth life experiences from long-term memory (as illustrated by students who related keys to personal experiences) and further the chunking process.

A final way student’s showed how thoughtful they were about the keys was experimenting with and practicing their application. The segment of one report presented in Table 3 clearly shows the student has used the key and has noticed an appreciable difference in his ability to listen. This application of course material is often what is sought as we teach social skills. The fact that student essays were illustrative of this goal is encouraging.

Discussion

While these results are only anecdotal, they do suggest that CK can be integrated into a traditional course with positive results. By providing students with the opportunity to link basic concepts and elements of a skill to their own lives in small, regular increments, educators can help students incorporate important skills into daily practice. As discussed previously, students related keys to their personal experiences and prior coursework, and experimented with keys to improve their listening ability.

These themes are also useful to illustrate the pedagogical goals to which a “traditional integration” is suited. One of the most important goals

of the original CK system is to assist education in teaching basic social skills. Unfortunately, students not only place barriers to learning these skills, but by the time students get to college many of their inappropriate communication behaviors are ingrained. To “unlearn bad habits” and to simplify the presentation of large amounts of information, CK presents students with small bits of information on a daily basis that takes approximately five minutes to complete. Even this short amount of time can produce considerable reflection, sparked by FFT questions and application. This positive finding suggests that more extensive and statistically reliable research needs to be done in the future on the impact of this type of instructional tool.

Likewise, a five-week mini-mester places constraints on the ability for the system to be implemented as intended. However, it should be noted that results from the present case study do not deviate from those presented elsewhere (Bodie et al., 2006; Powers, Bodie, & Fitch-Hauser, 2006). It would also have been useful to obtain pre- and post-test measures from students related to listening habits and biases to assess change over time. Two reasons are offered for why these data were not collected. First, the small number of students limits statistical power needed to detect even large effects. Second, the length of the course places into question the amount of absolute change that is likely. The results of study two offer some appeasement to such concerns. It is to that integration method we now turn.

Study Two: Student Authorship Project

In the spring semester of 2006, 20 students enrolled in an upper-level interpersonal communication course at a large mid-western university took part in a group project that involved researching and authoring a skills training program, as well as acting as participants for a similar program authored by classmates. Specifically, students

self-selected five-person groups then chose a general skill set on which to focus: intercultural communication competence, effective public speaking, effective parent-child communication, and effective employment interviewing. Students were responsible for two main tasks. First, groups developed a three-week CK program to enhance the skills of their chosen competency. Second, students were randomly assigned to take one of the four three-week programs near the end of the semester; the program ended one week before the final day of class and was scheduled to run Wednesday through Sunday with Monday and Tuesday as “off days.”⁵

A series of smaller steps was employed to better facilitate the project. After students formed groups, they were required to turn in an initial bibliography consisting of journal articles, book chapters, books, and other sources. After this bibliography was approved by the instructor, the students developed a list of 50 keys to their chosen competency. These 50 keys were refined and reduced to 15 and approved by the instructor. It was at this point that the groups began work on their series of micro-lessons. Five different micro-lessons were due at three different points in the semester. After all micro-lessons received final approval by the course instructor, the instructor put them into the CK template and randomly assigned individuals to take a program that they did not create. Students were graded on the quality of their authored programs as well as their participation in the three-week program as participants. In all, this project counted for 40% of the total course grade.

Several different measurement instruments were employed to test the effectiveness of the different project stages. A series of self-report scales were employed after the completion of this class project to assess different learning-related outcomes. In addition, a pre-post design (week three and week 16) was used to test knowledge relevant to the four competencies represented in the CK programs.

Self-Report Learning and Knowledge Outcomes

Concept Keys Assessment Instrument

To assess student perceptions of the utility of the CK program a 21-item scale was implemented (see Table 4 for all items). The scale is a modified version of the ART-Q (MacGeorge et al., in press) and asks students to report on their experience using the CK system without regard to any other element of the course, the group to which they were assigned, or other elements of the classroom. The scale was originally intended to measure seven areas relevant to the CK experience: time, interest (in the course), motivation, self-perceived learning, ease of use, fun, and liking. When submitted to a principle components factor analysis with Varimax rotation, a two factor solution that explained 57.6% of the item variance was found. These two factors were interpreted as CK enjoyment ($\alpha = .922$), how much the students enjoyed using the system, and CK knowledge ($\alpha = .871$), how much the students reported learning as a result of using the system (see Table 4 for items corresponding to these components).

Self-Reported Improvement

To assess student perceptions of learning several items were written that asked respondents to “refer to how much you think you learned as a result of the Concept Keys system.” A principle components factor analysis with Varimax rotation indicated a three factor solution that explained 77.8% of the item variance. However, after inspecting the rotated factor structure and the corresponding reliability analyses, the following items seemed to comprise the only interpretable and reliable scale: “How well do you think you have comprehended the content of the CK system?”; “How much improvement have you noticed in your ability to communicate since you started the CK program?”; and “How much has your level of anxiety about communication decreased due to the CK program?” Thus the variable perceived communication improvement was calculated

Table 4. Factor analysis for concept keys assessment scale

Scale Items	Component				
	1	2	3	4	5
CK boost my enthusiasm for studying the material we covered in this course.	.887	.272	.153	-.116	.088
CK helped me learn course material better.	.583	.186	.323	.168	.605
I did not like using CK. (R)	.847	.061	.182	.253	.078
I enjoyed using the CK system.	.629	.359	-.177	.463	-.119
I felt more engaged with the class because we used CK.	.812	.285	.339	-.154	.146
I had a good experience with CK.	.848	-.019	-.023	.174	.017
I had no problems using the CK system.	.191	.158	-.410	-.351	.521
I understood more in this class because we used CK.	.244	.838	.023	.092	.182
If we didn't use CK, I would have been less interested in the topics we covered in this course.	-.054	.834	.021	-.011	.206
Investing time in the CK program was a worthwhile use of class time.	.518	.461	.417	.476	.026
It was exciting to get daily e-mails from the CK system.	.540	.078	.721	-.061	.228
My knowledge of course material was improved by using CK.	.200	.832	.159	-.247	-.079
The CK project was good use of class time.	.356	.349	.554	.239	-.059
Using CK did NOT get me any more involved in the class. (R)	.101	-.026	.058	.882	.005
Using CK heightened my interest in other aspects of the class.	.750	.386	.350	-.258	-.107
Using CK made me more motivated to learn in this course.	.203	.873	.154	.149	-.025
Using the CK system was a waste of class time. (R)	.510	.516	.220	.250	-.433
Using the CK system was boring. (R)	.835	.071	.199	.150	.397
Using the CK system was easy.	-.032	.012	-.939	-.058	.107
Using the CK system was fun.	.678	.285	.031	.152	.569
Using the CK system was pretty hard. (R)	-.154	-.199	-.889	.020	-.043

from the means of these three items ($\alpha = .757$).
Affective Learning

Affective learning is defined as “an increasing internalization of positive attitudes toward the content or subject matter” and “is viewed typically as an important motivator of students’ willingness to learn, use, and generalize information and skills beyond the traditional classroom” (Rubin, Plamgreen, & Sypher, 1994, p. 81). To assess student affect toward learning with respect to the CK project, students completed a slightly modified version of Affective Learning Scale (Kearney, Plax, & Wendt-Wasco, 1985); they were instructed to “respond about how you perceived your learning as related to the CK system and not to other elements of the course.” Responses

were recorded on a series of semantic differential scales (1 to 5) with respect to three areas of the CK program: behaviors recommended by the CK program (good/bad, worthless/valuable, fair/unfair, and positive/negative), content/subject matter of the CK program (bad/good, valuable/worthless, unfair/fair, negative/positive), and in “real life” situations, your likelihood of actually attempting to engage in behaviors recommended in the program (likely/unlikely, impossible/possible, probable/improbable, would not/would). Affective learning with respect to the CK project was calculated by taking the mean of all items. Internal consistency for this scale as measured by Cronbach’s alpha was .921.

Pre-Post Design Measures

Intercultural Communication

Three measures were used to assess pre- and post-intervention knowledge of intercultural communication: the generalized ethnocentrism scale, the personal report of intercultural communication apprehension, and the uncertainty when communication with strangers scale. The generalized ethnocentrism scale (Neuliep, 2002; Neuliep & McCroskey, 1997a) consists of 22 items, only 15 of which are used, that assess the general tendency to see the world from one's own cultural perspective. The 15-item scale achieved excellent reliability both pre- ($\alpha = .908$) and post-test ($\alpha = .939$).

The Personal Report of Intercultural Communication Apprehension (PRICA) (Neuliep & McCroskey, 1997b) assesses anxiety within intercultural communication exchanges. This 14-item measure ($\alpha_{pre} = .881$; $\alpha_{pst} = .959$) produces scores between 14 and 70, with scores below 32 indicating low intercultural communication apprehension (ICA), scores above 52 indicating high ICA, and scores ranging between 32 and 52 indicating a moderate level of ICA.

Items from the Uncertainty When Communicating with Strangers Scale (Gudykunst, 1998) were modified slightly to measure confidence/uncertainty when engaged in cross-cultural communication. For example, the item "I am not confident when I communicate with strangers" was reworded to read "I am not confident when I communicate with members of other cultures." Alpha reliability for this scale was .830 pre-test and .520 post-test.⁶Public Speaking

One measure was used to assess levels of competence with public speaking. The Personal Report of Public Speaking Anxiety (PRPSA) (McCroskey, 1970) consists of 34 items that are added to form a composite score between 34 and 170. Given excellent reliability estimates ($\alpha_{pre} = .962$; $\alpha_{pst} = .965$), scores could be interpreted as consistent with prior research: highly apprehen-

sive (scores above 131), moderately apprehensive (scores between 98 and 131), and low apprehensive (scores below 98).Parent-Child Communication

Self-reported competence when communicating with one's parents was assessed in two primary ways. First, eight questions were written and embedded in the interpersonal competence questionnaire (Buhrmester, Furman, Wittenberg, & Reis, 1988), a 40-item scale that assesses five social competencies. Four items concerned how comfortably respondents handled situations with their father (e.g., talking to your father about personal problems or issues.) and the same four items concerned how comfortably respondents handled situations with their mother (e.g., handling a conflict with your mother.). Responses were recorded using a 5-point scale: 1 = I'm poor at this; I'd be so uncomfortable and unable to handle this situation that I'd avoid it if possible; 2 = I'm only fair at this; I'd feel very uncomfortable and would have lots of difficulty handling this situation; 3 = I'm okay at this; I'd feel somewhat uncomfortable and have some difficulty handling this situation; 4 = I'm good at this; I'd feel quite comfortable and able to handle this situation. 5 = I'm EXTREMELY good at this; I'd feel very comfortable and could handle this situation very well. Internal consistency was as follows: father and mother combined ($\alpha_{pre} = .858$; $\alpha_{pst} = .773$), father ($\alpha_{pre} = .920$; $\alpha_{pst} = .895$), mother ($\alpha_{pre} = .735$; $\alpha_{pst} = .855$).

Second, a family communication questionnaire was written to assess how likely a respondent is to talk with his or her father/mother about several situations. Those situations were as follows: (a) "If you are having problems with your homework," (b) "If you are trying to find a good book to read or a movie to watch," (c) "If you are thinking about your plans for the future," (d) "If you have had a quarrel with your best friend," (e) "If you want to know something about alcohol or other drugs," (f) "If you are really angry or upset about something," and (g) "If you feel bad or guilty about something you have done." Respondents

recorded responses on a 5-point scale from Almost Never (1) to Almost Always (5) with the midpoint indicating Sometimes (3). The scale achieved excellent reliability for father-oriented responses ($\alpha_{\text{pre}} = .929$; $\alpha_{\text{pst}} = .895$). After removing one item (If you are thinking about your plans for the future), the mother-oriented scale also achieved excellent reliability ($\alpha_{\text{pre}} = .907$; $\alpha_{\text{pst}} = .906$). The combined scale achieved adequate reliability ($\alpha_{\text{pre}} = .823$; $\alpha_{\text{pst}} = .833$) after the removal of the same item. Interviewing

Self-reported interviewing competence was assessed in two distinct ways. First, four interview competence questions were written and embedded in the Interpersonal Competence Questionnaire (Buhrmester et al., 1988). Those items were: (a) "During an interview, telling a potential employer my strengths," (b) "During an interview, telling a potential employer my weaknesses," (c) "Asking relevant questions at the end of an employment interview," and (d) "In a job interview, responding quickly and comfortably to questions." Response choices were the same as indicated in the previous section. Since alpha reliabilities did not indicate an internally consistent scale at either pre- ($\alpha = .381$) or post-test ($\alpha = .591$) this measure was not included in further analyses.

Second, a more objective measure of job interview knowledge was created which included both general (e.g., what is the purpose of the job interview?) and more applied questions (e.g., what is the best way to respond to the request, "Tell me about yourself?"). Respondents were given three answers in a multiple choice format. Questions had one correct and two incorrect answers, thus scores could range between 0 and 10.

Results

Self-Report Learning and Knowledge

To assess student self-perceived learning, a series of single sample t-tests were conducted with a value of 3 (the mean of all three variable scales) as the test value. Results showed statisti-

cally significant differences (90% CI) for CK knowledge, $t(17) = -2.05$, $p = .057$, $M = 2.63$, $SD = .778$, affective learning, $t(16) = 2.57$, $p = .021$, $M = 3.56$, $SD = .894$, and perceived communication improvement, $t(17) = 2.68$, $p = .016$, $M = 3.51$, $SD = .805$; there was a non-significant difference for CK enjoyment, $t(17) = .091$, $p = .929$, $M = 2.98$, $SD = .740$. An additional analysis was run to assess the utility of the CK project beyond simple classroom purposes. As previously mentioned, one subscale within the affective learning scale refers to the "likelihood of actually attempting to engage in behaviors recommended in the program" in "real life situations." This composite subscale achieved excellent reliability at .90. A one-sample t-test with 3 as the test value produced a marginally significant and positive result, $t(16) = 1.99$, $p = .063$, $M = 3.59$, $SD = 1.22$.

Thus, students seemed to enjoy the CK program an average amount but perceived the program to aid in their comprehension and improvement of key communicative behaviors. Moreover, their affect toward learning material related to the programs as well as their likelihood of engaging in relevant behaviors was also above the mean. The negative result with respect to CK Knowledge can be explained with respect to the specific items. As compared to the Perceived Communication Improvement and Affective Learning items, the CK Knowledge items seem to measure the CK program as assisting in learning course material. The course material was more theoretical than applied and exams were focused on this theoretical material. The CK program was highly applied and not tested explicitly on examinations. Thus, although the students did not feel as if the CK project heightened their understanding of course material per se, they still felt as if the project aided in their understanding of a core social skill and in the improvement of this skill. Pre-Post Design Measures

After the four programs were finalized, students were randomly assigned to take a program they had not authored. Thus, all students fell into

one of three groups for all programs: program author, program taker, or control group.⁷ To control for possible differences in pre-test scores a series of one-way ANCOVAs were run to test the expectations that, within each context, the author group would achieve the greatest improvement from pre- to post-test, the taker group would achieve the second greatest improvement from pre- to post-test, and the control group would achieve the least improvement from pre- to post-test.⁸ The rationale behind this hypothesized pattern of results is the time spent with the material. Individuals who engaged in the authoring process spent eight weeks engaged in researching and thinking about the concept under question. Meetings between group members and the instructor indicated the depth in which students were exploring the material and the exponential growth in their understanding as they attempted to translate scholarly research into real-life suggestions (in the form of micro-lessons) that took no more than five minutes for an individual to comprehend.

The dependent variable was always the post-test score, the fixed factor was group membership (author, taker, control), and the covariate was always the pre-test score. Given the small sample size, power analyses indicated that even a 90% level of statistical significance would be difficult to achieve: large effect (power = .40), medium effect (power = .20), small effect (power = .10) (Cohen, Cohen, West, & Aiken, 2003). Means, standard deviations, standard errors, and group sample sizes for all variables of interest are presented in Table 5. Table 6 presents the results of a series of ANCOVA analyses. As indicated in the table, the only significant result found was for public speaking anxiety. A series of simple contrasts showed that, as predicted, those students who authored the program had a lower level of public speaking anxiety post-test than did controls, Contrast Estimate = -27.2, $SE = 11.9$; however, authors did not differ significantly from takers, Contrast Estimate = -12.8, $SE = 13.7$, and takers did not differ significantly from controls, Contrast

Estimate = -14.5, $SE = 12.4$. Given the power to detect significant effects and the exploratory nature of the present study, the discussion section presents explanations for all findings in light of inherent limitations.

Discussion

Adding to the descriptions of how students incorporate CK material into their personal and professional lives obtained in study one, the present investigation allows for a slightly more rigorous test of the assumptions that the CK system provides students with a meaningful learning experience. Although the sample size in this study warrants caution be taken when extrapolating the results to a larger population, this study does provide evidence that students in the present study felt as if the system aids in their understanding of a particular social skill (at least within the confines of a typical semester project). Moreover, they report that engaging in behaviors recommended by the system is likely. Insofar as the behaviors recommended are appropriate for the skill in question, the system shows promise in allowing instructors to engage in a blended learning approach to teaching skills that may otherwise be overlooked, ignored, or given peripheral treatment in a more theoretically-driven classroom. As mentioned previously, the course in study two is largely theoretical with little emphasis on skills training. Incorporating CK in this manner increased student engagement with both scholarly literature and application potential of this material.

In terms of the pre- and post-test knowledge assessment, power to detect significant differences between groups was dismally low. Nevertheless, several results are worth extended discussion. First, the public speaking program produced the only statistically significant result with program authors achieving lower public speaking anxiety scores post-test than controls; no differences were found between program takers and program controls. In addition, as indicated in Table 5,

Table 5. Part one: Group size, means, standard deviations, and standard errors of cross cultural and public speaking measures

program authors seemed to decrease and controls seemed to increase their anxiety while program takers seemed to stay relatively stable. The fact that a significant result was found with respect with the public speaking program may reflect the fact that all students in the present class had been exposed to similar instruction prior to the class in

the form of the basic speaking course (a course that is required for most students at this particular university). Thus, additional reinforcement may have triggered cognitive stores of information (i.e., chunks) and strengthened the links between this information (see Bodie et al., 2006).

Parent-Child Communication — Family Communication Competence	.451	2,18	.646	.061	No
Parent-Child Communication — Family Communication Questionnaire	.072	2,18	.931	.010	Yes
Interviewing — Job Interview Knowledge	.136	2,18	.874	.019	No

One aspect of the class that may have influenced this result is the fact that all students were required to present an abstracted version of a scholarly article as a course requirement. Presentations were 15 to 20 minutes in length and basic public speaking criteria were used as a part of the grading rubric. This was done throughout the semester with approximately one student presenting per class period. It is possible that program authors, with an extended and in-depth exploration of this subject, felt better about this particular experience as a result of their research and program writing while the program takers did not have the opportunity in a three-week program to obtain all the positive benefits of such instruction. Those that neither authored nor took the public speaking program were not only exposed to an anxiety producing speaking event, but they had no further instruction as to how to manage their anxiety or how to improve their skills; they also lacked the potential additional feedback that such instruction may have afforded the other two groups. In other words, this recent public speaking event may have served as a reference point to all students as they answered the post-test questionnaire.

A second set of results that supports the utility of the CK system are those non-significant results that met expectations in terms of patterns of group means. Within the cross cultural communication program, program controls had the highest and authors had the lowest post-test ethnocentrism scores with the mean for program takers falling between. It is also notable that only the program controls exhibited a change of over .20 between pre- and post-test scores going from an average of 34 to an average of 36 on ethnocentrism over the course of the semester. Similarly, program controls had the highest and program authors had the lowest anxiety levels related to cross cultural communication with program takers falling in between. As with the ethnocentrism variable, pre- to post-test change for each group was also in line with expectations; control participants showed the smallest decrease in cross cultural communica-

tion anxiety (.77) and program authors showed the greatest decrease in this variable (2.35), with program takers falling between these two (1.2). Given that cross-cultural communication is likely a new topic, especially in relation to the other programs, it is possible that none of the students had much prior exposure. Thus, there may be little information stored in long-term memory to which students can incorporate new bits of information to form larger chunks. With increased exposure, we would expect this mechanism to begin operating and for the observed mean pattern to remain. This also points to a potential limitation of the CK system, namely, some material may need to be presented in longer or shorter sessions with more or less repetition and cross application depending on the nature of the material and the individual learner.

Finally, the results related to parent-child communication showed some awkward patterns (and they were not statistically significant). This, along with the job interview results, may suggest that certain topics are not as productively taught in the present format. In the case of parent-child communication, it may be that some individuals were raised and continue to communicate in single- or split-parent households; even those whose parents are still married may experience more or less productive talk in this context. In the case of some students it might be irrelevant to discuss strategies in terms of parents or of specific recommendations related to one or the other parent. Likewise, when responding to questionnaire items individuals from "non-traditional" family structures may interpret items differently. For instance, for those with step parents to whom should the student refer when answering about conflict?

For the job interview results, it might be that students, most of whom were in their junior year, were not particularly motivated to engage with material so seemingly distant. Moreover, as with the intercultural communication material, students taking the job interview program may have had little prior knowledge from which to build large

schema needed to fully become competent in this area. Alternatively, the material presented in the job interview program may have been at odds with previously learned tidbits about the job interview process. Investigation of, and comparison with, other material may be warranted with this and similar skills. It is possible that the CK system could also be used to integrate relevant opposing opinions and suggestions; however, the format of such a protocol would differ in substantial ways to that presented.

Overall, the student-authorship integration addressed goals similar to traditional integration (e.g., break down complex topics into small, manageable bits of information), but also dealt with the confines of a common service course. Theory and practice are inherently intertwined but semester time constraints often restrict serious focus on both. Incorporating CK as the skills-based component and using the online system as a group project allowed for the integration of theory, scholarly research pertinent to four areas of social skill, and direct hands-on application. The project was not without flaws, however. Limiting programs meant teaching social skills that have accumulated vast amounts of research to 15 keys. This poses problems of comprehensiveness and accuracy. It also limits repetition which can enhance code building and cross application which can help to build needed stores in long-term memory. Similarly, the programs contained material only as good as its authors. The potential downfalls of teaching either inappropriate or controversial information in a format meant to build mental stores that rest in a relatively stable long-term memory structure should not be overlooked and is one area in need of added attention if this integration is used in the future. Finally, multiple measures of similar constructs were used thus necessitating alpha correction for t-tests and multivariate statistics for the pre-post design. Thus, appropriate statistical tests were not run in many instances and assumptions related to other tests were certainly violated. Thus, results

should be replicated with larger samples in future research. Nevertheless, a second application was presented and seems to aid in achieving particular pedagogical goals.

CONCLUSION

Given the prevalence of technology for use in higher education, it is important for instructors to be informed of the ways in which different technology options can aid in or detract from achieving specific pedagogical goals and objectives. Concept Keys offers one way to break down complex topics into smaller, more manageable bits of information. This system is based on how students learn (see Bodie et al., 2006) and is easily integrated into existing curriculum. Two ways in which integration is possible were explored and data was presented that shows how students perceive the system and how learning may be affected. Although future research is needed, CK should be considered a viable alternative to traditional, lecture-based formats. This system provides instructors with an easy way to supplement textbook treatments of material or to offer an additional skills-based component to a more theoretically oriented class. Other integration strategies are also possible. For instance, basic communication course textbooks often do not treat listening in a thorough manner (Janusik & Wolvin, 2002). The CK program on effective listening might be used as a supplement for this lack of focus in such a course as opposed to a supplemental text in a course on listening. The sections below explore some reflections on why CK is likely to produce results seen thus far in our research.

Active Learning and Reflexive Thinking

Oftentimes lecture-based instruction does not allow for students to interact and wrestle with course material. Thus, good teachers structure the

classroom in a way that promotes active learning. Active learning is seen most directly in the skit activity from study one and the overall implementation of a student authored e-book in study two. Each of these learning centered approaches allowed students to become involved in the learning experience. The second integration strategy furthermore allowed students to have a voice in the production of course material. In groups, students selected material that they wanted to engage with and present in a skills training program. This may be an even more productive form of active learning than producing skits about mandated material.

An additional way to foster such an environment is by allowing students to self-manage their learning by increasing the responsibility of the learner to think critically about course material (Thomas & Busby, 2003). When teaching listening, Cost, Bishop, and Anderson (1992) “encouraged [students] to explore and understand what words, phrases, or topics get them emotionally involved; what their listening strengths and weaknesses are; and how to recognize what motivates other people to speak and behave as they do” (p. 42). In this way, the student is actively engaged with course material, reflexively thinking about that material, more likely to relate the material to his or her circumstances, and able to incorporate what it means to be socially competent within in his or her unique frame of reference.

CK encourages reflexive thinking on a daily basis through the use of the FFT questions; reflexive thinking was also explored through weekly essay assignments used in study one. Similarly, each week, after all five keys were presented, instructors can have students prompted by the question, “Of the five (5) most recent Keys you have received, which one is most important to your (career, personal, social) success?”⁹ After choosing this most important key students are asked, “How will you apply this most important Key in your everyday interaction?” In addition to these built-in personal relevance motivators (i.e., integrating, self-selection and self-determination)

the expected success of the CK system is also contingent upon the instructor taking on the role of program leader and providing motivational leadership in the form of high student involvement in program decision-making and assisting in making the learning process enjoyable and individualized (see Powers et al., 2005). This was accomplished in the first study by a written essay assignment and a group skit activity. In the student-authored integration students were actively involved in both creating a unique e-book and taking an online course that was created by classmates. On course evaluations, students in study two wrote most extensively about CK and how “cool” it was to be a published author as an undergraduate. Although not conclusive, this at least suggests students took learning into “their own hands.”

Our Continuing Challenge

It is not uncommon to hear students complain about taking courses on presentational speaking, listening, interpersonal communication, and other related topics because “I already know how to speak” or “I listen all the time.” However, as one of the authors explains to his students: simply because an individual possesses a car and drives daily does not mean he or she is a skilled driver. Social skills, like driving, can be performed more or less successfully. Social skills, like driving, also have many manifestations—communicating interpersonally is qualitatively different from public speaking which is different from effective group interaction or handling conflict.

The challenge then becomes not only how to engage the students with learning social skills, but also how to change thoroughly ingrained (and oftentimes bad) habits. In other words, the educator’s challenge is how to re-teach practices that are ingrained in the student’s way of thinking and way of interacting in a social environment. CK approaches this by engaging the student in his or her learning environment via daily e-mails that

incorporate elements of explanation and motivation. Given the likelihood of learning incorrect behavioral sequences related to social skills, CK attempts to aid the learning of correct behavioral and cognitive records to be recalled in the correct context in three distinct ways.

First, programs have been designed and future authors are encouraged to include micro-lessons that are repetitive and cross over potential applications. Not only will students attach different meanings to keys but the contexts in which the keys can be applied are inherently different. Thus, “repetition allows the student to build larger chunks of information based on similarities between Keys and allows for extended priming opportunities across contexts” (Bodie et al, 2006, p. 125). This motivation is furthered by the use of FFT questions which virtually force students to attach keys to personal experience. As mentioned above, the lack of such repetition in the form of repetitive keys was a main limitation of the student-authored study. Similarly, in study one learning was somewhat restricted to a three-and-a-half week delivery of material as opposed to the traditional 10 week structure. Even so, incorporating keys into personal experience was one of the three main themes found in study one.

Within the first study, the traditional 50 key sequence utilized the above components (explanation-motivation, repetition, etc.) in a way that was set previously by book authors. However, this same model was utilized when students authored their own e-books. Students were instructed that keys must be brief and clearly communicate the overall purpose for a particular day. It was also explained that the paragraphs constituting the remainder of the micro-lesson should both explain and motivate proper key usage. This model can be used or other protocol developed to more easily fit instructor goals. For instance, instructors who want to author unique e-books for specific classes can begin to blend current materials with the CK system in order to produce a third type of integration similar to but not isomorphic with

the authorship study. The point is that CK offers the hardware and online support some suggest (Bonk, 2001) as the primary obstacle for secondary educators instituting Web-based blended learning.

In sum, the CK system was built to teach social skills that are broad, ubiquitous, and often difficult to teach due to lack of student engagement and prior habits that are brought into the learning environment. Although the above studies do not cover the entire gamut of possibilities, we feel that what has been presented offers those who teach social skills the tools necessary to institute a fun and effective way to blend traditional instructional practices with Web-based learning. CK can be tailored to fit specific pedagogical objectives which is a mark of a useful instructional technology. Moreover, students appear to learn from the program in theoretically driven ways. The need for future research should not halt the extended use of this blended learning approach to social skill development.

FUTURE RESEARCH DIRECTIONS

The rapid rate at which technology is available to instructors presents a number of questions for future research. Questions specifically raised by this study include issues of online learning protocol in general and the CK system in particular. First, more research is needed that helps specify the boundary conditions for e-learning technology. For example, are some learning objectives, although possible to achieve online, better achieved in more traditional or blended classroom environments? If so, why? Is it because the classroom can foster active and peer learning, whereas online systems often stifle such learning potential? Are efforts to enable active learning and peer learning online effective and seen as productive? The answers to questions such as these should be based on sound theory. As previously discussed, the limitations of our research prevent us from making broad generalizations. Our findings do,

however, provide a foundation for testing existing and yet-to-be-developed learning systems that are similarly based on theories of learning, memory, and information processing.

The research that has been conducted with the CK system has been small-scale and mainly presented in the form of case studies. Experimental studies that randomly assign participants to engage or not engage with the CK program would be an ideal next step for research to progress. If truly experimental studies are not possible due to the design of the system (designed for use in a classroom setting), research needs to examine the effects of variables that exist on multiple levels within the same study. Building and testing multilevel models that enable the simultaneous inclusion of aggregate, group-level, and individual variables are needed to test such effects. Likewise, research should address the longitudinal effects of empty engines such as CK. Specifically, issues such as the extent to which CK enables students to build large chunks of information that can be recalled from long-term memory with appropriate priming stimuli and the identification of those primes should be addressed. Future researchers will also need to refine measurement devices needed to test such propositions.

A second set of questions addresses whether students learn differently when material is presented online versus offline. Future research in this area should examine the impact of presenting online information in its entirety as opposed to presenting it gradually and sequentially. In addition, given some of the results from study two, we should address whether the CK approach of breaking down complex ideas into small, manageable units of information is a better approach for all learners and for all subject matter. In other words, will online systems such as CK be able to provide more advanced learners with a meaningful learning experience? What about students who do not possess characteristics of self-motivated and self-managed learners? If not, how will it need to be modified to be the most effective?

Finally, future research should be conducted on potential additions and alterations to the CK learning system that are either currently unavailable or have the potential to evolve as technology itself evolves. For example, as video-conferencing capabilities develop for use in truly distance education contexts wherein teacher and student interactions will approximate the personal atmosphere found in the face-to-face traditional classroom and office environment, will increased or different learning outcomes be enhanced or comparable to the in-classroom or office face-to-face tradition?

Ultimately, the possibilities of research that are generated by the introduction of the CK and similar learning systems are limitless. Not only do we need to modify existing theories within education and learning, but we also need to build sound, novel theories that help explain the phenomena germane to online learning specifically. CK was developed from sound theories of education, and research is needed to support many of the assumptions underlying this approach. Further research and theory from the areas of technology acquisition, teacher immediacy, student-teacher interaction, learning and memory, and information processing, just to name a few, are also likely to prove fruitful for incorporation into and expansion of CK and similar learning systems.

ENDNOTES

- ¹ The authors would like to thank Dr. Steven Wilson and Dr. John Greene for their insights and help with various stages of the project reported in study two of this chapter. All correspondence regarding this chapter should be directed to the first author. Address: Department of Communication, Purdue University, 100 N. University Ave., Beering Hall 2114, West Lafayette, IN 47907-2098; Phone: 765-494-3429 E-mail: gbodie@purdue.edu.
- ² A space is created for this student that stores information relevant to programs in which he or she is enrolled, the number of keys completed and the number yet to be completed; answers to FFT questions, and the amount of time spent on each key. Other options available on the system include weekly retention quizzes and a final certification exam; all of this information is likewise stored in the student's individual database. Teachers or others in supervisory roles also have access to this information through the use of an administrative login. Readers are encouraged to visit www.conceptkeys.com, explore the options, and sign up for a trial program.
- ³ Syllabi and other instructional material for either application will be made available upon request.
- ⁴ This is a common practice when using the traditional CK system but is only one of several options included in the Student Learning Instructor's Manual (see also Table 2).

- ⁵ Technical difficulties (the beta version of the CK template software) and time constraints imposed by the semester format made Monday through Friday delivery impossible to implement. Participation indices obtained by the CK system indicated that this alternative delivery was not a problem for the majority of students. At most, students skipped one day, usually on the weekend, and completed two keys in one day in order to catch up.
- ⁶ Given the low reliability post-test, the measure of cross cultural uncertainty was excluded from further analyses.
- ⁷ Since all data are not independent, a main assumption of ANOVA has been violated. In addition, equal sample sizes were not achieved. Similarly, in most cases multiple dependent variables were used to measure pre-post differences. Thus, MANOVA and MANCOVA are arguably the more appropriate techniques (small sample sizes precluded a full multivariate form to be utilized). Thus, all results should be tempered by these limitations. However, given the primary goal of the project was for students to become “communication trainers” within an interpersonal

communication course, this limitation was disregarded and considered less important than the pedagogical objective. Thus, the analyses presented show preliminary evidence of the success of this project based on previously validated measures of the constructs in which students attempted to train their classmates.

- ⁸ Although only one of the DVs showed a significant difference between pre-test scores based on group membership in a series of oneway ANOVAs (data not presented but available from first author upon request), the lack of power to detect even large effect sizes seemed to warrant controlling for these pre-intervention assessments. Nevertheless, a series of 3 X 2 mixed model ANOVAs were also run with repeated measures on the last factor (pre-test, post-test scores). The between-subjects factor was always group membership (author, taker, control). The results from these analyses produced results comparable to the oneway analyses and are not reported but are available from the first author upon request.

Chapter 7.12

Conversation Design in the Electronic Discussion Age

Gregory MacKinnon
Acadia University, Canada

ABSTRACT

The electronic age offers technologies that have great potential to empower conversation. The following chapter introduces a model for coding electronic discussion. Inherently the use of the so-called “cognotes” has been shown to improve the quality of conversation by promoting more analytical and substantive contributions to asynchronous discussion. The chapter further elaborates on tested classroom models that embed the coding approach in second order technology exercises. The chapter culminates in a synopsis of what has been ascertained about the coding strategy over a range of action research studies.

DOI: 10.4018/978-1-60960-503-2.ch712

EDUCATOR’S INTEREST IN CONVERSATION

The study of discourse has long been of interest to educators (Cazden, 1988; Edwards & Westgate, 1994; Young, 1992) and has culminated in sophisticated research agendas that include semiotics (Lemke, 1997), symbolic interactionism (Charon, 1998), and most recently a renewed interest in the notion of distributed cognition (Courtney, 2002; Karasavvidis, 2002). In the context of teaching, these interests all surround the educational aim of supporting and promoting quality student conversation. Ideally, conversations within classrooms or asynchronously through communication technologies have the potential to promote social construction of knowledge (Brooks & Brooks, 1993;

Prawat, 1996). With respect to discussions, Davey and McBride (1986) suggest that the process of generating questions helps students' comprehension and "encourages them to focus attention, make predictions, identify relevant information, and think creatively about content" (McTighe & Lyman, 1988). Some instructors have gone so far as to devise analytical symbols to cue students to the nature of their conversation and further, to involve them in metacognitive exercises where they examine how it was that they interacted in conversation (Knight, 1990). All of these research endeavours point to the fact that conversation is a complex process.

Often conversations are categorized based on their purpose. As such, Jenlink and Carr (1996) have identified four types of conversations—dialectic, discussion, dialogue, and design. Taylor (2002) further elaborates on these. "Dialectic conversation is a form of 'disciplined inquiry into whatever is being examined' (Jenlink & Carr, 1996). Its procedures are those of logical argument, and the underlying intention is the formation of rigorously defensible interpretations." "Discussion is the form of conversation where participants tend to argue their own position, and is more subjectively influenced by opinion and supposition" (Jenlink & Carr, 1996). Thus personal experience and assumptions tend to be at the centre of the conversation."

Dialogue is a form of conversation focused on the sharing and construction of meaning. It helps to develop collective mindfulness, and thus, "is a community-building form of conversation." The dialogic processes require individuals to "first examine their personal assumptions or opinions and then suspend these assumptions before the entire group" (Jenlink & Carr, 1996).

Design is focused on the creation of something new through "disciplined inquiry grounded in systems philosophy, theory, and thinking and practice" (Jenlink & Carr, 1996).

In particular, design conversations tend to look beyond existing constraints, seeking to design new systems that avoid or minimize those constraints. They require that participants suspend assumptions about what 'ought to be,' as well as 'what is possible.' Thus design conversation 'goes beyond the suspension of personal opinions and moves into a suspension of mindsets themselves.' These types of conversations tend to be unusual in everyday experience, and to be associated with the work of creative teams.

These modes of conversation can easily be envisaged in face-to-face settings yet Web-based models and variations are becoming increasingly popular with educators.

ELECTRONIC CONVERSATION COMMUNITIES: PRODUCTIVE STRATEGIES?

Electronic discussion has become a typical tool for teaching in online learning environments. In addition, asynchronous electronic discussion is commonly used to: (1) prepare students for face-to-face (hereafter Ftf) discussions in an ensuing class, (2) introduce a new reading in preparation for an ensuing Ftf class meeting, (3) discuss a topic that required further investigation than the Ftf class time allowed, (4) interview class members, and (5) provide an open forum for discussion led by student interest.

From early studies (Harrington & Hathaway, 1994, 1995; Harrington & Quinn-Leering, 1994) it has become clear (Kuehn, 1994) that the asynchronous nature of the electronic discussion group (hereafter EDG) and the accessible transcripts of dialogue, make the EDG a unique phenomena that is curiously different from Ftf conversations.

Considerable effort has gone into developing electronic environments that foster positive and productive discourse (Daradoumis & Marques, 2002; Hewitt & Scardamalia 1989; Scardamalia, 2002; Scardamalia & Bereiter, 2003). The

CSILE (computer-supported intentional learning environment) is a communication tool developed by Scardamalia et al. that allows students to purposefully process information via access to a unique database of information. This electronic model promotes quality conversation based on the premises of the seminal notions of distributed cognition and knowledge building (Pea, 1993).

Sherry, Tavalin, and Billig (2001) describe a project where multimedia telecommunications are used to encourage, support, and create an electronic environment for student inquiry, expression, and dialogue around assigned literature. Ultimately, it serves as a medium for presenting and assessing student's creative art, music, and multimedia. Arguably, this approach is an example of the "design" category of conversation.

Paulus (2005) also makes a case for using electronic conversation to support constructivist learning. "One purpose of online group projects is to encourage collaborative dialogue for new knowledge construction. During such projects students have a dual objective: learn through constructing new knowledge together while also completing the task."

Van Aalst (2006) makes particular reference to "knowledge building" in asynchronous learning networks. He proposes that productive electronic conversation can be subdivided into processes of collaboration, learning how to learn and idea improvement.

As promising as electronic conversation may seem, Chen and Hung (2002) issue a warning.

In this chapter, we highlight a concern with using online discussion for learning. We argue that there is a lack of technological support for the development of personalized knowledge representation for most online discussion forums. Analyses of existing discussion forums suggest that there is a range of collective knowledge representation mechanisms which support a group or a community of learners. However, such mechanisms may not necessarily lead to learn-

ers' internalization of collective knowledge into personalized knowledge.

The Pitfalls of Traditional Electronic Discussion

Since its inception, electronic discussion has been used primarily as a forum where students could carry on discussions related to course curriculum. While this has provided a comfortable setting for some students to have conversation, the nature of the conversation need not be particularly substantive. In an effort to promote quality interchange in these communications, some instructors have devised simplistic rubrics to track, for instance, the number of times a participant engaged electronic discussion. Furthermore, some educators have insisted that students discuss a certain question and grades have been assigned based on threads and numbers of threads of related queries. Recent research has indicated (MacKinnon, unpublished) that these "forced conversation" schemes tend to contribute to artificial conversational interactions which bear little resemblance to the educational ideal of quality Ftf conversation rooted in real questions and sociological positions of difference. Students in these EDGs tend to make inventive, less-than-spontaneous token contributions to the conversational exchange. How can we improve the impact of this technology-enhanced conversation mode?

Elevating the Ultimate Goals of Electronic Discussion

It is important to realize from the onset that electronic discussion offers a distinctly different environment for conversation than Ftf classroom discussions. Research on gender issue discussions in science teacher training (Hemming & MacKinnon, 1999) has shown clearly that individuals have different comfort levels in each communication venue. For instance, even in small group Ftf settings, amongst an even gender distribution

of mature (25 year old) teacher interns, women in the course felt very uncomfortable verbally sharing their ideas around gender discrimination in schools; they expressed a certain pressure to conform to the ideology that gender discrimination was no longer an issue in schools. The electronic discussion format was generally the preferred means for them to engage a conversation about gender issues in schools. The men in the same class generally and conversely felt less comfortable writing (in the EDG) about their sense of high school discrimination and preferred to express themselves verbally in an Ftf conversation.

Clearly there is pedagogical potential for electronic conversation in situating the process within meaningful learning exercises. The research (MacKinnon & Aylward, 1998) has demonstrated that the quality of student's electronic conversations can be improved substantially by instituting a system of pictorial discussion codes (called *cognotes*) that cue students to engage discussion using more substantive conversation styles. This model is generic to all course curriculum as it emphasizes the process of conversing rather than the content. Subsequent sections of this chapter begin with a description of the cognote foundation system and continue with an outline of the continuum of strategies for incorporating this system in progressively more embedded pedagogical approaches. Research conducted on these systems generally followed a format of: survey (and associated quantitative analysis), semi-structure open-ended interviews (Patton, 2002), member checks, focus groups (Morgan, 1997), and peer debriefing (Sagor, 1992).

The System of Promoting More Substantive Electronic Discussion

By comparison to Ftf conversations, EDGs offer the additional benefit of a recorded transcript. This allows for a unique interaction between instructor and student.

A coding system (*cognotes*) has been developed (Aylward & MacKinnon, 1999; MacKinnon & Aylward, 2000) for use in EDGs. The choice of categories for this system was based on (a) an extension of hard-copy journal coding explored by Knight (1990) and (b) an analysis of patterns in a case study EDG (Hemming & MacKinnon, 1999).

Based on the concept of 'thinking tools,' Lyman (1987) developed an instructional strategy called "Thinktrix." This thinking matrix was a device that assisted students and teachers in their analyses of classroom discourse. Thinktrix involved using thinking types as a metacognitive aid for students to generate and organize their thought processes and knowledge production through questioning. The goal was to encourage the students to think creatively and critically about content.

Janice Knight (1990) employed seven adapted Thinktrix cues for use in reading response journals in elementary school. The pictorial codes helped students identify and construct journal entries based on thinking types whilst reminding students to include a range of response types. The present cognotes coding categories are adapted from Knight's cues for use in an electronic discussion context (Table 1).

The *cognotes* have a grounding in learning theory. The key theory guiding the development and use of cognotes is the concept of 'procedural facilitation' (Scardamalia et al., 1998). In her work she notes, "procedural facilitation is an approach that grew out of efforts to foster higher-order processes in written composition." The approach involves providing learners with temporary supports through the use of memory aids and structuring procedures. In designing instructional environments using procedural facilitation, the emphasis is placed on the ultimate cognitive aims.

Inherent to procedural facilitation is the metacognitive aspect of the cognote coding. The explicit choice of 'thinking types' in the students' written discourse encourages a reflection on their individual thinking processes. The assignment

Table 1. Cognote icons and categories

Specific Interaction Grade		Coding Icon
Acknowledgement of Opinions (evidence of participation)	1	
Question (thoughtful query)	1	
Compare (similarity, analogy)	2	
Contrast (distinction, discriminate)	2	
Evaluation (unsubstantiated opinion/judgment)	1	
Idea to Example (deduction, analogy)	2	
Example to Idea (induction, conclusion)	2	
Clarification. Elaboration (reiterating a point, building on a point)	2	
Cause & Effect (inference, consequence)	2	
Off-Topic/Faulty Reasoning (entry inappropriate)	0	

of codes identifies specifically ‘what they know about what they know.’

The *cognote* categories correlate with specific levels of *critical thinking* best characterised by Garrison (1992). In his model of critical thinking, cognote types correspond well with Stages 1-5 including: problem identification & definition, problem exploration & evaluation, and problem integration (Aylward & MacKinnon, 1999).

While the range of discussion pattern categories may seem endless, 10 cognotes (see Table 1) were eventually designated as a starting point (opinion acknowledgement, question, compare, contrast, evaluate, deductive, inductive, clarification, cause and effect, and off-topic). The assignment of grades (1 or 2, corresponding to a hierarchy cognitive engagement) to each of the cognotes was based on definitions that were clearly indicated to interns. Teacher interns were purposefully engaged in numerous coding exercises prior to the actual EDG in an effort to ensure that instructor and intern shared the meaning of the EDG contributions. Putting the intern in the role of evaluator of the discussion as

well as evaluator of the peer’s discussion was an intrinsically valuable pre-exercise.

The ultimate aim of the coding system is to encourage participants (at all educational levels) to engage in more substantive electronic discussion through a grading scheme that favors higher order discussion patterns.

The Simplest Model: Instructor Coding

The instructor posted a discussion question to the EDG. The interns were encouraged to visit the forum and participate in the electronic discussion. The conversation proceeded for 1-2 weeks at which point the instructor captured the discussion (which is html-based). Using a set of macros (see Figure 1) each intern’s contributions to the conversation were coded with the aforementioned pictorial cognotes. The graded contributions were then returned to the intern via e-mail attachment. Interns had the opportunity to revisit and rationalize the nature of their conversation input before continuing with ensuing discussions. Quantitative studies (MacKinnon, 2000) have demonstrated that, over the course of three successive discussion group sessions, interns tend to write less, interns tend to contribute more substantively (i.e., the higher cognotes are assigned more often), and the instructor has assigned more cognotes (implying that the quality is also improving). The cognote system seems to promote critical thinking in that teacher interns tend to use higher order argumentation patterns over a period of three successive EDG sessions.

As the cognotes began to be used in more diverse settings it became important to examine two research questions: (a) the dilemma of assigning grades to a discussion and its impact on the spontaneity of participants (MacKinnon, 2000) and (b) the inter-rater reliability of the coding system (MacKinnon, 2003).

The research (MacKinnon, 2000) has shown that interns do improve their discussion patterns

Figure 1. Macro-enabled template for applying cognotes

because of the coding system. It remains a dilemma as to whether interns consciously access cognitively higher-order conversation tools because of the grades achieved or because the higher order discussion is part of their new process skill set. Interview data with interns have indicated that, despite the positive results, there is an even distribution of these two possible rationale for improvement. One might also ask the question, does it really matter why they are more substantive participants in the conversations? It does matter when we consider transferability of discussion skills, an aspect of EDG research discussed later.

The work on inter-rater reliability indicates there is potential for this system to be used with confidence. The findings (MacKinnon, 2003), based on a sample of 30 teacher interns suggest three indicators of reliability: (a) that raters assign similar grades to interns' discussion group contributions, (b) that raters predominantly assign the same cognotes to interns' discussion group contributions, and (c) that raters are selecting in excess of 50% of the same text in assigning the same cognotes.

Transferability of Improved Patterns Across Disciplines?

Do interns retain their electronic discussion skills in conversations held in other teacher education courses? Research was conducted to help answer this question (Pelletier, MacKinnon, & Brown, 2002).

Physical education students ($n = 70$) were asked to participate in an electronic discussion surrounding content issues in physical education. An exercise was then conducted in which students were (a) introduced to cognotes, (b) asked to distinguish between critical categories, and (c) asked to complete several coding exercises. The instructor then arranged for an EDG session on a second curriculum topic. Students were encouraged to consider the cognote pre-exercise as they participated in the second EDG. After the second discussion was completed, students were prompted to reflect on their initial EDG (i.e., prior to the introduction of cognotes). By comparison, over 60% (45 of 70) of students improved their discussion patterns in the areas of (a) building upon another's opinion in some manner and (b) substan-

tiating one's opinion. It is important to note that students were still assigned a grade based only on participation. While there was a marked improvement in discussion patterns, it was interesting to consider whether a grading scale may have had the impact noted in earlier work by MacKinnon (2000). These same physical education students were asked by a second professor (in an inclusive education course) to discuss two inclusion issues within an EDG format over separate, successive sessions. Concurrent with this, another section of inclusive education students, those who had not received any preamble to cognotes, were also asked to participate in two successive EDGs. Using the cognotes to evaluate the students' contributions, two trends became clear when comparing the two sections. The group that had received instruction on higher order thinking (i.e., through considering cognotes) in the physical education class showed, on average, more substantive discussion patterns in the inclusive education class than those who had received no instruction. A second observation was that students who had received instruction in the physical education class continued to improve their discussion patterns over two EDGs.

This research demonstrates that, given short time frames, a significant group of students transfer their improved skill of discussion between courses. From earlier work (MacKinnon, 2000), there also appears to be a trend strongly suggesting that applying higher grades to more substantive contributions improves discussion. Given this finding, it seems reasonable to suggest that the application of a grading scheme to inclusion course discussion sessions might also have led to an improvement in the transfer of discussion skills beyond what was recognized in this study (Pelletier, MacKinnon, & Brown, 2002).

Conversation Nested in Higher-Order Applications

There is tremendous potential for technology in going beyond the intended uses (Squires, 1999)

and incorporating technologies as "*mindtools*" for critical thinking (Jonassen, 1996). The practice of nesting technologies in higher order exercises, that in some ways subvert their initial intended use, is referred to by Maddux and Johnson (2006) as *Type II* technology applications. The following are three examples of how the coding exercise can serve greater aims irrespective of the content.

Why Not Have Interns Code Their Peer's Work?

MacKinnon and Bellefontaine (2000) have studied the use of the cognote tools in a middle school teacher education course. Seventy teacher interns were supplied with a CD-ROM containing case studies on middle school issues. Interns were placed in teams of three. Each team was responsible for participating in two electronic conversations concerning two separate case studies on their CD-ROM. In one EDG, a group was responsible for coordinating (focusing and leading) the discussion of a case study. In a separate second EDG, interns were participants (not leaders) discussing another case study. The discussions took place over a 3-week period. Each member of the coordinating team was responsible for leading the discussion during one of the 3 weeks. In addition, each member of the coordinating group was expected to use the cognote system to code and grade each of the participant's discussions for the 3 week period.

The added educational impact for teacher interns was evident through the means chosen for evaluating the activity. Each intern in the coordinating group was required to submit a written report on the case study over which they presided. A required component of that report was the "hard copy" captures of the online conversations they coordinated. They were expected to use the electronic discussion transcripts as a source of qualitative data for responding to the case study. The interns, knowing this in advance, had a sig-

nificant vested interest in leading a substantive discussion on their case study.

The electronic discussion is not simply used to share ideas but instead is further primed by the leaders to lend support and substantiation to the analysis of a case study. Moreover, facilitators may direct and focus the discussion to uncover new ideas and perspectives that potentially support or challenge their own ideas and analysis of the case. From a teacher educator perspective, this activity was especially important because it gave teacher-interns an opportunity to practice the role of coordinating a good discussion (whether the conversation may be electronic or Ftf) while simultaneously participating in a quality discussion and improving their cognitive engagement levels. It should be clear that embedding a rationale for contributing substantively to conversation in EDGs goes well beyond the token participation grade.

Coding to Scaffold Concept Mapping

In science education it is particularly valuable to employ concept maps to establish relationships between ideas in a hierarchal fashion (Novak, 1990). Recently (MacKinnon, 2006), the cognote system has been used to promote substantive conversation regarding the contentious issue of evolution versus creationism. More specifically, teacher-interns have been taught to support their understanding of the issues by drawing on the electronic discussion forum to improve relational understandings within a concept map.

In science education, teacher-interns are taught systematic strategies for engaging contentious issues in science (NSTA, 2000) with their students. In particular, science teacher interns are anxious to gain experience in dealing with the complicated controversy of creationism versus evolution.

The instructor supplied interns with an incomplete electronic hierarchical *concept map* (Novak, 1990) prepared with the software [®] Inspiration (see Figure 2). A conscious choice was made to

access electronic concept mapping tools in that they have been shown to result in more conceptually complex mapping amongst interns (Royer & Royer, 2004). The concept map was based on component ideas that the instructor would introduce in three consecutive class lectures on aspects of engaging evolution vs. creationism in science classrooms. The concept map was incomplete in that the relational phrases between concepts were left blank.

A special power of the Inspiration software[®] is the ability to hyperlink external documents not only to concept boxes but also to the propositional phrases that link the concepts. Priming this capability, interns can build up a meaningful graphic organizer in one dimension while providing substantiation of their understanding through hyperlinked supplemental information in the second dimension (see Figure 3).

Science teacher interns were introduced to the creation controversy in three consecutive lectures that conceptually were represented in a concept map (see Figure 2). As they constructed new knowledge they electronically added relational propositions (links between concepts) to their own individual concept maps. Interns were asked to write reflective journals (as Word[®] documents) corresponding to each of the concepts in the concept map which they then hyperlinked to their concept map. The Inspiration[®] map and linked local journal entries were saved to CD ROM.

Interns were then asked to link their relational phrases to html-based captured electronic conversation. Asynchronous electronic discussion was organized in such a way that each intern led a discussion and participated in at least three other discussions. Interns directed their coordinated electronic discussions in such a way as to promote and accumulate fruitful conversation around the nature of the propositional phrases they had applied to their individual concept maps. After 2 weeks of asynchronous electronic discussions, interns captured their discussion and then selectively quoted useful components which they

Figure 2. Incomplete concept map of evolution vs. creationism topic

Figure 3. Substantiating relationships in the concept map

in turn linked to their concept map propositions (see Figure 3). Flexibility in the approach was ensured by maintaining that (a) interns could choose to add additional concept boxes beyond what was provided by the instructor, (b) interns were encouraged to prepare journal entries around all concepts, and (c) interns had the choice of selecting which propositional phrases they wished to hyperlink to electronic discussion. In evaluation of this activity, the onus was on the intern to demonstrate to the instructor they understood the topic by hyperlinking to well-chosen appropriate supporting documents as outlined.

The impact of the *concept mapping* exercise was deemed to be dependent on the quality of the linked documents which served to express the intern's depth of understandings. This is where the use of the cognotes became important. The conversations coordinated by interns had to demonstrate two characteristics: (a) they must lend an understanding to the relational phrase between the selected concepts and (b) they must be led in such a way as to promote critical thinking through productive conversation patterns. In an effort to promote substantive discussion within individual discussion groups, a series of preliminary exercises were undertaken with all interns.

Grounded in previous work (MacKinnon & Aylward, 2000), five categories of *critical thinking* modes were promoted: compare, contrast, cause and effect, inductive, and deductive reasoning. For each of these categories a graphic icon and macro was developed for Microsoft Word® such that interns could assign a cognote to specific portions of text in a discussion transcript. In three successive exercises, interns were supplied with a single page of captured electronic discussion. They were then asked to code the entire discussion based on the five aforementioned contribution styles. After each successive exercise, interns were paired with another intern to discuss their comparative recognition and assignment of the codes. Interns then compared their own assignment of codes to that of the instructors in a closure session. Ambiguity

in the assignment of cognotes was discussed. This was repeated in three independent exercises. The instructor noted that interns began to recognize discussion patterns in an analytical process; the rationale for instituting such an exercise being to extend intern awareness of the higher-order thinking patterns in which they could “contribute” to an asynchronous electronic discussion. In the end, the instructor hoped that interns would consciously promote substantive discussion so as to support their understandings of the conceptual relationships within their concept maps.

With their coding experience behind them, interns were encouraged to use the identified discussion patterns in their ensuing electronic discussions. The concept map-linked discussions were later evaluated based on the clarity of argumentation and support for the propositional relationships in the first dimension of the concept map.

At the conclusion of the project, teacher interns submitted for evaluation a CD ROM containing the concept map hyperlinked to “CDROM-local” reflective journals and electronic discussion captures.

Cognotes and Literature Databases

In another *Type II* application, the electronic discussion was used to support critical thinking around the qualities of children's literature (MacKinnon, 2005).

In this model, interns were first taught the tenants of good children's literature. An online electronic surveying system was made accessible to interns. This survey/questionnaire included fields that defined the characteristics of the chosen piece of literature (see Figure 4). Interns were asked to enter data for five of their best choices for children's books. Near the close of the semester, the survey data was compiled and made into a Microsoft Access© database and burned to CD ROM. In a workshop session, interns were then taught how to search the *database* to locate best

Figure 4. Book information: 72 entry fields

The screenshot shows a Netscape 6 browser window with the address bar displaying <http://plato.acadiau.ca/courses/educ/gmacdonn/surveys/booksurveyF2003.htm>. The page content includes the instruction "Please enter text information in the boxes provided and then press the submit button." followed by five numbered questions, each with a corresponding text input field:

1. The complete title of the book?
2. Please give a 75 word abstract of the story line of the book.
3. The author(s) of the book?
4. Is the author Canadian? ☐ no ☐ yes
5. The illustrator(s) of the book?

The browser's status bar at the bottom indicates "Document: Done (0.38 sec)" and the Windows taskbar shows the time as 9:47 AM.

resources for their teaching practice. For instance, interns could search and filter by author, title, media type, theme, and so forth (see Figure 5).

The cognote system was used in this project in the following way. An extended assignment was that interns needed to coordinate and lead an

electronic discussion with at least five peers. In this discussion the coordinator would individually pose their chosen book titles and correspondingly prompt discussion as to why each book was considered a piece of quality literature. During the discussion coordinators were responsible for

Figure 5. Filtering the data through a form search

This screenshot is identical to the one in Figure 4, showing the same Netscape 6 browser window with the book information form. The address bar, instructions, numbered questions, and input fields are all the same as in Figure 4. The status bar and taskbar also show the same information.

grading their peers contributions to the conversation using the cognote scheme outlined in Table 1. (It should be noted that the entire activity was prefaced with a “coding practice” session). The cognote system was employed in an effort to promote substantive conversation. This was done because the intern-coordinator then captured pieces of the electronic discussion to submit in a report designed to justify their choices of literature. In subsequent research interviews, coordinators indicated that participants in their EDGs were particularly focussed and that they felt the cognote implementation was a contributing factor to the quality of the conversations.

Synopsis of Research Findings

The cognote coding system has demonstrated (MacKinnon & Aylward, 2000) its utility in the simplest application of an instructor coding their student’s work for improved conversation patterns. Moreover, the system of assigning cognote grades has been shown to possess *inter-rater reliability* (MacKinnon, 2003). It has become clear that the application of the cognote system to classroom instruction benefits greatly from preliminary exercises where instructors and students become familiar with meaning of the individual codes. Studies have shown (Pelletier, MacKinnon, & Brown, 2002) that students exposed to cognote-assisted EDGs tend to transfer their improved discussion patterns to other curricular settings at least in the short term.

The aforementioned examples demonstrate that the cognote system can be embedded in educational exercises which capitalize on (a) the improvement in the conversation and (b) the ability to capture the discussion for use in substantiating ideas and concepts in related work.

The use of the cognote system in teacher education has been particularly valuable as it develops not only better discussion patterns amongst interns but also teaches them how to coordinate and promote engaging conversations. The inher-

ent organization and critical thinking that this requires is of great value as a process skill for the practicing teacher.

THE PRACTICALITIES OF USING THE COGNOTE SYSTEM

Objectives

In designing the cognote system, the instructors were most concerned that students engage content from a critical perspective. The content in itself was a lesser priority and the work described herein should demonstrate the general applicability of the coding system. The intent then, was not to simply have students discuss more but to develop their potential for higher order discussion patterns and in turn, better quality conversation. This objective was met when at least three successive iterations of electronic discussion and concomitant coding were undertaken. The system was initially designed for asynchronous conversation in a face-to-face course but due to its technological simplicity, has broad applicability to solely Web-based instruction involving variable content.

In the context of teacher training, the ability to communicate ideas effectively, formalize argumentation approaches, and coordinate objective-directed discussions was a most important goal for the instructor. Consensus was reached in focus group sessions involving students and instructors (using the system) that the cognotes were achieving all of these objectives to varying extents.

Student Response

Students from the onset have recognized improvement in their conversations commenting frequently that the metacognitive exercise of examining the nature of their discussion structures (with feedback) has improved their articulation of ideas. Moreover they have indicated in focus groups that the inherent formalized analysis of

the critical thinking strategies involved have not only activated new approaches to voicing their ideas but prompted them to deconstruct their ideas in ways that were not previously part of their thinking patterns. In addition, students suggested that reading the more carefully articulated conversations online improved their recognition of the impact of methodical idea development. In affect, they became much better listeners and processors of ideas. Students were quick to point out that preliminary exercises that clarified the nature of each of the codes were most crucial to them with regard to both understanding the coded conversation returned to them as well helping them to code other's discussion with consistency. Culminating interview data from all studies done to date has demonstrated that students need much practice using the codes in order that they begin to internalize legitimate changes in their conversation patterns. Ironically, some students have suggested that there are too many codes to remember while others feel there are discussion styles that "fall through the cracks" for lack of an appropriate code. Finally, it has been clear that students do not mind the additional work to employ the cognote system providing that the assessment of the activity is fair and most importantly emphasizes the process. Students have unanimously indicated that their understanding of the content is more highly developed because of the improved richness of the conversation.

System Support

The cognote system is relatively trivial to prepare from a technological perspective. The coding icons are easily constructed using any simple graphics program keeping in mind that appropriate sizing of the icon will be necessary. Microsoft Word® allows for the preparation of customized toolbars and simple macros to allow assignment of the cognotes to the html-based text.

Implementation of the system in a model where the instructor does the coding in three successive

iterations can be onerous if not undertaken systematically. Obviously, class size has a bearing on the efficiency with which the instructor can "turn around" coded conversation. The aforementioned coding research has shown that students will ultimately write far less in later iterations of the electronic discussion thus coding gets easier as verbosity decreases and articulation improves. As mentioned earlier, the value of doing preliminary coding exercises in a student-instructor activity can not be overstated. Clearly one benefit of instructor coding is the consistency with which the "definitions" of the cognote are applied to real conversation. While the research has shown the system to have *inter-rater reliability*, a single rater is bound to apply cognotes more consistently. Periodic discussions of the meaning of the codes helps to reinforce consistency as students are exposed to a wide range of conversation styles.

A system that employs students in coding each other's work has many benefits, not to speak of the instructors' workload implications. The ability of students to coordinate and promote quality conversation is a "life skill." Their improved communication of the ideas has the added benefit of promoting deeper understanding of the content. The engagement of ideas at higher cognitive levels with more critical stances is an objective most instructors will feel is worth the effort in terms of establishing the cognote system. The cognote system has no obvious limitations with regard to exclusive implementation in distance education. Introduction of the coding system, associated practice exercises, formal coding, and ultimate conversation exchange are all easily achievable via conventional e-mail exchange, much less more elaborate online learning systems (e.g., Blackboard®, WebCT®, & Moodle®). Instructors need only the ability to capture discussion from a html-based forum. Once the text is saved it can be opened in Microsoft Word®, codes assigned, and the entire coded work returned to students. The coding template is easily shared and implemented on students computers so they may participate, if

the instructor so chooses, to embed the coding in a higher order type II technology exercise (Maddux & Johnson, 2006).

For teacher education students, this system demonstrates how technology can be used to empower learning through development of more substantive conversations. The level of interaction and quality of feedback that the technology affords was never before possible.

Chapter 7.13

E–Social Constructivism and Collaborative E–Learning

Janet Salmons

Vision2Lead, Inc., USA & Capella University, USA

ABSTRACT

Social constructivism is an established educational theory based on the principle that learners and teachers co-construct knowledge through social processes. This chapter proposes an updated theory, e-social constructivism, that takes into account the milieu of electronic communications in which e-learning occurs. Thinkers such as Dewey, Piaget, Vygotsky, and Bruner, who laid the theoretical foundations of social constructivism, wrote in a time when face-to-face interactions were the basis for instruction. The works of these writers are reviewed in this chapter. Together with the results of the author's phenomenological study of collaborative e-learning, they form the basis of e-social constructivist theory. The author uses grounded theory and situational analysis to derive

and support e-social constructivist theory. This chapter discusses the implication of that theory for research, teaching and instructional design.

INTRODUCTION

In online classes, interaction between learners and instructors occurs electronically. Online classes may expect learners to interact through discussions involving the whole class, in small groups, or in pairs. When assignments are designed for completion by collaborative teams, the objective is for peers to learn from and with each other. This instructional approach, called *collaborative e-learning*, is defined as: "Constructing knowledge, negotiating meanings and/or solving problems through mutual engagement of two or more learners in a coordinated effort using Internet

DOI: 10.4018/978-1-60960-503-2.ch713

and electronic communications”(Salmons, 2008, p. 131).

The rationale for including highly interactive collaborative assignments is usually supported by references to the theory of social constructivism. A core notion of constructivism is that knowledge has a subjective dimension because people construct meaning based on their relationships with the world. Each individual learner imposes meaning on his or her experience. A teacher cannot impose meaning on learners. Social constructivism focuses on the social phenomena that occur when conceptual schemes are transmitted by means of language. From a social constructivist's view, knowledge is not simply constructed, it is co-constructed. Constructivism is considered antithetical to positivism or objectivism, the theoretical position that explanations must be empirically verifiable and knowledge exists independent of our own perceptions of it (Schutt, 2006). Positivist world views translate into instructional theory based on the assumption that the instructor transmits knowledge through direct instruction (Arbaugh & Benbunan-Fich, 2006).

Theories of social constructivism have their roots in the thinking of Dewey, Piaget, and Vygotsky and Bruner. These theorists described social learning that took place face-to-face in classrooms with children. To what extent do their theories support and explain social learning in online classrooms at the college level and with adult learners? What new principles are needed? The author proposes e-social constructivism as a framework for answering these questions.

METHODOLOGY

Employing phenomenological, grounded theory and situational analysis methods, this chapter meshes analysis of two sets of data. One set of data is derived from a theoretical sample of literature. A second set of data is drawn from in-depth

interviews the author conducted with a purposeful sample of experienced online educators.

Phenomenological research methods provide a way to investigate human experience through the perceptions of research participants. Theorist Husserl distinguished between “noema,” the phenomenon which is experienced and “noesis,” the act of experiencing the phenomenon (Husserl, 1931). In the author's study, phenomenological research methodology provided a structured approach for inquiry into the perceptions of success factors for instruction using collaborative e-learning. The four basic steps of phenomenological research described by Moustakas (1994) provided a methodological framework for the study. The author used in-depth dialogue with research participants at each of the four stages of the process: preparing to collect data, collecting data through in-depth interviews, analyzing data, and reporting outcomes. The study investigated noesis, the experiences of teaching with collaborative methods online, and noema, the organization and design of the learning activities participants used to promote collaboration.

Grounded theory complements phenomenological research. To apply this theory, researchers build on the understanding of individuals' experiences derived through phenomenological methods to generate theoretical principles (Creswell, 2007; Straus, 1987). They look at categories discovered in the data and construct explanatory theoretical frameworks, which provide abstract, conceptual understandings of the studied phenomena. Situational analysis is a style of grounded theory. Situational analysis looks at the social *situation* while grounded theory looks at social *process*. Situational analysts diagram elements in the research *situation* to capture the complexities and show relationships in the data. Theory is thus “grounded” in the data from participants who have experienced the phenomenon. Grounded theory can help explain practice or provide a framework for further research and more formal theory development.

Analysis of both sets of data was organized in three broad steps: data management, descriptive accounts, and explanatory accounts. At the descriptive accounts stage the researcher worked with the ordered data to identify key dimensions, to map the range of diversity of each phenomenon and to develop categories. The researcher used inductive reasoning to look for and compare patterns and associations in the data, and to locate linkages between sets of phenomena. Situational analysis maps were used to compare online and face-to-face learning situations. The explanatory account is the researcher's interpretations of the significance, implications, and theoretical conceptions of the findings.

DESCRIPTIVE ACCOUNT SUMMARY: FROM THE LITERATURE

Contemporary literature in education and instructional design draws on constructivist theory to support active, rather than receptive, models of teaching and learning. When learning activities expect *individuals* to investigate, discover, and construct new meanings they actualize cognitive constructivist principles. When learning activities expect *groups* of students to exchange and explore ideas together, they embody social constructivist principles. The following sections briefly review the theoretical contributions of foundational thinkers in the field of constructivism. Principles that apply to the theory of e-social constructivism are highlighted.

John Dewey (1859–1952): Progressive Education

John Dewey's work sets the stage for inquiry into social constructivism. John Dewey wrote at the advent of the industrial age, and observed the potential of the railroad and telegraph to "eliminate distance between peoples and classes previously hemmed off from one another" (Dewey, 1916, p.

85). He predicted that new forms of educative community would emerge because new connections would be made between people who previously had limited access to one another. "Persons do not become a society by living in physical proximity [...] A book or a letter may institute a more intimate association between human beings separated thousands of miles from each other than exists between dwellers under the same roof" (Dewey, 1916, p. 4). Dewey foresaw the potential, as well as the challenges new communications would bring to established ways of thinking and learning.

Dewey created a theory that links education with experience because he believed that learning occurs by "constant reorganizing or reconstructing of experience which adds to the meaning of experience, and which increases ability to direct the course of subsequent experience" (Dewey, 1916, p. 76). Dewey's theory is based on the premise that learning is a social function, with a central principle of *interaction*. He described interaction between the student and teacher, between the student and the *situation*, and among students (Dewey, 1916, 1938). Dewey recommended that learners actively participate in learning situations outside of the classroom, equating the community to the laboratory—a place to experiment (Dewey, 1938).

Dewey was a philosopher who was concerned with education within the larger contexts of participatory democracy. He believed that to be fulfilled and successful contributors to a complex world, students need an education that supports development of creativity, critical thinking, and problem-solving skills.

Jean Piaget (1896–1980): Sociocognitive Constructivism

Jean Piaget was a pioneer in child development. He was especially concerned with children's development of logical thinking capabilities (Piaget, 1952). Piaget's work is cited as a foundation for a thread of constructivism called sociocognitive or cognitive constructivism.

When students learn, according to sociocognitive constructivism, they create, adapt and refine knowledge (Piaget, 1971). They create knowledge structures and mental models through experience and observation (Tuominen & Savolainen, 2004). This perspective drew on Piaget's theory of cognitive development. Piaget's theory proposed that teaching knowledge learners can understand and use goes beyond just transmitting information. Instead, humans must construct their own knowledge. Individuals build their knowledge through experiences that they can abstract into conceptual frameworks or *schema* of the world (Maraon, Benarroch, & Gaomez, 2000; Tuominen & Savolainen, 2004).

The teacher's task is to help students move from their inaccurate ideas and schemas toward conceptions more in consonance with what has been validated by disciplinary communities (Windschitl, 2002). While Sociocognitive Constructivism is primarily concerned with the individual's learning, Piaget saw peer interactions as crucial to a child's affective development and construction of social and moral feelings, values, and social and intellectual competence (DeVries, 1997). Piaget and subsequent sociocognitive researchers typically based their research on comparisons between pairs of child subjects of the same age or developmental level.

Lev Vygotsky (1896–1934): Sociocultural Constructivism

Sociocultural Constructivism views knowledge as primarily a cultural product and learning as a causal relationship between social interaction and individual cognitive change (Dillenbourg, Baker, Blaye, & O'Malley, 1996; Vygotsky, 1978). Vygotsky is frequently cited as the foundational thinker for sociocultural constructivism. He argued that development and learning involve the interplay of interpsychological and intra-psychological dimensions. He characterized these dimensions as functions of language with social speech used to

communicate with others and inner speech used to reflect and think.

Vygotsky's conception of a *zone of proximal development* (ZPD) describes the distance between what one can do alone and what can be accomplished in collaboration with others who are more capable (Vygotsky, 1978). This is also called "appropriation" because a learner "appropriates" strategies used by a teacher, parent or more experienced learner. When one learner is more knowledgeable than the other, it is expected that the latter learns from the former. However, researchers have discovered that when students work together learning extends to the more able peer, who also benefits from the interaction.

The teacher's task is to offer meaningful, "whole" activities, constructive tasks or problem-solving situations, where more knowledgeable learners can assist others. Constructive tasks, such as conducting scientific inquiries, solving mathematical problems, and creating and interpreting literary texts, are contrasted with decontextualized skill-building (Windschitl, 2002).

Jerome Bruner: Discovery and Spiral Learning

Bruner outlined three steps of the learning process: acquisition of new information, transformation of the new information to fit new tasks, and evaluation, which takes place when learners check whether the new information is adequate to the task. He did not see these as discrete steps, but as part of a spiral, where learning continues to build and evolve through interactions with new ideas and people (Bruner, 1966, 1977). The concept of spiral curriculum inspired the practice called *scaffolding*. Scaffolding is described by Wood, Bruner, and Ross as "...controlling those elements of the task that are initially beyond the learners capability thus permitting him to concentrate upon and complete only those elements that are within his range of competence" (Wood, Bruner, & Ross, 1976, p. 90).

Scaffolding is most effective when learners and educators iteratively communicate their growing understandings. With respect to collaborative learning, at least two classes of scaffolds can be distinguished: (a) scaffolds that provide support on a content-related or conceptual level, and (b) scaffolds that provide support related to the interactive processes between the collaborators.

Social Constructivism: Contemporary Interpretations

The concept of social models of teaching and learning has generated many interpretations. A few summarized below.

- *Social learning theory* explains human behavior in terms of continuous reciprocal interaction between cognitive, behavioral, and environmental influences. Albert Bandura termed this interaction “reciprocal determinism.” He formulated a four stage process: (1) Attention: the individual notices something in the environment; (2) Retention: the individual remembers what was noticed; (3) Reproduction: the individual produces an action that is a copy of what was noticed; and (4) Motivation: the environment delivers a consequence that changes the probability the behavior will be repeated through reinforcement or punishment (Bandura, 1977, 1986). The basic principles proposed by Bandura are that people learn by observing others, and that learning can occur without an observable change in behavior. Cognition plays a role in learning, with attention as the critical factor. Modeling teaches new behaviors, may influence the frequency of previously learned behaviors and may also encourage previously forbidden behaviors. The model may be a “live model,” the actual person, or a “symbolic model” portrayed in print or media.
- *Exogenous, Dialectical, and Endogenous Constructivism* exist on a continuum, according to a model offered by Moshman (Moshman & Geil, 1998). *Exogenous Constructivism* emphasizes “external” knowledge is best taught through direct instruction, in conjunction with exercises requiring learners to be cognitively active. *Dialectical Constructivism* proposes that learning occurs through realistic experience, but that learners require *scaffolding* provided by teachers or experts as well as collaboration with peers. *Endogenous Constructivism* emphasizes the individual nature of each learner’s knowledge construction process, and suggests that the role of the teacher should be to act as a facilitator in providing experiences that are likely to result in challenges to learners’ existing models.
- *Ideas-Based Social Constructivism* changes the focus from learning through practical problem-solving to direct encounters with ideas. Prawat suggests that curriculum be thought of as a matrix of “big ideas.” Teachers serve as “managers or orchestrators” who work alongside students as they explore ideas together (Prawat, 1993).
- *Sociotransformative Constructivism* merges multicultural education with social constructivism, providing an “orientation to teaching and learning that pays close attention to how issues of power, gender, and equity influence not only what subject matter (curriculum) is covered but also how it is taught and to whom” (Rodriguez & Berryman, 2002, p. 1019). These theorists point to the concept of *agency* that bridges knowledge and transformative action. They believe that agency can lead to a deeper understanding of the subject matter and to the application of newly gained knowledge in socially relevant

ways (Rodriguez & Berryman, 2002; Zozakiewicz & Rodriguez, 2007).

- *Radical Constructivism* is “a theory of rational knowing” championed by Ernst Von Glasersfeld. Von Glasersfeld wrote:

Radical constructivism holds that the only instruction or information a knower can possibly receive from ‘nature’ or ‘reality’ is negative. In other words, the world beyond our experiential interface may show us what concepts, theories and actions are not viable, but it cannot instruct us what to think (Glasersfeld, 1996).

Radical constructivists believe teachers or facilitators should provide limited support, and learners should construct their own mental models within the environment that exemplifies the topics being studied (Dalgarno, 2001).

Summary of Social Constructivist Theories

The theorists cited above explored a wide range of pedagogic and philosophical questions. This section analyses positions expressed by these writers with respect to their applicability to an instructional theory of e-social constructivism.

Positional maps are a tool used in situational analysis to visualize major positions taken in the data (Clarke, 2005). Figure 1 illustrates relationships among theories reviewed in this chapter, with respect to the two dimensions: learning style and instructional style. This map provides a reference for understanding e-social learning theory in relation to earlier theories.

The vertical axis represents a continuum from the individual to the group as the focus of learning.

- In the first position, the focus is on the individual’s learning experience.

- In the middle position, the individual’s learning is catalyzed by the social process with the group.
- In the third position, the group is the focus with learning through interactions with peers and instructors.

The horizontal axis shows a continuum of instructional styles from instructor to learner-driven.

- In the first position, an instructor organizes and sequences content to convey information through direct instruction.
- In the middle position, an instructor facilitates learning by organizing and scaffolding assignments. The instructor shares knowledge, clarifies expectations and parameters, and keeps learners on topic and on task. The instructor is flexible and provides guidance as needed.
- In the third position, an instructor provides minimal guidance. Learners discover, contribute or generate knowledge independently.

Figure 1. Constructivist positions

DESCRIPTIVE ANALYSIS: FROM THE INTERVIEWS

In the author's pheomenological study of collaborative e-learning, participants were interviewed. The participants were instructors who taught various subjects using collaborative e-learning activities. Research participants self-identified as committed to constructivist epistemological views and pedagogies. While specific constructivist theories were not discussed, they generally reported a desire to teach in a "learner-centered" way. The interview questions were designed to elicit perspectives about instructional strategies the instructors used. They considered "success" in terms of sustained learner engagement throughout all stages of the activity, learners' ability to participate and contribute to the activity, as well as achievement of curricular objectives.

Three broad categories in the data from the study relate to the current analysis: (1) knowledge and skills needed to teach online with collaborative methods; (2) instructor commitment to collaboration; and (3) instructional milieu.

Knowledge and Skills Needed to Teach Online with Collaborative Methods

Research participants identified kinds of knowledge and skills they felt are essential for educators who teach using online collaborative methods. Throughout this section, quoted material is from research participants' responses unless otherwise noted. Responses were categorized into four areas:

- *Understand the new paradigm.* To be effective in designing and guiding collaborative learning, instructors need updated practical and theoretical understandings about teaching and learning. A research participant observed, "In order for faculty and students to succeed, [they] need to get

the sense of working in [a] different paradigm. [There is a] need for bridging theory and application."

- *Be an advocate:* Instructors need to be able to advocate the benefits of collaborative e-learning and overcome resistance and other barriers. A research participant asserted, "[the instructor] must be the enabler to get the collaboration done, the 'driver' to push the things."
- *Model collaborative behaviors.* The best way that instructors drive productive collaborative behaviors is by modeling them. A research participant said, "I make sure I am modeling openness and experimentation, being an equal learner with others in the class."
- *Have skills in online communication and facilitation.* Research participants spoke at length about what they considered the most essential skills: online communication and facilitation. Given the potential for dispersed class members to feel isolated, a research participant observed that, while in a face-to face lecture it is not necessary for instructors to know learners, in an online class, they interact one-on-one. Another research participant described the importance of using people skills online: being sensitive, patient and able to "show[ing] concern and guidance as needed, with a nurturing style."

Instructor Commitment to Online Collaboration

Research participants believed it is critically important for online instructors to be committed to collaborative methods and prepared to take varied individual and group actions to facilitate collaborative activities in online classes. All respondents made the point that, for online collaboration to successfully occur, the instructor must be prepared

to take an active role. Laying the groundwork for interaction between instructor and learners as well as among learners requires careful attention. They described three key responsibilities for instructors:

- *Designing, planning and structuring learning activities.* Study participants emphasized the value of well-planned learning activities. While in some cases the assignments are already in place as part of an online class design, instructional choices remain.

Research participants emphasized that successful collaboration happens when online learners trust each other *and* trust the process. This generalization is widely supported in the research literature on the subject. Learners, who may lack previous experience with virtual collaboration, want to know that the expectations, allocation of tasks in the collaborative group and assessments of shared outcomes are fair. They want assurance that instructor's assistance is readily available if the process is not working.

Several research participants pointed out that when the work is structured into stages, learners focus on the task and course content without being overwhelmed by the process. Participants recommended that the instructor direct the approach in the early stages of collaboration and increasingly put responsibility into learners' hands. The instructor begins by assessing learners' readiness for collaboration and makes choices about how, when and to what extent responsibility can shift to the learners. The instructor can gradually "allow learners to build on or suggest options so learners co-create the next steps."

Instructors "provide a framework so students can focus on the task. Define clearly the time limits, geographic or conceptual limits of the task." The instructor should work to "move students toward being autonomous and self-organized but, initially, show them how to participate." Research

participants were in consensus that expectations and specific instructional guidelines help learners understand how to move from one stage of the collaborative process to another.

- *Being a learning coach.* As instructors, research participants encourage critical thinking about learning, meta-thinking or meta-learning and reflection. A research participant pointed out that online instructors need to "be present but not present," to allow groups to solve their own problems and intervene only when the group cannot resolve a difficulty. Another participant made a similar suggestion: "when there is discomfort, be silent, be there and listen. Listen before intervening." In addition to group coaching, several research participants suggested that private coaching or one-to-one communication with a learner is appropriate when the collaborative process is stuck. A learner may benefit from the instructor's individual attention if that learner falls behind or surges ahead. In either case, such learners can jeopardize the success of the team. A participant depicted the circumstance where a highly motivated, capable learner works independently to complete an entire task, thereby disempowering the collaborative group and undercutting shared agreements and timelines. On the other end of the spectrum is the passive lurker, someone who is not pulling his or her weight. Instructors should intervene to explain relevant points about the collaborative process and motivate the learner to fulfill his or her responsibility to the team, and/or encourage the team to review work agreements for completing the project. In such situations timely involvement of the instructor can help the group avoid getting sidetracked by group process.

- *Developing learners' collaboration skills.* A participant made the collaborative process part of the lesson: "it is extremely important to discuss nature and value of collaboration before embarking." Several participants assigned regular and frequent partner work, then built up to the small group so learners get a taste of success. They provide suggestions for different roles people can take in teams and let learners choose, and allow learners to build on or suggest options so learners cocreate activities.

In summary, at each stage of the instructional process research participants took active, responsive roles to help learners structure, organize and complete the collaborative activity. In the process, they sought to build learners' skills in online collaboration while learners worked to achieve curricular goals.

Instructional Milieu

When asked, "Why do you think the collaborative e-learning was a success?" research participants discussed issues of trust and safety as the most important factors. Research participants described a safe learning environment as one where learners can take risks, "have wild ideas, be creative and innovative." A research participant suggested that instructors need to: "reduce stakes for participation to the point that people do not perceive a high risk for failure or perceive that not succeeding to the highest degree is a learning opportunity, with no comebacks or humiliating criticism." One participant stressed the importance of making mistakes in the class to avoid making them in professional life later on, when they could be very costly. This participant told learners that making such mistakes was a course expectation from the outset.

EXPLANATORY ANALYSIS: COMPARING CATEGORIES FROM RESEARCH AND LITERATURE

John Dewey talked about learning as interaction involving students, teachers, content, and situation. Later Joseph Schwab used the term *commonplaces* to describe these four interrelated factors (Schwab, 1983). The first three commonplaces receive similar consideration in the literature and in the results of the author's research. The fourth commonplace, *situation*, differentiates the literature written to describe instruction in the face-to-face classroom from the perceptions of those who teach in online milieu. The theoretical literature made only passing reference to the situation, whereas online instructors described it as critically important.

In situational analysis, researchers chart elements for comparison in an *abstract situational map* (Clarke, 2005). This type of map lays out the major human and nonhuman elements in the research situation. The following figure highlights elements that influence the instructor's role in collaborative e-learning.

Research participants discussed several ways that online milieu influence collaborative e-learning. They highlighted three points with important implications for online settings: trust and safety, *transactional distance*, and skills and equipment.

Issues of trust and safety were at the top of every research participant's list. Research participants described a safe learning environment as one where learners can build relationships and gain the trust needed to share ideas and learn together. Research participants believe that the instructor has an important role in creating this kind of atmosphere. They described the use of the constructivist principle of scaffolding, where learning activities build progressively to "gently walk learners" into the collaborative activities. They discussed starting with "low risk activities that encourage a sense of group" by inviting

everyone to participate. No grades are given for these foundational activities. In contrast, trust and safety issues were not referenced in previous theoretical literature.

Another aspect of online communications relevant to the collaborative process is transactional distance. The term *transactional distance* describes the gap in time between comment and response in discussions that occur asynchronously, not simultaneously. Online interaction differs from face-to-face conversation because nonverbal cues are absent. Researchers discuss the importance of creating presence (Rourke, Garrison, Anderson, & Archer, 2000) and immediacy (Conaway, Easton, & Schmidt, 2005) to overcome the isolation learners may feel. Instructors demonstrate social presence to make sure learners are engaged in the interactive process. They demonstrate cognitive presence by providing explanations, guidance, and resources to ensure learners are finding, comprehending and analyzing class content. When multimedia synchronous meeting tools and immersive environments are used to bring online classes and instructors together, learners may report fewer problems with isolation and transactional distance may decrease.

A third difference in the online environment is that special skills, hardware and software are needed to enter the virtual classroom and participate. This fundamental question of access was discussed by research participants, but not in the literature. (The literature reviewed was written before “access” for children with disabilities had become a consideration—or a mandate.)

Findings from this study suggest that online instructors need to support development of trusting relationships, demonstrate presence to prevent isolation that would keep learners from engaging in social learning exchanges, help learners either develop skills or find technical support services necessary for online participation, and guide them toward intellectual exchange and growth. An important conclusion based on this is that a radical hands-off interpretation of constructivism would

not offer optimal instructional presence necessary to support collaborative e-learning activities.

A THEORY OF E-SOCIAL CONSTRUCTIVISM

Based on the comparison of categories in the theoretical literature and the practical experiences described in the interview data, I propose e-social constructivism as an updated educational theory. Since this theory aims to contribute toward improvement of teaching and learning, it can be described as an *instructional theory*. Educational theories can be classified as either learning theories or instructional theories. According to Jerome Bruner, theories of learning are descriptive, while a theory of instruction is prescriptive (Morrison, Ross, & Kemp, 2004). Learning theories describe, after the fact, how people learn. A theory of instruction recommends the most effective way of designing and conducting instructional activities so learners acquire the knowledge or skill (Morrison et al., 2004). A theory of instruction is concerned with *improving* rather than describing learning.

In the following figure, the *theory of e-social constructivism* is placed in a central position. This position represents a balanced, guided facilitation role for instructors and a balance of individual and social learning. The theory acknowledges the interplay of individual and social constructions of knowledge, the need for internalized speech and reflection, and individual and collective contributions in the collaborative process.

This *e-social constructivism* theory recognizes the unique set of opportunities and limitations of the online social and learning milieu. While learner-centered, this theory recommends important roles for educators who endeavor to teach online with collaborative methods. Kouzes and Posner point out that, “As paradoxical as it might seem, leadership is more essential—not less—when collaboration is required” (p. 243). The same might be said in the educational context,

Figure 2.

where more instructional presence is needed for collaborative, in contrast to individual, online assignments. Thoughtful attention to structure, purpose, and guidance can result in collaborative e-learning that truly engages learners in construction of new meanings.

PRINCIPLES OF E-SOCIAL CONSTRUCTIVISM

Learning occurs through meaningful interaction with content, content experts (who may include instructors, authorities or skilled practitioners) and peers. Learning is supported in online milieu that are conducive to social exchange and to exploration by both individuals and groups. The collaborative process and the subject matter that is the focus of collaborative activity both provide important context as learners construct meaning from their activities.

Through collaborative e-learning activities, learners acquire new knowledge together with partners, exchange and appropriate knowledge through peer exchange, and/or create new,

innovative knowledge, skills and solutions. Instructors should acknowledge that learners' prior experiences and cultural, institutional, and historical contexts influence individual and team accomplishment.

If online courses are designed with social, collaborative activates, instructors must help learners avoid isolation and separation from the interactive process. Using the principles of scaffolding, instructors provide support and information learners need to interact successfully in online milieu. Instructors' social and cognitive presence is essential to the success of learners and learning teams.

Instructors should encourage learners to develop and use information and communications technology (ICT), competencies by integrating opportunities to develop progressively more complex online research, collaboration, and communication skills.

CONCLUSION

This chapter presented a grounded theory and situational analysis of two sources: theoretical concepts from the literature and perceptions of educators who participated in a phenomenological study of collaborative e-learning. After comparing positions of various theorists with tested, practical ideas reported by constructivist online instructors, those ideas and positions most applicable to collaborative e-learning were integrated into a theory of e-social constructivism. *E-social constructivism* principles integrate applicable ideas from previous theories with considerations specific to the online learning milieu. I hypothesize that designing, planning and teaching with collaborative e-learning activities based on principles of e-social constructivism will measurably improve learning outcomes as well as learner engagement and satisfaction.

The present version of this theory may serve as a framework for those who create and facilitate

learners in collaborative e-learning activities. However, I hope that the *e-social constructivism* theory will evolve with future research, discussion and thinking by other researchers and instructors. The theory will also evolve with the integration of more multimedia, synchronous tools into online learning—which may erase some of the distinctions between online and face-to-face learning situations. Like other constructivist theories that came before, I hope it will motivate educators and researchers to create new directions and advance the field.

KEY TERMS AND DEFINITIONS

Appropriation: A kind of peer learning that occurs when a learner "appropriates" strategies used by a stronger or more experienced learner.

Collaborative E-Learning: Constructing knowledge, negotiating meanings, and/or solving problems through mutual engagement of two or more learners in a coordinated effort using Internet and electronic communications.

Collaboration Software: Collaboration software may operate either synchronously, allowing all users to participate simultaneously, or asynchronously, allowing users to participate at any time. Synchronous tools allow collaborative partners to meet and discuss projects, give presentations, view and edit documents in real time, or share applications. Synchronous collaboration tools include videoconferencing, online meeting platforms, shared whiteboard, Voice Over Internet, voting, chat or messaging, and immersive 3-D

environments. Asynchronous tools allow collaborative partners to exchange materials, contact lists, or to access shared files or resources, libraries or archives. Asynchronous collaboration tools include e-mail, Wikis, blogs, shared calendars, polling, track changes, and document exchange

Constructivism: Constructivism both an epistemological view and an instructional method. A core notion of constructivism is that individuals live in the world of their subjective experiences—a world where they construct their own meanings.

E-Learning: An educational activity or course conducted in an electronic learning milieu, using Internet communication technologies for delivery of instruction, curricular materials and learning activities. In this study, e-learning refers to instructor-lead academic courses which may be offered partially or entirely online.

Interaction: Reciprocal actions, effects or influences; the effect of one variable on another variable (Soanes & Stevenson, 2004). Between individuals, interaction entails acting in such a way to have an effect on each other; or a mutually affecting experience. Whether online or face-to-face, interaction typically involves communication between individuals.

Social Constructivism: An educational theory based on the principle that learners and teachers coconstruct knowledge through social processes.

Teaching with Collaborative Methods: Organizing learning activities and creating an environment where collaborative e-learning occurs, and assessing the success of outcomes.

Threaded Discussion: Threaded discussion (or discussion forum) is a form of asynchronous discussion where original comments and responses are organized by topic. Threaded discussion occurs when one user posts a message that is visible to other users, who respond in their owntime. A “thread” is formed when the software groups users’ comments hierarchically under the original post. Threaded discussions create a linear format with continuity of comments on topic.

Transactional Distance: Transactional distance describes the gap in time between comment and response in discussions that occur asynchronously, not simultaneously.

Zone of Proximal Development (ZPD): Zone of Proximal Development (ZPD) describes the distance between what one can do alone and what can be accomplished in collaboration with others who are more capable (Vygotsky, 1978).

Chapter 7.14

Ethics in Interactions in Distance Education

Paul Kawachi
Open Education Network, Japan

ABSTRACT

This chapter presents the desirable interactions involved in teaching and learning at a distance. In these interactions, there are considerable ethical issues—notably that one’s own learner autonomy should be reduced at times in order to help others learn, to achieve the learning task, and at the same time help oneself to learn. Accordingly, learner autonomy is not an overarching goal of education. This is controversial, and this chapter deals with this issue in detail to explain that learner autonomy at best is a rough guideline, and ethically based on reasoning that autonomy should be interpreted as flexibly applied. The maxim that learner autonomy must be flexibly applied is particularly true in both cooperative group learning and in collaborative group learning in distance education where student

interactions with other students constitute a major part of the education process. The ethics in interaction in distance education are extended to cover all possible interactions, especially the important interaction by the teacher to each student followed by the interactions by the student with the learning process, that can initiate the aesthetic social intrinsic motivation to lifelong learning and thus to one’s own emancipation. Accordingly, ethics are defined here as those pro-active interactions that induce the motivation to lifelong learning in all the students. Such ethics should override individualist autonomy as a goal in education.

INTRODUCTION

This chapter aims to define what is meant by ethics in interactions in distance education and presents the 2007 current state of the art with respect to

DOI: 10.4018/978-1-60960-503-2.ch714

such ethics. At first it is best to define and frame what is meant by ethics. Here, ethics covers what human conduct is right or wrong based on reasoning, whereas morals can be interpreted as that conduct based on social custom. This chapter will focus on only that human conduct that is good practice, and not on that which is bad. Therefore, bad practices such as copyright infringement, plagiarism, and intellectual property theft are not discussed, mainly because they are generally covered by relevant local law.

It is also important to explain what is covered by interactions in distance education. There are at least five types of interaction reported in the literature: student-teacher, student-student, student-content, student-technology, and vicarious interaction. The fifth one of vicarious interaction was suggested by Sutton (2001) to occur when a student observes interactions between or among others, but in a carefully controlled study, Kawachi (2003a) found that no educational advantage was attributable to such vicarious interaction, likely due to those active participants who were interacting also deploying similar attention so no significant difference was found. Because some poorer quality of learning was seen in those not participating, then vicarious interaction was concluded to be disadvantageous and that active participation was to be emphasized for learning. The fourth, student-technology interaction, was suggested by Hillman, Willis and Gunawardena (1994) mainly in terms of there being a human-computer interface barrier to learning for some students with weak computer and technological literacy. Both these are not discussed any further here. This chapter will focus on the other three interactions.

Distance education may need clarification, and here the definition is drawn from the transactional distance theory of Moore (1993). Transactional distance may be interpreted as the psychological gap between what the student already knows and the content about to be learned. In particular, this theory describes transactional distance in terms

of the three dimensions of structure, dialogue, and autonomy. Based on this theory, a four-stage model of learning has been proposed and validated by Kawachi (2003b, 2005), notably in open and distance education in 15 regions throughout Asia. How to interact optimally and therefore ethically through applying this model will be one of the two key points presented in this chapter. The other key point will be that autonomy must be moderated by some affective motivations in the student in order to interact optimally to learn.

METHODS

Transactional distance theory postulates four categories of distance education according to the amount of structure (S+) imposed by the institution, and the amount of educative dialogue (D+) between the student and other persons. The most distant category has no dialogue and no structure (D- S-), the next closer has added structure (D- S+), the third has then added dialogue (D+ S+), and the fourth category of minimal transactional distance has dialogue and freedom (no imposed structure) (D+ S-). It should be kept in mind here that dialogue (D+) means being with educative intent. Accordingly, it should be mentioned somewhere here that young distant students often want student-teacher interaction such as face-to-face tutorial time to get their money's worth, and at the other end of the scale, older distant students want student-student interaction for socialization purposes, but because other students may be much younger, then they choose student-teacher interaction. Both these can be moved aside as not being ideally educative in purpose or intent.

Based on these categories, a model of learning in distance education has been designed and tested out as effective by Kawachi (2004) with four stages that constitute the learning process, bringing the student from furthest transactional distance to closest; in other words, bridging the gap between not knowing and knowing. The first

Stage 1 (D- S-) is characterized by cooperative brainstorming and eliciting the student's prior knowledge and ideas; the second Stage 2 (D- S+) is characterized by vertical thinking to discern collaboratively the theory underlying the student's knowledge; Stage 3 (D+ S+) is characterized by collaborative hypotheses testing, problem solving or disjunctive horizontal thinking to consider all other possible solutions and ideas, and find a potentially better way forward; and then Stage 4 (D+ S-) is characterized by experiential learning cooperatively to test out this potential new way to socially construct new personal meaning, as detailed in Kawachi (2003c). These four stages constitute one cycle, and new learning then proceeds iteratively.

Worldwide, validation has found that students have difficulty in the collaborative theorizing of Stage 2 and in collaboratively performing disjunctive reasoning in Stage 3. Generally, students successfully completed the four-stage cycle and achieved deep quality learning if they were in small groups of 4-8 students, if they had high prior knowledge, or if they received close tutor monitoring and guidance. When in large classes, with low or mixed prior knowledge, and when given normal tutor care, then students were unable to move into and through Stage 3. Similar findings have been reported by Perry (1970), who found college students in large classes could not acquire critical thinking skills. Piaget (1977) has also acknowledged that many people do not reach the Stage 3 level of formal operations involving hypotheses-generating and testing even in adulthood. Similarly, Renner (1976) has reported that only 81% of final-year law students, and McKinnon (1976) that only 50% of college students overall at seven different colleges, could acquire critical thinking skills, expressed here as the goals in Stages 3 and 4. In their analysis of computer-mediated conferencing, Gunawardena, Lowe and Anderson (1997) found that participants did not proceed beyond the discovery and sharing of ideas, concepts and statements of Stage 1, and

did not reach any collaborative phase of negotiation and co-construction of new knowledge. The participants in their study were relative experts in the use of distance education being (likely) graduate students and university-level teachers participating in ICDE95-Online virtual preconference of the International Council on Distance Education. In a following study, Gunawardena, Plass and Salisbury (2001, p. 39) found that the "intended collaboration and sharing of ideas and issues simply did not happen."

In cooperative group learning in which one participant already knows the content to be learned by the others, the ethics of the cooperative interactions by the knower—either the teacher or an expert student—have been reported by Lewis (1995, p. 27) as being limited to the four following educative purposes: (1) summative to explain a grade, discuss and link the student's work to the institutional criteria; (2) formative to further the student's learning; (3) summarising what has been done; and (4) comment to help the student plan future learning. The ethics of all other cooperative interactions need to be weighed carefully according to whether the interaction is performed synchronously or asynchronously. In synchronous media, other participants may not have adequate time to read or listen to long utterances. Being overly verbose in synchronous mode may be deemed unethical by others in the group. In asynchronous mode, files can be transferred and read more easily. Cooperative lengthy exposition is unethical during the collaborative learning stages, Stage 2 and Stage 3, and should be put aside into a Virtual Coffee Shop or other chat forum for the explicit purpose of keeping the collaborative forum uncluttered. It is, however, in the collaborative stages that all the participants (the teacher here is equally as unknowing as the students) need to understand and follow some right conduct based on reasoning, in other words, abide by some ethics in the interactions they engage in, for learning together.

Scaffolding has been suggested (Kawachi, 2003b) to guide students through collaborative group learning, particularly the disjunctive reasoning and group interactions of Stage 3 (D+ S+) for hypotheses testing and co-construction of new nonfoundational knowledge. Scaffolding may be cooperative between a participant (such as the teacher) who knows the content and the student who does not, where according to Wood, Bruner and Ross (1976, p. 89) “an adult or expert helps somebody who is less adult or less expert ... a situation in which one member knows the answer and the other does not,” while Vygotsky (1978, p. 86) indicates that cooperative scaffolding can be from a “more capable” student to a less capable student. The ethics of teacher to student interaction in Stage 1 involve the teacher making explicit to the student the aims and objectives of the task so the student can indeed comprehend these, noting that if the teacher fails here, then any later teacher feedback and error correction become merely vehicles for imitation and copying (which in turn may be described as student unethical conduct). The difficulty actually lies in scaffolding the collaborative interactions, and ethics here can pre-empt needless “flaming” and irrelevant argumentation in countering views from others.

Zimmer (1995) has proposed the collaborative scaffolding, involving three functional turn-taking steps ABA between two persons A and B, which when repeated as BAB give both participants the opportunities each to give opinions and receive counter-opinions empathically, as follows.

- (A) (Hello) Affirm + Elicitation
- (B) Opinion + Request understanding
- (A) Confirm + Counter-opinion
- (B) Affirm + Elicitation
- (A) Opinion + Request understanding
- (B) Confirm + Counter-opinion

Figure 1. Ethical interactions in collaborative distance education

The scaffolding of the ethical interactions necessary is reproduced here from Zimmer (1995, p. 142) as a three-leaf pattern in Figure 1.

In Figure 1, the ethical expressions are as follows: (1) warm affirmation “you’re okay by me;” (2) inviting open disclosure in response “please tell me what you want to do here, so that I can see your point of view;” (3) open disclosure “here’s my own experience and what I want to do ...;” (4) inviting empathic comprehension in response “I’d welcome knowing what you think I mean, to be sure my feelings are accepted” or “I’d like your sense of what I mean;” (5) empathic comprehension “what I think you mean in essence is ...;” and (6) “my own view differs ...” or “I’d like you to hear my own view” inviting warm affirmation in response.

The phrases in the above paragraph for use in the interactions are reproduced almost verbatim from Zimmer (1995, p. 142 and p. 144). Zimmer suggests that these interactions (p. 143) “dissolve competitive opposition, by inviting open disclosure, warm affirmation and empathic comprehension in direct response to perceived dogmatism, disparagement and invalidation.” It can be noticed for ethics that the interactions (3), (4) and (6) on the left side deal only with one’s own learning, and the interactions (1), (2) and (5) on the right side deal altruistically with the learning in the other student. Moreover, I suggest that

any participant(s) may be behind either voice, so the scaffold could be effective for more than two persons at the same time. In the distance education virtual classroom in a collaborative group task, the author can confirm that prior awareness of this template by (at least) one participant can successfully scaffold the interactions to reach the task goal.

Now a literature search has found (only) one other scaffolding model, suggested by Probst (1987) as transactional theory for literature. From reading his work, I have drawn the ethical interactions for collaborative learning in literature and art, in which the interactions are not aimed at hypotheses-testing characterised by counter-opinion, but rather aimed at achieving a new insight built on critical reflection that while shared may be personalised in each individual. In literature, learning is not cooperative: There is no “knower,” the teacher or expert student does not guide the less able student to some preset conclusion of the meaning of the text. In literature, the teacher or any expert student (A) elicits opinion to initiate the three functional turn-taking steps BAB, and then followed by ABA, as follows.

- (A) (Hello) Affirm + Elicitation
- (B) Opinion/Analysis + Request understanding
- (A) Affirm + Elicitation of Evidence
- (B) Reflect + Elicit other opinions/Analyses
- (A) Opinion/Analysis + Request understanding
- (B) Affirm + Elicitation of Evidence
- (A) Reflect + Elicit other opinions/Analyses

This scaffolding model involves reflective analysis followed by articulation, bringing in ideas from one's own prior reading or ideas elicited from other students, then repeating the reflective analysis with accommodation to construct a new personal insight. As in Zimmer's model, I suggest any participant may be behind each voice, so any number of participants can be collaboratively involved.

RESULTS

These two models each illustrate and scaffold the desirable ethical interactions which are essential for achieving one's own collaborative learning and ethically helping others to learn. The interactions can be performed either synchronously in a virtual classroom or asynchronously through e-mail or discussion board. In each model, the scaffolding clearly and explicitly indicates what content should optimally be included in an utterance (and therefore what should not be included), and specifies in what serial order to progress toward achieving discovery and co-construction of new understanding and new knowledge. It should also be noted that the use of a framework also implies some timeliness in replies. The system would not function if turn-taking were violated or not forthcoming. Participants need to take responsibility for the group succeeding by actively providing ethically what is required and when it is required. In this way, some pacing is inevitable if the group is to move toward achieving its goal. To some large extent, nonresponse in an asynchronous environment can be overcome by others offering up the required content in time. This is often the case in synchronous free discussions. However, group cohesiveness depends on the active participation of all members of the group. If a student does not participate, the group is fragmented and not functioning as a whole. Prior to the task, coping strategies should be acquired, agreed upon, and then used when required, such as pre-arranging the time interval allowed within which a student should contribute, pairing up students to provide back-up in case one is at a loss, or behind-the-scenes coaxing and elicitation by the moderator.

DISCUSSION

Ethics in interactions in distance education can be determined as those that are appropriate to achieving emancipation and learning for one's

self, and to helping altruistically learning in others. Such help may be at one's own expense in money, time and effort, and are not just with kind intentions but constituting educationally effective help. There is an old Indian proverb that is relevant here concerning these ethics: "Help your friend's boat cross the raging river, and lo you will find that you yourself have crossed the river."

Here then, the ethically good interactions are identified. And it is noted en passant that student-student interaction such as only commenting "Great work!" on another student's Web-log does not ethically qualify as fulfilling a course requirement for interaction.

The above discussion has looked at the two dimensions of structure (S+) and dialogue (D+) in distance education. There is the third dimension of autonomy to be discussed now. Autonomy was defined by Moore (1990, p. 13) as "the extent to which the learner determines objectives, implementation procedures, and resources and evaluation." Generally, definitions of autonomy in learning have in common an emphasis on the capacity to think rationally, reflect, analyse evidence, and make judgements; to know oneself and be free to form and express one's own opinions; and finally, to be able to act in the world, according to Tennant and Pogson (1995). These qualities characterise the collaborative thought processes of Stage 3, and also the experiential aspect of Stage 4. Stage 1 has maximal transactional distance, and for a student to succeed here in independent learning Moore (1993, p. 27) points out that the student would need maximum autonomy. Autonomy is thus seen as a highly powerful and desirable quality for independent learners. Not all students bring this high level of autonomy with them initially into their studies, and so the teacher must bring the student around to acquire this autonomy. The four-stage model of learning illustrates the cyclic iterative process through Stages 1 to 4 to equip and bring the student to go onto independent learning in a further new cycle starting at Stage 1 in a new learning venture. Autonomy has also

been related to recognizing one's interdependence on others (Boud, 1988). Interdependence relates to understanding the need to learn together with others either in cooperative mode or at other times in collaborative mode. Interdependence is a maturity characterising an adult student, and is acquired through awareness and prior experience of the critical thinking process. Toward the end of Stage 4, the student can have acquired this sense of interdependence. So in entering a new Stage 1 iteration, the student may be interdependent (post-Stage 4) and once more newly independent (starting a fresh Stage 1). These attributes of independence and interdependence have already been found to be separate, orthogonal, and coexisting in mature students at the end their course (Chen & Willits, 1999). While autonomy is defined as an attribute of the student, different distance education programmes and the different stages in the model relate to different levels of autonomy for the student to be a successful learner. In a programme at Stage 2, the deployed structure means that the student is charged with thinking rationally but vertically rather than horizontally, and is analysing already given evidence, rather than finding new evidence, so the quality of autonomy is somewhat measured to fit the limited freedom given to the student. At Stage 3, different qualities of autonomy for hypotheses testing are needed for success, including a mature openness to new ideas that might be in conflict with one's previous and present conceived view of the world. The student needs to exercise the freedom to formulate or reformulate one's own conceptions. While in Stage 4, the quality of autonomy should include the willingness and ability to act to test out these newly constructed ideas to see experientially how they operate in practice. The amount of autonomy in each stage or different programme varies according to the task and nature of the course. The ethics involved in the interactions then in distance education govern the conduct of autonomy at some times requiring certain qualities to be forthcoming and at other times different qualities in order

to achieve learning. It is difficult therefore and moreover unhelpful to assign an integrated level of autonomy to each stage in the model of learning. The student should utilize measured amounts of the various qualities that constitute autonomy during each stage to support learning.

Clearly, ethics are needed in interactions in distance education to achieve efficiently one's own learning, and also to help others to learn cooperatively and collaboratively in a group, as detailed in the four-stage model of learning.

Finally, in this chapter it may be useful to consider the various lines of interaction between the student and content, student and teacher, and between the student and other students, and the affective motivations that drive these interactions and consequently moderate the level of autonomy. Here "modulating" the level of autonomy may be a more appropriate term, because autonomy must be varied and at times be consciously reduced, and such variation and occasional reduction is ethics in the interaction: One does not single-mindedly pursue ever-increasing autonomy; rather, some aspects are relaxed or reduced while other aspects are increased to achieve one's own learning goals and, more importantly for ethics, to help others learn. This chapter has so far considered aspects in three of the four known dimensions of learning: the cognitive, metacognitive, and the environment. The fourth dimension is the affective domain, involving the will and motivations that drive learning, detailed in Kawachi (2006). A comprehensive categorization of the motivations to learn was discovered and drawn by Taylor (1983) with the vocational, academic, personal, and social motivations, and later divided by Gibbs, Morgan and Taylor (1984, p. 170) into their subcategories of extrinsic and intrinsic. Of interest here is the social intrinsic motivation to learn, that acts along the lines of the interactions in distance education.

The three interactions involved here are the student-student, student-teacher, and student-content. The first two are already covered above in cooperative learning and in collaborative learning.

The third interaction between the student and the content which is collaborative has been described as being aesthetic reading in transaction theory by Rosenblatt (1994, p. 27). The process of motivation to learn is described in detail by Kawachi (2006). Briefly, the student is motivated to learn when the student compares his or her own perception of her current state with some reference goal value, when the observed gap (constituting a want or need) drives the student to act to reduce the discrepancy. The standard reference goals are generally preset socially and culturally, and the teacher should ethically make all efforts to know these in the distant students. The other factor here is that the student must also perceive there to be an opportunity to act and that there is a reasonable chance of success based on prior learning experience. The student-teacher interactions above have covered these points.

The student-content aesthetic interaction gives rise to the motivation for lifelong learning (Kawachi, 2005, 2006), which is generally recognized as being a central goal of education. The teacher or any other participant can initiate this motivation in the student. It occurs through experiencing pleasure or joy. There are only three positive affects in the affective domain. These are interest, pleasure, and joy, according to Tomkins (1984), and six negative affects (distress, fear, shame, contempt, disgust, and anger). It may be worthwhile reiterating here that ethics in interactions in distance education should carefully avoid causing these negative affects in others, and they are not discussed further here.

Barthes (1976) developed a theory of pleasure distinguishing between pleasure and joy, in which pleasure is the gratification usually previously experienced and therefore within the known world of the student. The student knows what brings pleasure and can look forward to experiencing it again by revisiting similar circumstances. Joy, on the other hand, occurs at the boundary of the student's world. When the boundary is momentarily and unexpected broken, then at that instant

of ecstasy, the student experiences the joy of learning. The teacher or any other participant can bring the student to within reach of this by moving the student toward his limit and then presenting surprising new information. “The penny drops” in the student’s mind, sometimes immediately, sometimes much later unexpectedly, and sometimes never. The aesthetic experience derives from this process or activity of group learning, and is addictive.

The interactions involved and the ethics involved here in the interactions to promote aesthetic motivation and lifelong learning in others are important. When carefully guiding others in this direction, one must suspend one’s own desire for increasing one’s own learning autonomy. Autonomy is accordingly ethically modulated by these affective factors for learning. Whether or not one is engaged in learning for oneself as a simple-minded student or is helping others to learn as a mature responsible student or teacher, nevertheless one must be careful ethically so as not to disturb others negatively, and ideally one should help others if at all possible.

FUTURE RESEARCH DIRECTIONS

Future research is warranted into optimal transactions for learning online. In particular, scaffolds should be constructed and provided to students to facilitate their cooperative learning in a group and for their collaborative learning in a group. For students new to online learning, these scaffolds can be detailed templates for them to use to support their learning, and at the same time will serve as metacognitive tools to guide their thinking and reflection. The templates will also comprise an e-learning portfolio for the students individually and as a group, and for the teachers and accrediting institution. At more advanced levels, the templates can be less detailed and more flexible.

Future research should not only focus on ways to promote ethically good practice, but should

analyse online discourse to illustrate where and how unreasoned practice leads to breakdown in communication and poorer quality learning outcomes. So, three-way control studies should be undertaken into online discourse analysis of learning. Three groups are needed to detect the influence of observations and any novelty or Hawthorne effects.

How students learn online independently of others is also a worthwhile avenue to explore in future research. It is generally accepted that in conventional face-to-face education studying in a group leads to better quality learning than studying alone independently, but while hundreds of studies have demonstrated this in face-to-face education, there are none so far to date that have compared these ways of learning in an online e-learning course. This maybe due to the transfer of what works best in the conventional mode into the online mode. However, the online mode now offers rich learning environments that likely support independent study. These rich environments include search engines that can pick out key phrases from blogs, wikis, stored powerpoint presentations, lecture notes, annotations by previous students, and so forth. Moreover, if learning-by-doing has validity in face-to-face conventional education, it may also have validity in online virtual reality and other technologies. Studying alone will raise many more questions of online ethics, which have hitherto not yet been considered.

CONCLUSION

This chapter has looked at what is distance education and at the three dimensions of structure, dialogue, and autonomy of transactional distance theory that can describe distance education. It has also looked at the interactions involved in distance education to achieve learning in one’s own mind and to help others to learn, both in the cooperative mode and in the collaborative mode, and it has looked at the desirable good conduct that is

based on reasoning which is known as ethics. All these points have defined ethics in interactions in distance education.

Some reports in the literature (for a typical example, see Conrad, 2002) have tried to uncover student thoughts and ways of learning online through teacher observations, but it is noted here that the author of this chapter has been a lifelong student within online interactivity, and this discussion draws from this long, wide and continuing learning experience. In particular, the author thanks my tutor Fred Lockwood at the British Open University, now Professor Emeritus at Manchester Metro University, and my teaching staff Stacey Rowland, Janet Gubbins and Melanie Clay at the University of West Georgia, from where the author graduated in Advanced Technologies for Distance Education in July 2007, and the fellow distance education students there, including Pam Miller, Bessie Nkonge, Diane Fulkerson, Sue Walters, Mauri Collins, and others.

Chapter 7.15

Implications of Anonymity in Cyber Education

Bobbe Baggio

Advantage Learning Technologies, USA

Yoany Beldarrain

Florida Virtual School, USA

ABSTRACT

This chapter explores the pros and cons of anonymity in cyber education and discusses possible ethical and social implications for online learning. It evaluates both sides of the anonymity issue and presents strategies that may help cyber educators and instructional designers safeguard academic integrity. The educational implications include concern for authenticity and academic integrity, and the dynamics found in social presence. This chapter discusses pertinent policy while analyzing anonymity's potential for limiting and monitoring academic freedom and the social benefits it brings. Strategies are suggested to enhance social presence by planning for interaction through the instructional design process. The far-reaching

effects of anonymity within online educational settings and group dynamics have immediate and long term implications for instruction and learning.

CHAPTER OBJECTIVES

The reader will be able to:

- Understand the educational implications of anonymity in cyber education
- Understand how the enactment of policies attempt to protect individuals as well as institutions
- Identify the main two ways in which academic integrity breaches may occur in on-line courses.
- Evaluate different strategies that may be used to safeguard academic integrity.

DOI: 10.4018/978-1-60960-503-2.ch715

INTRODUCTION

The topic of anonymity in cyber education presents ethical concerns as well as benefits. The privacy offered by the anonymity of cyberspace can influence a person's level of isolation. This is a risk that online learners take and which instructional designers must minimize by planning for interactions that increase social presence. Anonymity also brings about the added concerns of academic integrity and authenticity. This chapter will explore ethical and social implications of anonymity in cyber education.

Anonymity affects class discussions, emerging online identities, and interpretations. This brings a new freedom for learners or instructors who do not want to feel categorized, such as those with a physical disability who could be perceived negatively (Lance, 2002). The benefits of anonymity also create challenges. Constructivist learning theories support online instructional modeling strategies that may help enhance social presence and thus reduce the feelings of remoteness.

While some individuals may actually prefer seclusion, most online learners either choose or are required to actively participate in the course. New social norms are developed within the course room as students get to know each other through interactions. These norms require that individuals use new communication skills (Kerka, 1996). Monitoring within the online environment is also a necessary task for instructors and administrators alike. E-learning platforms, such as WebCT, not only let instructors monitor how learners are using the course room, but also offer features for administrators to go behind the scenes and assess the effectiveness of the instructor.

There is a dichotomy in a technological society: on one hand, anonymity is one of the characteristics of technology; on the other hand, evolving technologies are making anonymity increasingly less evident. Misconduct and improper use of the Internet have prompted governments around the globe to seek regulation and control over the

anonymity inherent in Web-based communications. The online community, including distance learners, is affected by these policies and/or lack of them.

Anonymity is the capability to act in private. Privacy means the ability to act without being known or isolated from the invasion of others. In years past, choosing not to reveal one's name or writing with a pseudonym enabled anonymity. Through anonymity, individuals have the freedom to think and express their ideals, even if these ideals may not be in favor politically or socially. It also offers protection from ridicule and retribution. Being unreachable though, has other consequences (Nissenbaum, 1999). Some of these consequences include identity theft, lack of authenticity, and lack of personalization. Anonymity may also exaggerate fear and isolation.

Cyber culture may present a false sense of online security. While the learners hold that their interactions are private and secure, the reality is that everything is traceable. The ability to track, profile, trace, and categorize are inherent in the media. It is inescapable that in order for data to travel to a designation around the world it must know where to go. "Most of society is not equipped to understand what is going on underneath the shiny, glossy surface of the World Wide Web. While it appears that most of the Internet makes it possible for us to lose contact with our bodies and assume some ethereal cyber presence, the amount of surveillance also possible is surprising" (Herman & Swiss, 2000, p.148).

Improvements in telecommunications and mobile learning, as well as the continuing development of alternative technologies to deliver education, are creating a climate of digital access that has more user entry points daily. The kinds of issues surrounding anonymity and the way these issues influence cyber education are difficult to pin down. According to the National Research Council, the observations we make today will not only be different from observations in the past, but will be changed by the events in the future

(Kettler, Klensin, Medin et al., 2001). On the other hand, good policies cannot be developed unless a constant conversation is taking place regarding the issues faced by distance educators, especially those who are part of online learning communities. As national boundaries disappear, the international concern for safeguarding individuals and their information from possible misuse also grows (Karmaker, 2002). The protection afforded by policy varies not only by nation, but also by economic sector. Educational institutions in the United States are affected primarily by the Family Educational Rights and Privacy Act of 1974 (FERPA) and the Uniting and Strengthening America By Providing Appropriate Tools Required To Intercept and Obstruct Terrorism (U.S. Patriot) Act, which will be discussed in the next section.

In order to plan for cyber education successfully, it is critical that the issues confronting the extended cyber space community are understood (Kettler et al., 2001). The term cyber education will be used throughout this chapter when referring to online teaching and learning. The implications of anonymity are far-reaching in cyber education, and instructional designers will need to focus on ways to create engaging online courses while maintaining accountability for students and instructors.

PROTECTION AFFORDED BY POLICY

The meaning of anonymity today is not the same as it was as 25 years ago. The concept becomes obscure in a society that is electronically capable of sending information around the world in nanoseconds and has implications far beyond those of just remaining nameless. Anonymity takes on new a meaning when technologies make it possible to trace people or access networks in ways that World Wide Web pioneers never imagined. Security breaches are a real concern for institutions and governments, which have enacted policies

and laws to protect the rights of individuals, and protect themselves from intruders.

Security breaches are an unpleasant reality for educational institutions as well as businesses. In a 2005 report to Congress, it was revealed that about half of all security breaches in the U.S. happen within higher education settings (Tehan, 2005). Many major U.S. universities such as Indiana University, Michigan State University, and California State University among many others, have experienced security breaches that have put at risk of exposure confidential information residing in the school's server. Personal information, such as social security numbers and bank accounts, has been accessed by hackers and virus infections have threatened entire networks.

While the institutions at risk may have taken great steps to remedy this situation, one can not help but wonder how much information from anonymous surveys and confidential documents is actually out there. Certainly one way to minimize security breaches is to let technology correct the problem. Technologies have been developed to deter the loss of privacy and anonymity, which include firewalls, Web browsers that can deny loading personal information, and Platform for Privacy Preferences (P3P) that allow Websites to communicate their privacy practices to end users (Wenning, 2006). Regulation through the enactment of laws is another approach (Spinello, 2003).

In 1960, the Supreme Court passed a law declaring privacy as a separate right. The federal government has since passed several laws upholding this right including the Privacy Act of 1988 (Adamson & Mietus, 2000). This Privacy Act has 11 Information Privacy Principles (IPPs) and 10 Nation Privacy Principles (NPP) that apply to government agencies, the states, health care, and the private sector. The federal government has also passed a host of additional legislations to address data mining, matching, and telecommunications (Office of the Privacy Commissioner, 2006). As educational initiatives move into this dimension

of cyberspace, personal privacy is affected, thus influencing the anonymity inherent in distance education.

Even though Internet use policies warn users of the open nature of the Internet, caution should still prevail. The Privacy Rights Clearinghouse Document "Privacy in Cyber Space: Rules of the Road for the Information Super Highway" states "there are virtually no online activities or services that guarantee an absolute right of privacy" (Academic Senate of California Community Colleges, 1999).

U.S. vs. Europe: Policy on Internet Anonymity

The European Union has taken a stronger stance than the United States to assure privacy and anonymity on the Internet. Because of the global reach of cyber education, it is interesting to examine the diverging paths taken by these entities. While the United States has relied on a "hands off" policy and self regulation, Europe has passed laws to protect privacy and the individual directly.

The United States' stance is founded on the belief that market regulation and self-policing by technology tools is the best way. Instead of sweeping policy regarding the issues of privacy and anonymity of Internet data, the United States has taken the approach of regulating specific industries. Laws such FERPA offer control and protection in situations where sensitive data could be compromised (Spinello, 2003; United States Department of Education, 2006).

Europe has taken an opposite approach. The European Union has chosen to directly regulate the privacy rights of the individual across all sectors. The legislation covers the next generation of Internet protocol and requires the maintenance of proper confidentiality with respect to location, actual data, and information trafficking (British Parliament, 2000). This initiative empowers users to take control of safeguarding their own personal information. The major problem with this policy is that it is not supported by the technologies

currently available for Internet communications. The current protocol gives away the location and traffic information when a user accesses the Internet. What is important is the philosophical underpinning behind the laws.

FERPA vs. U.S. PATRIOT Act

In an attempt to protect citizens from unforeseen terrorist attacks, the U.S. government has enacted laws that make monitoring easier. While these laws may mean well, they have impacted the ability for individuals to take shelter in anonymity. The U.S. Patriot Act, although amended, may have limited academic freedom and diversity of perspective. These limitations come about the heightened concerns for protecting national security at a time when expressing divergent opinions publicly may be construed as a threat. Only a good balance of different views can ensure freedom of academic pursuit. The problem is compounded in a digitally connected world of traceable information and profiling.

The importance of protecting the privacy of online learners may be seldom discussed, but the consequences may be brought to light under the U.S. Patriot Act (Kettler et al., 2001). Because of the implications of this act, face-to-face, as well as online, learners may have to make politically correct displays of opinion and interests, or they could potentially experience the inquisition of government officials. It could be argued that this type of limitation may warn off the pursuit of academic freedom. Interactions within the virtual course room for example, are easily identified and traced, thus potentially discouraging intellectual discourse and difference of opinion if placed in the wrong hands. These interactions could be e-mails, blogs, wikis, discussion postings, or written assignments that could include subversive political thoughts.

FERPA provides a tough standard for the review of educational records by third parties. Prior to September 11, 2001, few third party inquiries

required release of student records. Only a court subpoena or pursuit of a subpoena could disclose student records. In *Gonzaga University and Roberta S. League v. John Doe* (Supreme Court of the United States, 2001), the rights guaranteed under FERPA were somewhat diminished, as the case restricted the threat of exposing a learner's private record to loss of federal funding. With the federal government given easy access to a student's records and undermining privacy rights in enforcing FERPA, the privacy of student records is vulnerable (American Civil Liberties Union, 2001).

Policies enacted in Europe and the United States affect the educational sector as well as other sectors which rely on the Internet (Spinello, 2003). Cyber education could be affected by the methods used to empower the users to determine which information is communicated and allow them to select control of their anonymity. As cyber educators take into consideration how the different policies impact educational practices, taking a balanced approach to anonymity remains a challenge.

ETHICAL IMPLICATIONS OF ANONYMITY IN THE ONLINE LEARNING ENVIRONMENT

In addition to traditional ways of securing the individual's information, educational institutions must now monitor the quality of their online programs and ensure the authenticity of student work. The feelings of "distance" inherent in anonymity may tempt some individuals to cheat (Burgoon, Stoner, Bonito, & Dunbar, 2003). This realization has cyber educators seeking to secure assessments in an effort to validate the grades they issue. Two ways to possibly deter ethical infractions are through monitoring the learning environment and implementing certain design strategies to enhance authenticity of student work.

Just like there are rules for driving on roads and highways, it is necessary to have guidelines for navigating and interacting within online environments. Shea (1994) introduced 10 core rules of Netiquette. Although these were developed for commercial application, they apply to all cyber communications. These include:

- Remember to be human
- Adhere to the same standards of behavior online, that you would follow in real life
- Know where you are in cyberspace
- Respect other people's time and bandwidth
- Make yourself look good online
- Share expert knowledge
- Help keep the flame wars under control
- Respect other people's privacy
- Don't abuse your power
- Be forgiving of other people's mistakes

These 10 core rules have served as a bare minimum in cyber courtesies. The legal status of anonymity on the Internet is unanswered and debatable. Yet, basic guidelines such as these 10 Netiquette rules may help set ethical boundaries to help safeguard academic integrity and reinforce an online learner's sense of presence in the course.

Authenticity of student work and sense of presence may well be influenced by the level of anonymity experienced. Every learner is required in most asynchronous and blended courses to participate in online discussions and assignment postings. These discussions and assignment postings reveal the person's name but not the physical cues that help form an opinion about the individual. Therefore, in this semi-anonymous environment there is both safety and concern. Threaded discussions, for example, are captured digitally and can be retained for extended periods of time. Academic institutions, such as Baker College (Heberling, 2002), archive entire online courses for quality control. A student's interaction patterns can be analyzed for any particular purpose and opinions can be formed based on the patterns found.

The level of anonymity may affect student contributions and feedback. Because of the permanent and visible characteristics of posting information online, many students, for example, may hesitate to share unpopular ideas. One way to protect against fear of retribution is to provide anonymity to the learners. Because discussions are so critical to learner exchange and communications in cyber space, developing interesting and robust exchanges is desirable.

While instructors are not in the business of judging students, they must monitor their course room interaction and the quality of their discussion postings, which is often a large component of their grade. Instructors and peer learners are bound to form unintentional misunderstandings and misconceptions if the social constraints of anonymity are not removed by purposely creating safe online learning environments.

In Pursuit of Academic Integrity

The lack of identity brings to light serious issues about how we distinguish, handle, and negotiate identifying information. Having authentic records is critical to cyber education, the credibility of entire educational institutions rides on the ability to prove who did what work. Authenticity then becomes an interdependent of anonymity. In face-to-face settings, anonymity is generally indistinguishable if the norms are followed and socially acceptable behaviors are adhered. In cyberspace, the observance of mainstream and socially acceptable behaviors are mainstay. The counterweight to anonymity is accountability, thus safeguarding academic integrity is of utmost importance to cyber educators.

Anonymity is seen as undesirable when it becomes an enabler for fraud or deception, yet the need for accountability creates ambiguity and concern. Minor educational implications include tracking when and how long a student has accessed the virtual classroom, documenting interaction and “surfing” patterns, and personal tendencies

or preferences. Major implications can include tracking subversive political views or actions that are perceived to be threatening. While the latter is a provocative thought, academic institutions may be more interested in curtailing plagiarism than following radical points of view. Academic integrity is mainly breached in two ways: when students plagiarize from Internet or other written sources and when students have someone else do their online assignments or assessments.

The problems that cause students to cheat are the same in face-to-face and online classrooms; for example, a student may feel pressured to produce an essay he did not have time to write, or maybe he did not understand the topic covered (Christe, 2003). Anonymity can be wrongfully used in ways that would be more evident in the face-to-face classroom, such as having someone else take the exam. Nonetheless, educators are responsible for safeguarding the authenticity of assignments and assessments and may do so utilizing specific tools and strategies

Tracking student access to a course can provide important information to the instructor. For example, if the student has spent little time in the course, or has not navigated to the appropriate lessons, yet produces high quality assessments for those lessons, a flag of concern is raised. In this case, the student may be getting information from someone who has previously taken the same course.

In the online environment, distance and anonymity may tempt a student to bend socially accepted norms. Although tracking personal tendencies and preferences could possibly be mishandled, instructors may gather clues as to the writing and communication style of their students. When an instructor knows students as individuals, she or he is better prepared to notice any sudden changes in a person’s writing or communication style that may indicate some one else has completed the assignment.

The most common type of academic integrity breach may be plagiarism. Cheating online is

often seen as easier both psychologically and technologically. Academic institutions, however, rely on services such as *Turnitin.com*. to identify and curtail such behavior. Equipped with search engines, these companies can scan Web-published documents, online books, and their own repertoire of previously scanned documents, to find any matching content. This technology has empowered cyber educators to easily detect plagiarized work.

Instructional designers can employ different strategies that enhance authenticity and promote honesty in the virtual classroom. Attention must be paid to assessments and appropriate monitoring. The consequence of ignoring academic integrity in the online environment is a threat to online credibility (Christe, 2003). Authentication is only as valid as the morality of the person accessing the information (Rezmierski & Soules, 2000).

Designing for Authenticity

In a midst of frustration and a sense of urgency, distance educators are looking to the instructional designer to provide added security and authenticity in the online course room. Anonymity should remain part of the environment if it indeed protects privacy and promotes academic freedom. This must be balanced with the need to have a secure environment free of security or academic integrity breaches. Teachers and learners must be protected from anonymity concerns that compromise work, their identity, or their validity (Rezmierski & Soules, 2000). Two strategies that may help cultivate academic integrity are to create meaningful assessments (Olt, 2002) and monitor student activities.

Good assessment tools are fundamental to ensuring the quality of online learning. Carefully selected and crafted, these tools can support the positive aspects of anonymity online and decrease the impact of the negative. Using multiple techniques and selecting various methods that evaluate students in an authentic manner may foster academic integrity.

These techniques include synchronous activities such as virtual presentations, debates, position statements, or interviews. Another approach might be to craft questions that are broad enough to be authentic and allow the learner to apply the knowledge to their life and their world. These techniques may also have the side effect of not only diminishing the “need” to cheat, but also facilitating transfer by internalizing the knowledge gained. Although these synchronous assessment strategies are a departure from the more popular multiple choice tests, they still do not guarantee that the person participating is indeed the student enrolled.

Overall, instructors and designers should strive to design assessments and assignments that are meaningful, require mastery of the subject matter, and call for real-world applications. Thus cyber educators can focus on the process instead of the product. If the designers make the assessments a learning experience and add variety and meaning, the learner is more likely to see the assessments as meaningful and less likely to cheat (Rowe, 2004).

Several other things can be done to help minimize cheating in online assessments and curtail plagiarism. Expectations and consequences for breaching academic integrity should be communicated to learners at the beginning of the course. The instructor may also use monitoring tools within the Learner Management System (LMS) to track student activity. If such monitoring tools are available, they should be used to monitor participation, times, and duration (Christe, 2003). Other strategies include: (1) changing the assessment each time the course is offered, (2) using a larger pool of questions for the assessment, (3) conducting oral assessments via phone, and (4) monitoring student communication. These strategies may be helpful but are not without weaknesses and challenges.

Course design and instructional methods can make a critical difference in reducing the negative effects of anonymity online and supporting the positive attributes. The classroom should be

supportive and impartial. Communications and interactions can enhance collaboration and sharing, and minimize remoteness. Designers and instructors need to meet the increasing ethical challenges of assessment in online education. The biggest challenge is awareness and acceptance of the problems brought about by technologies and the temptations afforded by anonymity.

SOCIAL IMPLICATIONS OF ANONYMITY THAT IMPACT EDUCATION

The social implications of anonymity are evident in the interactions of online learners. Student-student as well as student-instructor interactions display clues to the level of anonymity as well as the type of emergent persona chosen by each individual. Proper interactions provided by instructional design and modeling can help create safe environments where learners are encouraged to participate in academic discourse. Activities should be designed to support authenticity and help instructor and learners build a learning community.

The potential to experiment and explore different perspectives is at the heart of online teaching and learning. The anonymity of teaching and learning in cyberspace supports the experience of leaving one's culture and wandering into another, or experimenting with one's sense of identity and returning home safe and sound. It also supports the freedom that is responsible for challenging and shifting perspectives and encouraging appreciation for differences, while valuing members of the learning community as independent thinkers (Chester & Gwynne, 1998; Rheingold, 1994).

Social presence is a way of defining our place in cyberspace. Heim (1992) implies that interactions in cyberspace are a way of defining our sense of reality. Kennedy (2000, p.13) defines cyberspace as the "cultural space in cyberculture" where "subjective empowerment, pleasure, play, and creative connection(s)" occur. Social position-

ing in cyberspace becomes one of questioning the subjective and pre-subjective elements of the encounter. Whether it is through course management systems, e-mail, bulletin boards or the Web, encounters in cyberspace rely on positioning through discourse. In cyberspace, each learner is at equal distance from the learning stimuli. It is only the learner's perception of closeness and intimacy, which is influenced through interactions that provides a sense of presence and social identity (Gunawardena, 1995).

Current educational epistemology supports the theories of constructivism. Constructivist theorists Cote (1996) and McAdams (1998) support the theory that each individual has some control over the development of his or her identity. An online learner's identity is constructed through a combination of social forces and the learner's ability to navigate through these powers (Cote). Online identity is often put together through the use of language as a text through which identity is constructed and maintained. Reality is then born through narrative assumptions that help shape identities (McAdams).

Constructivist theory has greatly influenced how collaborative learning is applied in the online environment and supports the concept that thinking is grounded in social and physical experiences. Knowledge is constructed by interactions with others and the learning environment. Constructivist pedagogy asserts that knowledge is constructed by the learner through meaningful interactions and this can lead to substantial learning gains (Jonassen, 1999).

In a constructivist environment, learners and instructors do not exist independent of each other, nor can knowledge transfer be measured by an end-of-unit test. Each learner has a host of responses applicable to a situation depending on progression, cognitive processes, and resources. There are qualities inherent in meaningful and engaging constructivist learning environments, which can be applied to understand the why and how individuals engage in an activity (Jonassen &

Rohrer-Murphy, 1999). These qualities include use of active, constructive, collaborative, intentional, complex, contextual, conversational, and reflective environments (Jonassen, 1999; Jonassen & Rohrer-Murphy, 1999). Where many instructional designers fall short is not effectively integrating these aspects into a distributed learning environment (Morice, 2002).

Building environments that support multiple perspectives and authentic examples can support collaboration and the construction of knowledge through social negotiations. Learning environments that support the active construction of knowledge must also foster social presence and trust. The promotion of social presence may be a significant factor in instructional effectiveness and collaborative learning.

Minimizing Perceived Instructor Authority: Benefit or Detriment?

Because these Internet communications lack the initial social and emotional cues that are provided in face-to-face environments, there is an initial feeling of anonymity. This allows introverted learners to participate in discussions and share feelings in ways they may not be able to do in face-to-face classrooms. This same distancing also creates equality between professors and students by eliminating things like standing in front of the class and divesting the professor of some authority. Learners feel a greater sense of anonymity and therefore empowerment to express ideas and open discussions, which leads to a changing role for the instructor. The role is certainly more of a facilitator and less of an expert; it breaks down the authority structure and opens up channels of communication.

Disarming the traditional lecturer of some perceived authority has its own social implications. For instance, traditional societies that have long valued and respected educators will find it inappropriate for a student to address the instructor by

the first name or question the grade received on an assignment. Placing the instructor at a more equal level with the student can potentially undermine the instructor's authority, especially when the student is frustrated about something that could otherwise have been resolved in a face-to-face environment (DeVries & Lim, 2003). Instructors and designers must take this aspect of anonymity into consideration, as it can impact the way learners from different cultural backgrounds interact with the instructor.

Equalizing instructor and learner roles can bring benefits to building online learning communities. Online learning communities are the framework that facilitates the exchange of social information as well as reinforcement of key concepts learned. Wegerif (1998) agrees that learning communities provide the social dimensions necessary for learners to be successful in asynchronous learning environments.

The Emergence of a New Persona

This initial sense of anonymity and freedom gives way to a different feeling, as individuals experience the emergence of a new online identity. The acknowledgement that one's style and presence can be easily identified by the consistencies expressed in writing and the ideas and attitudes that have not only been captured but also preserved over time. Anonymity may also affect the quality of comments offered in communications by students. Peer accountability and anonymity can affect the degree to which learners communicate with each other as well as the quality of these communications.

Asynchronous learning environments create a new dimension for learner interaction. New patterns of social interactions emerge as students take on their new online identity. Gender differences can play a huge role in the way a learner interacts within a course room (Rovai & Baker, 2005). Rovai and Baker found that female online

learners felt more connected during their learning experience. But how does interaction relate to anonymity?

The feelings of anonymity will impact the student's interaction patterns. If females tend to feel more connected, this could mean that females deal differently with the feelings of anonymity than males. Further research is needed to investigate the relationship between anonymity and interaction as they are impacted by gender. Recent research shows that there are personality factors which may influence a person's inclination to follow norms or be academically dishonest. Etter, Cramer and Finn (2006) found that students who perceived sensation-seeking behaviors to be acceptable, were at a higher risk of breaching academic integrity, yet cheating in church-affiliated institutions versus traditional institutions was very similar.

Earlier studies in online learning showed contradictory conclusions in regards to anonymity. Kiesler, Seigel and McGuire (1984) suggested that anonymity would minimize gender differences. But, Herring (2000) insisted that gender-based communication styles carry over into electronic environments. Herring bases his claim on research showing that males who tend to be more aggressive face-to-face, also displayed the same behaviors in online environments, such as listserves. Meanwhile, the women tended to be more assertive in male-dominated groups. Herring found a myriad of gender differences that are visible in online environments; thus, he believes that true anonymity is very hard to achieve.

Deindividuation: Setting "Self" Free

Deindividuation is the psychological state of mind that causes a person to become less inhibited and less self-evaluative (Postmes, Spears, & Lea, 1998). Postmes et al.'s social identity model of deindividuation (SIDE) targets the interaction of online learners as individuals and as members of a learning community. They found that computer-mediated communications did not free individuals

from being influenced by social norms or pressures. This is contrary to the idea that anonymity only brings freedom of expression.

Other researchers, such as Scott (1999), have concluded that when a person's identity is salient or emergent, the person is less likely to follow the group norms. But, when a more social identity emerges, the person is more likely to follow group norms and feel part of the social structure. He contends that the same anonymity that causes students to become uninhibited creates social salient identities that in turn increase the stereotypical behaviors of those individuals. In other words, when we identify ourselves with a group, we are likely to behave according to the group's norms. The effects of depersonalization on group dynamics are astounding. When learners are depersonalized, their individuality is less salient, thus they bond with the group, giving way to the emergence of stereotypes (Postmes et al., 2002).

The power of culture is also a factor to consider. Individualistic cultures influence the way learners from that particular culture identify themselves. Jetten, Postmes, and McAuliffe (2002) found that people from individualistic cultures, like in North America, tend to have low identifiers, in contrast to cultures that value collectivism. Collectivist cultures, such as those from Asia, show high identifiers, but follow the salient group norms, more so than low identifiers. This reveals how cultural background influences a learner's interactivity and feelings of anonymity.

The question as to whether asynchronous learning environments are better at sustaining anonymity poses a concern for designers who are being asked to do just that. Research has shown that computer mediated communications are not necessarily asynchronous. Wegerif (1998) cites the example of frustrated students and instructors having to sort through an extensive list of messages after being a short time away from the course room. The first challenge is to provide a sense of community for learners of both individualistic as well as collectivist tendencies while the second

challenge is to design learning environments that encourage learners to actively participate.

Designing for Interaction

From the instructional design standpoint, the positive aspects of anonymity can possibly be nurtured while deterring fraud or deception. Courses may be created to include activities that support learner-learner and learner-instructor communications, foster collaboration, and fight isolation. The more connected the learners feel to each other and to their instructor the less likely they are to cheat and or be successful at it (Burgoon et al., 2003).

Face-to-face interactions have the effect of immediacy as the results of unethical and improper behaviors are immediately conveyed. On the other hand, online interactions can establish a mental distance that may make individuals feel more distant from ramifications (Rowe, 2004). Overtime, though, and with established guidelines, this psychological detachment can be reduced. Cheating is a genuine concern for cyber educators. Pressure to get good grades and lack of knowledge on how to address cheating may contribute to even more academic infractions (Gearhart, 2001).

Instructional designers have the responsibility of modifying instructional design models to ensure that different types of interaction are built into the course for diverse purposes. Best practices in the field should include those that have set guidelines for dealing with plagiarism, building online communities, and planning and organizing to implement learning theories that promote interaction. Message boards, IM, chats, blogs, wikis, and social networking software are just some of the tools that can be used to foster interaction in the course room. These tools help enhance social presence and build a sense of community. Many of these technologies already have built-in features to password protect and trace published content, thus providing other ways to monitor academic integrity.

Design frameworks should support building good and close relationships between instructors and learners as well as encourage direct and regular communication. Multiple communication methods enhance social presence and reduce the negative effects related to anonymity, such as remoteness. Furthermore, such interactions should purposely take into account differences in gender, culture and individual preferences.

Gunawardena (1995) conducted a study that indicates participants in online conferences create social presence by projecting their identities and building online communities. In order to encourage collaboration and interactive learning, it is important that learning environments are conducive to the creation of social and individual presence. Building social cohesiveness requires that instructional designers build interactive learning environment where learners feel comfortable choosing the level of anonymity and where instructors encourage and respect freedom of expression. Recognition and acknowledgement of learner presence by the instructor as well as developing protocols, etiquette and expectations will also enhance interactions and communications, thus potentially decreasing the desire to cheat.

Building an online community is as important as dealing with ethical infractions. Ethical guidelines must be practiced and enforced daily (Campbell, 2001). Palloff and Pratt (1999) stipulate that there is no online course without a learning community. It would then be logical to say that a learning community cannot exist without interactivity. Yet, these communities must be built with academic integrity as the foundation.

Planning and organization are pillars for building interaction among learners as well as between learner and instructor. There are a myriad of other skills and responsibilities that stem from planning, such as facilitating collaborative groups; choosing questioning strategies (Cyrs, 1997) and applying the most pedagogically sound practices that fit the objectives.

Cyber educators are responsible for creating a student-centered environment that encourages interaction for different purposes. According to Wagner (1997), there can be interaction for the purpose of increasing participation, developing communication, enhancing retention, supporting learner control/self-regulation, and interaction to receive feedback or clarification. Another important purpose of interaction is to increase motivation, which is a big factor of learner success in distance education.

Sims (2000) cites four dimensions that should be taken into account when assessing learning theories for the purpose of identifying how they promote interactivity:

1. **Learners:** The who of the learning process
2. **Content:** The what of the learning process
3. **Pedagogy:** The how of the learning process
4. **Context:** The when and where of the learning process

Seasoned cyber educators understand the need for interactivity. As Pelz (2004) puts it, "interactivity is the heart and soul of effective asynchronous learning."

Two defining elements of online learning are the creation of learner identity and social presence. Learner identity can not be addressed in cyberspace without including the balancing act innate in anonymity. The opacity of cyberspace invites the learner to play with identity and build multiple selves (Turkle, 1997). The culture of cyberspace must be advanced with an open and eclectic approach to instructional design and modeling.

CONCLUSION

Anonymity in cyber education presents ethical concerns as well as benefits that must be taken into consideration when designing online courses. The privacy offered by the anonymity of cyberspace is threatened by the technological advancements

that make possible the access to personal information. Online learners take the risk of having their ideas and thoughts exposed, thus it is the duty of instructional designers, instructors, and educational institutions to create a safe haven for scholarly discourse.

Anonymity affects class discussions, emerging online identities, and interpretations. But, at the same time, there are new dimensions, such as group dynamics, that affect the quality of discussions. New social patterns and norms emerge, as learners tend to identify themselves with their cultural background or relate to specific group behaviors. The tendency is to prefer either individualism or collectivism; such preferences will dictate how a person will blend in a group situation that is deindividualized.

Gender differences, once believed to equalize computer-mediated communication, emerge in asynchronous and synchronous learning environments. Furthermore, online courses cannot be successful without a learning community, and a learning community cannot exist without interactivity. Only by understanding this relationship can cyber educators realize the impact of anonymity.

There is now a heightened awareness on the part of governments and educational institutions on the need to protect personal privacy and anonymity. This awareness has prompted legislations such as the FERPA and Patriot Act in the United States. While these initiatives are meant to protect, they may set back the intellectual exchange of ideas, especially those with political connotations. Political tensions around the globe aggravate the problems with privacy already faced by cyber educators. The European Union has taken a different approach than the United States, leading the way in the enactment of laws that directly protect consumers. Only time will tell how the rest of the world will deal with these issues. Educational institutions face the challenge of maintaining data secure from intruders, as well as safeguarding the academic integrity of online programs.

In the mean time, cyber educators and instructional designers must evaluate implementation choices that build interactivity in online courses without compromising a learner's self-identity or the institution's academic integrity. By carefully balancing anonymity and identity, cyber educators have the task of creating online learning environments where students can safely exchange ideas that promote cultural understanding; a daunting task in a world that craves diplomatic dialogue.

Chapter 7.16

An Ontological Approach to Online Instructional Design

Robert Z. Zheng
University of Utah, USA

Laura B. Dahl
University of Utah, USA

ABSTRACT

This chapter introduces the ontological instructional design as an alternative to the traditional instructional design in teaching and learning. By comparing the differences between traditional instructional design and e-Learning, the authors suggest that instructional design in e-Learning require a different model than the existing traditional models due to the idiosyncratic nature of e-Learning in terms of population, environment, and resources. An ontological instructional design model is proposed with a focus on the sharability, reusability and interoperability of ontological entities and design components within the ontological entities, which provides a holistic approach to online instructional design compared to the segmented, linear design approach in traditional

instructional design models. A case study is included to illustrate the use and application of the ontological instructional design model in an online business course. Finally, guidelines for implementing the model are made with suggestions for future research.

INTRODUCTION

The proliferation of web technology in education, particularly with the introduction and implementation of semantic web, has called for the need of re-examining the traditional instructional design in online learning (Snelbecker, Miller, & Zheng, 2007; Zheng & Ferris, 2007). The traditional instructional design models focus primarily on epistemological approach in design by examining the experiential process related to knowledge representation as well as the means related to the

DOI: 10.4018/978-1-60960-503-2.ch716

production of knowledge based on various principles in instructional design (Han & Park, 2008; Spector, 2001). Although the epistemological approach contributes to a general understanding of the relationship between the knowledge representation and the knowledge production, the implementation of epistemological approach in terms of shared conceptualization of domains in online learning remains an area that warrants further exploration and validation. In other words, how to implement instruction, particularly online instruction from an ontological perspective has been the focus of many online instructional designers and researchers (Abel et al., 2004; Berners-Lee, Hendler, & Lassila, 2001). The present chapter offers a discussion on (1) issues in applying traditional instructional design models to online learning; (2) differences between epistemological design and ontological design in instruction; (3) the need to apply ontological design to e-learning with respect to recent development in semantic web; finally (4) a conceptual framework for ontological instructional design in online teaching and learning.

ISSUES OF APPLYING TRADITIONAL INSTRUCTIONAL DESIGN MODELS TO ONLINE LEARNING

Studies over the last decade have focused on the issues related to the applicability of traditional instructional design models to e-Learning (Akbulut, 2007; Rutherford & Kerr, 2008). Research in this field has so far produced mixed results. Some believe that traditional instructional design models can be universally applied to any instruction, online or offline (Anglada, 2008; Bi, 2000). Others argue that traditional instructional design models may not fit e-Learning due to their rigidity and lack of flexibility in design (DeSchryver & Spiro, 2008; Gunawardena, Ortegado-Layne, & Carabajal, 2006; Koh & Branch, 2004). Crawford (2004) explored online learning and traditional instructional design

and found that there were apparent discrepancies between the two models. According to Crawford, the e-Learning model allows for exploratory, constructivist concept building whereas the traditional instructional design model is procedure-centric which allows little room for creative learning. Consistent with Crawford's finding, Barron, Orwig, Ivers, and Lilavois (2002) found mismatches between traditional design models and e-Learning models in terms of individualized learning, collaboration, instructional delivery, and instructional design.

Individualized Learning

There are significant differences regarding the theoretical assumptions of individualized learning between traditional design models and e-Learning models (Barron et al., 2002; Harris, 1998). Traditional design models assume that all learners must learn at exactly the same pace and at the same level of content mastery. As such, instructional goals and learning objectives in traditional instructional design are routinely set to fit the normal curve, with little concern for the individual outliers (Moller, Foshay, & Huett, 2008). The above theoretical assumptions and their resultant approaches in traditional instructional design can be problematic because it is difficult to fit online learners into this traditional normal curve. An online learning community is characterized by its diversity in terms of prior knowledge, learner characteristics, motivation, social and economic status, and so forth (Moller et al., 2008; Proske, Narciss, & Korndle, 2007). Therefore, designing online instruction based on normal curve practice and the assumptions of traditional design theory would adversely affect the online learning community where individualized support at various levels is needed.

Collaborative Learning

Although both traditional instructional design and online learning emphasize the importance of collaboration in learning, there are fundamental

differences between the two due to the distinct learning mode that each takes in learning. In the traditional classroom, collaborative learning occurs in a face-to-face environment where students concurrently interact with each other in the same place (Topper, 2007). The physical and time constraints thus restrict the mode of collaboration in instructional design. Typically, instructional designers would maneuver factors related to physical environment such as seating arrangement, student grouping, and so on in order to maximize learners' learning (Lim, Kim, Chen, & Ryder, 2008; Rutherford & Kerr, 2008). Contrary to traditional collaborative learning, collaboration in online learning is defined as virtual collaboration, meaning the physical interaction that is present in traditional learning environment is not available in online learning. As a result, synchronous and asynchronous communication, virtual grouping, as well as transactional distance (e.g., the interaction among the students, between the students and the instructor, etc.) in online learning become the foci in online instructional design (Giguere, Formica, Harding, & Cummins, 2007; Murphy & Rodriguez-Manzanares, 2008).

Instructional Delivery

What makes online learning idiosyncratic and different from traditional learning is the unique way that the online instruction is delivered. Traditional teaching relies heavily on the instructor, texts, and classroom media to deliver the content (Rutherford & Kerr, 2008; Solimeno, Mebane, & Tomai, 2008). An instructor would typically resort to texts, handouts, worksheets, and sometimes classroom media like Smartboard, video, or PowerPoint to deliver the content. Solimeno et al. (2008) point out that in a traditional classroom environment the instructor simply coordinates what is available to make the content delivery successful. They argue that the traditional teacher-centered approach impedes learners' self-initiation in learning. Learners have little control over the

content delivery and learning process. Conversely, in an online learning environment, learners have much control over the content delivery and are able to make decisions during the learning process (DeSchryver & Spiro, 2008). For example, e-Learning is characterized by multiple nodes and nonlinear presentation of information. Learners can thus choose the information appropriate at their level of learning. Moreover, since the content in e-Learning is delivered digitally, there is an opportunity for the instructional designer to incorporate various media including multimedia and hypermedia and various communication tools like email, blogs, threaded discussion, synchronous and asynchronous learning, and so on to deliver the content in the way that promotes learner self-initiation and constructivist learning (Papastergiou, 2006). Papastergiou noted that the traditional instructional design that capitalizes on teacher-centered approach in content delivery appears to be ill-fitted for e-Learning environment where learner-centered information access and delivery are emphasized.

Instructional Design

Most of traditional instructional design models were derived from behavioral models (Gustafson & Branch, 1997). This behavioral origin underscores the philosophical differences between the traditional learning and e-Learning, which result in differences in design between the two camps. Crawford (2004) observed several differences between traditional instructional design and e-Learning design. First, the traditional instructional design follows a hierarchical, linear approach in which the design components are disconnected and segmented whereas the e-Learning design is characterized by a non-linear approach in which instructional information is presented in a form of web or network. Second, in traditional instructional design, goals and objectives are always defined by quantifiable behavioral indicators, whereas in e-Learning design the focus is on

open-ended learning process. Crawford argued that because of the differences between e-Learning and traditional learning, the instructional design related to each type of learning has been distinctly different: the instructional design in e-Learning accentuates developing a learning environment where learners are able to share and construct new knowledge whereas the design of traditional learning focuses on achievement of a set of specific goals or objectives (see also Shoop, Nordstrom, & Clariana, 2007; Rutherford & Kerr, 2008).

As was mentioned, there are significant differences between traditional and e-Learning design. Such differences derive primarily from the underlying design philosophy of the two schools. Research indicates that simply migrating traditional instructional design to online instructional design without considering the unique characteristics of e-Learning would cause more harm than doing good (Wuensch, Aziz, & Ozan, 2008). Instructional designers should therefore be cautious about applying traditional instructional design models to e-Learning. Researchers (e.g., Abel et al., 2004; Gasevic & Hatala, 2006) suggest that the current study on e-Learning should go beyond the superficial differences such as learning environments to explore the epistemological and ontological aspects in design, particularly by examining the design consequences of each in teaching and learning.

EPISTEMOLOGICAL AND ONTOLOGICAL INSTRUCTIONAL DESIGN

Epistemology and ontology are related and at the same time are distinct from each other. They differ in the approaches toward the nature of knowledge which consequently result in different learning outcomes. The following is a discussion of the differences between epistemological and ontological instructional design.

Ontology

The term ontology essentially refers to the study of being or existing. It seeks to describe or posit the basic categories and relationships of being or existing to define entities and types of entities within its framework. In modern era the theory of ontology has been mapped to a new discipline -- computer science and has thus assumed a new meaning different from its philosophical origin.

Ontology in Philosophy

In Greek philosophy, ontology means understanding the eternal reality (Reginald, 1985; Spector, 2001). Plato defined the reality as primary and the perception and experience of reality as secondary. Socrates held the similar view that the purpose of learning was to recognize eternal truth and therefore the instruction was to remind someone of something already known and accepted as true (Spector, 2001). This classical view of ontology has changed due to a realization that the explication and uncovering of external reality involves human as perceiver and that human judgment, with respect to such uncovering, is subject to error.

One of the assumptions of modern ontology is that instruction should focus on bodies of knowledge rather than individual knowledge (Merricks, 2007). Instead of relying on one-to-one correspondence between individual beliefs and external reality, the modern ontology proposes a coherence theory of truth in which acceptance or rejection of new beliefs should be based on how well new beliefs fit with and how coherent they are with the established beliefs (Merricks, 2007; Quine & Ullian, 1978; Spector, 2001). This assumption is important in that it influences the formation of ontology in computer science in which the shared conceptualization of reality across knowledge domains is emphasized.

Ontology in Computer Science

Derived from its philosophical origin, the ontology in computer science is a data model that represents a set of concepts within a domain and the relationships among those concepts. For example, in artificial intelligence, software engineering, biomedical informatics and information architecture, the ontology is defined as a form of knowledge representation about the world. Ontologies in computer science generally describe:

- Individuals: the basic or “ground level” objects
- Classes: sets, collections, or types of objects
- Attributes properties, features, characteristics, or parameters that objects can have and share
- Relations: ways that objects can be related to one another
- Events: the changing of attributes or relations

The advent of web technology, particularly the semantic web, necessitates educators, instructional designers, and other educational professionals to re-examine the existing practice in web-based instructional design by putting in perspective the ontological design as they develop their web-based instruction. Henze, Dolog, and Nejd1 (2004) point out that the challenge of web-based learning is to provide distributed information with well-defined meaning, understandable for different parties. They assert that one solution to such challenge is to develop an ontological approach so that applications will be used to “provide individually optimized access to information by taking the individual needs and requirements of the users into account” (p. 82). Sampson, Lytras, Wagner, and Diaz (2004) concurred that ontology, which is a major component of semantic web, should play a key role in enabling the representation and

dynamic construction of shared and reusable learning content (see also Yang, Chen, & Shao, 2004).

The Semantic Web is an evolving extension of the World Wide Web in which the semantics of information and services on the web are defined, making it possible for networked computers to understand the requests of people and machines to use the online content. Berners-Lee et al. (2001) posit that the Web as a universal medium for data, information, and knowledge exchange ought to comprise a set of machine-readable content using design principles, collaborative working groups, and a variety of enabling technologies. Some elements of the semantic web are expressed as prospective future possibilities that are yet to be implemented or realized. Other elements of the semantic web have been defined and are expressed in formal specifications. They include eXtensible Markup Language (XML), database connections (SQL), Resource Description Framework (RDF), and notations such as RDF Schema (RDFS) and the Web Ontology Language (WOL), all of which are intended to provide a formal description of concepts, terms, and relationships within a given knowledge domain (Antoniou & van Harmelen, 2004). In addition, people-readable specifications using notations such as Cascading Style Sheets (CSS) and eXtensible Stylesheet Language (XSL) have been widely accepted as standard forms for machine-readable documents to enhance sharability and reusability.

Epistemology

Epistemology or theory of knowledge is the branch of philosophy that studies the nature, methods, limitations, and validity of knowledge and belief. Much of the debate in this field has been focused on analyzing the nature of knowledge and how it relates to similar notions such as truth, belief, and justification (Spector, 2001). The early epistemology such as Cartesian philosophy emphasized the first truths as a foundation to construct a picture of reality (Fuller, 1955; Williams, 2001). Differ-

ing from the classical ontology as represented by Plato and Socrates, Descarte's epistemology challenged the established truths by questioning every belief that one holds about external reality. This view of beliefs was associated with the rise of science and the success associated with the scientific method, which Descartes helped codify (Spector, 2001). Descarte's work laid the foundation for epistemological study which centers on the experience of reality through perception and persuasion, the very "enemies" which Socrates and Plato attacked with such vigor.

One approach that epistemology tries to reach truth is through empiricism - what we can know through our senses - which we can summarize as "we believe what we see". Another approach is skepticism which asks "how can we believe what we see?" Fisher and Nicholas-Everitt (1994) point out that empiricism and skepticism are two ways of approaching our experience of life and the subjectivity of our minds. By relating this philosophical view to the educational practices, we saw the boom of behaviorism which taps into in the empirical aspect in learning (Bloom, 1956; Skinner, 1953), and the rise of cognitive information process theory which explores the unknown of the mind pertaining to learning processes (Baddeley, 1986; Klahr & Wallace, 1976).

Differences between Epistemological and Ontological Views on Knowledge

Epistemology and ontology differ significantly on the views of knowledge with former focusing on the nature and production of knowledge, and the latter on the concept of knowledge. For example, epistemology primarily addresses the following questions: "What is knowledge?", "How is knowledge acquired?", and "What do people know?" whereas ontology searches for answers to the question "How do you know it?" So far, there has been a great emphasis on epistemology in instruction. For example, most instructional design

models and strategies are based on epistemology to answer the questions of how knowledge is acquired and what people know. Little attention has been given to the ontological aspect in the design of instruction.

THE NEED TO APPLY ONTOLOGICAL DESIGN TO E-LEARNING

As was mentioned elsewhere, the current status of instructional design has been characterized by the epistemological approach which focuses primarily on single knowledge domain in design. With the increasing use of World Wide Web in teaching and learning, particularly the use of semantic web, it is important to consider the ontological aspect of knowledge in design by answering the question "How do you know it?" We believe that there is an imminent need to develop a framework for ontological instructional design in e-Learning. However, before we proceed to an indepth discussion of the issue, let us first examine the existing ontological models in computing.

A Review of Computational Ontological Models

To date, research on ontological design has been primarily focused on computational perspective with an emphasis on instances and classes, objects and property attributes associated with domains. Several computational models of ontological design have been proposed that include Hendler's (2001) ontological design model, Henze, Dolog, and Nejdl's (2004) domain ontology model, and Abel et al.'s (2004) ontology-based organizational memory model. The first two are generic ontological models whereas the latter one deals with organizational memory work in ontological design. For the purpose of this chapter our discussion will center on generic models in computational ontological design.

Hendler's Ontological Design Model

Hendler's (2001) model represents a data model that describes the relationship between domains. The model defines the domains in terms of dimensions and values. For example, a weather service domain may be represented by dimensions containing advertisement, description, and logic, as well as values that include format, service type, and service logic. The values corresponding to their respective dimensions can be expressed as follows:

```
advertisement.format:=[multimedia];
description.description:=[service
type];
logic.transfer:=[TransferOccurs(#co
st, service):= Reached (ServState),
ServiceCost(#cost)].
```

The logic.transfer notation describes the information about services associated with a transfer action during severe weather (Figure 1). In Hendler's model, different domains (e.g., weather service and transfer service) are connected based on semantic rules of dimensions, values, and universal resource indicators (URIs). The model describes objects that act as binding glue between different systems and services and serve as a basis for interoperability among various ontological entities (Ullrich, 2004). Hendler

(2001) points out that the model enables computer program constructor to "use ontologies to ensure that everyone agrees on terms, types, constraints, and so forth" (p. 32).

Domain Ontology Model

While Hendler's model defines domains in terms of dimensions and values, the domain ontology model proposed by Henze et al. (2004) focuses on classes and object properties. The model uses computational notation to define class type and object properties. In the example of weather service mentioned above, the weather service domain is related to other domains in terms of class type and object property. For example, weather service can be defined as a service class type which includes the properties of information, guidelines and resources. The weather service class is related to the transfer service class through the activation of emergency object property. Thus, the above relationship can be expressed by following computational notations.

```
type:weatherService[
type:class ->weatherService:object_
oriented
weatherService:information->type:web_
doc
weatherService:guidelines->type:web_
```

Figure 1. Comparing ontological design model with domain ontology model

```
doc
weatherService:resources->type:web_
doc]
type:transferService[
type:class->transferService:object_
oriented
transferService:cost->type:web_doc]
```

The above computational notations indicate that weather service and transfer service are two reusable objects, each of which is defined by its properties. The object properties in the notations are web document type that is subsumed under the relevant domains. Figure 1 shows the differences between two models discussed above.

Limitations of Computational Models in Ontological Design

Although computational models of ontological design provide a blueprint for e-Learning by examining the components across domains in a web environment, they are limited by their micro-level analysis that deals exclusively with computational objects and pertinent semantic relationships. In addition, the models are marked by such high level technicality that renders little applicability to general educational community. To conclude, the models are effective tools for designing computational semantic web, but are insufficient in terms of serving the purpose of general educational community.

A MODEL FOR ONTOLOGICAL DESIGN IN E-LEARNING

As indicated, the epistemological instructional design is limited by its narrow focus on single knowledge domain and can be problematic when applying to the design of e-Learning, partly because most traditional models were developed well before online learning becomes a reality in education, and partly due to the fact that online

learning is characterized by interoperation among multi-domains that form a new knowledge representation in learning (Lundin, 2000; Snelbecker et al., 2007). On the other hand, the computational model of ontological design demonstrates little relevancy for general educational purposes because of its high technicality. Having discussed the limitations of both models in e-Learning, we would like to offer a different perspective on e-Learning by proposing an ontological approach toward online instructional design.

A Model of Ontological Instructional Design in E-Learning

One of the key issues that frequently surfaces in the study of e-Learning is learners' self-initiation in learning (Allen, 2005; Berge et al., 2000). Allen (2005) examined the variables that affect learners' self-initiation in e-Learning and concluded that self-initiation is critically related to (a) the presence of constructivist learning environment in learning, (b) levels of content challenge and learners' prior knowledge, and (c) the connection between the target domain and germane domains of knowledge. According to Allen (2005), learners become more active in learning if they are given the opportunity to construct their own knowledge by relating the new content to their prior knowledge and to make meaningful connections among various domains of knowledge. Berge et al. (2000) point out that active online learning entails collaboration in learning where knowledge collaborators share knowledge and new ideas through various social negotiation processes. Research shows that quality collaboration can influence the quantity and quality of knowledge that flow into the virtual learning community (Chapman, Ramondt, & Smiley, 2005) and that effective collaboration is characterized by positive interdependence, individual and group accountability, and interpersonal and small group skills in learning (Johnson & Johnson, 1994; Zheng, 2009).

Recently, efforts have been made to incorporate the above factors in the design of learning (Morrison, Ross, & Kemp, 2007; Yang et al., 2004). Morrison et al. propose a model that focuses on fostering active learning and collaborative experience for students. Instead of presenting the instruction with a linear, segmented design, Morrison et al.'s model takes a holistic approach by examining the critical role of each design component in learning as well as the interoperability and sharability among the design components. Yang et al. delineate a design architecture for knowledge management for collaborative learning in virtual learning community. Their architecture presents the relationship between ontological entities in a knowledge management system that promotes learners' self-initiation in learning.

Drawn from both Morrison et al.'s model and Yang et al.'s design architecture, we propose an ontological instructional design model that incorporates the features of sharability and interoperability from Morrison et al.'s model and the interactive relationship of ontological entities from Yang et al.'s design architecture. Figure 2 shows the model of ontological instructional design for E-Learning.

The model in Figure 2 describes the relationship between ontological entities in an educational system. At the right end are the interaction entities (e.g., knowledge representation and media). The learner accesses the knowledge representation via media that combine one or more media instances (e.g., visual, auditory, haptic, etc.) with one communication mode (e.g., synchronous or asynchronous) to deliver the content. At the left end are the design entities (e.g., knowledge repository, media repository, and design component repository) that interact with one another in the design process and provide inputs to the structure of knowledge components in knowledge representation. The above model demonstrates the architecture of an ontological instructional design showing the relationship among different ontological entities (i.e., interaction entities and design entities) within an instructional system. A discussion of the proposed ontological design model follows.

Ontological Entities and Design Principles

Reigeluth (1983) defines the instructional design principles as means to explain and predict instruc-

Figure 2. A model of ontological instructional design for e-learning

tional phenomena. The instructional principles are primarily based on the relationship between strategy components, in this case, the ontological entities, in an instructional model. For example, if the strategy components show a sequential relationship, the design principle derived from this relationship would define a linear, hierarchical approach as its design strategy. The following discussions focus on relationship among different ontological entities that include design entities (e.g., knowledge repository, media repository, and design component repository) and interaction entities (e.g., knowledge representation and media,), followed by a presentation of the ontological design principles related to the ontological instructional design.

Knowledge Repository and Knowledge Representation

The interaction entity of knowledge representation is directly interfaced with the knowledge repository, a design entity, and indirectly related to the media repository via the media entity. According to Yang et al. (2004), knowledge representation in e-Learning is composed of content structure and format. For the knowledge representation to be functionally meaningful, it must draw on and interact with the knowledge repository and be shaped by the design principles and strategies in the design repository. In other words, the content structure of knowledge representation is formulated based on the inputs from the knowledge repository and the design component repository.

The knowledge representation has two formats: carriers and shells. The carriers are knowledge representation tools to deliver the concepts and skills to learners whereas the shells represent the space for knowledge construction and creation (for details on the discussion of knowledge representation as carriers and shells, see Kyzylkaya, Torun, & Askar, 2007). In the event of e-Learning, the selection of the format is dependent on the purpose of the instruction. For example, if the instruction

is to deliver the content for learners to learn the basic concepts and skills, the carrier presentation will be used to deliver the content. If the purpose of the instruction is to develop skills in knowledge construction, the shell presentation will be used for learners to construct new knowledge. In short, the shells enable learners to create new knowledge and share it with other learners. The carriers store the knowledge which is presented to the learner.

Media Repository and Modality Concerns

Media are interfaced with the media repository to support the knowledge representation in e-Learning. They can be integrated with the carrier to present the content. Examples include using multimedia or hypermedia to present the content. They can also be used with the shell to support knowledge construction. For example, learners can use multimedia tools to create a learning object that contains the new knowledge created by the learner and post it to the web to share with others.

A related issue concerning the use of media is modality effect on learning (Mayer, 2001; Zheng, 2007). Although there is an overlap between media and modality, they are distinct from each other in terms of the role they play in e-Learning. Media refers to the use of one medium (e.g., video) or a combination of several media (e.g., video, audio, textbook, etc) in instruction. Modality means the presentation of information that is cognitively processed in a certain way by the working memory. For example, information can be presented through either auditory or visual channels. Positive modality effect occurs when the information presented through auditory or visual or both formats assists in knowledge acquisition. Negative modality effect is observed when the information presented through visual or auditory channels competes with limited cognitive resources in working memory, thus impeding learning (Mayer, 2001; Mayer & Johnson, 2008; Sweller & Chandler, 1991). Presenting knowledge

with multiple media does not necessarily produce positive modality effect. Selecting media or determining instructional modes often depends on the nature of, and structure of knowledge to be presented (Zheng, Miller, Snelbecker, & Cohen, 2006). When learning simple declarative knowledge such as the name of a place, the text mode would suffice. However, when learning complex procedural knowledge such as advanced geometry, images, text, even auditory modes become essential for understanding the content (Butcher, 2006). In an ontological design environment, selection and design of media should be considered in conjunction with modality effects.

Design Component Repository

The design component repository consists of rules, strategies, principles, and procedures of instructional design (Dick, Carey, & Carey, 2005; Gustafson & Branch, 1997; Smith & Ragan, 2005). It interacts with other design entities (e.g., knowledge repository and media repository) to provide support to knowledge representation. Its primary roles are to package an instructional material based on the instructional design principles and to deliver it to learners in a more effective manner. Because of its organizational and delivery functions, design component repository is included in this model as one of the key functions for e-Learning.

Taken together, the above ontological entities demonstrate a high level of sharability and interoperability across domains. Figure 3 shows the relationship among knowledge repository, design component repository, and knowledge representation.

As was demonstrated, the outer circle in Figure 3 is the knowledge repository that contains domains operating on semantic rules. The middle circle shows the design component repository that consists of design components operating on the shared knowledge rules. Distinct from traditional design models, the proposed ontological instructional design model emphasizes sharabil-

Figure 3. Relationship among knowledge repository, design component repository, and knowledge representation

ity and interoperability of knowledge domains and design components. The ontological design underscores a holistic approach in which the analyses of goals, learners, instructional strategies, and so forth are interdependent on one another. For example, the determination of an instructional goal is affected by variables in both design entities and representation entities. That is, considerations should be given simultaneously to such factors as the task, the content, and so forth (knowledge repository) and mode of presentation, instructional strategies, etc. (media and design repositories). The interoperability between ontological entities characterizes what is called dynamic ontological instructional design in this model. Further discussion on the component interoperability will be presented later in a case study in the chapter.

Ontological Design Principles

By definition, ontology means to query “how do people know it” in the process of knowledge acquisition. Following this fundamental philosophical view, we propose three basic ontological instructional design principles based on which we design and develop the instruction.

Principle One: Ontological design is most effective when it promotes “how do people know it” rather than “what do people know.”

This principle is based on the coherence theory of ontology that emphasizes the coherence between new knowledge and an established body of knowledge (Spector, 2001). New knowledge is gained through successful social negotiation with a larger social group to reach a harmony between new beliefs and established beliefs. This principle reflects the basic tenets of social constructivist learning in which self-initiation and social collaboration are at the core of knowledge construction (Bi, 2000; Bird, 2007; Brooks & Brooks, 1993).

Principle Two. Ontological design is most effective when ontologies are interfaced with each other to form a network of knowledge domains.

This principle is based on recent research on computational ontological design and studies on semantic web (Hendler, 2001; Henze et al., 2004). Research on semantic web reveals that learning becomes more effective when instructional resources are organized in a meaningful network that facilitates knowledge association and creation (Gasevic & Hatala, 2006; Yang et al., 2004).

Principle Three. Ontological design is most effective when a network of known knowledge exists to facilitate the construction of new knowledge.

Based on the second principle, this principle focuses on constructing new knowledge by relying on an existing body of knowledge. It aligns with the schema learning theory which posits that meaningful learning occurs when new knowledge is integrated with the existing schemata (Piaget, 1952; Zheng, Yang, Garcia, & McCadden, 2008). An ontological design for learning becomes meaningful when learners' learning experience, both as knowledge consumers and as knowledge constructors, is supported by a larger body of

knowledge to which learners are able to relate themselves in the process of learning (Winberg & Hedman, 2008).

The ontological entities and design principles identified above provide a theoretical framework for designing and developing an ontological instruction in learning, particularly in online learning. To understand the application aspect of the principles, we introduce a case study in which the above principles are applied to teaching and learning in an online environment.

APPLYING THE ONTOLOGICAL INSTRUCTIONAL DESIGN MODEL TO ONLINE LEARNING: A CASE STUDY

This section focuses on the practical aspects of ontological design model, that is, the application of the ontological instructional design to online learning. Our discussion starts with a case study on a course design related to international leasing, followed by an analysis on the challenges pertaining to the course design and delivery. Finally, an ontological design approach is suggested with a focus on the application of identified design principles and the ontological design model.

The Case Study

Due to the fast growing economy in Asia, the international leasing business has blossomed, bringing an annual net revenue of 53 billion USDollars for the industry. Accompanied with this growing business are issues related to culture, business regulations and practices, international laws, and so forth. A recent study shows that litigations on international leasing are on the rise, partly due to a lack of understanding of different cultures, and partly because of unfamiliarity with the business regulations and practices in the partner countries. Therefore, there is an immediate need to train people to become familiar with the areas mentioned above.

S University decides to start a joint online program on international leasing with its partner university in Asia. The purpose is to bridge the gap between two countries by training people to become familiar with the cultures and business regulations of both countries and to independently problem solve complex situations in international leasing. Students enrolled in this program are expected to go beyond the minimum requirement of learners as consumers of knowledge but would be able to share and construct new knowledge in learning.

Challenges

There are several challenges pertinent to the design of the new program. First, there is a lack of adequate resources. Although general resources can be found in the library or other academic database, a well-organized resource on perspective culture related to leasing business is lacking. Secondly, due to a rapidly changing market economy in the partner country, the business regulations have been under constant revisions. This becomes a challenge to the program in keeping up with the changes so that the information does not become dated. Finally, there is a big challenge to the instructional design in terms of meeting the expectation that students go beyond knowledge consumers to become sharers and constructors of new knowledge.

Using Ontological Instructional Design Model to Meet the Challenges

The application of ontological instructional design model involves examining the relationships between ontological entities in a system and between ontological components within an ontological entity. As the ontological design model is used to organize and make connections between various ontological entities in the system, considerations must be given to whether the ontological entities facilitate learners' experience in knowledge

construction and sharing (principle one) and whether the ontological entities operate on the rule of interoperability and sharability so that a network of knowledge domains can be created (principle two). Further, it is important to have a mechanism within the established network of knowledge domains that supports the creation of new knowledge (principle three). Figure 4 displays the relationship between ontological entities in ontological instructional design.

The above ontological model enables the designer to clearly identify the functions and roles of the ontological entities in the system. For example, knowledge representation provides the learner with the access to the domain content which is connected to a larger ontological entity called knowledge repository. Both knowledge repository and design component repository provide the inputs in determining the content structure in knowledge representation. Finally, knowledge presentation is presented via media which draws resources from the media repository. Each ontological entity is defined by domain, method, and value. For example, knowledge representation consists of international leasing as its domain that is represented in modules. The quality of the modules is defined by the value of structural rules. A well organized and structured module means it is well executed and highly efficient whereas a poorly organized and structured module means less efficiency. Besides, by looking at the diagram in Figure 4 we find that the modules in knowledge representation have two forms: carriers and shells. This means the learner can access the content either via carriers or shells. In the former, the learner plays the role of knowledge consumer. In the latter, the learner becomes a knowledge constructor.

As indicated, Figure 4 provides a map of the relationship among ontological entities. However, understanding such relationship requires a further examination of the components within an ontological entity as well as the association and connections among those components. In the following

Figure 4. Relationship between ontological entities in the ontological design model

sections, we first describe the components in each entity (i.e., knowledge repository and design repository), then we present a discussion on the associative relationship among the components from each entity and how they are effected in the knowledge representation.

Knowledge Repository

Since international leasing is known as a multinational business, it encompasses several domains of knowledge. The domains may include cultures, business regulations, international leasing, international laws, history of international leasing, and so forth (Figure 4). A semantic web approach is used to organize the individual domains into an ontology of knowledge domain. For example, specific identifiers are used to define the domains in the metadata section of a HTML or XML so that they become searchable in the web. In a semantic web, learners are able to develop, as the webmaster does, sharable ontological content with many built-in tools in the Web. Thus, the domains are no longer a static repertoire of knowledge. Instead, they become active, dynamic resources powered

by the learners who become actively involved in the learning process by creating ontological learning content which is further shared by a larger group of online learners.

Design Component Repository

The design component repository consists of all the design components in instructional design. Not every instructional design needs to include all the design components. They can be selectively used based on the purpose of the instruction. However, when the components are used, they must be considered simultaneously in the design process. Table 1 shows a matrix that demonstrates the horizontal and vertical relationships between the components.

In this matrix, the horizontal relationship describes the interrelation between components whereas the vertical relationship delineates the dimensions of the component in relation to other components. For example, by examining the horizontal relationship between the instructional strategy and learner characteristics, the designer is able to determine the degree to which instruc-

Table 1. Component matrix of ontological instructional design

Components Components	Content	Learner Characteristics	Instructional Strategy	Assessment
Content	Understanding the concepts and principles in international leasing, cultural factors, local business regulations, international laws that influence the business operation	Determining the relationship between content and learner characteristics	Identifying instructional media and strategies for content delivery	Determining assessment strategies to measure the delivery of content
Learner Characteristics		Identifying the range of learner characteristics	Developing instruction that gears toward individual needs	Identifying assessment tools to measure learner characteristics
Instructional Strategy			Developing instructional strategies that support knowledge sharing and construction	Developing the assessment to measure the effects of media and instructional strategies in content delivery
Assessment				Developing the assessment that measures students' basic knowledge, creativity, and constructivist thinking.

tional strategy is related to learner characteristics, thus detect the level of interplay between two components. Likewise, by examining the vertical relationship of the instructional strategy with other components such as content and learner characteristics, the designer identifies the functional dimensions of instructional strategy. That is, instructional strategy can be functionally operated at the level of learner characteristics and content. Obviously, the matrix analysis enables the instructional designer to gain an understanding of the design components in considerable depth and breadth.

Knowledge Representation

Next, the components identified in both ontological entities, i.e., knowledge repository and design repository, are being considered in a larger context in terms of representing the knowledge to learners. For example, the design of semantic web for multiple knowledge domains is examined through the lens of design components. Specifically, the designer looks at the associative strength between

the knowledge domains and the design components such as learner characteristics, instructional strategies, and so forth.

Based on the inputs from design component and domain knowledge analyses, the knowledge representation is formed. Various learning modules are formulated to represent the knowledge identified and at the same time the rules of reusability and sharability are applied to the design and development of instructional modules. Different from the traditional design, the ontological approach of representing knowledge enables learners to experience the construction and creation of knowledge through multiple venues, thus promoting a learning process that focuses on the understanding of “how do people know it” rather than “what do people know.”

In conclusion, the ontological design model is used in the case study to illustrate how an online instructional program can be created to facilitate dynamic knowledge acquisition and creation, as well as promote learners' self-initiation and collaboration in learning. The model identifies the relationship among ontological entities in the

design process. It reveals the interactive nature of components within an ontological entity and their connection with other ontological entities.

GUIDELINES FOR APPLYING ONTOLOGICAL DESIGN TO ONLINE LEARNING

As an alternative to traditional instructional design, the ontological instructional design has been increasingly adopted by instructional designers who perceive it as a promising approach to teaching and learning, especially in online learning (Kyzylkaya et al., 2007; Ullrich, 2004). With the advent of semantic web, knowledge is no longer considered to be individualized entities. Instead, they are ontologies of domains that can be constructed, reused, and shared. This change of knowledge representation demands a parallel change in instructional design. Rather than following a sequential, segmented approach in traditional instructional design, the ontological instructional design takes a nonlinear, interactive design approach in which resources become globally sharable and learning is regarded as a process of knowledge construction and creation (DeSchryver & Spiro, 2008).

Although ontological instructional design has shown its presence in teaching and learning, the complexity and evolving nature of the design requires instructional designers to take careful consideration of the factors that may affect the application and implementation of the design. It should be noted that the model could not be expected to address all aspects of the issues in ontological instructional design. However, it can help designers to identify the critical elements in design by examining the knowledge domains, knowledge representation, and relationship between ontological design components. Here are some general guidelines to consider:

1. The ontological instructional design should take in perspective the differences between ontological and epistemology approaches toward instructional design by distinguishing the epistemological view of *what-do-people-know* from the ontological view of *how-do-people-know-it* in learning.
2. The ontological instructional design should take into consideration the interoperability and sharability of ontologies and use a design approach that examines simultaneously various ontological entities as well as the components within an ontological entity.
3. The implementation of the ontological instructional design should take into consideration the design principles so that effective learning occurs in an ontological learning environment.
4. A balanced approach should be taken toward ontological instructional design which draws strengths from different research and practices including computational ontological design, instructional design in epistemological approach, pedagogies and best practices related to everyday classroom teaching and learning.

SUMMARY

The traditional design approach that focuses on linear, single domain design has become inadequate to address the increasing challenges faced by online learners, especially when the growth of knowledge has outpaced human's processing capacity (Andrade, Ares, & Garcia, 2008; Dede, 2004). A new mode of learning that emphasizes knowledge interoperability, reusability, and sharability should be instated to meet the challenges of new learning. The ontological instructional design model proposed in this chapter is to provide an alternative perspective to the traditional design by introducing a methodology that will affect an ontological approach in learning.

By identifying the ontological entities which include knowledge representation, knowledge repository, design component repository, and so on, the model presents a holistic view of the functions and roles of ontological entities in design. Rather than presenting segmented instructional units, the ontological entities are related and interfaced with each other to promote knowledge sharing and construction. For example, knowledge representation is interfaced with knowledge repository so that domain knowledge in the knowledge representation is not segmented or isolated pieces of information. Instead, knowledge that flows from knowledge repository enriches the domain content in knowledge representation.

Related to knowledge repository and knowledge presentation is the design component repository. As an ontological entity, design component repository contains all the design components essential to the instructional design. In traditional design, the design components are sequenced in a hierarchical manner. The drawback for such design is that the designer typically focuses on one component at a time. There is a lack of holistic approach to the design. The proposed model provides a holistic approach by coordinating different design components in a single design platform called design matrix so that the designer will be able to simultaneously consider multiple factors in terms of their horizontal and vertical relationship.

To summarize, the proposed model presents an ontological approach to instructional design. The model can be applied in various online instructional design and learning. Taking an ontological approach, the design zeros in on knowledge sharability and reusability which have been commonly accepted as a design rule in semantic web. Drawn from its philosophical origin as well as major tenets from constructivist learning theory, the model promotes the experience of knowledge construction as the way of knowing. A case study is provided to illustrate how the model can be applied to the design and development of an

online curriculum. As has been pointed out, the model cannot be expected to address all aspects of the issues in ontological instructional design. Future research is needed to test the model and its design principles in variety of online learning environments.

FUTURE RESEARCH

Online instructional design can be challenging to educators who are accustomed to traditional models of teaching. The proposed ontological instructional design model suggests a different way to traditional instructional design by drawing attention to the interplay of various design components and the relationship between ontological entities in a learning system. Instead of examining the roles of individual design component as does the traditional design model, the ontological model proposed in this chapter underscores the functions and roles of ontological entities in supporting various instructional goals and objectives. Future research is needed to test the generalizability of the model that can be applied to various online learning curricula and subject areas. Further empirical studies are needed to prove the validity and reliability of the principles, especially when they are used to support online learning. Finally, research should be conducted to examine the correlation between the proposed model and other online models to further validate the usability and applicability of the model.

KEY TERMS AND DEFINITIONS

Design Component Repository: The design component repository consists of design components similar to those in traditional design models

(Dick, Carey, & Carey, 2005; Gustafson & Branch, 1997; Smith & Ragan, 2005). It operates on the shared knowledge rule which determines the interactivity of the design components and the level of interfacing with the domains in knowledge repository.

Epistemology: Epistemology or theory of knowledge is the branch of philosophy that studies the nature, methods, limitations, and validity of knowledge and belief. The early epistemology such as Descartes emphasized the first truths as a foundation to construct a picture of reality (Fuller, 1955). Differing from the classical ontology as represented by Plato and Socrates, Descartes' epistemology challenged the established truths by questioning every belief that one holds about external reality. This view of beliefs was associated with the rise of science and the successes associated with the scientific method, which Descartes helped codify (Spector, 2001). An important focus in epistemology is to try to reach truth through empiricism - what we can know through our senses - which we can summarize as “we believe what we see”.

Knowledge Repository: Knowledge repository refers to a wide range of knowledge domains across various subject areas including math, physics, biology, social science, language, etc. Domains within the knowledge depository are connected by semantic rules and can be accessed through domain identifiers and classes. Knowledge repository primarily interfaces with the design component depository in which the design components like goal analysis, task analysis, learner characteristics, and so forth interact with the knowledge domains to provide inputs for the design of knowledge representation. Since knowledge repository operates on semantic rules, the domains become sharable within the knowledge repository as well as with ontological entities outside the knowledge repository such as design component repository.

Knowledge Representation: Knowledge representation in ontological design consists of content structure and format. The content struc-

ture of knowledge representation is formulated based on the inputs from knowledge repository and design component repository. The format often takes the form of modules which have two different presentations, shells and carriers, the selection of which is dependent on the purpose of the instruction. For example, if the instruction is to deliver the content for learners to learn the basic concepts and skills, the carrier presentation will be used to deliver the content. If the purpose of the instruction is to develop skills in knowledge construction, the shell presentation will be used for learners to construct new knowledge. In short, the shells enable learners to create new knowledge and share it with other learners. The carriers store the knowledge which is presented to the learner.

Ontology: The term ontology essentially refers to the study of being or existence. It seeks to describe or posit the basic categories and relationships of being or existence to define entities and types of entities within its frame work. In Greek philosophy, ontology means understanding the eternal reality (Reginald, 1985). Plato defined the reality as primary and the perception and experience of reality as secondary. Socrates held the similar view that the purpose of learning was to recognize eternal truth and therefore the instruction was to remind someone of something already known and accepted as true (Spector, 2001). This classical view of ontology has changed due to a realization that the explication and uncovering of external reality involve human perceiver and that human judgment with respect to such uncovering is subject to error. One of the assumptions of modern ontology is that instruction should focus on bodies of knowledge rather than individual knowledge. Instead of relying on one-to-one correspondence between individual beliefs and external reality, the modern ontology proposes

a coherence theory of truth in which acceptance or rejection of new beliefs should be based on how well new beliefs fit with and how coherent they are with the established beliefs (Quine & Ullian, 1978; Spector, 2001). This assumption is important in that it influences the formation of ontology in computer science in which the shared conceptualization of reality across knowledge domains is emphasized.

Ontology in Computer Science: Derived from its philosophical origin, an ontology in computer science is a data model that represents a set of concepts within a domain and the relationships between those concepts. For example, in artificial intelligence, software engineering, biomedical informatics and information architecture, the ontology is defined as a form of knowledge representation about the world. Ontologies in computer science generally describe (1) Individuals: the basic or “ground level” objects; (2) Classes: sets, collections, or types of objects; (3) Attributes: properties, features, characteristics, or parameters that objects can have and share; (4) Relations: ways that objects can be related to one another; and (5) Events: the changing of attributes or relations

Ontological Instructional Design: Ontological instructional design involves examining the relationships between ontological entities in a system and between ontological components within an ontological entity. The ontological design model is used to organize and make connections between various ontological entities in the system. Considerations must be given to whether the ontological entities facilitate learners’ experience in knowledge construction and sharing and whether the ontological entities operate on the rule of interoperability and sharability so that a network of knowledge domains can be created.

Chapter 7.17

Lost in Translation: Improving the Transition Between Design and Production of Instructional Software

Eddy Boot

Università della Svizzera Italiana, Switzerland

ABSTRACT

Developing modern instructional software has become very complex. As a result, the communication between instructional designers and other stakeholders in the development process is becoming increasingly important. However, due to differences in background, focus, and tools among ISD stakeholders instructional designers lack the means to provide reasonably unequivocal design documentation for these stakeholders. These differences in stakeholders create a context where the design documents produced are not sufficiently related to the specific needs of the stakeholders, in terms of meaningful organization and differentiation of level of detail. This problem is complicated by the lack of shared design languages. These problems prevent precise expression of design

information. The 3D-model is introduced to support instructional designers to stratify, elaborate, and formalize design documents, even if design languages are hardly shared between designers and other stakeholders. Two validation studies show that the 3D-model contributes to a better information transition between instructional designers and software producers—one of the stakeholders in the development process.

INTRODUCTION

Currently, the educational field is characterized by many innovations: mobile learning, next-generation e-learning systems that retrieve information from business processes, or case-based learning in virtual environments. These innovations, and others, provide the flexibility to enable the integration of working and learning,

DOI: 10.4018/978-1-60960-503-2.ch717

with time and place independent learning, and adaptive learning, personalized for individual learners (Rosenberg, 2000). These innovations illustrate how organizational, technological, and pedagogical aspects of instructional software can change rapidly. Also affected by these innovations is the way instructional software is developed. The combination of organizational considerations (e.g., “What are the new roles of teachers using instructional software?”), pedagogical considerations (e.g., “How can authentic learning tasks be implemented in the instructional software?”), and technological considerations (e.g., “Which media mix is optimal?”) makes the development process highly complex (Jochems, van Merriënboer, & Koper, 2003). Consequently, a structured approach to design, production, and implementation of instructional software is required.

One area in the instructional software development process that appears to be negatively affected by this increased complexity is the transition of information from the design phase to subsequent phases, or, from an instructional designer to the other stakeholders in the process (Boot, van Merriënboer & Theunissen, submitted). A bottleneck is created in that the intentions of the instructional design, described in training blueprints and storyboards, are not communicated clearly enough to other stakeholders of the development process. For example, instructional design information may be insufficiently represented in the specifications created by software producers. As a result, time-consuming reviews and frequent discussions between instructional designers and software producers are often required to reach correct technical specifications that are fully in line with the blueprint and storyboard. This sub-optimal transition process is further undermined by the fact that many software producers are not specialized in instructional software, and therefore inexperienced in specifying and creating instructional software programs. When reviews and discussions are impossible, due, for example, to legal reasons, the production process often results

in an unsatisfactory outcome: flawed instructional software that requires correction afterwards (“design by debugging”). This example focused on the most obvious stakeholders, as designers traditionally interact mostly with producers. Of course, modern, complex development processes require that a large number of other stakeholders are also sufficiently informed.

In this chapter, we discuss the transition problem between design and other development phases, and identify three major causes for this problem. To overcome these three problems, we introduce the 3D-model as an aid to stratify, elaborate, and formalize design documents, even if design languages are hardly shared between designers and stakeholders. Finally, we present an empirical validation of the 3D-model and discuss the implications of the use of that model.

THE TRANSITION BETWEEN DESIGN AND PRODUCTION

Most instructional software is developed using some variation of the instructional systems development (ISD) model, which often is an instantiation of the generic, five-step ADDIE model: analysis, design, development, implementation, and evaluation model (Dick & Carey, 1996). Every phase in the ISD model identifies specific types of activities and outcomes for which any number of different specialists (e.g., subject matter experts, instructional designers, or software producers) are responsible.

In contrast to ISD models, instructional design (ID) models are a subset of ISD models and encompass only the first two steps of ISD, namely analysis and design (van Merriënboer, 1997). This distinction is useful because it helps to highlight a logical grouping of activities. In general, instructional designers are the specialists responsible for the activities that occur during these two phases (van Merriënboer, 1994).

By the end of the instructional design, the designer usually has some sort of description or documentation of his design (e.g., a training blueprint or a storyboard) that is ready to be delivered to the next phase to be used by the specialists responsible. This is central to the task of the instructional designer, or, as McDonald states in Chapter II (p. 19): “It may not be overstating the point to say that the business of instructional design cannot be separated from communication.” The next phase is the development phase and the responsible specialists may include software programmers, audio and/or video producers, graphic designers, or other multimedia specialists.

Regardless of the form the design documentation takes, there is an expectation that it will be able to effectively communicate the intentions of the instructional designer. This is an important assumption as producers will make specifications for their products based upon this design and subsequently create the instructional software (see Figure 1 for a process description of the several transitions that take place). Although producers are an important target group, the design documents are also used to communicate the instructional design to other stakeholders who are responsible for the following steps in the ISD process (i.e., implementation and evaluation) or validating the previous ISD steps (i.e., analysis and design).

The transition process from design to production and other ISD phases is not without problems. Many instructional designers lack the necessary means to provide design documentation that ensures a reasonably unequivocal representation of

the design to the other ISD stakeholders. As can be seen in Table 1, the concerns of different ISD stakeholders are related to a variety of organizational, pedagogical, and technical issues. Consequently, there is an expectation placed upon the instructional designer to produce a design document that will answer the need for different kinds of information. However, in most situations, instructional designers will have a different background than most of the other stakeholders (e.g., educational vs. management) and use different tools (e.g., analysis and design tools vs. technical production tools), and are therefore unaware or unable to provide the right information to the right stakeholder. As McDonald (Chapter II) puts it:

“Designers do need to act with integrity and communicate in ways that maintain the essential qualities of their message. But they also need to remember that they are not designing only for themselves, and so have an obligation to make sure they present ideas in ways that communicate clearly to others outside of design communities” (p.28). Yet, it is quite unfeasible that instructional designers are able to “collect” all the needs of the other ISD stakeholders, for it is quite difficult to speak in a design language that is not mastered by others. Nonetheless, *“instructional designers should be careful not to confuse meaning with mechanics so that when necessary they can separate the two and express their meaning in other ways”* (McDonald, Chapter II, p. 24).

The next section discusses three problems with conventional design documentation, which are

Figure 1. Transition process of instructional design information

Table 1. Concerns of different stakeholders in the ISD process

Kind of stakeholders	Types of Stakeholder Activities	Examples of Concerns
Project Leader	Manage the whole ISD process	Optimal transfer of information and product during the ISD process
Subject Matter Experts	Validate the domain content	Impact on work floor
Instructors	Validate the didactical model	Impact of instructional design on their teaching (e.g., classroom based, coaching in practice)
Managers	Approve the instructional design	Impact of instructional design on their organization (e.g., financial, roles, infrastructure)
Producers	Translate instructional design into technical specifications (often conduct their own type of analysis and design)	Impact of instructional design on production process (e.g., selection of tools and media, programming, interfacing, usability)
Implementers	Use the instructional design as guidelines	Impact of instructional design on infrastructure, roles, school management, etc.
Learners	Participate in usability studies, interface design studies, and other formative evaluation activities.	Personal preferences and impact of instructional design on their learning processes
Evaluators	Use the objectives set in the instructional design as evaluation criteria	Impact of instructional design on assessment process

the result of the differences between instructional designers and other ISD stakeholders.

THREE PROBLEMS IN THE TRANSITION PROCESS

Highly Integrated Design Documents

The first problem relates to the meaningful organization of the design documentation, more precisely, its highly integrated character. In conventional design documents, there is often little to differentiate the organizational, technical, and pedagogical aspects of the documents. As a result, if a particular aspect of the design changes, it is difficult and time-consuming to trace the resulting consequences throughout the design. For instance, if a stakeholder such as a manager decides that instruction by synchronous communication (e.g., using Webcams or instant messaging) is not feasible due to relative high costs or security issues, all aspects in the instructional design related to the possibilities of synchronous communication must be traced and modified. This one change could affect organizational aspects such as dif-

ferent infrastructure, technical aspects such as different e-learning systems, and pedagogical aspects such as different learning tasks, which are all connected to each other

Inconsistent Level of Detail in Design Documents

The second problem relates to the level of detail of the design documentation. The level of detail in conventional design documents varies depending on the capabilities of the designer. For example, more capable designers will typically add more detail to instructional issues but not to technical issues. However, the level of detail should also depend on the needs of the receiver of the information, that is, a particular stakeholder. For instance, for designers to communicate among themselves, the application of delayed cognitive feedback following a particular learning task, a rather conceptual description will suffice. The designers will readily understand each other. But for a producer or an implementer, much more detailed descriptions of timing, content, and presentation of feedback are needed to be able to specify, produce, and implement it as intended by the designer.

The result from the two problems described above is that design documents are not related to the specific needs of particular stakeholders, in terms of meaningful organization and differentiation in level of detail.

Lack of Design Languages for Design Documents

The third problem may deserve more attention, for the lack of design languages that are shared between designers and other ID stakeholders is actually more serious than the previous concerns, because unless an agreed-upon design language is established, it may be difficult also to define an optimal organization and detail level of design documents. In domains other than the instructional design field (e.g., architecture, music, movies), visual design languages are able to capture and describe the design in design documents (e.g., building blueprints, music-books, storyboards) with such a level of detail that they will be interpreted reasonably unequivocally by other stakeholders (e.g., contractors, musicians, directors). Gibbons & Brewer (2005) state that we may speculate that some of the differences in composer excellence are the result of a more expressive set of (personal) design language terms or a better set of (personal) rules for synthesizing expressions from the terms. In the field of Instructional Design, visual design languages are mostly used to explore design spaces and solutions, for they provide common, explicit notation systems for describing an instructional design in design documents (Gibbons, Nelson, & Richards, 2000; Waters & Gibbons, 2004). A notation system is an embedded element of a visual design language and captures abstract ideas to create transferable designs (Gibbons & Brewer, 2005). Examples are the blueprints symbols of an architect or the musical notation system for composers.

In instructional design, visual design languages require such notation systems to convey their message by means of symbolic, graphical, textual

or other conventions. An example of a graphical modeling language, not bound to the field of instructional design, is the unified modeling language (UML; Booch, 1994; see also Chapter 11). The notation system of UML (i.e., diagrams) enables different stakeholders to describe and understand a particular software design.

Among the most recent attempts to introduce design languages in the field of instructional software development is IMS learning design (IMS-LD; Koper & Tattersall, 2005; see also Chapter XV). Yet, the IMS-LD language is meant to promote the design of de-contextualized learning objects (Chapter XIII), needed for instructional strategies “that engage the learners in authentic tasks that are relevant to their personal needs and goals” (Reigeluth, 2005, p. 212). Hence, the cooperative problem-based learning meta-model (CPM; Nodenot et al., 2003, Chapter XIII) was introduced to design contextualized learning scenarios, particularly problem-based ones. Other design languages are at stake too. Think for instance of the recently proposed educational environment modeling language (E²ML; Botturi, 2006; see also Chapter VII), which allows its users to represent the components of an instructional environment through a visual notation system. Another example is the typified objects visual modeling language MOT and its extensions, whose purpose is to help designers to visualize activity sequences, actors and tools (Chapter VIII) of the instruction to be designed. The classification scheme of Botturi, Derntl, Boot, and Figl (2006) shows that each of these design languages has a set of identifiable features and may be used for various purposes (e.g., creative purposes versus final documentation). However, for the most part, each design language is created for a particular target group, and therefore seldom shared among different stakeholders in the ISD process. For instance, the more precise the design language is, the more technical its notation system is likely to be, making the language too difficult for non-technical stakeholders.

Ideally, the design should be transferred from the instructional designer (or design team) to the software producer and other stakeholders only once, and be completely understood. In this way, there is either no further information exchange necessary, or stakeholders can formulate clear and concrete questions about, for instance, details of the task domain. Thus, in the case of outsourcing, an ideal design document should allow the production company to make an exact estimation of costs and time (before the contract is signed), and ensure a product that is fully compatible with the original design (after the contract is signed).

In the next section, a decision model for instructional designers is introduced to provide support in improving design documents for better communication of their designs, taking into account the three problems described above.

THE 3D-MODEL FOR SUPPORTING INSTRUCTIONAL DESIGNERS

A good solution to overcome the transition problem should focus on supporting instructional designers to provide stakeholders with exactly the design-related information they need. This chapter focuses on supporting instructional designers rather than software producers or other stakeholders; this choice was not without reason, because the designers are pre-eminently responsible for the didactic quality of the final instructional products (defined as the extent to which desired learning outcomes are attained in an efficient manner). This didactic quality is of utmost importance, because technical quality (defined as the extent to which the software takes care of the input, information processing, and output as intended, and the responsibility of the producers) alone is a necessary but insufficient condition to fuel the desired learning processes and reach intended learning outcomes.

As described in the previous sections, the three problems regarding the transition of the instructional design are related to the affect upon

the various stakeholders due to (a) the integrated character of instructional design documents, (b) the lack of differentiation in level of detail, and (c) lack of instructional design languages and matching notation systems. As a result, design documents may be difficult to interpret for three reasons: (a) different instructional and technical structures are often not meaningfully organized; (b) different levels of detail are inconsistently applied, and (c) different expressions are used in a non-standardized manner, as designers and producers have hardly any shared design languages to their proposal.

The 3D-model (developing design documents) was developed to support designers in creating better design documents. The three components of the model include (a) stratification, (b) elaboration, and (c) formalization.

Stratification

To overcome the highly integrated nature of design documents and to create more meaningful organization, Gibbons' model of design layers (Gibbons, 2003; see also Chapter XVII) is used to stratify the instructional software design into seven, interrelated layers: content, strategy, control, message, representation, media logic, and data management. Each layer is typified by the designer's selection of design languages pertaining to the solution of different instructional design subproblems. Collectively, the functional designs at each layer together make up the total design. Stratification helps to determine the relations between the functionally different instructional and technical structures that are relevant for a particular stakeholder, while at the same time staying cognizant of the need for integration of those structures within the complete design.

Elaboration

To overcome the inconsistent level of detail and to create more differentiation between the informa-

tion offer to stakeholders, the three perspectives of Fowler (2004) are used for the *elaboration* of the instructional software design: (a) A conceptual perspective, with more or less superficial and descriptive information; (b) a specification perspective, with more or less comprehensive and detailed information, and (c) an implementation perspective, with more or less technical and highly-detailed information. Elaboration helps to determine the required level of detail used in the design documentation, depending on the capabilities of the designer and the needs of a particular stakeholder.

Formalization

To overcome the lack of instructional design languages and matching notation systems and to promote more unequivocal understanding of the design, designers may achieve *formalization* of their design by making their selection between informal and formal design languages explicit. They should strive for combinations of formal languages, as these languages provide the most precise and concrete designs descriptions. However, depending on their capabilities and the needs of a particular stakeholder, they can also apply combinations of informal languages as well. Formalization is not necessarily a requirement, nor is it always desirable because, as stated above, not many complete formal instructional design languages are available yet. Formalization helps to determine the required various levels of standardization used in the design documentation.

As Figure 2 shows, the 3D-model uses stratification, elaboration and formalization as its three dimensions. Designers, with or without producers, may first analyze their design situation in order to determine the optimal configuration of the 3D-model (e.g., What kind of designers are involved? Who are the stakeholders to be addressed? What kind of design languages are shared with those stakeholders? Which design tools are available?), and then use this configuration to stratify, elabo-

rate, and formalize their design documents. For instance, they can determine which design layers to address along the stratification dimension, and which combination of level of detail (elaboration dimension) and notation system (formalization) will be used for that layer. Figure 3 shows two possible resulting configurations of the 3D-model.

For stakeholders, on the other hand, the particular configuration of the 3D-model provides insight in the underlying structure and content of the design documentation they were given, even when the design languages used are not standardized or completely shared.

VALIDATION OF THE 3D-MODEL

In order to evaluate the 3D-model, an empirical study was set up (Boot, Nelson, van Merriënboer, Gibbons submitted), which was replicated in a second study. Both studies will be described here briefly. The studies focused on the communication of the instructional design to one important kind of stakeholders, software producers.

Participants

Study 1. Sixteen master and PhD students from an American University's Computer Science Depart-

Figure 2. The 3D-model for developing design documents in its full configuration

Figure 3. Two possible configurations of the 3D-model

ment participated in this study, acting as producers of instructional software. They were randomly assigned to either the conventional instructional design documents group ($n = 8$) or the improved instructional design documents (based upon the 3D-model, see below) group ($n = 8$).

Study 2. Thirteen bachelor students from a Swiss university's Computer Science Faculty participated in the same role as in the first study. They were randomly assigned to either the conventional documents group ($n=6$) or the improved documents group ($n = 7$).

Both groups had considerable experience in specifying and programming software. Table 2 presents the experience of the participants with typical producer tasks such as object-oriented modeling and programming. There were no significant differences with regard to this experience

between the conventional and improved conditions within both studies.

Materials

The conventional and improved design documents covered an identical topic (an instructional software application for learning to drive a car) and had identical functionality (providing input for the technical specification process for an advanced educational car-driving simulation).

With respect to the *elaboration* and *stratification* dimensions of the conventional design document, the document is mostly directed at providing much detail (implementation level) at the content and strategy layers, average detail (specification level) on the control, message, and representation layers, and little detail (conceptual level) at the media logic and data management layers.

Table 2. Means and standard deviations of proficiency with programming languages and ratings on experience with object-oriented software development

	Study 1				Study 2			
	Conventional design documents group ($n = 8$)		Improved design documents group ($n = 8$)		Conventional design documents group ($n = 6$)		Improved design documents group ($n = 7$)	
	M	SD	M	SD	M	SD	M	SD

Figure 4. Example page of conventional design document

Considering the *formalization* dimension in the 3D-model, the conventional design document is based upon informal representations only, such as text and sketches. This configuration reflects the traditional approach towards design documents (see for instance Driscoll, 1998; Kruse & Keil, 2000; Van Merriënboer, Clark, & de Croock, 2002), and is presented as Configuration 1 in Figure 3. Figure 4 presents an example page of the conventional design document.

The improved design document is based upon both informal representations and formal representations (*formalization* dimension in the 3D-model). For the informal representations, the values on the *elaboration* dimension are conceptual, specification, and the values on the content and strategy layers are implementation. For the formal representations, the values on the *elaboration* dimension are specification and conceptual for the layers content up to data management. For these formal representations, UML diagrams are used. This configuration reflects the use of the 3D-model to stimulate and support designers to stratify, elaborate, and formalize design documents more than they usually do, and is presented as

Configuration 2 in Figure 3. For instance, Figure 5 presents an example page of the improved design document, showing such a formal representation of a media logic structure, from a specification perspective.

Measurements

Specification questionnaire. The ability to translate the design document into technical specifications, defined as the agreement between technical specifications and the intentions of the instructional design documents, was measured by the specification questionnaire. It consisted of 25 open questions, each question on one printed page with sufficient space to note down the answer. There was no time limit for answering the questionnaire, but the experimenter measured the time on task for each question unobtrusively. Each question addressed a particular aspect of translating the design document into technical specifications. For instance, the participants had to distill from the design document how many databases should be used in the instructional software; what the consequences would be from changing text-based

Figure 5. Example page of improved design document

messages into audio-based messages (the so-called “ripple effect”); how a particular program flow should be implemented; what it meant if just-in-time information would be applied in a particular learning task; where the producer would need a subject matter expert to provide additional domain information; which instructional design components should be implemented as reusable learning objects, and so forth. Based on a checklist with correct answers (as determined by instructional designers and production experts), two reviewers rated items as correct or incorrect (the Intra Correlation Coefficient, ICC, is .94, which is very good, Fleiss, 1981).

Cognitive load questionnaire. This questionnaire measured the perceived cognitive load for each question in the specification questionnaire, defined as part of the costs of the translation process. It used the standard 9-point rating scale developed by Paas (1992; see also Paas, Tuovinen, Tabbers, & van Gerven, 2003). The rating scale was included at the bottom of each page of the

specification questionnaire, and ranged from 1 = “very, very low perceived load” to 9 = “very, very high perceived load.” The ICC for the questionnaire is .89, which is good.

Results

The use of the 3D-model for generating instructional design documentation, as applied in the enhanced document set, showed a significant increase in efficiency of creating technical specifications while requiring the same time and cognitive load. Table 3 shows that the improved design documents indeed resulted in higher scores for the agreement between technical specifications and the intentions of the instructional design documents. This indicates a higher level of understanding of the instructional design documents, which is required to translate the functional model into technical specifications. The results with regard to time were mixed. In Study 1, working with the

improved design documents required less time, but in Study 2 there was no significant difference. In both studies, there were no significant differences in perceived cognitive load when comparing the same question on the conventional and the improved design documents.

CONCLUSION

This study investigated the transition problem between design and other development phases and identified three major causes for this problem. It also introduced a means to improve the efficiency of the translation process between the design phase and the production phase. The results of two studies show that the application of a structured, three-dimensional approach by designers helps producers come to an understanding of the design that is more in agreement with the intentions of the instructional designer. Developing design documents while supported by the 3D-model results in a higher efficiency of the translation process, reflecting better results with the same time and cognitive load input. Further study should demonstrate if design documents based upon the 3D-model also promote a better transition process to other ISD stakeholders, as listed in Table 1.

The use of the 3D-model by ISD stakeholders has several implications, among others, for

training/education, support tools, and the further development of design languages.

First, with respect to training/education, this study suggests that instructional designers need to become proficient in at least three new activities. Besides being knowledgeable and skilled in traditional instructional design activities such as domain and task analysis, strategy selection, and media selection (see Richey, Fields, & Foxon, 2001), our results indicate that they should be able to (a) stratify instructional design documents to describe aspects associated with design as well as the concerns of different ISD stakeholders (see Table 1), (b) decide for each layer how much detail is required for unequivocal understanding of the design by these stakeholders, and (c) represent—where possible—their designs in formal design languages. Second, with respect to support tools, this study suggests new generation tools should be used. An example of such a support tool is ADAPT-IT (De Croock, Paas, Schlanbusch, & van Merriënboer, 2002), which supports the creation of design documents in a structured manner. If analyzed based upon the dimensions of the 3D-model, then ADAPT-IT helps designers to create design documents that are both formal and informal, are elaborated at the conceptual and specification level, and describe the content and strategy layers. Future research may either investigate the contribution of support tools such as ADAPT-IT to the creation of design

Table 3. Means and standard deviations for measures of the communication process

documents, or use the 3D-model to develop new tools that take the stratification, elaboration, and formalization dimensions into account.

Second, with respect to further development of design languages, this study suggests that more instructional design languages are necessary to provide formal representations of instructional designs in order to sufficiently balance formal and informal representations according to the formalization dimension. Although the number of visual instructional design languages is rising, it is yet to be demonstrated which impact this has on the development process. For instance, it is likely it will promote a better transition process in terms of shared understanding, but as the application of such rich languages can be quite complex, will it also save time? And will less-skilled developers be able to deal with this (additional) complexity, or does it require more proficient developers, therefore potentially limiting the wide acceptance of such design languages in the developer community?

Ultimately, the proposed research efforts should result in improved design languages and design documents, so less of the designers' intentions are "lost in translation," preventing the specification and production of sub-optimal products.

Chapter 7.18

Pask and Ma Join Forces in an Elementary Mathematics Methods Course

Jean Morrow

Janet Holland

Emporia State University, USA

ABSTRACT

This chapter introduces conversation theory as a means of creating an active learning environment in an elementary mathematics methods course. It argues that such an environment, designed for undergraduate candidates in teacher education, will engage the learners in the task of developing deep conceptual understanding to support and give rationale to the procedural knowledge most of them already have. Furthermore, the authors hope that an understanding of conversation theory as applied to teaching mathematics will help instructors and instructional designers to facilitate preservice teachers' engagement in reaching a deep conceptual understanding of the mathematics they are preparing to teach.

DOI: 10.4018/978-1-60960-503-2.ch718

INTRODUCTION AND BACKGROUND

This chapter addresses issues and technologies arising from a consideration of conversation theory. The concepts covered include developing a mathematics methods course for preservice elementary teachers that focuses on conceptual understanding. Two strands are woven together to create the needed scaffolding for learning in this course. The work of Liping Ma, noted mathematics educator and scholar, and a proponent of deep conceptual understanding, suggests that a sophisticated understanding of measurement, functions, geometry, algebra, probability, statistics, and arithmetic can only be developed through strong conversation and reflection. The use of dialogue for learning is well supported by Pask's conversation theory, based on the use of high-level

cognitive question strategies, that begins with “why” questions and moves into “how” questions.

Most mathematics educators will agree that preparing mathematics teachers is a challenging and difficult assignment. A careful application of Pask’s conversation theory will facilitate the development of deep conceptual understanding of mathematics, as espoused by Ma.

CONVERSATION THEORY AND MATHEMATICAL DISCOURSE

According to Gordon Pask, “Learning depends upon the strategies used by a student” (Pask, 1975). Breaking the learning goals into separate and smaller subgoals allows students better to focus their attention on the learning tasks at hand. In this way, educational objectives are partitioned into smaller more manageable units to ease acquisition and mastery of the content. By splitting learning into these smaller units, students will not feel overwhelmed when trying to solve learning problems while working to gain proficiency. In breaking the learning goals into separate and smaller subgoals, it is essential that preservice teachers understand that the instruction should not jump directly to the selection of an algorithm or solution strategy—as can so easily happen if, for instance, the subgoal is “key words.” If a subgoal is to learn that “how many” means to add or that “how many more” means to subtract or that “of” always means multiplication, then instruction has neglected the steps of understanding and modeling. Jonassen (2003) cites research supporting the negative impact that a direct translation strategy (of key words) has not only resulted in a lack of conceptual understanding but the inability to transfer any problem-solving skills that are developed. Appropriate subgoals for problem solving, for instance, would include modeling the problem, determining the relationships among the elements of the problem, developing a meaningful repre-

sentation of the problem, using those elements to select a strategy, and then apply the strategy. Leaping to the strategy without conceptual understanding of the problem solving process also leads to students accepting solutions that do not make sense. A familiar problem illustrating this point is the one that goes like this:

A class is preparing to go on a field trip. There are 120 fifth grade students who will be going on the field trip. Busses have been hired to take the students. If each bus holds 36 students, how many busses will be needed?

Too frequently, students turn in the answer “3 $\frac{1}{3}$ busses.”

Pask also pointed out, “At the other extreme, the strategies may be imposed upon the student as teaching strategies” (Pask, 1975). The teacher directs the learning activities towards reaching desired learning goals, objectives, or benchmarks. Instructors implement teaching strategies in an effort to target specific learning deficiencies thus assisting students in successfully acquiring new content to be learned. In these situations, students who attempt to offer another way of solving a problem will be met with “that’s not the way you’ve been taught to do them” or something similar. A teacher with deep conceptual understanding of the mathematics being learned and who has an understanding of Pask’s conversation theory is much more likely to be a facilitator, “a guide on the side,” of students’ learning rather than imposing a “one way fits all” or “this is the right way to do it” strategy.

Pask commented, “Many real situations lie between these extremes. One of them is a tutorial conversation in which methods of learning are open to discussion and in which the strategy is selected as a result of a compromise between the student and teacher” (Pask, 1975). In this situation, learning becomes more of a matter of give and take, or a shared responsibility for learning, requiring efforts to be made by both the teacher and the student. Conversational instruction allows

students to participate in making choices in a “free-learning environment” (Pask, 1977). Students are able to ask questions and choose where to direct their attention by making comments or elaborating on topics of interest.

Since the introduction of the *Curriculum and Evaluation Standards for School Mathematics* (NCTM, 1989), the call for meaningful discourse has grown increasingly strong. The call for “more meaningful discourse (is) grounded in the social nature of mathematics learning, a vision of school mathematics practices that reflects both the essence of practices in the discipline itself and the need for students to be able to communicate their mathematical knowledge in a technological society” (Knuth & Peressini, 2001). Indeed, mathematics is increasingly seen as a field in which effective communication is essential as both a learning process and an outcome (Clark, Jacobs, Pittman, & Borko, 2005). Meaningful discourse flourishes in Pask’s free-learning environment. Conversation, or communication, is an essential part of mathematics and mathematics education because it is a “way of sharing ideas and clarifying understanding. Through communication, ideas become objects of reflection, refinement, discussion, and amendment. The communication process helps build meaning and permanence for ideas and makes them public” (NCTM, 2000).

To engage students in meaningful discourse, teachers must have developed a “profound understanding of fundamental mathematics” (Ma, 1999). Ma posits four properties of profound understanding—basic ideas, connectedness, multiple representations, and coherence. It becomes the challenge for the mathematics teacher educator to model this meaningful discourse and help preservice teachers often move from a superficial procedural knowledge (i.e., knowing *how* to perform an algorithm) to a profound understanding of fundamental mathematics (i.e., knowing *why* an algorithm “works”). Thus, in teaching the subtraction algorithm to second graders, a teacher would not use the rationale that you “can’t subtract

a larger number from a smaller number” as a reason for “borrowing” in a problem such as 84-69. For the teacher with a profound understanding of fundamental mathematics knows when his or her students reach the intermediate or middle grades they will study integers (the set of positive and negative numbers) where, in fact, it is not only possible to subtract a larger number from a smaller number, but is often required.

Listening to children’s discourse in a mathematics lesson and determining what they are saying or where they are heading requires a profound understanding of fundamental mathematics (Ball, 2000). However, it is too frequently the case that the conceptualization and organization of elementary teachers’ mathematics preparation in both content and methodology is on “how”—how procedures are performed or how manipulatives are used—rather than “why.” Where, then, do preservice teachers develop the context of profound mathematical understanding and insight that allows them to guide, probe, hint, or explain in such a way as to keep the discourse meaningful? This is a serious issue in light of the TIMMS 1999 Video Study of mathematics classrooms in the United States in which a survey revealed that the teacher-to-student word ratio was on average 8:1 and student utterances were generally five words or less (Hiebert et al., 2003). The ratio found by the TIMMS study implies a monologue rather than a dialogue.

LEARNING STRATEGIES AND CLASSROOM CONVERSATION

When a specific learning strategy is implemented, it needs to align with the desired educational or curriculum outcomes. Learning is also more effective when the “... strategy is matched to the student’s existing competence” (Pask, 1975). Because not all learners are alike, there is a wide range of learning styles needing to be addressed. Through the use of dialogue, teachers discover

students' learning strategies and assist by making suggestions, as needed, to ensure students are successful in their learning efforts. As can be clearly seen, it takes a variety of instructional strategies to design and foster effective learning activities for students. Consider the situation where a teacher is introducing the topic of subtraction with regrouping. Today, many teachers will begin with manipulatives such as base 10 blocks or connecting cubes. Students will be directed to "take away" 69 from 84. Using base 10 blocks and left to his or her own devices, the student will proceed in a manner similar to the steps:

1. Here is 84 (8 ten sticks and 4 units):

Figure 1.

2. Take 60 away:

Figure 2.

which leaves:

Figure 3.

3. Now, in order to take 9 away, exchange one 10 stick for 10 units which gives:

Figure 4.

4. Taking 9 away leaves 15 for the answer.

Figure 5.

Figure 6.

$$\begin{array}{r} 7 \overline{)84} \\ - 69 \\ \hline 15 \end{array}$$

The student has arrived at the correct answer. If the teaching strategy is focused simply upon the algorithm, how does the student progress in developing deep conceptual understanding? What follows is not related to what the student has just done in any apparent or meaningful way (other than the original problem and the answer being the same!)?

Pask makes a distinction between performance and learning or teaching strategies. He views performance strategies as necessary to operationalize, demonstrate, or prove the skills are acquired. Performance strategies are considered to be "manifest in the hierarchical organization of problem solving procedures" (Pask, 1975). As a result, performance strategies represent a "very wide spectrum of the mental processes" (Pask, 1975). Differences in individual performance strategies become apparent when examining a variety of individuals, each with different ap-

proaches to solving problems. Performance strategies ultimately serve as the foundation upon which subsequent learning or teaching strategies are constructed. Examining the properties of problem solving requires one to look at “compatibility, incompatibility, consistency, inconsistency, reproducibility, and cognitive fixity” (Pask, 1975). When translating problem solving properties into conversational modes, as is found in classroom discourse, one must include “explanation, understanding, appreciation, and the like” (Pask, 1975). Thus, in teaching the subtraction algorithm to second graders, a teacher who asks if you can take a number in the sixties away from a number in the eighties, can then guide the discussion for students into a consideration of how that can be done. When students respond that it makes sense that you can take a number in the sixties away from a number in the eighties, and follow with “but you can’t take 9 from 4,” a teacher with a profound understanding of the concept of subtraction avoids the next pitfall—that “... the value of numbers does not have to remain constant in computation” (Ma, 1999). The next step in the subtraction algorithm for the problem $84 - 69$ is not to borrow 10 from the other number 8 in order to make 4 into 14 and thus “big enough” so that 9 can be subtracted from it. To do that, is to treat the problem as $4 - 9$ and $80 - 60$ rather than as a number in the sixties taken from a number in the eighties. Rather, the next step is to take something from *the other part of the number* that will enable us to subtract. As Ma explains, “The difference between the phrases ‘other number’ and ‘the other part of the number’ is subtle, but the mathematical meanings conveyed are significantly different” (Ma, 1999). In a similar vein, it can be questioned whether mathematical terms such as “fixed point” or “clockwise” have or will have any significance for students. “Fixed point” because the accepted meaning of “fixed” is “repaired” and yet a “fixed point” is considered one that does not move and “clockwise” because

digital timepieces are pushing “clocks and clock faces” towards oblivion.

One issue making it difficult for students to learn is “... cognitive fixity, a tendency to adhere to an originally selected strategy even in the face of evidence showing it to be inappropriate” (Pask, 1975). Once an individual invests his or her time, effort, and energy resources into a concept or project, it is not easy to let go and change. The longer the student maintains his or her position the more difficult it is to change. Students “... need to accumulate much evidence before they will autonomously change their minds and adopt a more appropriate strategy than the one they chose originally” (Pask, 1975). One of the great benefits of using dialogue for learning is that it allows students to be able to reduce their cognitive fixation and be more receptive to new ideas and concepts. Ultimately, the students should make adjustments and changes in thinking through the numerous contributions found in their classroom discourse. In fact, Pask states “... the major obstacle in the path of effective learning can only be reduced by an outside influence” (Pask, 1975). Through conversation, “students’ uncertainty decreases faster and more smoothly” (Pask, 1977). A second grader who learns to think of $84 - 69$ as taking away a number in the sixties from a number in the eighties will likely be more receptive to working with integers in middle school because he or she has a conceptual understanding of subtraction as well as a procedural understanding of the standard algorithm.

To return to learning and teaching strategies, one way to scaffold learners’ efforts is by providing clarity to the curriculum tasks. Students need to understand the educational objectives or learning outcomes to be able to demonstrate new skills or acquire new content knowledge. Modeling is one approach used for defining the learning objectives. One of the models often used in mathematics classes when introducing a new topic is a manipulative such as base 10 blocks when teaching operations. Taking the problem

84 – 69 once again, teachers with a profound understanding of the concept of subtraction will model taking a “ten stick” and exchanging it with 10 units. A key part of the conversation here is the discussion of the relationship between 8 “10 sticks” and 4 units and 7 “10 sticks” and 14 units. Has anything been added to or subtracted from 84? No, and so what happens when you take 69 (six tens and nine ones) from 7 tens and 14 ones? Students who have learned the subtraction process in this way can use modeling by serving as tutors or peer mentor facilitators supporting peer knowledge acquisition. Organizing content into logical sequences through careful instructional design helps students to encode new information into long-term memory. Analogies assist in retaining the subject matter by helping learners to make sense of what may be difficult to comprehend. As a result, discussions and projects are another way to further support learning efforts by helping students move new knowledge from short-term memory to long-term memory.

What about the students who suggest other ways of doing it? Suppose a student asks if it would be all right to represent 84 as 7 ten sticks, 10 units and 4 units because, “I can take 9 from 10 and add the one unit left to the 4 units and then take 6 tens from 7 tens. My answer is 1 ten and 5 units or 15.” Or what about the student who says, “69 is $60 + 4 + 5$, so I can take 4 from 84 and have 80 and then take 5 from 80 and have 75, and then take 60 from 75 and have 15?” A teacher with a profound understanding of the mathematics of subtraction will avoid the “that’s not the way we do it” response but will engage students in a conversation comparing the three different ways described for subtracting 69 from 84 and in what situations one way might be more helpful than another.

The conversations are descriptive of Boyd’s (n.d.) explanation of “... (t)he minimal requirement for teaching-learning conversations is that they occur at least two distinct levels: (1) the task level: ‘What are you doing/I am doing this’ and (2)

the explanatory level: ‘why are you doing this/I am doing this because...’” Another way to model the learning process can be perhaps best represented through a cycle of (1) explanations, (2) justifications, (3) comparisons, and (4) evaluations, until (5) areas of agreements are reached regarding the topic goal or clusters of topics covered (Figure 7).

Ma advocates a profound conceptual understanding of a mathematical topic whereas much mathematics teaching in the United States has for decades concentrated on procedural understanding. The parody of a line of poetry, “Ours not to understand why, just invert and multiply,” is descriptive of students’ typical learning of division of fractions. Without a profound conceptual understanding of any given mathematical topic, teachers cannot engage in the conversation theory of Pask as seen applied to learning strategies in Figure 7. Nor would teachers know whether or not the classroom conversation about students’ invented ways to “do” subtraction or “do” division of fractions was accurate and evidence of true learning.

When possible, learning activities should be aligned to “real-life tasks” (Pask, 1977). By making connections to real world, authentic learning, cognitive bridges facilitate the transfer of learning to long-term memory. Creative and academic learning is a part of “real-life decision making” (Pask, 1977). By finding ways of making the

Figure 7. Conversation theory applied to learning strategies

content personally relevant, students' attention, motivation, and engagement can be captured to further enhance learning opportunities and collaboration. One of the recommendations arising from the first publication of the National Council of Teachers of Mathematics (NCTM) *Curriculum and Evaluation Standards* in 1989 was the imbedding of mathematical problem solving in real-world situations and across curricular areas.

Pask's "theoretical superstructure" includes learning within the areas of (1) perceptual-motor skills, (2) cognitive knowledge, and (3) social processes. It is through combining the three domains that a more comprehensive understanding is fostered as illustrated in Figure 8.

Learning through conversations allows for a "positive transfer effect" (Pask, 1975). Both teachers and students "profit from observing the learning strategies" (Pask, 1975). Making the processes known improves the ability to "learn how to learn" (Pask, 1975). The ensuing conversations include questions, responses, and interchanges used to develop methods for "probing, observing," and externalizing "cognitive events which normally remain concealed" (Pask, 1976). In addition to the academic pursuits of learning, there is a vital "interpersonal component" (Pask, 1976) needed to provide students with a socially rewarding experience. When students are socially satisfied and engaged in the learning community, participation increases, and learning opportunities naturally follow suit. In order for a teacher to engage students in the conversation that allows for a positive transfer effect, he or she must know

how to engage in a meaningful learning conversation and have a deep conceptual understanding of the mathematics being learned. Reflect back on the students proposing different ways of subtracting 69 from 84. If the teacher does not have a deep conceptual understanding of place value and the rate of composing and decomposing higher value units, that is, 84 is 70 and 14 or 69 is 60 and 4 and 5, then a conversation with and among the students and the teacher about why each method works and when one might be more appropriate to use than another, will not happen. The teacher will simply direct students to "do it the way I showed you."

CONVERSATION THEORY AND ASSESSMENT

Evaluation of learning is a critical component in assessing student progress, performance, and understanding. By providing feedback to learners on "indices of success and goal approximation" (Pask, 1977), corrective actions can be taken. Students in mathematics need to be introduced a modeling method as a systematic approach to the design of a mathematical problem, concept, proof, or theory. Modeling instruction expresses an emphasis on making and using conceptual models of physical phenomena as central to learning and doing mathematics (ASU, 1997). Too often, students see a mathematical problem but do not know how "what they know" aligns with the problem they are looking at. Students need to have a detailed knowledge of their assessment results to know if they are on target or need to make further adjustments to be successful in their learning efforts. To assist students in making those further adjustments, teachers can engage students in a systematic modeling method for all aspects of problem solving.

Figure 8. Pask's theoretical superstructure

Consider how this might be used when students are faced with a problem such as:

Ms. Edwards has two yards of material. She is going to make doll clothes for her granddaughter. Each pattern Ms. Edwards is using requires $\frac{2}{3}$ of a yard of material for each outfit. How many outfits will Ms. Edwards be able to make for her granddaughter's doll?

The first step in the modeling method or cycle (ASU, 1997) is a conversation between the teacher and the class to insure a common understanding of the question being asked—that is, how many sets of $\frac{2}{3}$'s are in 2? The next step involves the students in small groups collaborating on the planning and solving of the problem. Students in the small groups may suggest a variety of ways to approach the solution—manipulatives such as fraction bars or fraction circles, drawings, or a “common denominator” approach to the division problem. For this step, the teacher who possesses a deep conceptual understanding of division of fractions will be able to serve as facilitator and guide but will not dictate the “right way” to solve the problem. Finally, the students are required to present and justify their strategy and solution to the class. Again, the teacher with a deep conceptual understanding of division of fractions will scaffold the student presentations—moving from the most concrete to the least concrete approach. There is a twofold reason for this scaffolding—it validates each approach and then presents another way of doing the problem that students can see and hear the process, that may enable them to say, “Oh, I understand. I think I can do that with the next problem.” Once all the strategies and solutions are provided, the students and teacher can engage in a dialogue that evaluates the strategies and solutions. That dialogue can also result in a comparison of approaches and a discussion of when it is more appropriate to use one rather than another. This modeling cycle is in keeping with Pask's theoretical superstructure, as illustrated in Figure 9.

Figure 9. Pask's theoretical superstructure and the modeling cycle

Competency can be assessed through performance activities or various quizzes or tests relevant to the learning task at hand. Assessments can be accomplished using instructors, students, or peers, using quality rubrics or guidelines. Acceptance of Pask's statement on providing feedback to learners provides additional support for teachers who want to change their assessment practices from “giving a grade” to greater use of more supportive formative assessments that enable teachers and students to develop an action plan for the pursuit of further learning. Again, without a deep understanding of fundamental mathematics, teachers will all too often label a careless error as “not understanding the procedure” or will not be able to identify the root cause of the error—a lack of conceptual understanding—and will simply review the steps of the procedure with the student. Assessment practices and feedback to students must shift from a focus on grades, credentials, and rank to those that integrate with learning activities, that support students' conversation in constructing their own knowledge and that reflect the diversity of learning outcomes found in the learners themselves.

Another approach to evaluation is through the use of “teachback,” a method used to ensure the “student understands a topic to the extent that he can teach it back to the teacher” (Pask, 1977). Teachback, the equivalent of the final step of the modeling cycle, provides a way to extend

learning even further by requesting students to reflect, explain, and justify how and why they came to the conclusion or solution they arrived at. The students who asked about different ways of doing the subtraction problem of $84 - 69$ are engaging in a form of “teachback” as they “teach” the teacher why their procedures also work. Restructuring helps learners to process and understand the concepts on a deeper and more personal level. Having students reformulate and teach the concepts is very effective because teachers know comprehension and retention is increased when teaching new material to others. So, when applied to the class discussion that occurs in student centered learning, the students benefit from viewing their classmates’ thinking processes. Dialogue transcripts are another way to confirm students’ content understanding, through a simple review of what was written. Thus, having students demonstrate their processes by the use of available classroom technology—whether an overhead projector or document camera (ELMO) or virtual manipulatives on the computer, is another way of sharing dialogue transcripts. Students in the class can review what another student is demonstrating either with manipulatives or drawings in order to confirm their content understanding.

FUTURE RESEARCH DIRECTIONS

Future research needs to address the components and methodology that mathematics content courses as well as the methods courses must consist of in order to produce highly qualified, effective mathematics teachers for elementary and secondary classrooms. How can teacher education and professional development for inservice teachers facilitate teachers reflecting critically on their views and acting on their understanding? In what ways can Pask’s conversation theory support and facilitate the “profound understanding of fundamental mathematics” that Ma espouses?

CONCLUSION

Instructors in higher education responsible for mathematics methods courses can benefit from an understanding and application of Gordon Pask’s conversation theory in conjunction with Liping Ma’s call for a profound understanding of fundamental mathematics to their instructional design. The use of tutorial conversations with preservice teachers can be effective in helping them engage in meaningful mathematical dialogue that leads to a deep conceptual understanding of mathematics. Until preservice teachers are engaged in true mathematical discourse, applying the tenets of conversation theory, they will most likely continue “to teach as they’ve been taught,” that is, with an emphasis on procedural rather than conceptual knowledge.

Chapter 7.19

Assessing 3D Virtual World Learning Environments with the CIMPLe System: A Multidisciplinary Evaluation Rubric¹

Sean D. Williams
Clemson University, USA

Deborah M. Switzer
Clemson University, USA

ABSTRACT

This chapter introduces an assessment rubric for virtual world learning environments (VWLEs) built from proven principles of user experience design, instructional design, interface design, learning theory, technical communication, instructional systems design (ISD), and VIE motivation theory. Titled the “CIMPLe System,” this rubric captures the ways that context, interactivity, motivation, presence, and cognitive load weave together to form a successful VWLE. The CIMPLe System offers an advance in how educators can assess the quality and predict the success of the VWLEs that they build. The holistic approach achieved in the CIMPLe System arises from the multidisciplinary approach represented in the

tool. As designers consider what to build into the environment, they can refer to the CIMPLe System as a checklist to ensure that the environment meets the needs that the cross-disciplinary theory suggests are necessary.

INTRODUCTION

Although the idea of virtual environments in education might seem radical, it is not new; rather, programs such as Quest Atlantis (Indiana University), River City (Harvard University) and SciCentr (Cornell Theory Center) have been in use for more than ten years. Research from these programs suggests that students exhibit gains in engagement, efficacy and achievement (Barab, et al, 2005; Ketelhut, et al, 2006). Additionally, a recent study (Hansen *et al*, 2004) noted that

DOI: 10.4018/978-1-60960-503-2.ch719

students actively involved in three-dimensional construction of computational models had a more sophisticated understanding of dynamic spatial relationships than students in a traditional classroom environment. Other studies (e.g., Kim, 2006) suggest a statistically significant effect of 3-D virtual environments on both achievement and on developing a positive attitude toward science.

Finally, Jones (2004) proposed that multi-user, 3-D, online learning environments demonstrate numerous important educational benefits such as engaged immersion, situated learning, multi-modal communications, breakdown of socio-cultural barriers, bridging the digital divide, problem solving, and the ability to create empathy and understanding for complex systems. Other advantages of virtual environments for learning include the ability to provide experiences that may not be available in real life, the ability to analyze phenomena from different points of view to gain deeper understanding, and the ability to work with virtual companions distributed over different geographical locations (Chittaro and Ranon, 2007).

Why do learners respond so well to virtual environments? In the late 1990s, researchers began hypothesizing, for example, that the level of presence in a virtual world—the feeling of being somewhere else—as well as the level of immersion—the feeling of interacting directly with the environment—account for the success of instructional virtual worlds (Witmer & Singer 1998). More recent studies investigate other aspects of successful virtual worlds for instructional contexts, including the role of social facilitation, or the degree to which having others “present” impacts performance (Park & Catrambone, 2007); (Bronack, Cheney, Riedl, & Tashner, 2008); the role of place metaphors in guiding action (Prasolova-Forland, 2008) and the complementary concerns of cognitive load and system adaptivity (Scheiter & Gerjets, 2007); (Kalyuga, 2007).

While these and many other studies analyze 3D virtual worlds from the perspective of one

discipline or another and offer recommendations about building these worlds from those perspectives, none of these studies have proposed a multidisciplinary method of evaluating the success of a virtual world learning environment (*VWLE*) that considers the complex interactions of context, interactivity, motivation, presence and cognitive load. Virtual worlds require simultaneous attention to a number of factors to ensure that they are successful and when we add the complications of instructional purposes, the range of considerations expands even further. Consequently, many of the approaches that focus on a single aspect of a virtual world, such as presence or interactivity, gloss over the complexity that these environments require. *To begin moving instructional designers, trainers, and researchers toward a more complex understanding of assessing these environments, this chapter introduces an assessment rubric for virtual world learning environments built from proven principles of user experiencedesign, instructional design, interface design, learning theory, technical communication, instructional systems design (ISD), and VIE motivation theory.* We have titled this rubric the “CIMPLe System” since it captures the ways that context, interactivity, motivation, presence, and cognitive load weave together to form a successful virtual world learning environment.

To arrive at the CIMPLe System rubric, the chapter first positions the rubric within the larger, more general context of instructional design theory. As a field, instructional design encompasses the requirements for building successful learning experiences regardless of the medium where those experiences appear. Therefore, we begin the discussion of instructional design by situating our chapter within the ADDIE framework (Gagne, Wager, Golas, Keller, & Russell, 2005)—a generally accepted instructional design method—and specifically within the “design” phase. The chapter then combines this framework with the principles of “user experience design” to demonstrate the three necessary parts of experience:

attraction, engagement, and conclusion (Shedroff, 2001). The majority of the chapter develops this framework, offering theoretical principles on what constitutes successful attractions, engagements, and conclusions within a learning context. Within this discussion, engagement—the most sophisticated component of the actual experience—assumes the bulk of the discussion. Finally, after theorizing the nature of a learning experience, we present the fully-developed CIMPL System, a multidisciplinary rubric for analyzing virtual world learning environments.

BACKGROUND: INSTRUCTIONAL DESIGN

Given all of the benefits that VWLEs can provide, but also given the relative complexity of implementing successful multimodal VWLEs, instructional designers need a complex, multidisciplinary frame that encompasses the entire process of designing an instructional element regardless of the medium (e.g. classroom, online, 3D virtual world). Although there are many instructional design models we could adopt that would meet the complex needs of VWLEs, we situate the CIMPL System within the ADDIE model (Gagne, Wager, Golas, Keller, & Russell, 2005) because the system is complete, yet not overly complicated. ADDIE orders the elements of instructional design into five stages: analysis, design, development, implementation, and evaluation.

The *analysis stage* consists of activities that determine the context in which the instruction will take place—the pre-existing conditions that must be considered in order to design the most appropriate and effective instructional element. In this stage, the designer determines what needs are driving the creation of the instruction and these needs lead to the delineation of the goals of the instruction, with consideration given to the cognitive, behavioral, and attitudinal changes desired. In addition, designers must determine what prior

knowledge and skills the learners will have when they begin the instruction. Finally, designers determine the time available for instruction.

The *design stage* is where the instruction unit is built. This begins with designers determining what learning objectives will address which instructional goals. From these objectives, a list of topics to cover is made, with an approximation of the time each topic will take. Designers then sequence the topics, with consideration given to the prior knowledge determined during the analysis stage. The topics are fully expanded, and mapped to the original learning objectives and activities are added to reinforce the learning. Finally, points for assessment are inserted, both those that inform the direction and progress of the instruction as well as those that assess the final achievement of the learning objectives.

The *development stage* includes those activities that will refine the instructional element. In this stage the materials are used with a group that represents the target audience. From the information gleaned from this initial use, designers revise the materials. Also in this stage, designers develop any required teacher materials and/or user manuals.

The *implementation stage* occurs when the instructional element is marketed and distributed. The target population is advised of the opportunity and resources are made available for solving any problems or confusions that arise as the instruction proceeds.

Finally, data gathered in the *evaluation stage* are used to fine-tune the instructional element. Evaluators compare the learning outcomes to the goals and objectives of the instructional element and plans are devised for ongoing revision and maintenance.

Understanding all stages of the ADDIE model are important for the quality of the instructional element because any element that is developed without reference to the entire system will likely be far less successful than one that was systematically constructed. While we recognize that following the entire ADDIE model produces the

best products, space limitations prevent us from fully exploring how to develop elements for virtual worlds against this model. Instead, as a sort of “quick start,” the CIMPL System presented in this chapter focuses mostly on the design phase of the process, outlining the characteristics of a successful VWLE. Even though the tool primarily focuses on the design phase and using the tool as a heuristic, it can nonetheless inform the development stage and the evaluation stage as a lens through which designers might assess their learning environments after they have been built.

EXPANDING THE VIEW OF THE DESIGN PHASE

As noted above, our chapter focuses on the “design” phase of the process for creating instructional materials because creating an optimal experience can occur only if designers begin with a solid process that is both well-theorized and reproducible. As noted user experience designer Nathan Shedroff argues, “the elements that contribute to superior experiences are knowable and reproducible, which makes them designable” (Shedroff, 2001). Shedroff himself suggests many of these elements (which we’ll take up later) but chief among them is the overall structure of the optimal user experience, an experience that progresses from *attraction* to *engagement* to *conclusion*.

Attraction represents the reasons a participant would begin an experience. Sometimes the attraction derives from necessity—we have to go the grocery store in order to buy food or a teacher tells students that they must do an exercise. Preferably, though, attraction is intrinsic, where learners choose to undertake the experience because they are drawn to it by their senses—it sounded interesting—or because they have an intellectual attraction—they wanted to learn about something—or because of an emotional appeal—it looks fun. Regardless of the specific reason for the attraction, each experience must draw learners

into the experience, setting the context for how and why learners would want to engage with the experience. Attraction gets learners “in the door,” so to speak.

Engagement represents the primary focus of the experience. After learners begin the experience, their interest must be maintained by challenging them in interesting ways, motivating them to continue exploring and solving problems of personal relevance, and providing them with feedback so that they can measure their progress. The engagement must also strike a balance between challenge and reward, taking care not to overload learners with complexity but must provide enough ambiguity to encourage continuing engagement. Finally, the engagement must enable social interaction where learners can reveal their image of “self” to others, learn about others’ views of the problems and environment, and build shared meanings with colleagues. Engagement keeps learners “in the house,” in other words.

Conclusion represents the moment when learners feel that they have completed the goal. Successful conclusions enable learners to see the experience in a larger context, where the meaning of the experience extends into future experiences as learners look back and learn lessons that they can apply in future settings. Good conclusions also bring closure to an experience, confirming that what the participant set out to learn or accomplish has in fact been learned or accomplished. In Shedroff’s terms, the conclusion presents learners with awareness that they have internalized the experience and can now count it as “wisdom” applicable across multiple settings, enabling learners to see themselves as more complex.

Engagement is chief among these components of the successful experience because learners spend the majority of their time with the engagement. The majority of our chapter, therefore, focuses on designing the characteristics of engagement, although our theoretical frame includes attraction and conclusions as well. Figure 1 visually represents the nested theoretical frames operating

Figure 1. The nested framework of the CIMPLLe system

in our chapter as instructional design and user experience design merge into a single approach for designing virtual world learning environments.

THEORETICAL FRAME FOR THE CIMPLE SYSTEM

As we introduced above, designing a 3-D virtual world learning experience—or really any experience—proceeds from attraction to engagement to conclusion. Each of these categories, though, contains several concerns that instructional designers must recognize as they build a world. These elements of successful design also lead to categories for evaluating the effectiveness of a 3-D virtual world learning environment. In what follows, we discuss the three major stages of an experience—attraction, engagement and conclusion—and within each of these stages outline the multiple concerns that must be considered within that stage. From these concerns, we derive the categories that we compile into the complete evaluation rubric presented later in the chapter.

Attraction: Inspiring Learners to Begin the Experience

Imagine it's about seven p.m. on a spring evening and you and a couple friends are walking down

a city street where cafes and restaurants have opened their doors to allow the aromas of their cooking to waft into the street. One particular restaurant catches your attention because the aromas carry spices you can't quite place, and so you glance over the menu posted in the window. You see that the meals are priced reasonably and that the restaurant offers an interesting variety of dishes you've never heard of, let alone eaten. Your group enters, a host seats your group, you order drinks, and then settle in to study the menu more closely. Music, maybe it's Ethiopian, plays in the background as servers weave effortlessly among tables carefully set with small oil lamps and silverware, speaking with smiles to customers in an accent you can't quite identify. Your group agrees on some appetizers and then orders the next time your server comes by your table.

This scenario metaphorically represents what happens in any context where learners are enticed to begin an experience. The learners have a need—they are hungry and need to eat—and following the enticing aromas, they are drawn into a particular experience—the restaurant—where they hope that their needs will be met. The environment of the restaurant also attracts their interest, with its oil lamps and hint of foreign culture. The scenario, then, demonstrates the two key features of an attraction: clear goals and contextual factors.

Clear Goals

In order for people to be attracted to an experience, they must be at least moderately aware of their needs and the experience must present clear steps for meeting those needs. Learners usually have a set of schemas for how things work, and if the initial encounter diverges too far from the schema, learners will be confused at best and frustrated at worst. Either way, if the goals aren't clear, then learners will disengage from the experience. Richard Saul Wurman, "father" of the field of information design, summarizes this idea in *Information Anxiety 2*, arguing that experiences must contain, among other things, a purpose, objectives, core steps, and periodic feedback (Wurman, 2000). In Wurman's terms, *purpose* is the overarching goal, why somebody is doing something, to fulfill hunger in our case. *Objectives* represent the ways people meet that purpose, in this case to eat. The *core steps* present the procedure, the small steps along the way to achieving the objectives, so entering the restaurant, being seated, ordering drinks, studying the menu, and ordering meals in our example. Finally, *feedback* alerts learners whether or not they are doing things correctly (a concept we'll discuss in detail later). Each of these steps represents a match between the learners' goals and the experience's goals: the learners' expectations have been met upon the initial encounter and so they continue with the experience.

Context Factors

However, in addition to the cognitive aspects of attraction where the experience initially meets the learners' goals and needs, the context itself attracts learners. First, as information processing theory teaches us, attractions must surprise us, must present us with something unique or out of place, something that dazzles us with bright colors and interesting sounds. These are called orienting stimuli (Howes, 1990). Several scholars

in the emerging field of user experience design make similar arguments, noting that the visceral level of an experience represents one of the most important aspects of attracting—and retaining—learners' attention as learners' bodies and senses become engaged in the experience (Norman, 2004). This "physio-pleasure," as Patrick Jordan (2000) calls it, or "sensorial design" as Shedroff (2001) calls it, is not just a property of the experience (or product); it represents an interaction between an experience and a person, where the experience engages multiple aspects of a person's body or senses. We build, in other words, this type of physio-pleasure by immersing learners in an environment with fantastic features, things that they wouldn't experience otherwise (Screven, 2000). Referencing our opening scenario, recall that the initial attraction was spices that the group couldn't quite identify and menu items that they hadn't eaten. Upon entering the restaurant, the environment itself pleased the group, with its smiling staff and oil lamps. These aspects contribute to a richness of the environment (Witmer & Singer, 1998) that bears a relationship to reality because the concept of eating at a foreign restaurant is a common schema, yet the experience also presents a certain lack of realism because of the novelty.

In addition to these visceral aspects, information designers frequently talk about the usability of the environment. In other words, the experience must work. If the experience initially promises to meet the needs of learners and draws them in with seductive sensorial input but then fails to deliver on the practical promises that the sensorial design only hinted toward, learners will immediately end the experience, either literally by discontinuing their work within the system, or figuratively by allowing their attention to wander elsewhere. Norman (2004) calls this the "behavioral level" of a product or experience because at this level, learners are concerned with how well a thing works. If, for example, the staff had not been attentive in our scenario, the experience would have failed on practical grounds: the group mem-

bers are hungry and want to eat and that major objective has not been realized. Additionally, the aspects of an experience must complement each other such that the system has a certain holistic integrity (Prasolova-Forland, 2008). The oil lamps provide “foreign atmosphere” (visceral level) but they also provide light (behavioral level); the wait staff speaks with accents (visceral level) but clearly interacts well in your native language (behavioral). Finally, the experience allows multiple ways to interact, yet constrains those possibilities within a closed system (Gasperini, 2000). In other words, the experience allows the participants multiple opportunities for realizing their goal of eating through the different menu items, yet the menu isn’t limitless. Similarly, in a VWLE learners need the opportunity to explore possibilities, but should be limited to only a finite number of possibilities.

Evaluation Rubric Items

Designers of virtual world learning environments must attend carefully to the attractions they build by integrating methods that confirm learners’ goals are being met and by constructing a context that maintains interest. Without this clear evidence that the experience and the participant share goals, a learner has no reason to continue the interaction. Why work through a system if the system isn’t going to meet your needs? Second, meeting learners’ instrumental goals represents just half of the picture because the system must engage learners’ bodies and emotions to attract them in the first place. As Norman (2004) writes, “Attractive things work better.” And attractive things work better both to attract learners in the first place and to maintain that interest throughout the engagement.

Based on these concepts of attraction, the following rubric items emerge:

- Promises a novel or unique experience
- Experience follows predictable schemas
- Attracts through initial sensorial pleasures

- Technologies and functions operate appropriately
- Presents multiple ways for learners to interact with the environment that correlate with the environment’s metaphorical/cognitive scheme.

Engagement: Immersing Learners in the Experience

Learners spend the majority of their time occupied in the actual task of learning, engaged in the experience itself, in other words. After learners have been attracted to an experience, several factors must be present to maintain the learners’ interest. *Motivation* is foremost among these considerations because learning will not take place if learners feel no need to continue, whether that motivation is extrinsic or intrinsic. Learners must also be engaged with *problem solving* in ways that lead to learning. Without seeing the actual rewards of their activity in terms of increased knowledge—and being made aware through feedback that they are, in fact, learning—learners will direct their attention toward other tasks that they feel are more rewarding. Therefore, learners must be consistently aware of their progress toward learning objectives as they learn but not in such a way that it causes cognitive overload. Finally, successful engagements rely on genuine interaction among learners that constructs a sense of community, even if that community is temporary. This synchronous *presence*, more than any other characteristic, distinguishes learning in 3-D virtual worlds from other virtual learning environments since the presence of avatars makes learners feel like others are “there.”

In what follows, we discuss each of these concepts in more detail and present the evaluation rubric items that emerge from each of these three essential areas: motivation, learning and problem solving, and social presence.

Motivation

Learning rarely takes place in the absence of motivation to learn. Motivation is the focus of time and effort toward performing a specific behavior. It is possible for this motivation to be intrinsic—to come from learners' personal interests and goals—but most instructional situations rely on extrinsic motivation, where the characteristics of the instruction entice learners to spend their time and effort on the task. VIE Theory (Green, 1992) provides a powerful theory for conceptualizing the complexities associated with motivation by decomposing motivation into three essential elements: *Valance*, *Instrumentality*, and *Expectancy*.

One concern that occurs across all three characteristics of VIE theory is the result learners expect to achieve by performing the activity. The goal can be simple and short-term: if I do this, I expect to feel joy. Alternatively, the goal can be complex and long-term: if I do this, I will be more likely to get a job promotion next year. Learners must be aware of the goals toward which their behavior is directed for motivation to occur. Motivation in learning, therefore, can only be reviewed in reference to a particular goal, whether that goal is extrinsic or intrinsic. This mirrors the concept of optimal experience called "Flow" (Csikszentihalyi, 1990) in which individuals voluntarily participate in activities that stretch their capacities as they attempt to accomplish something difficult because they believe that activity is worthwhile.

Valance, the first characteristic associated with this type of optimal experience, represents the value associated with the behavior. This value can come from the behavior itself—the activity is fun or interesting by itself—or it can come from the value of the goals associated with the behavior. Valance is additive—the more learners enjoy the situation, the more it piques their interest or satisfies their curiosity, the more goals they associate with the task, and consequently, the higher the overall valance for the behavior will be. Because each individual will perceive the valance of a

situation differently based on personal values and interests, designers of virtual world learning environments must provide multiple sources of valence by anticipating what goals individual learners might have, both intrinsic and extrinsic. Without meeting these goals—without providing the necessary conditions for valence—VIE Theory states that there will be no motivation.

Instrumentality represents the strength of a connection learners perceive between the behavior and its associated goal. If learners do not see the utility of the behavior at moving them toward a goal, then there will be no instrumentality. Providing an articulated, written contract delineating the behavior-consequence connection often proves to be a good way to increase the perceived probability that the behavior will lead to the goal. In other words, if learners know upon entering an activity how particular actions lead to particular goals—the rules of the game, so to speak—the learners are more likely to feel a higher sense of instrumentality. Within the conceptualizations of both VIE Theory and Flow, this goal-directed, rule-bound system enables the learners to gather regular feedback on their progress toward the goal which increases the instrumentality present in the experience. Unless a system contains boundaries and unless learners receive commentary upon their progress toward goals within those boundaries, they will not develop a sense that they have made progress toward achieving those goals. Therefore, the concept of instrumentality requires that a VWLE provide opportunities for learners to review their progress at consistent intervals based upon their performance against a set of expectations established by the experience itself. Without these items, instrumentality does not exist and where there is no instrumentality, there will be no motivation.

Expectancy provides the final conceptual thread in VIE theory and measures learners' confidence in their ability to perform a behavior successfully. In order to have this confidence, learners must believe that they possess the knowl-

edge, skills, and resources necessary to perform the behavior. To adopt an example from the concept of Flow, if a certain person believes that they can play tennis well, they are more likely to engage in the activity (Csikszentihalyi, 1990). However, the tennis player must also feel that the experience challenges their skills, although not too much, so that the experience matches—or perhaps slightly exceeds—their skill level. In this case, the tennis player's game improves as the quality of the competition increases. In terms of a VWLE, learners must believe that they possess skills adequate to cope with the task at hand. Conversely, the tasks must continue to challenge the learners to retain their engagement (we'll discuss more on this topic below in the section on problem solving and cognitive load) and not be so easy to accomplish that learners' confidence levels remain static in spite of accomplishing the goal. Some ways to increase expectancy include building on the learners' past successes on similar tasks, observing others being successful at the task, observing that others believe you can be successful at the task, and receiving constructive feedback on your behavior. Like the other features of VIE Theory, expectancy is a necessary condition for motivation. If learners are not confident that they will eventually succeed in the tasks or behaviors, then there will be no motivation.

The discussion above has hinted at a subtle, but extremely important, component of VIE Theory: its multiplicative nature. If any of the three terms, valence, instrumentality, or expectancy, equals zero then no motivation will be present. One single zero cancels whatever gains might exist in the other terms. However, as the quantity of any of the three items increases, the overall motivation increases. Consequently, having some success in each term becomes necessary for a virtual world learning environment and having great success in any one term creates profound impacts across the entire system.

Based on the elements of motivation discussed here, the following rubric items emerge:

- Provides resources to build learners' confidence with tasks
- Provides feedback to learners' actions
- Checks on learner perceptions of goals as achievable
- Checks that the learner values the goals
- Checks on learner perceptions that the environment provides necessary resources.

Learning and Problem Solving

Learning means storing, or encoding, new information into long-term memory in such a way that learners can retrieve the information for later use. Information Processing Theory (IPT) offers a model that incorporates much of the research about this process of moving information from our experiences to long-term memory. IPT organizes the learning process into a chronological structure that includes sensory input and the sensory registers, attention and perception, working memory, and encoding into long-term memory. This process mirrors the “data to wisdom” transfer where learners first interact with unstructured information known as *data*, then construct some order for that data transforming it into *information*, then relate that information to a context of use transforming it into knowledge. The final step moves knowledge from a single context of use to broader, cross-context understanding where learners view the knowledge in flexible ways that transforms it into *wisdom* since the knowledge has been internalized as a general principle for understanding the world (Shedroff, 2001). Schematically, the transformation looks like this:

Data→Information→Knowledge→Wisdom.

Combining Information Processing Theory (IPT) with the data to wisdom transfer, we begin to see how the process of learning and problem solving works. Specifically, we have five senses (seeing, hearing, touching, smelling, and tasting) that continually pull data into the sensory registers.

Although the registers will hold a lot of data, they do so for a very short period of time (a matter of a few seconds, at best), and so the processes of attention and perception are critical to understanding how data continues through the system to become information. Attention represents the stage in the process, then, where we notice specific data in the sensory registers and then begin to organize it into meaningful structures. Attention is a learning bottleneck, because although there are huge amounts of data in the registers, we can attend to only a few pieces at a time as we attempt to transform it into information. Expectations and prior experiences participate in giving meaning to the data at this stage, essentially determining how we process what we are seeing and hearing. Each participant comes to our VWLE, that is, with a unique set of knowledge and experiences, and therefore a potentially different perception of the information there. That is why it is important to test regularly that the VWLE participant is processing their experience in the same way that designers intend. Once perceived, the new information continues to the working memory as it moves from information to knowledge.

In the working memory, learners transform information into knowledge by giving it conscious consideration. We commonly understand this stage as thinking, problem solving, and decision making. The working memory adds to the processing bottleneck because it is a very small space and this small “processing capability”—what the working memory can consider at any one time—is referred to as cognitive load (Sweller, 1988). There are three types of cognitive load (CL): extrinsic, intrinsic, and germane. Extrinsic CL includes information that takes up space in the working memory, but is not necessary for the task at hand. For example, consider a conversation you are having with a person you have just met in which you are hearing several new facts and are trying to determine which facts might be false. *Extrinsic CL* would be the part of working memory that holds the person’s name as you converse with the person.

Although their name is held in working memory, it probably is not necessary for solving the problem of sorting fact from fiction. *Intrinsic CL*, by comparison, includes all the useful facts and tools that can be used to solve the problem at hand. In the conversation example, intrinsic information would be the facts that have come up during the conversation that you are attempting to sort. In order to complete the task, all of these facts must be held in working memory. Finally, *germane CL* results from actually doing the processing required by the problem. In the conversation example, germane CL would consist of comparing and contrasting the facts from the conversation to uncover the false statement.

These three types of CL vie for working memory space at the same time as learners attempt to transform information into knowledge. Efficient use of working memory requires that potential extrinsic CL be ignored, and intrinsic CL be practiced until it can be stored in long term memory to the point of automaticity (retrievable with little effort), leaving a maximum amount of working memory available for germane CL. In a VWLE, this means that learners need to be trained to ignore potentially useless information such as the complex visual architecture of spaces, and that they need to practice skills like manipulating virtual objects and avatars. Once learners can operate in the environment with little conscious effort, a maximum amount of working memory space can be used for processing relevant information and solving problems.

The final stage of the transformation moves knowledge to wisdom as learners permanently store information in long-term memory—the core of learning. Research tells us much about how to enhance the encoding process (e.g. Baddeley, 1990) and this research leads to specific design strategies for 3-D virtual world learning environments. We know, for example, that when information is presented both visually and verbally, learners are more likely to retain and understand the material. This concept, called “media redun-

dancy” (Markel, 1998), suggests that the visual texture of a VWLE should be supplemented by corollary verbal exercises since the combination enables learning greater than either individual part. Additionally, VWLEs favor problem-based learning where learners engage in real tasks that require manipulating objects and navigating within the environment (Prasolova-Forland, 2008). Many tactics for building problem-based learning into VWLEs come to us from the field of Museology, where researchers have demonstrated the success of these tactics:

- Incorporating leading questions in verbal displays
- Including animated and simulated processes
- Noting contradictions between presentations or objects
- Allowing learners to act on the environment to see cause/effect relationships
- Reporting findings to colleagues (Screven, 2000).

Encoding knowledge as wisdom is also enhanced when learners make meaningful connections to prior knowledge. This elaboration of knowledge enables learners to construct a type of cross-context understanding by building flexible networks of knowledge that bend and morph as new knowledge joins that knowledge already present in long-term memory. This prior knowledge, then, serves as a hook for incoming information because it allows learners to understand the new knowledge in context of existing knowledge. We should attempt, in other words, to see things in the next larger context—to consider a chair in a room, a room in a house, a house on a block—and connecting new knowledge with existing knowledge enables learners to achieve this vision, a state we previously referred to as “wisdom” (Wurman, 2000); (Shedroff, 2001).

The transformation to wisdom, though, is only complete when learners become aware of their

own learning. This concept, called metacognitive skill, allows learners to see their own learning in terms of larger contexts and applications, making the learning more meaningful to them. And as we know from VIE Theory, when learners know the learning objectives, and those objectives meet instrumental goals, motivation to learn increases. The increased motivation leads to becoming a more sophisticated learner, which itself increases expectancy—the belief in ability to accomplish tasks. Consequently, knowing how to learn—learning metacognitive skills—empowers learners to regulate their learning and take ownership of the learning tasks. The more metacognitively sophisticated a learner can become, the more they can automate learning and problem solving strategies, leaving more room for germane tasks.

As Information Processing Theory and user experience design show us, learning occurs when learners move information from their experiences to long-term memory. This transformation of data to wisdom enables learners to begin reflecting on learning itself, to build metacognitive skills where they can think about their own thinking in a context larger than the individual experience. We also know that learning is constrained by the concept of cognitive load at each stage of the process and that certain learning strategies, like simulations and reporting to colleagues, enhance the encoding of experiences.

Based on the combination of these theories, the following rubric items emerge:

- Provides supplemental instruction for gaps in prior knowledge
- Makes learners aware of the learning goals
- Organizes information according to a consistent scheme
- Presents context that aids in remembering key information
- Challenges learners through problems or puzzles to solve
- Articulates strategies for learning the information

- Uses modalities (verbal, visual, sound) that do not require simultaneous attention.

Presence

The concept of “presence” represents the key differentiator between 3-D virtual world environments and other types of online environments (Bronack, Cheney, Riedl, & Tashner, 2008). Presence can be compared to the idea of immersion that many researchers have discussed over the last 20 years or so where learners “perceive that they are interacting directly with an [online] environment” (Witmer & Singer, 1998), although VWLEs add the component of people interacting with other people through avatars. Consequently, while the prior descriptions of immersion for web-based virtual environments still pertain, the newer, interactive 3-D environments require a more complex understanding than environments where a single individual interacts with an environment, for example in a flight simulator. Heeter conceptualized this broader definition even before the massive deployment of virtual worlds that we currently experience by proposing that presence within virtual worlds contains three components: environmental presence, personal presence, and social presence. We address each of these in turn below (Heeter, 1992).

Environmental presence relates to the ways that a system enables learners to interact with each other by building those functions into the system components itself (Heeter, 1992). For example, the environment must create opportunities for learners to share their thoughts through chat or voice—to leave traces, that is, of human activity within the system. We can further refine this concept by dividing interactivity into six separate types of functions that include

- *Feedback* where the system or individuals acknowledge that others have initiated action;
- *Control* where the learners are able to act on the environment and leave traces of their actions for others to see;
- *Productivity* where learners can utilize the system and interactions with others to solve real problems;
- *Communications* where the system enables bi-directional communication between individuals and between the system and learners;
- *Adaptively* where the system “learns” on its own about participant needs and changes to better suit those needs (Shedroff, 2001).

Each of these six components contributes to the environmental presence that a VWLE demonstrates and when they combine with compelling metaphors of location (Prasolova-Forland, 2008), learners understand exactly what is possible within the environment.

Research on *personal presence*, the second presence concept, possesses a long history in computer science, human factors and instructional technology (Heeter, 1992). Often thought of as “immersion,” personal presence refers to a participant’s sense of “being there” in the virtual environment, or the degree to which learners forget that they are interacting with something artificial. In detailed studies of personal presence conducted for the U.S. Army, Witmer and Singer (1998) discovered that four factors contribute to the success of these artificial worlds:

Control factors: or the naturalness of activity within the environment;

Sensory factors: or the environmental richness present through multiple interaction modalities like visual and aural;

Distraction factors: or the degree to which the interface forces itself in front of learners or uses novelty to divert attention from the interface;

Realism factors: or the correspondence between the artificial world and the lived world.

These factors certainly weave closely together with environmental presence components. How-

ever, the personal presence components focus on individual learners' sense of being "there" rather than the functionality of the environment. The difference, then, rests on the distinction between form—personal presence—and function—environmental presence.

The third presence factor, *social presence*, represents the key distinguishing feature of 3-D virtual worlds. While most online environments can build environmental and personal presence to lesser or greater degrees, the real sense of sharing an environment with other people in real time is felt most strongly in 3-D VWLEs. Learners feel a significant difference between working synchronously with an avatar that lets learners "see" their collaborators and working synchronously with others through Skype or IM (Bronack, Cheney, Riedl, & Tashner, 2008). The idea that learners can see collaborators causes learners to make a metaphorical jump to the real world where people can only be in one place at a time. In other words, if you're here with me now, then you can't be somewhere else at the same time—you are present with me. In addition to this sense of being able to see those we interact with, avatars enable certain non-verbal cues that approximate physical presence between real people which further strengthens the sense of social presence. For example, avatars enable learners to approximate cues such as gaze, gestures and proximity (Bailenson, 2006). Bronack et. al. (2008) expand on this notion, offering these components of social presence:

Personal space: where avatars' positions indicate their involvement with one another;

Appearance where the way an avatar is presented reflects, in theory, an aspect of a person's identity (whether real or experimental);

Modeling behavior: where real world non-verbal cues such as eye contact or expressions are purposely used to engage others;

Emotional impact: where avatars can imitate real expressions and articulate feelings beyond simply saying or typing the corresponding emotions.

In all of these cases, the ultimate purpose is to lead learners to feel like they are interacting with other real people rather than just computer-generated "bots." Everybody knows when it's just a bot—like on the telephone voice response systems so common today—even when those bots are good. However, social presence aims to present the real person behind the avatar to other real people represented by avatars in real time because research shows that the more human-like our interactions with computers become, the more engaging learners find those experiences to be (Andre, Rist, & Muller, 1999).

Building environments based on the notion of presence will significantly enhance the outcomes because "the factors that appear to affect presence are known to enhance learning and performance" (Witmer & Singer, 1998). Classroom teachers certainly know that better physical environments, better-structured activities, and genuine interaction all lead to positive learning outcomes. Three-dimensional virtual environments for learning present many of the same opportunities as face-to-face learning when these environments are conceived well.

Based on the discussion of presence in 3-D VWLEs, the following rubric items emerge:

- Uses multiple modalities (verbal, visual, sound)
- Adapts to learner activity
- Employs compelling metaphors to create an environment with fantastic features
- Reflects some correspondence to the real world
- Uses avatars to establish presence of others
- Enables communication in real time
- Allows learners to alter or add to the environment to enhance its meaning
- Enables learners to collaborate
- Enables learners to personalize an avatar.

Summary of Engagement Items

Clearly, the engagement aspect of a 3-D virtual world built for learning should occupy the most time for an evaluator since the learners themselves spend the majority of their time in the actual engagement. Returning to our restaurant metaphor, compare the amount of time that you might spend actually IN a restaurant compared to the amount of time that you might spend ENTERING the restaurant and initiating the dining experience. Attraction certainly bleeds over into engagement, particularly in a well-designed experience, but the engagement components nonetheless comprise the major part of a learning experience. Similarly, the components of the engagement blur into one another as *motivation* factors blend with *learning and problem solving* since learning usually only occurs if people maintain their motivation to learn by remaining challenged but are not overburdened by the *cognitive load* of the challenges. *Presence* factors lean into motivation because as learners begin to feel immersed in an environment by interacting with others and realizing that their actions have an impact on the VWLE, motivation increases. Social presence also leads to effective learning and problem solving because one of the most effective methods of learning—one facilitated particularly well by 3-D virtual worlds—is collaborative work on real problems. Successful engagement in a learning experience, then, becomes circular as *motivation* leads to *learning*, and *problem-based learning* comes from *presence*, but *presence* leads to *motivation*: it's a large interdependent ecology of concerns.

In summary, these three components characterize a successful engagement, the major part of a learning environment:

- Motivation
- Learning and problem solving;
- Presence

CONCLUSION: EXITING THE EXPERIENCE

Let's return for a moment to our restaurant fable. Your group was attracted to the restaurant, was engaged in dining at the restaurant, and now you've had dessert and coffee and have motioned for the server to bring the check. The check arrives, your group pays, rises from the table, and you exit to the street chatting about the good food and how you'd like to come back another time. The experience has concluded.

Conceptually, learning experiences should follow the same pattern. Learners should know when they have accomplished what they set out to learn; they should be able to exit the experience confident with their new knowledge; and they should be able to reflect on their knowledge and its applications for the future. If the conclusion doesn't satisfy learners, the future implications of the experience will be unclear and rather than feeling satisfied or pleased with the experience, learners might feel dissonance or confusion. In either case, as Norman (2003) reminds us, the negative emotions dampen retention. In other words, without a successful conclusion, learning might not have taken place at all.

A conclusion to an experience, therefore, has at least three components that designers must enable.

An announcement of the exit: The end of an experience must be clear to those within it so that learners know that they have just a little time to explore any areas that remain (Siegel, 1997). Learners shouldn't be rushed out, but they should have a limited opportunity to explore things that interest them. Within a VWLE, this means that connections to the "outside" should be clearly marked, either by geographical features such as doors or by instructors (perhaps bots) who are present in the environment. However, because virtual learning environments are often self-directed, the exit should also be a station where learners are questioned about the experience and their learning outcomes because quite possibly the

learners wouldn't be aware that they've "seen" everything they need to.

A request for something from the learners: In our restaurant example, we might be tempted to see the check as the request for something and indeed it is. However, the check really serves more as the signal of the ending rather than a request. A more appropriate example would be completing a card to evaluate the dining experience. And in VWLEs we can do exactly the same thing: ask learners to complete assessment tasks to gauge their learning (Screven, 2000). What better way to confirm that learners have, in fact, accomplished their goals than to allow a test or survey or final activity to confirm that the learners have achieved something? As implied above in the discussion of the announcement, the exit serves also as a checkpoint, a spot where learners can confirm that they have accomplished their goals and the goals of the learning activity.

An opportunity to reflect on the experience in a larger context: Metacognition requires that learners become aware of their learning and place that learning into a new, more broadly applicable, schema. Just as your dinner companions reflected on their experience in relationship to other dining experiences, virtual environments should encourage learners to place any particular experience within a larger context of related activities (Wurman, 2000). Recalling our discussion of the data to wisdom transformation, the final transformation occurs only when learners can broadly apply what they've learned in novel contexts. In VWLEs this means that learners should be given opportunities within the system to reflect on their learning, quite possibly leaving "traces" of their learning for others in the future. These traces, then, become part of the environment, enhancing the sense of presence for future learners while enabling present learners with an opportunity to reflect.

Based on these concepts related to conclusions, the following rubric items emerge:

- Provides feedback to learners' actions
- Enables learners to assess their learning
- Enables learners to reflect
- Enables learners to leave traces of their understanding of their experiences
- Signals the conclusion/exit.

THE COMPLETE EVALUATION RUBRIC

Attraction, Engagement Conclusion: these items represent the key features of an experience and when placed within the ADDIE instructional design frame, we see that designers of 3-D virtual world learning environments must understand not just experience design, not just instructional design, and not just learning theory. Rather, a successful 3-D virtual world for instruction must combine features of all these components. Drawing on the principles that we've outlined so far, we offer below the compiled evaluation rubric for assessing a virtual world learning environment.

The rubric presented below distills the concepts presented above in the more complex theoretical frame into twenty-eight key components. We have dubbed this approach the "CIMPLe System" (pronounced "simple") because we have grouped items according to our fundamental categories: Context, Interactivity, Motivation, Presence, and cognitive Load. The "e" stands for "evaluator." The CIMPLe System arranges the evaluation items in a slightly different order than they are presented above in the theoretical discussion to enable users of the tool to more readily remember the key parts of an effective virtual world learning environment by using the acronym for the key parts—context, interactivity, motivation, presence, and load. Finally, in Appendix A, we provide a reproducible version of the instrument that individuals can actually use to assess VWLEs.

Context, Interactivity, Motivation, Presence and Load Evaluator (CIMPLe)

Context: Factors that characterize the “physical” construction and function of the environment:

- C1. Attracts through initial sensorial pleasures.
- C2. Promises a novel or unique experience
- C3. Employs compelling metaphors to create an environment with fantastic features.
- C4. Uses multiple modalities (verbal, visual, etc.) that do not require simultaneous attention.
- C5. Technologies and functions operate appropriately
- C6. Signals the conclusion/exit.

Interactivity: Factors that characterize the ways that learners affect the environment and other learners within the environment:

- I1. Presents multiple ways for learners to interact with the environment that are consistent with the environment’s scheme.
- I2. Enables learners to collaborate.
- I3. Challenges learners through problems or puzzles to solve.
- I4. Allows learners to alter or add to the environment to enhance its meaning.
- I5. Enables learners to leave traces of their understanding of their experiences.

Motivation Factors that impact learners’ desire to achieve the goals built into the environment:

- M1. Makes learners aware of the learning goals.
- M2. Checks that the learner values the goals.
- M3. Checks on learner perceptions of goals as achievable.
- M4. Checks on learner perceptions that the environment provides necessary resources.
- M5. Provides resources to build learners’ confidence with tasks.
- M6. Provides feedback to learners’ actions.

Presence: Factors that give learners a sense of immersion in the environment:

- P1. Enables learners to personalize an avatar.
- P2. Uses avatars to establish presence of others.

P3. Enables communication in real time.

P4. Adapts to learner activity.

P5. Reflects some correspondence to the real world.

Load: Factors that help the environment strike a balance between cognitive overload and challenging tasks that increase learning:

- L1. Organizes information according to a consistent scheme.
- L2. Experience follows predictable schemas.
- L3. Provides supplemental instruction for gaps in prior knowledge.
- L4. Presents context that aids in remembering key information.
- L5. Articulates strategies for learning the information.
- L6. Enables learners to reflect on their learning.

CONCLUSION

The CIMPLe System presented in this chapter offers an advance in how educators can assess the quality of the virtual world learning environments that they build. Most prior literature on 3D virtual worlds focuses on a single aspect represented in the CIMPLe framework as researchers have discussed, for example, the importance of the context, interactive features, or presence. Instead, the CIMPLe framework combines multiple concerns present in virtual worlds into a single, sophisticated system that demonstrates concerns for the interactions among the various components of a virtual world. In other words, this short tool based on relatively complex theories enables instructional designers to begin thinking holistically about their constructions rather than compartmentalizing the components of a successful virtual world learning environment

The holistic approach to evaluating VWLEs achieved in the CIMPLe System arises from the thoroughly multidisciplinary approach represented in the tool’s theoretical backing. Research in user experience design, instructional design, interface design, learning and motivation theory, technical

communication—to name the most dominant traditions—combine in the CIMPLLe System to present evaluators with a perspective that works across different types of virtual environments. Our concern here has been primarily with 3D worlds, but the CIMPLLe System could be used across a variety of virtual learning environments, whether they are three-dimensional or not, because of the system's cross-disciplinary nature.

Finally, one limitation of the approach presented here, of course, is that it cannot measure or suggest content or goals. Instead, the CIMPLLe System suggests generic types of activities or categories of features that must be present in a successful virtual world learning environment. For this reason, we want to draw attention, once again, to the importance of positioning the evaluation offered by the CIMPLLe System into a larger instructional design framework that includes all five stages of the ADDIE paradigm: analysis, design, development, implementation, and evaluation. The CIMPLLe System fits primarily within the “design” phase because at this stage instructional designers can use the rubric as a heuristic for building the type of environment that will succeed. In other words, as they consider what to build into the environment, designers can refer to the CIMPLLe System as a sort of best practices checklist to ensure that the environment meets the needs that the cross-disciplinary theory suggests are necessary. What the rubric cannot do, however, is suggest content or learning goals. That must be left to the individual designer and specific learning situation.

A second limitation arises because the CIMPLLe System has only recently been introduced and no research record exists to validate the construct. However, since the CIMPLLe System combines components of approaches that other researchers have already validated such as the ADDIE framework, the system has a strong theoretical grounding that we believe will most likely prove valid in future case studies. That is not to suggest that specific items on the rubric might not be modi-

fied or that new items won't be added. It is to say, though, that we believe the primary conceptual structure of the system—context, interactivity, motivation, presence, and load—will withstand empirical validation. Indeed, a case study that uses the system for a cohort of teachers designing materials for seventh graders is underway as this chapter goes to press.

Even with these limitations, the CIMPLLe System can be used to diagnose usability issues and suggest why an environment might be successful or why it might fail. For example, at the evaluation stage—the final stage of the ADDIE paradigm—designers can determine how successfully the VWLE employs interactive features. Perhaps those interactive features appear but maybe they don't seem to enable learners to grasp the concepts appropriately. The CIMPLLe model tells us that we need to have these interactive features and what they should look like in the abstract, so designers can go back and revisit whether or not those interactive features actually are the best ones to achieve the learning goals. The fact that the interactive features must be present doesn't change; the way those features are enacted in the system might need to change. Perhaps future case studies that investigate VWLEs built according to the CIMPLLe System will point us toward the most effective ways to implement such features.

We hope that instructional designers will take away some practical guidelines for developing virtual world learning environments from our chapter. The practical guidelines found in the CIMPLLe System evolve from a substantial, cross-disciplinary theoretical approach and we hope that these discussions proved useful for demonstrating the genesis of the CIMPLLe System. We also hope that researchers will interrogate the system and that those investigations will combine with feedback from instructional designers so that the CIMPLLe System can continue to evolve and be refined into an exceptional tool for assessing virtual worlds designed for instruction.

KEY TERMS AND DEFINITIONS

Virtual World Learning Environments:

Electronic learning spaces, usually available through the Internet, that use computers to simulate aspects of the real world with the intention of teaching users some particular topic or content.

Context: The factors that characterize the way a virtual experience operates, including the experience's construction and functionality.

Interactivity: The factors that characterize ways that individuals can affect the environment or other participants within the environment including the opportunity to provide feedback, control the experience, produce something, or have the system adapt to their individual needs.

Motivation: The set of characteristics—valence, instrumentality and expectancy—that helps learners to maintain interest in learning activities, to succeed at learning, and to assess their degree of gain.

Presence: This often refers to the level of immersion that a person feels when the participate in a virtual experience. Presence consists of environmental presence that enables interaction with the system; personal presence that gauges the level of immersion a person feels; and social presence or the degree to which one can interact with others synchronously.

Cognitive Load: The processing capability individuals possess as they consider information in the environment, the relevance of that information, and the application of the information to problems they attempt to solve.

User Experience Design: A method of planning, designing, building, implementing and testing products with a focus on the user's complete experience. The approach is used for computer-based products such as websites, but also for product design of items such as phones.

Attraction: In user experience design, this represents the reasons that a person might begin particular experience. Reasons for undertaking the experience are either intrinsic or evolve from the user's own needs, or extrinsic in which case the user must be meet

Engagement: In user experience design, this represents the major portion of an experience, the thing that a user seeks in the experience. The engagement occupies the bulk of the time a user maintains contact with a particular experience.

Conclusion: In user experience design, the actions that signal the end of the experience or

when the end is announced, assess participants' opinions or learning, and provides an opportunity for learners to reflect on the experience.

Data to Wisdom Transfer: This means moving receiving information, processing that information according to its usefulness for solving problems, and ultimately storing that solution in long term memory as a schema for future use in a novel context.

Problem-based learning: Experiences that place learners in situations where they have to think through concepts and apply them to solve meaningful problems rather than reciting information from memory.

ENDNOTE

- ¹ We'd like to express our thanks to the Carolina Virtual Worlds Consortium (CVWC) and the National Science Foundation for supporting the research and instructional activities from which this chapter has evolved.

APPENDIX A: THE CIMPLE SYSTEM FOR REPRODUCTION AND USE

Table 1. Context

	C=Complete	I=In Process	A=Absent
Attracts through initial sensorial pleasures.			
Promises a novel or unique experience.			
Employs compelling metaphors to create an environment with fantastic features.			
Uses multiple modalities (verbal, visual, etc.) that do not require simultaneous attention.			
Technologies and functions operate appropriately.			
Signals the conclusion/exit.			

Table 2. Interactivity

	C=Complete	I=In Process	A=Absent
Presents multiple ways for learners to interact with the environment that are consistent with the environment's scheme.			
Enables learners to collaborate			
Challenges learners through problems or puzzles to solve			
Allows learners to alter or add to the environment to enhance its meaning.			
Enables learners to leave traces of their understanding of their experiences			

Table 3. Motivation

	C=Complete	I=In Process	A=Absent
Makes learners aware of the learning goals.			
Checks that the learner values the goals.			
Checks on learner perceptions of goals as achievable.			
Checks on learner perceptions that the environment provides necessary resources.			
Provides resources to build learners' confidence with tasks.			
Provides feedback to learners' actions.			

Table 4. Presence

	C=Complete	I=In Process	A=Absent
Enables learners to personalize an avatar.			
Uses avatars to establish presence of others.			
Enables learners to communicate in real time.			
Adapts to learner activity.			
Reflects some correspondence to the real world.			

Table 5. Load

	C=Complete	I=In Process	A=Absent
Organizes information according to a consistent scheme.			
Experience follows predictable schemas.			
Provides supplemental instruction for gaps in prior knowledge.			
Presents context that aids in remembering key information.			
Articulates strategies for learning the information.			
Enables learners to reflect on their learning.

Section VIII

Emerging Trends

The final section explores the latest trends and developments, and suggests future research potential within the field of instructional design while exploring uncharted areas of study for the advancement of the discipline. Introducing this section are chapters that describe some of the most recent issues in technology-assisted education, followed by new topics on adult education and virtual inquiry. Of special note to those looking for the design portion of instructional design, two of the final chapters discuss aesthetics and new practices in instructional design. These and several other emerging trends and suggestions for future research can be found within the final section of this exhaustive multi-volume set.

Chapter 8.1

Contemporary Issues in Teaching and Learning with Technology

Jerry P. Galloway

Texas Wesleyan University, USA & University of Texas at Arlington, USA

INTRODUCTION

To speak of contemporary issues in instructional technology is like counting wave crests in a stormy ocean: they are changing quickly all the time. New technologies and new issues present themselves daily. Educators struggle with both the instructional integration of computing and developing the skills and knowledge necessary to use technology effectively (Lipscomb & Doppen, 2005). Why, after over 30 years of having computers in schools, are educators still having such difficulties?

Today's population is much more accustomed to electronics, yet knowledge is weak, concepts are misunderstood, and the difficulties of teaching

with technology seem as serious and convoluted today as ever before. The great physicist and thinker, Richard Feynman, offered some critical comments about the challenges of educators. "What happens is that you get all kinds of statements of fact about education, about sociology, even psychology — all kinds of things which are, I'd say, pseudoscience" (Feynman, 1999, p. 242). Today, we understand "more about education [but] the test scores are going down... we just don't understand it at all. It just isn't working" (p. 243). Being critical of how the scientific method is applied to education, Feynman's comments highlight how the study of teaching and learning yields limited or questionable results. Teacher trainers take their best guess on how to prepare teachers to use technology.

DOI: 10.4018/978-1-60960-503-2.ch801

BACKGROUND

Educational computing is a relatively new discipline compared to mathematics and science. While the earliest uses of computers might have been by departments of mathematics, it quickly became important for virtually all teachers to become computer literate. But what exactly that entails was not exactly clear (Galloway, 1985) for learning and in society (Beaty & Tucker, 1987).

Microcomputer technology, primitive by today's standards, lacked user-friendly applications, any sort of consistent user interface, or easy-to-use telecommunications and interconnectivity. There was an early division between those who learned to program computers vs. those who focused more exclusively on applications software. Conceptual development, improvement of problem solving, and higher-order thinking skills in computing have been directly linked to the inclusion of Logo programming (Allen, 1993; Battista, 1994; Borer, 1993; Dalton & Goodrum, 1991) and BASIC programming (Overbaugh, 1993). Yet, in spite of an overwhelming need to operate early microcomputers through programming, educators focused instead on the actions and procedural tasks of specific applications (Galloway & Bright, 1987).

With this as a foundation, decades of training have followed in which educators have tried to master new devices and software. So, how long does it take to reach a point of nationwide competency, to develop the protocols of effective use, to establish the knowledge of how best to learn computing? Compared to centuries of science and mathematics, perhaps our 30-plus years do not seem so long.

EDUCATORS LEARN COMPUTING: A PROBLEM OF PERSPECTIVE

Our collective perspective on what it means to learn computing affect what goals we pursue and how we proceed. For example, the use of rubrics

or portfolios were not commonly emphasized in education 30 years ago. Today, they are an accepted or at least popular tool for preparing educators (Galloway, 2006; Rural School and Community Trust, 2001). Does this represent progress or perhaps just a symptom of changing fads? Is this a function of real knowledge or mere opinions? This is again reminiscent of a Feynman (1999) criticism, as he suggests that professionals 30 years ago have as much right to a correct opinion as we have today, "to equally unscientifically come to a conclusion" (p. 243)—even if wrong.

Preparing Teachers

It is unlikely that educators younger than their mid-40s graduated high school without having computers in their education. There has been, since the late 1970s, a continual focus on the needs of teachers to learn and adapt to a technology-based profession.

Our attempt over the years to change educators into computer-literate professionals essentially failed. Many will argue the point, as clearly there are countless success stories. But, with the exception of the techies and innovative pioneers, educators across the profession a generation ago did not, have not changed their basic approach to integrate technology.

Compared to in-service classes, college courses, training, or other options, an overwhelming majority of teachers maintain that their primary methods of learning computing was through self-study and personal experimentation (Galloway, 1997). It can be argued that teachers must assume a responsibility for advancing their technological knowledge and be engaged learners.

When taking a computer class, one must go beyond the prescribed activities. For example, it is not likely that one would be assigned the experience of losing a file or opening a file with the wrong program. These frustrations can be a very necessary part of learning. Far too often educators are passive and restrict their involvement to oc-

casional and discrete enrichment offered through someone else's initiative. Delays and intermittent and partial commitments inhibit learning.

As an analogy, when this author was young, rock-n-roll music was still the choice of the young, but grandfather did not relate and found it quite distasteful. In elevators in 1968, one would hear music from Lawrence Welk and such. This author believed that if elders could simply understand and learn about rock-n-roll and what the artists were attempting to express musically that society could change and the music would be accepted. Today, one is likely to hear McCartney, Dillon, The Beatles, Buddy Holly, or many of the other artists that were objectionable in those earlier years. One might think that, indeed, things changed.

However, the point is that this did not occur because the elders were influenced or convinced. The younger, rock-n-roll generation did not change anyone. The elders were not convinced. No metamorphosis occurred. The young simply grew older and brought their music with them. As the elders died off, the young with a new culture replaced the old.

The same seems true for the computer-using generation. Our efforts a generation ago were ineffective. We have simply waited around while a new generation grows older bringing their technology-based lifestyle with them. Until our children have time to take their place, today's teachers are still introduced to computing as beginners.

Training vs. Education

What do current educators expect from computer training? If we accept that it is difficult to teach someone who does not want to learn, what do students expect from their training? Unfortunately, the most popular notion in instructional technology is that teachers are to be trained, not educated. More than mere semantics, teaching tends to emphasize *showing teachers how to use technology* — rather than facilitating insight, understanding, and conceptual development. In-

service programs and college curricula emphasize only what teachers are expected to use rather than what might develop good concepts. Omitting programming is a classic example where teachers as end users of software never see the construction process or design methods behind what they are supposed to learn. Today's design tools (for Web pages and such) are a modern example of where these issues still apply.

Teaching for conceptual understanding and higher-order thinking skills should not be only a part of teaching programming (Tu & Falgout, 1995), but also a fundamental goal of instruction for beginners in computing. Skills and even performance standards can still fail to generate important understandings, perspectives, concepts — integrated knowledge — that all contribute a fundamental and critical basis for problem solving and adaptability.

Focusing on conceptual development will still involve procedures and tasks just as focusing on discrete skills will likely yield some insights and discoveries. But instruction should yield a more complete, fundamental understanding of computing. Most programs and perspectives fail to recognize this important viewpoint and instead pursue skills and competencies to the detriment of understanding, insight, and problem solving.

It is common in other disciplines to speak of *education* rather than *training*. Conceptual development is often the primary focus in the study of science (Trumper, 1997). Even when the preparation of teachers is described in terms of training, science concepts are emphasized, not skills (Thompson & Schumacher, 1995). In spite of the procedures and skills inherent in science and mathematics, students are guided toward the development of a conceptual understanding as they are educated — not trained.

A training model targets activities and the software teachers will use. Much like an airline reservations clerk must learn the keystrokes and procedures for prescribed tasks, educational computing is similarly conceived. An education

model, on the other hand, calls for activities and experiences that will yield a deeper kind of learning. Keystrokes and software familiarity would be incidental to the more important yield of experiences, much like those in science and mathematics, that develop understanding, concepts, problem solving, and critical thinking skills. An education-based program would provide experiences because of their educational value regardless of whether they are part of an anticipated skill set. Skill sets, tasks, and the procedural rituals of training will inevitably change and evolve far beyond the scope of any training experience.

Student teachers can be part of the problem as they, very often, prefer the training model. Contrary to any real value or longevity of such an approach, a more involved education presents an undesirable challenge. They prefer to simply be shown what to do. Guided tasks, prescribed procedures, and discrete tasks are all a matter of doing, not becoming. However, an education calls for change.

Acquiring mindless task sequences is often viewed by educators as success. Improved teaching is then viewed as having more complete checklists for more tasks. This *recipe mentality* of discrete procedural rituals ignores the need for discovery learning, transfer, and adaptability, and could be responsible for continuing the inhibited progress of the past 30 years.

Integration

Limiting factors for the integration of technology include funding, professional development, support for experimentation, and inadequate technology planning (Mehlinger & Powers, 2002). As Galloway (1997) examined technology adoption, it was learned that effective usage is related to the combination of both professional and personal adoption of technology. Virtually no one used technology in their classrooms where personal adoption was not combined with professional use.

It has been said that teachers exist only for the children. They express the sentiment that student needs are the primary, if not the only mission of teachers. It is easy, however, to draw the wrong conclusions from such a self-evident premise. For instructional technology, consistent with this perspective, trends have been directed away from empowering teachers, focusing instead on classroom integration. This may seem justified, but a serious problem remains: it is not reasonable to teach non-computer users to use technology in the classroom. Educating teachers to become computer-using, technology-competent professionals would more likely yield classroom integration as a matter of natural consequence.

While there are training programs targeting classroom integration, what success can be had if teachers are not computer literate or have never adopted computing in their lives? In other words, one must adopt technology as a life-changing metamorphosis. The approach of the past, training over education and rituals over holistic adoption, may likely continue the inhibited progress in integration and technological mastery.

Learning and Working

Everyone agrees that students must be prepared for a technological future, but perceptions vary widely on exactly how to achieve that. This is a challenge of pedagogy.

Computers have been perceived as tools (Beaty & Tucker, 1987) and have been used in that fashion. An alternative view might suggest that the computer is not a tool at all. As a tool might be selected or discarded based on a particular need, technology is too often viewed as independent from everyday life powered-up if the need is sufficiently demanding. Instead, computers are perhaps best viewed as a complete *environment*. It is where we live, work, and play. It is the medium of our planning, our creativity, and an extension of both our short-term and long-term memory.

This thinking places different expectations on educators than has traditionally been made. The notion that one can remain a non-computer-using person while merely executing discrete tasks as needed must change.

FUTURE TRENDS

How has learning changed and what is *learning* in the modern tech-based world? Learning is far too often viewed by teachers as a matter of acquiring information. Teachers deliver information to the students who in turn sit on it for a period of time only to hand it back to teachers again in some form of quiz or standardized test. If students regurgitate and return the information accurately, they are said to have *learned*. In fact, students assume this is what is expected of them and resist anything more personally demanding. The notion that they must change, must invent, or synthesize is foreign to them.

Learning is no longer about the acquisition of information. We have information. It is possible to find the average price of a hang guilder, the architect of the Brooklyn Bridge, design plans for a new home, or a translation of the Dead Sea Scrolls in mere minutes — all while sitting in a hotel lobby or even lying in bed in a dormitory room. Acquisition of information is neither the problem nor the goal. Learning to think is the real challenge. Education has become about skill development with demonstrable competencies rather than about becoming smarter or learning to think. Education, as distinct from training, should improve problem-solving abilities, critical thinking abilities, developing an understanding, learning to discriminate and make good choices, and developing a contextual intuition.

Computing students do not want to have to explore and discover, wanting instead to be shown how to execute procedures. Alluded to earlier, this amounts to distributing recipes for subsequent replication. Being ready for tomorrow's computing

world depends on understanding, problem-solving skills, and the ability to adapt to the unknown, not on knowing procedures in some software program.

Technology continues to develop faster than anyone can sufficiently learn it. Merely being able to operate the functions and tools in a program is usually considered a success. But achieving a deeper knowledge of how best to adopt, integrate, and teach in a world of technology is quite a different thing.

The Distant Future

Does today's science fantasy help to create the reality of tomorrow? That is of course debatable, but at least imagination does its part on one side of the evolution equation. Clearly, our children will experience amazing and incredible advancements that today seem like science fiction.

So, extend your vision to consider the following: a kind of futuristic electronic *bubble* as a kind of spherical energy shell that would surround one's head and face. The shell might not be spherical and could instead extend vertically downward in front of the face and chest somewhat like a large energy shield in front of the body. Generally, it may be maintained and kept active throughout the waking hours.

The shell or *e-bubble* would be generated by a multifunctional microchip and would act like a virtual outer skin or electronic membrane extending perhaps 10 to 12 inches in front of the body. Perhaps the orientation of the membrane (up/down, sections, areas, etc.) could be determined by detecting and interfacing with an electrical field from the heart or brain, much like an electrocardiogram or electroencephalogram. This would be important to establish a directional configuration since a microchip might be located more on convenience or medical necessity. The e-bubble should maintain a functional orientation to the body. The membrane can function in sections, quadrants, or areas, as well as operating as a whole or singular entity.

The e-bubble would serve as a communications interface for all sorts of input and output in work, learning, and recreation. The microchip and power supply might be worn as external hardware, like in a necklace, belt buckle, or collar. Perhaps the electronic membrane might exist in the form of a mere hologram projection from specialized glasses. Today's military pilots see electronic projections of critical data superimposed on their natural view of their environment during flight. Some hardware today can feed visual information into one eye, leaving the other eye normal as the brain integrates the two views. The integration of visual and auditory hardware with the body has already begun its prosthetic progression from the separate and independent technologies of yesterday's cathode-ray tube (CRT) and today's plasma flat screens.

Eventually, the development of the e-bubble would evolve beyond the independent device carried in hand. Even with the convenience of a wristwatch or techno-necklace, such devices are external and thus their service to our lives is an add-on not truly integrated and natural. The e-bubble will evolve beyond a separate prosthetic to such a size and state that it becomes an implant no more intrusive than an inner ear replacement.

Images displayed in the membrane fields would include all of the variations we know of today: pictures, graphics, text, color, and of course, full-motion video. One can imagine that these fields appear from the back side, viewed by others, as opaque with no detail or instead translucent with imagery appearing in reverse.

One can imagine interactive fields for drawing, writing, or other tactile manipulations. Perhaps an image might be relocated in the field matrix to open or power another area for a secondary purpose. The various fields might provide a multi-tasking experience of work and play, business and entertainment, or integrated learning and study experiences.

It is really an extension of what has already occurred. Star Trek and many other sources of imagination today illustrate not just an exciting possibility but an inevitable reality.

CONCLUSION

Are we to continue passively as followers of our children or step up as leaders, which the nobility of our profession demands? The overwhelming theme of the past 30 years is that training for discrete tasks must be replaced by holistic adoption and education. Being successful at computing is not a function of memorized procedures or specific skill sets. Procedural rituals, however conveniently arranged or exhaustively accounted, cannot substitute for intuition, problem solving, and a deeper understanding of computing.

The future depends on adaptability and learning transfer, which again attest to the inadequacy of mere training. It will be an exciting future, but challenging to us all. To quote Peter Drucker, 20th-century business pioneer, "The best way to predict the future is to create it."

KEY TERMS AND DEFINITIONS

Computer Literacy: The ability to effectively use computer technology to solve problems and efficiently meet personal and professional needs.

Education: Contrary to mere training, the process engaging in supportive and generative experiences for acquiring the broader understanding and mastery.

Educational Computing: Full range of uses of computers pursuant to conducting the profession.

Instructional Technology: The broader field of studying the use or related issues of all technologies in education.

Integration: The effective, instructional use of technology in the classroom.

Learning: Contrary to the acquisition of mere facts, and more than acquiring discrete skills and competencies, learning is the development of knowledge, conceptual understanding, and critical thinking abilities in a prescribed context.

Science Fiction: Imagining future developments in technology and the human-machine interface, including living and working in virtual worlds.

Training: Limited and highly specific instruction for learning discrete tasks and procedural rituals.

ABSTRACT

This chapter presents the results of a systematic review of literature in which the authors examined instructional technology integration in career and technical education, mathematics, language arts, social studies, and science. Three lenses were used to examine the literature: a research design framework, a teacher knowledge framework (CFTK), and a technology integration framework (TPACK). The research design framework revealed a low percentage of papers that were actually research studies (41.2%), favoring qualitative design (70% of the 41.2%). Consequently, educators may have difficulty sifting through high proportions of non-research to find the most informative,

up-to-date instructional technology research. Three CFTK aspects of teacher knowledge were addressed less than others in the research studies: Individual Context (16%), Subject Matter (33%), and Discernment (29%). Pedagogical Knowledge was addressed the most (65%). The TPACK developmental framework revealed an emphasis on the lowest three levels of instructional technology integration (60%), indicating a gap in the research at the upper two levels. Mathematics studies accounted for almost half of all research addressing TPACK developmental stages (47%). From these findings, the authors conclude that pedagogical knowledge alone is not enough to ensure high levels of technology integration and offer recommendations for improving the disjointed nature of research on instructional technology.

DOI: 10.4018/978-1-60960-503-2.ch802

INTRODUCTION

Teachers use instructional technology for online courses, video conferencing, electronic portfolios, and other exploratory projects. Literature reviews are important tools that teachers can use to evaluate instructional technology and develop strategies for its effective use. A systematic review of literature can make such evaluations far easier and more effective by synthesizing the results of the studies on a given topic using well-articulated methodological processes. The purpose of this chapter is to provide a systematic review of the impact of technology on teaching and learning and to propose a framework for looking at teacher knowledge from which gaps in the literature can be addressed. In this paper, the term “technology” refers to digital technology as opposed to other forms of instructional tools (e.g., overhead projectors, manipulatives).

Means, Wagner, Haertel, and Javitz (2003) identified two major issues regarding the use of technology for instruction: the pedagogical value of specific technology tools and the cumulative effects of technology exposure over time on student learning. In order to address these issues, educators need to assess specific sub-questions to gauge the effectiveness of technology as a teaching tool (e.g., What conditions foster learning with technology; what pedagogical strategies promote learning with technology; what teacher qualifications are related to content, technology, and implementation of pedagogical strategies; and to what internal and external classroom constraints must teachers attend when incorporating technology?). The complex nature of these questions requires multiple types of research and design.

Bell, Schrum, and Thompson (2009) suggested that the types of research needed to adequately address these issues include: (1) experimental or quasi-experimental studies, (2) large-scale studies, (3) studies with sufficient statistical information to be included in meta analysis and mixed-methodology studies, (4) studies with rich analysis of student content knowledge, and (5) studies that

address the complexities of learners, classrooms, and schools. Recently, federal funding agencies such as the Institute of Education Sciences (IES; Whitehurst, 2003) have emphasized large scale experimental studies as the gold standard for scientific research. One such study, *Effectiveness of Reading and Mathematics Software Products: Findings from the First Student Cohort* (Dynarski et al., 2007), found that the technology programs used showed no significant improvement in student test scores in mathematics and reading. However, the results from a single study, even a large scale experimental study, are not conclusive in and of themselves. For example, Fitzer et al. (2007) challenged the generalizability of the Dynarski et al. (2007) study, noting that “this study oversimplifies the case by pushing aside these complicated relationships, and treating all the software programs as members of the same generic set of ‘mathematics software’ (or ‘reading software’)” (p. 3). Ronau et al. (2008) added that “The absence of teacher considerations along with a seemingly accepted view of a transmission model of learning with technology left the door open for better and richer technology research — research that addresses the complex situations occurring when various technologies are used in the mathematics classroom” (p. 19). From this example, we see that no one study or type of study can answer every pertinent question; small-scale empirical studies and qualitative studies fulfill an important role for research by answering focused questions in more detail than is feasible on a large scale. We suggest therefore that researchers seek a balance between various methodologies to better answer the multiple facets of key questions asked by stakeholders regarding the integration of technology in the classroom.

FRAMEWORKS FOR TEACHER KNOWLEDGE

In addition to research design, this chapter is also interested in how previous studies have taken into

account the impact of teacher knowledge on the effectiveness of the integration of technology in the classroom. Within the past few years, two new teacher knowledge frameworks have been proposed with the potential to support the research community in responding to questions on the impact of technology on learning. The Comprehensive Framework of Teacher Knowledge (CFTK) provides a three-dimensional model of teacher knowledge (Ronau et al., 2009). The Technology, Pedagogy, And Content Knowledge (TPACK) framework focuses on teachers' interconnected and interrelated knowledge of content, pedagogy, and technology (Mishra & Koehler, 2006; Niess, 2005a). Both structures emanate from the pedagogical content knowledge (PCK) framework proposed by Shulman (1986) as the specialized knowledge that teachers need for teaching.

Comprehensive Framework for Teacher Knowledge

CFTK organizes teacher knowledge into a three-dimensional model, each dimension comprised of two aspects: Field, comprised of the aspects Subject Matter Knowledge and Pedagogical Knowledge; Mode, consisting of the aspects Discernment and Orientation; and Context, composed of the aspects Individual and Environment. This framework, depicted by the model in Figure 1, integrates multiple frameworks that address components of teacher knowledge to create an all-encompassing structure for studying and understanding the complex nature of knowledge required for the teaching profession (Ronau et al., 2009).

The first dimension of CFTK, Field, incorporates a broader scope and a more complex construct than simply the merging of pedagogy and subject matter as PCK (An, Kulm, & Wu, 2004; Davis & Simmt, 2003; Groth, 2007; Marks, 1990; Mishra & Koehler, 2006; Peressini, Borko, Romagnano, Knuth, & Willis, 2004; Wittmann, 1998; Zurita & Nussbaum, 2007). Instead, CFTK represents

PCK as only one possible interaction within teacher knowledge. Subject matter and pedagogy also interact with teacher knowledge of Mode and Context to better capture the complexity of interplay between all three dimensions.

The second dimension of CFTK, Mode, describes the knowledge teachers rely on as they are engaged in their teaching profession; that is, knowledge about what to teach, how to teach, the ways students learn, and ways for a classroom to meet the needs of every student. The Orientation and Discernment aspects characterize knowledge of Mode. *Orientation* describes the knowledge of beliefs, dispositions, values, goals, and other personal qualities that embody and define an individual's views and actions toward learning and teaching. Teachers access this knowledge to understand and manage the way all affective issues impact a learning situation. *Discernment*, on the other hand, illustrates the knowledge lens through which teachers understand the impact of the cognitive domain (e.g., reflection in action, reflection on action, on-the-spot decision making). The interaction of these two aspects creates a dynamic knowledge base with which teachers can effectively manage multiple internal influences on student learning.

Figure 1. CFTK framework of teacher knowledge as a three-dimensional structure

The third dimension of CFTK, Context, explains the knowledge teachers need of external factors that influence a learning situation. Two aspects of Context describe its sources: Individual and Environment. Contextual factors have a significant impact on the teaching and learning process, making knowledge of these factors essential to both teachers and researchers (for the importance of Context to teaching, see Bryk & Driscoll, 1998; Eraut, 1994; Felner et al., 1995, 2001; Scribner, 1999; for the importance of Context to research, see Cobb & Bowers, 1999; Datnow & Stringfield, 2000; diSessa & Cobb, 2004; Rossi & Stringfield, 1995a, 1995b; Stringfield, 1995; Teddlie & Stringfield, 1985; Wayman, Stringfield, & Yakimowski, 2004). *Individual* describes the knowledge of individual characteristics such as socioeconomic status (SES), gender, age, background, learning styles, and other contextual factors that impact an individual's approach to learning that teachers must understand and manage to be effective in a given learning situation. *Environment* describes knowledge on the impact of external factors on learning such as school climate, classroom climate, student teacher relationships, classroom organizational structures, school procedures, and other classroom, school, and community factors.

The understanding of learning contexts has evolved from simple considerations of individual characteristics and classroom environments to that of more all-encompassing, dynamic learning systems (Davis & Simmt, 2003; Davis & Sumara, 1997, 2001; Ding & Sherman, 2006). The interactions of the two aspects of Context with each other and with those of Field and Mode are able to more completely capture the complexity of learning under different demands and within a variety of situations.

Technology, Pedagogy, and Content Knowledge

TPACK provides a basic framework for more research attention to specifically address the role

of technology in changing teacher behavior and in impacting student learning. TPACK is a response to the failure to actively integrate technologies in education during the 1980s and 1990s. During that period, many believed that increasing teacher awareness of the potential benefits of technology to learning would be enough to engender high levels of integration. Thus, teacher education programs were configured to provide teachers with opportunities to explore technology uses in the classroom. Yet, despite these educational supports, little active, meaningful, and continued integration of technology in learning environments occurred. With little evidence to suggest a reason for the lack of progress, multiple researchers began examining how teachers' understanding of technologies and PCK interact with one another to produce effective teaching with technology (Koehler & Mishra, 2008). Initially, the knowledge framework of Technological Pedagogical Content Knowledge (TPCK) was proposed as a complex interaction among three bodies of knowledge – technology, pedagogy, and subject matter content (Mishra & Koehler, 2006; Niess, 2005a). Late in 2007, TPCK was recast as TPACK, or the “total package” required for integrating technology, pedagogy, and content knowledge in the design of instruction for thinking and learning with technology; this recasting acknowledged the importance of the interactions between the individual constructs of the model technologies (Niess, 2007, 2008; Thompson & Mishra, 2007). Figure 2 shows the model used in visualizing this framework.

The TPACK framework provides a structure to guide research into the nature and development of teacher knowledge for teaching with technologies. Niess and colleagues (Niess, 2006; Niess, Lee, & Sadri, 2007; Niess et al., 2009) described teacher growth for technology integration in the classroom through five progressive stages:

1. **Recognizing (knowledge):** in which teachers are able to use the technology and recognize the alignment of the technology with

Figure 2. Venn diagram of TPACK as the intersection of content, pedagogy, and technology knowledge (adapted from Niess, 2008, p. 9)

subject matter content yet do not integrate the technology in the teaching and learning of subject matter.

2. **Accepting (persuasion):** in which teachers form a favorable or unfavorable attitude toward teaching and learning subject matter content with an appropriate technology.
3. **Adapting (decision):** in which teachers borrow from their prior experiences with the technology and implement the ideas in their classroom instruction, leading them to a choice to adopt or reject teaching and

learning subject matter content with an appropriate technology.

4. **Exploring (implementation):** in which teachers actively integrate teaching and learning of subject matter content with an appropriate technology, designing their own ideas that allow more student-directed actions as they think about and plan their curriculum and instruction.
5. **Advancing (confirmation):** in which teachers make revisions in their curriculum as a result of the technology capabilities and evaluate the results of the decision to integrate teaching and learning subject matter content with an appropriate technology.

The Association of Mathematics Teacher Educator's (AMTE) Technology Committee then created a visual description for thinking about these TPACK levels as they began the process of drafting a TPACK framework for mathematics teachers (Niess et al., 2009). Figure 3 portrays the levels that teachers engage in as they expand their knowledge and understandings in ways that merge multiple knowledge bases - technology, content, and pedagogy.

On the left side of the graphic, the figure highlights PCK as the intersection of pedagogy and content. As the knowledge of technology expands and begins to intersect with pedagogical and content knowledge, the teacher knowledge

Figure 3. Model of teacher thinking and understanding as their knowledge develops toward the intersection identified as important by TPACK (from Niess et al., 2009, p. 7)

base described as TPACK emerges: This is a space in which teachers actively engage in guiding student learning of mathematics with appropriate technologies. The Committee's work in developing the framework considered the ideas provided by the National Educational Technology Standards for Teachers (NETS-T). These NETS-T standards were developed in 2002 and revised in 2008 by the International Society for Technology in Education (ISTE, 2008). The NETS-T standards were described for all teachers, regardless of content area. The Committee provided a content-specific view for mathematics teachers; Appendix A contains AMTE Board approved Mathematics TPACK framework.

Integrating the Frameworks

These two frameworks may seem to be competing images of the knowledge base teachers need for teaching with technology. However, a combination of the two frameworks may enhance our understanding of how technology integration and teacher knowledge interact in a learning environment. TPACK defines a framework that describes a series of levels for technology integration while CFTK provides insight into the teacher knowledge aspects and their interactions needed to implement the guidelines within that framework. For example, the first AMTE guideline for developing TPACK in the classroom, *Designing and developing digital-age learning environments and experiences - Teachers design and develop authentic learning environments and experiences incorporating appropriate digital-age tools and resources to maximize mathematical learning in Context* (Appendix A; Niess et al., 2009) requires more than just the knowledge of Subject Matter and Pedagogy, but also the knowledge of Orientation (for both teacher and student) and knowledge of individual and environmental contexts. In like fashion, the implementation of the second guideline (Teaching, Learning, and Curriculum) requires teacher knowledge best described by the

knowledge of content and pedagogy (i.e., Field), student orientations and cognitive dynamics (i.e., Mode), and group dynamics (i.e., Context) integrated into a single construct. In a similar way, meeting the third AMTE guideline (Assessment and Evaluation) also requires the interaction of all six aspects of CFTK, particularly with the alignment of assessment tasks and procedures with that of classroom activities and expectations. Finally, the fourth guideline (Productivity and Professional Practice) incorporates the "Professional Identity" interaction described in the CFTK model (Ronau et al., 2009), originally defined by Peressini et al. (2004) and others.

In addition to these guidelines, the identification of the five developmental levels within TPACK for integrating technology into the classroom aligns easily with the interactions of the CFTK aspects, providing a way to gauge the degree or sophistication with which individuals incorporate technology into their teaching and learning. Treating technology as an interaction in CFTK expands the notion of TPACK from the one-dimensional foundation of PCK to a three-dimensional base that includes six aspects of teacher knowledge. For example, in moving from the Recognizing to the Accepting levels of TPACK, the teacher must not only merge Pedagogical knowledge with Subject Matter Knowledge but in the process, allow them to interact. They must also begin to tap into knowledge of Orientation.

To move from Accepting to Adapting, more sophisticated knowledge of subject matter is needed to facilitate the recognition of the fundamental differences of conceptual versus procedural knowledge. More development of pedagogical knowledge is also needed in order to construct new assessments and recognize the value of these new assessments over the old, procedural-based assessments. To progress from Adapting to Exploring, teachers develop their knowledge of student orientations and personal orientations further, recognizing the benefits of enhancing curriculum with technology-based instruction. Concurrently,

the blending of subject matter and pedagogical knowledge continues through the Exploring stage. In order to begin exploring technology enhancements, teachers must also begin to tap into their knowledge of individual and environmental contexts. During the Exploring stage, teachers begin to mature in their understanding of the aspects of Field, and they begin to incorporate components of Mode and Context. As Exploring gives way to Advancing, the aspects of Mode and Context are further clarified and begin to interact. As teachers develop into higher levels of the Advancing TPACK stages, all six aspects of CFTK must be fully engaged and interacting.

The natural alignment between the TPACK and CFTK frameworks makes their integration uniquely capable of enabling researchers and practitioners to more fully understand the teacher knowledge required for the integration of technology into the classroom.

Methods

This study uses three frameworks (research design, CFTK, and TPACK) to interpret instructional technology research. We began by asking what types of research designs were used and how well the CFTK and TPACK models explained the teacher knowledge needed to integrate technology effectively in different content strands. To attend to these questions, we conducted a broad review of the research literature.

Study Inclusion Criteria

Three criteria were used to select the studies examined in this review: (1) Studies were found in scholarly, peer-reviewed journals, reports, dissertations, or conference proceedings, (2) Studies involved the use of technology in an educational setting, and (3) Studies focused on one of five specific fields (i.e., mathematics, science, career and technical education, language arts, or social studies).

Electronic Literature Search Strategy

In order to locate studies that met the criteria for this review, several electronic databases related to education and psychological sciences were searched. For mathematics, science, and career and technical education, these included the EBSCOhost databases: Academic Search Premier, Education Administration Abstracts, ERIC, Middle Search Plus, Psychology and Behavioral Sciences Collection, PsycINFO, Sociological Collection, and Teacher Reference Center; two H.W. Wilson databases: Education Full Text and the Social Sciences Index; JSTOR; five ProQuest databases: Career and Technical Education, Dissertations & Theses, Ethnic NewsWatch, GenderWatch, and Research Library; the IEEE Electronic Library; and three ISI Web of Knowledge databases: the Science Citation Index Expanded, the Social Sciences Citation Index, and the Arts and Humanities Citation Index. Because some databases are specific to the language arts, extra H.W. Wilson databases were included when searching for literature in that field: Art Abstracts, Art Retrospective, Essay & General Lit, Humanities Index, and Short Story Index. Due to the overlapping nature of some social studies and language arts journal indexing, these extra databases were also used for searching social studies publications.

Keywords varied for each content area and database. Basic search terms were used to begin searching keywords and subject indices in each database (e.g., language arts, technology, education, social studies, history, geography, science, mathematics, career and technical education). Each database uses different keywords and search terms, so for each search, the basic search terms were altered to maximize the number of results and their relevance. For example, EBSCOhost databases used the subject term "Career and Technical Education," whereas ProQuest used the term "Vocational Education" (see Appendix C for full list of search terms).

Random Sample

The literature search identified a population of journal articles, reports, dissertations, and conference papers dating from 1967 to 2009. For the remainder of this paper, the term “study” refers to any one of these categories. To ensure equal representation, a stratified random sample of approximately 30 studies was extracted from the population of each content area using random number generator software from Minitab Version 15 (see Table 1).

Sample Coding

The coding instrument was developed by the team at the University of Louisville (Appendix B). The developers then tested and revised the instrument and eventually distributed it to the coding team. The coding protocol for this instrument captured information about the study itself (e.g., author, year the paper was published or the study was carried out), type of research design where applicable (e.g., qualitative, quantitative, theory development, or practitioner resource), the type of technology being examined or described, the type of knowledge being described/developed by the study, and TPACK level(s) supported by the study.

To code the sample studies, we began by screening titles and abstracts for eligibility based on the study inclusion criteria, as previously described. For studies that met inclusion criteria, we recorded all applicable information on the coding instrument.

Studies identified with a quantitative research design were also coded as being either randomized or quasi-experimental. We also recorded their outcome measures, reliability measures, and validity measures as well as their selection mechanisms and use of measures to control pre-existing differences. Studies identified as qualitative, were coded by their research design (e.g., narrative/historical, biography, design study, phenomenology, ethnography, grounded theory, or case study), the methodology employed (e.g., covert/overt observation, interview, or focus group), alignment of the study methodology with outcome(s) of interest, and evidence of trustworthiness. For studies with the purpose of theory development, we recorded as much applicable information as possible and marked the rest as “not applicable.” In some fields, studies were intermingled with presentations of pedagogical strategies. These studies were not excluded if they were found in a peer-reviewed, scholarly journal. In these cases, the lack of research foundation was noted, and all other relevant information was coded.

Inter-rater reliability. In order to reduce the variation in coding decisions, we developed coding tables with closed response systems. Furthermore, coders began by examining exemplar studies with various research designs. Due to the expected variation across the five subject areas and the low degree of commonalities, we chose to rely on coordinated discussions with each coder to maintain uniformity of decisions. These discussions centered on difficulties deciding how a particular study’s characteristics fit into the coding rubrics, mostly resulting from the emergent nature of the

Table 1. Stratified random sample of studies

Subject Matter	Number of Published Papers	Final Sample Size
Mathematics	309	30
Science	335	29
Career and Technical Education	497	28
Language Arts	179	30
Social Studies	465	28
Total	1785	145

coding process (Patton, 2002). For example, every coder encountered a surprising number of papers that did not report research findings. We decided to add a non-research category to the coding results to fully report those findings. Another example of the evolving nature of this review surfaced as the types of qualitative inquiry from each content area were cross-checked. Specifically, the mathematics sample contained no narrative methodology studies, but the social studies and language arts fields did. Therefore, the mathematics sample was re-examined through that lens to ensure uniformity across the five content areas.

RESULTS

Summary of the Literature

Coders noted the distinctly low percentage of literature in scholarly, peer-reviewed journals actually dedicated to the presentation of research findings: 46% in career and technical education,

29% in social studies, 31% in science, 23% in language arts, 44% in mathematics, and 34% across all five subject matter areas (see Table 2). Of the non-research articles, 41% provided anecdotal descriptions of specific strategies used in classrooms for integrating technology. Only 20% of the non-empirical articles were dedicated to the development of theoretical models based on prior research. A few scholarly articles only offered opinions (9%). In Table 2 and in the descriptions that follow, studies may be counted more than once in the subcategories, so the totals in the subcategories may be greater than the number of studies in that category. For example, in the mathematics area, the 10 qualitative studies register as 12 subcategories.

Career and Technical Education (CTE). CTE research carried a distinctly international flavor. Studies included the use of email and discussion groups by rural farmers in Australia (Mulcahy, 1998), the introduction of Information and Communication Technology (ICT) into all of the schools in Estonia (Toots & Lanpere, 2004), the

introduction of interactive whiteboards into African schools (Slay, Siebörger, & Hodgkinson-Williams, 2008), and the use of on-line discussion groups (De Smet, Van Keer, & Valcke, 2008; Steinkuehler & Duncan, 2008). These studies focused primarily on upper middle grades through adult education. Of the 28 studies in this sample, 57% were categorized as non-research, 36% qualitative, 7% were quantitative, and 0% were mixed methods (see Table 2). The non-research papers were mostly composed of anecdotal description (25%), opinion papers (25%), and theory development (19%).

Social Studies. The social studies sample also included an international scope. For example, in the United Kingdom (UK), studies have explored the impact and potential of web-based technologies (Fernandez-Cardenas, 2008; Richards & Wrigley, 1996; Selwyn, 2007); in Canada, researchers have viewed information technology as a vector for enhancing collaborative learning (Reed & Mitchell, 2001); in Japan, the use of geographic information systems has evolved far enough to be considered a distinct field (Sasaki, Oguchi, Okabe, & Sadahiro, 2008).

Approximately 33% of the sample literature of technology in social studies focused on the learning of history, 23.3% on bridging theory and practice, 20% on the learning of geography, 16.7% on the understanding of culture, and 6.7% on teacher education. These percentages indicated a potential gap in the area of teacher education and over-representation of practice related pieces.

These practice-related pieces often provided the description of one or two technology products and described how they could be applied in educational settings (e.g., Bodson, 2008; Lynch et al., 2008). These articles advocated for the versatility that was possible through technology for teaching geography, although the authors often failed to provide specific illustrative examples that would move the discussion about technology innovations forward. One promising work described the use of computer simulations as a tool for replicating

real-life phenomenon through the exploration of visual interactions within artificial societies (Berson & Berson, 2007). Such models may hold the potential to assist students understanding of the complex dynamics that influence how societies evolve and adjust.

The paucity of research publications in social studies obscured potential trends in research design and methodology. The majority of this sample reported using qualitative methodologies (88%), primarily depending on interviews (e.g., Hess, 2007) and to a lesser extent, observations as the primary data collection tools. Ethnographic methods were also used to explore the communicative acts in the collaborative creation of web pages (e.g., Fernandez-Cardenal, 2008). Case studies using the class as the unit of analysis were also found (e.g., Reed & Mitchell, 2001), though some studies involved multiple sections of specific courses at different universities. Surveys were employed in several studies (e.g., Longhurst, 2003); however, the method of analysis varied widely, from the use of simple descriptive statistics to more sophisticated inferential techniques. Several studies offered ideas on a research agenda for the field (e.g., Defazio, 2006; Ely, 2008), lending support to the belief that current literature lacks the ability to link instructional theory to practice.

The 28 studies in the social studies sample were categorized as 71% non-research, 25% qualitative, 4% mixed methods, and 0% quantitative (see Table 2). The 20 non-research papers were mostly composed of instructional strategies (35%), anecdotal description (35%), theory development (19%), and opinion papers (5%).

Science. The science sample included studies from multiple fields of science education (e.g., middle school science, high school science, computer science education, and first-year engineering learning communities). These studies varied widely in focus. For example, Lawrence (2000) developed a framework for curriculum development in science education using apprenticeship activities with high school students.

Bowman, Koirala, and Edmonds (2000), on the other hand, investigated how one teacher altered her pedagogy to include graphing calculators. Boulet, Boudreault, and Guerette (1997) compared the effects of distance education versus the traditional classroom in computer science education and found a slight advantage for distance over traditional education. Jenkins (2006) reported on the attitudes of students in England toward their secondary school science education. Min (2005) examined the effect of a hypermedia-enhanced problem-based learning environment in astronomy on sixth-graders' science knowledge, attitudes toward learning science with technology, and motivation toward learning. The 29 studies in the science sample were categorized as 69% non-research, 14% quantitative, 10% qualitative, and 7% mixed methods (see Table 2). The 20 non-research papers included anecdotal description (55%), instructional strategies (30%), and theory development (15%).

Language arts. A review of the literature in language arts revealed that many of these studies also did not present research findings. These studies discussed the integration of technology through multiple tools and strategies (e.g., interactive whiteboards, computer-assisted instruction, computer-assisted discussions, computer-aided peer review, use of the internet, multimedia presentation of museum education, and digital technology to enhance literacy).

The six studies reporting research findings represented three distinct types of inquiry: (1) investigating teachers' perception of the use of case methodology for instruction in a graduate level course (Baker, 2005; Gray, 2001); (2) examining the nature of English language arts teachers' learning during technology professional development activities and the impact on their later technology-supported pedagogy (Hughes, 2005); and, (3) studying language arts teachers from the United States, Canada, and Australia and their use of literature-based collaborative Internet projects in their elementary classrooms

(Karchmer-Klein & Layton, 2006; Malloy & Gambrell, 2006; Siegel, 2006).

The 30 studies in the language arts sample were categorized as 80% non-research, 17% qualitative, 3% mixed methods, and 0% quantitative (see Table 2). The non-research papers were mostly composed of anecdotal descriptions of experiences with technology use in the classroom (58%), followed by opinion pieces (16.7%), theory development (13%), and instructional strategies (13%).

Mathematics. The mathematics sample studies investigated and discussed a wide variety of technology (e.g., computers, computer software, online courses and course materials and grading, web-based learning environments, multimedia, and interactive whiteboards) with over half of the studies focusing on computers and the Internet. With the emergence of new web-based technologies and the rise of java- and flash-based applications (i.e., virtual manipulatives as in Cavanaugh et al., 2008; Suh & Moyer, 2007), this new emphasis caused little surprise or concern. However, we also expected that the large number of debates surrounding the effectiveness of calculators and graphing calculators (e.g., Ellington, 2003, 2006) would have resulted in another cluster of studies reporting such research. In this sample, none of the articles discussed the use of calculators in the classroom. Although the absence of such research in the sample does not translate into a complete absence of the topic from the greater population of studies, it does raise a concern about a potential weak point or gap in the mathematics research literature.

Finally, in three studies, approximately 10% of the sample, methodology was either not addressed or lacked sampling information such as sample sizes (Hayes & Mayerick, 2001; O'Connell & Phye, 2005; Zucker, Tinker, Staudt, Mansfield, & Metcalf, 2008). Other reviews have called for better reporting of standard information such as methodology, sample sizes, and standard deviations (e.g., McCoy, 1998; Mervielde, 1977; Nowak, 1969; Triandis, 1976). In light of these

calls, we concluded that these studies may be indicative of a general weakness in the research literature. So, not only are there gaps in the existing literature, but the studies that have been completed in this area may be limited by their design and the information they provide. As a result, educators are left to evaluate the effectiveness of some types of instructional technology on their own without a dependable research foundation.

We identified 50% of the 30 mathematics sample studies as non-research, 33% as qualitative, 17% as quantitative, and 0% as mixed methods (see Table 2). The non-research papers were mostly composed of instructional strategies (40%), followed by theory development (33%), anecdotal description (20%), and book reviews (7%).

RESEARCH DESIGNS

An examination of research designs revealed an imbalance across all five subject areas. Quantitative designs accounted for only 22% of all studies; mixed methodology was only 8%, and qualitative designs accounted for the remaining 70% (see Table 2). These research methodologies represent fundamentally different beliefs. Quantitative methodology, seeks to capture the essence of reality, setting the researcher as a dispassionate, objective observer. In this methodology, controls are set in place to isolate causal factors in a system (Hewitt, 2006). Qualitative methodology, on the other hand, recognizes the need to understand the unquantifiable factors that influence the way people behave in different settings. Postmodernist, constructionist, and advocacy researchers tend to gravitate toward these methodologies (Cresswell, 2007; Patton, 2002). Rather than attempting to create generalizability or lay claim to causal inference, qualitative inquiry seeks to understand why something happens in a particular setting. In both cases, the research question should drive the methodology rather than the reverse (Tashakkori & Teddlie, 1998). Researchers need to be well-

versed in both types of methodology so that the types of questions they can ask are not limited by methodological concerns.

Alternatively, pragmatists choose whatever methodologies fit the question, taking advantage of the power of both quantitative and qualitative methodology (Cresswell, 2007; Patton, 2002). Tashakkori and Teddlie (1998) and Datta (1994) described several practical reasons for using mixed methodology (historical use of both quantitative and qualitative methods, support of research community and funding agencies for both methods, the influence of both methods on educational policy, and the demonstrable effectiveness of both methods). Shadish (1995) also made a case for the complementary nature of quantitative and qualitative methods. With such important advantages to mixed methodology, its low representation in every subject matter reveals a significant weakness in educational technology research.

TEACHER KNOWLEDGE

We used the CFTK framework to identify aspects of teacher knowledge in technology studies across the five fields. Of the 145 studies, 48 addressed teacher knowledge in some manner (see Table 3). Only eight of the 48 addressed knowledge of Individual Context. In fact, the samples for language arts and science failed to address Individual Context at all. Surprisingly, only one third addressed knowledge of Subject Matter. Finally, less than one third included knowledge of Discernment.

Individual Context represents the aspect of knowledge related to understanding the way student characteristics affect a learning situation. Distinct from the internal factors of Orientation (e.g., beliefs, affect, efficacy), these Contextual factors (e.g., gender, culture) may influence the way students react to cooperative learning, mastery learning, and peer tutoring or to technology or the Subject Matter (Ronau et al., 2009). Because technology tools often rely heavily on each of

Table 3. Aspects of teacher knowledge addressed

CFTK Aspects	Career & Technical Education	Social Studies	Science	Language Arts	Mathematics	Total
Subject Matter	2	5	1	1	7	16
Pedagogical Knowledge	3	6	5	4	13	31
Orientation	2	6	4	4	10	26

Individual Context	1	2	0	0	5	8
Environmental Context	5	6	7	4	7	29
Total Number Relevant	11	8	9	5	15	48
Note. Some studies addressed more than one aspect, so aspect numbers may not add up to the overall number of relevant studies.						

these strategies, the lack of research to address the effect teacher knowledge of contextual differences limits the ability of that research to adequately address the needs of educators wishing to integrate technology effectively.

STAGES OF TECHNOLOGY INTEGRATION

Table 4 reveals a large imbalance in the number of studies across each subject matter area addressing the stages of TPACK favoring the mathematics field. Because TPACK has been more actively pursued in the mathematics field, it came as no surprise to see that this field demonstrated a more comprehensive examination of each stage of tech-

nology integration, accounting for a minimum of 60% of all studies addressing any particular aspect.

Although 65% of the sample studies addressed pedagogical knowledge, very few studies addressed TPACK stages of integrating technology, explicitly or implicitly, in any area besides mathematics. By blending CFTK and TPACK developmental views, a new understanding of instructional technology emerges: Pedagogical knowledge alone will not ensure effective technology integration. Tankersley, Landrum, and Cook (2004) suggested that one reason teachers fail to make instructional changes may be a lack of support. In the case of instructional technology, support may simply mean providing access to technology tools. It may also include professional development that familiarizes teachers with the TPACK

Table 4. TPACK stages addressed

TPACK Stages	Career & Technical Education	Social Studies	Science	Language Arts	Mathematics	Total
Recognizing	4	7	3	3	21	38
Accepting	4	4	0	3	21	32
Adapting	4	2	5	3	21	35
Exploring	1	0	0	2	17	20
Advancing	0	0	1	3	18	22
Total Number of Studies	5	8	9	5	25	53
Note. Some studies addressed more than one stage of TPACK, so studies addressing a particular stage may not add up to the total number of studies addressing TPACK.						

framework and methods of integrating technology into instruction.

DISCUSSION

This chapter endeavored to provide a systematic review of the literature about instructional technology. The authors hope that this information increases the ease with which teacher educators can synthesize research findings to integrate the most effective instructional technology tools into their courses. We also hope that the three frameworks presented here inform future instructional technology studies regarding the needs of the research community and educators. To summarize, we consider the limitations of this review along with the findings and the utility of our three research lenses: research design, teacher knowledge, and technology integration. We conclude with some final recommendations.

LIMITATIONS

The subjective nature of much of the coding constituted the greatest limitation to this study. Although great effort was made to coordinate responses through the use of coding tables and discussions for each ambiguous decision, some variability was unavoidable. However, we did attempt to ensure a systematic process through coordinating discussions to increase the possibility of replication and verification.

A second limitation arose from the use of a single random sample from each subject area. The randomization process is the most robust way to ensure representativeness and lack of sampling bias (Shadish, Cook, & Campbell, 2002), and each subject area had a large enough sample size to achieve sufficient power to realize that representativeness. However, multiple samples could have been used to cross-validate our findings.

The new design of using the CFTK and TPACK models together as a lens for examining research designs created a third limitation to this study. With the relatively new nature of each framework (TPACK from Niess, 2005a, 2008; CFTK from Ronau et al., 2009), a certain degree of misalignment between the vocabulary of the sample studies and the frameworks was inevitable.

FINDINGS

The use of the research design lens revealed a surprisingly low percentage (34%) of research studies. Of these research studies, qualitative research designs constituted a disproportionate amount of the methodology types (70%). Mixed methodology, on the other hand, was nearly nonexistent (8%). Finally, rather than an even 20% for each field, the breakdown of studies indicated an imbalance in the number of papers on instructional technology across the fields (mathematics, 17%; science, 19%; CTE, 28%; language arts, 10%; and social studies, 26%), highlighting a lack of focus on language arts technology education.

THE RESEARCH LENSES

As a byproduct of the review, we also considered the degree to which the lenses of research design, teacher knowledge, and technology integration interacted to contribute to understanding of the depth, scope, and balance of the available research in educational technology. The research design lens allowed us to compare published papers and study methodologies. The CFTK lens contributed an understanding of the types of teacher knowledge addressed by the sample literature. The TPACK lens offered insight into the way papers addressed technology integration in education. Taken together, these three frameworks revealed significant bias toward the use of certain designs, aspects of teacher knowledge, and only moderate

levels of technology integration. Broad research interests and findings exist; however, the large percentages of anecdotal descriptions and opinion papers disguise the lower number of research reports and theoretical models. The continuation of such a trend only hinders the ease with which teacher educators and researchers can integrate existing theory into practice.

RECOMMENDATIONS

The results of this study indicated that 65% of the sample studies on educational technology did not actually report research, and 70% of the research studies employed qualitative designs. This finding does not address the relative value of qualitative or quantitative studies or of research versus non-research studies: All of these designs have the potential of being valuable for understanding the role and impact of technology in education. On the other hand, if the assumption is that all of these study types are of equivalent value, then a reasonable conclusion would be a call for a balance among these designs in order to provide a broader lens to increase the understanding of educational technology. Currently, the evidence suggests that an imbalance exists in our research data that is biased toward non-research papers and qualitative designs among the research studies. Furthermore, as Whitehurst (2002) suggested, all types of evidence are not equal; their value to compare, evaluate, and monitor progress of the target of study forms a hierarchy of evidence or of study designs that are ranked from 1 (high value) to 6 (low value): (1) randomized trial (true experiment), (2) comparison groups (quasi-experiment), (3) pre-post comparison, (4) correlational studies, (5) case studies, and (6) anecdotes. Using his hierarchy as a lens, we see from the present study that the trend in educational technology study designs is to emphasize these methodologies in reverse order. Therefore, we recommend that the

educational community work toward a balance of evidence quality.

One way to address this imbalance is to use more mixed methodology designs. Tashakkori & Teddlie (1998) rejected the notion that qualitative and quantitative research designs are opposing sides of a long-standing argument; instead, they adopted a pragmatic viewpoint that uses each as a complementary tool to answer the complex educational questions that researchers are being challenged to answer today. They developed mixed methodology models that structurally employ both qualitative and quantitative designs at various stages of a research project. Only four papers out of the 145 papers analyzed in this chapter contained mixed methodology reports. As the research community strives toward balance in research design, mixed methodology should become a predominant design.

Further use of the CFTK and TPACK frameworks combined with a consideration for design and methodology may also help increase balance in educational technology research. TPACK offers a balance of developmental levels of technology integration by providing a structure for focus and scale, whereas CFTK contributes balances six different aspects of teacher knowledge. Taken together, educators have a robust tool for analyzing the effectiveness of instructional technology methods and bringing the best tools to the classroom.

APPENDIX A

American Mathematics Teacher Educators Association Guidelines for Implementing the TPACK Framework (Adopted June 19, 2009)

I. Design and develop technology-enhanced mathematics learning environments and experiences.

Educators use their knowledge of technology, pedagogy, and content to design and develop learning environments and experiences to maximize mathematics learning. They:

- a. Establish and utilize mathematical environments, tasks, experiences and resources to integrate technology tools that support learners' individual and collaborative mathematical learning and creativity;
- b. Design challenging and engaging mathematical learning experiences that utilize appropriate technologies to support the diverse needs of learners; and
- c. Identify and utilize strategies and activities that promote equitable access to and facility with technology resources.

II. Facilitate mathematics instruction with technology as an integrated tool. Educators implement curricular plans that integrate appropriate technology to maximize mathematical learning and creativity. They:

- a. Incorporate knowledge of learner characteristics, orientation, and thinking to foster learning of mathematics with technology;
- b. Facilitate technology-enriched, mathematical experiences that foster creativity, develop conceptual understanding, and cultivate higher order thinking skills;
- c. Promote mathematical discourse between and among instructors and learners in a technology-enriched learning community;
- d. Use technology to support learner-centered strategies that address the diverse needs of all learners of mathematics; and
- e. Encourage learners to become responsible for and reflect upon their own technology-enriched mathematics learning.

III. Assess and evaluate technology-enriched mathematics teaching and learning. Educators assess and evaluate mathematics teaching and learning using appropriate assessment tools and strategies. They:

- a. Assess learning of mathematics applying technologies when appropriate, reflect upon the assessment results, and communicate those results using a variety of tools and techniques;
- b. Assess learners' appropriate and ethical use of technology resources in learning and communicating mathematics;
- c. Use formative assessment of technology-enriched lessons and activities to evaluate mathematics learning and adjust instructional strategies accordingly;

- d. Align the technology expectations for assessment tasks and practices with that of mathematics instructional activities; and
- e. Evaluate and reflect on the effective use of existing and emerging technologies to enhance the mathematical learning of all.

IV. Engage in ongoing professional development to enhance technological pedagogical content knowledge. Educators seek, identify, and use technology to enhance their knowledge, productivity, and professional practice. They:

- a. Collaborate with others in ongoing professional activities to promote excellence in learning mathematics in technology-enriched environments;
- b. Promote social justice for access to and facility with technology in learning mathematics;
- c. Advocate, model, and promote safe, legal, and ethical use of technology for learning and exploring mathematics with learners, families and caregivers, and colleagues;
- d. Communicate and collaborate with families and caregivers, colleagues, and the larger community using appropriate technologies in order to nurture mathematical learners; and
- e. Exhibit leadership by demonstrating a research-based vision for integrating technology in teaching mathematics.

Appendix B

Coding instrument

Report Characteristics	Description
Author(s)	
Year	
Title	
1. Journal	
2. Volume	
3. Pages	
4. Content Area	
5. Content Topic	
6. Grade Level	
7. Description of Technology Tool:	
8. Description of the Outcome of Interest (Mark all that apply)	a) Student Achievement b) Teacher Knowledge c) Teacher Orientation d) Student Orientation e) Knowledge Transfer f) Other _____ g) Can't Tell

Appendix B continued

Report Characteristics	Description
9. Was the study population well described?	a) Yes b) No c) Can't Tell
10. Did the authors specify the sampling frame or universe of selection for the study population?	a) Yes b) No c) Can't Tell
11. Were the exposure variables valid measures of the intervention under study?	a) Yes b) No c) Can't Tell
12. Were the outcome and other independent (or predictor) variables reliable (consistent and reproducible) measures of the outcome of interest?	a) Yes b) No c) Can't Tell
13. Did the authors conduct appropriate analysis by conducting statistical testing (where appropriate)?	a) Yes b) No c) Can't Tell d) Not appropriate for this study e) Explain: _____
14. Did at least 80% of enrolled participants complete the study?	a) Yes b) No c) Can't Tell
15. Did the authors correct for controllable variables or institute study procedures to limit bias appropriately?	a) Yes b) No c) Can't Tell
16. Describe all potential biases or unmeasured/contextual confounders described by the authors.	
17. Other important limitations of the study not identified elsewhere?	
18. CFTK Aspects Explicitly Addressed for teachers	a) Subject Matter b) Pedagogical Knowledge c) Orientation d) Discernment e) Individual Context f) Environmental Context g) Can't Tell
19. CFTK Aspects Explicitly addressed for students	a) Subject Matter b) Pedagogical Knowledge c) Orientation d) Discernment e) Individual Context f) Environmental Context g) Can't Tell
20. TPACK Stages described (teachers only)	a) Recognizing b) Accepting c) Adapting d) Exploring e) Advancing f) Can't Tell
21. What type of research does this study conduct?	a) Quantitative b) Qualitative c) Theory Development/Literature Driven d) Other _____

continued on following page

Appendix B continued

Report Characteristics	Description
For Quantitative Studies	
22. Research design	a) Randomized experiment b) Non-equivalent control group c) Other _____ d) Can't tell
23. Group assignment mechanism	a) Random assignment b) Haphazard assignment c) Other nonrandom assignment d) Can't tell
24. Selection mechanism	a) Self-selected into groups b) Selected into groups by others on a basis related to outcome (e.g., good readers placed in the expectancy group) c) Selected into groups by others not known to be related to outcome (e.g., randomized experiment) d) Can't tell
25. Equating variables	a) None b) Prior achievement c) Other _____ d) Can't tell
26. If equating was done, was it done using a statistical process (e.g., ANCOVA, weighting) or manually (e.g., hand matching)?	a) n/a, equating was not done b) Statistically c) Manual matching
27. Sample Sizes	
28. Achievement measure used in study	a) Researcher Designed Assessment b) Teacher Made Assessment c) Standardized Assessment d) Other _____ e) Can't tell _____
29. Score reliability for achievement measure (note: if a range is given, code the median value)	
30. Metric for score reliability	a) Internal consistency b) Split-half c) Test-retest d) Can't tell e) None given
31. Source of score reliability estimate	a) Current sample b) Citation from another study c) Can't tell d) None given
32. Is the validity of the achievement measure mentioned?	a) No b) Yes
33. If yes, was a specific validity estimate given?	a) No b) Yes
34. If yes, what was the estimate?	
35. If a validity estimate was given in the report, what was the source of the estimate?	a) Current sample b) Citation from another study c) Can't tell d) n/a, validity was not mentioned in the report

continued on following page

Appendix B continued

Report Characteristics	Description
36. What was the nature of the validity estimate?	a) Concurrent validity b) Convergent validity c) Predictive validity d) Other e) Can't tell (e.g., simply asserted that the measure is "valid") f) n/a, validity was not mentioned in the report
For Qualitative Studies	
37. Type of Study	a) Narrative/Historical b) Biography c) Design Study d) Phenomenology e) Ethnography f) Grounded theory g) Case Study
38. Describe the methodology. (Mark all that apply)	a) Covert Observation b) Overt Observation c) Interview d) Focus Group e) Other _____ f) Can't Tell
39. Was there alignment between the nature of the data collected and the questions posed?	a) No Describe Issue: b) Yes Summarize: c) Can't Tell
40. Did the author proceed systematically (with the logic of decisions addressed)?	a) No b) Yes c) Can't tell
41. Was trustworthiness addressed?	a) No b) Yes Describe: 1) Persistent observation 2) Use of triangulation techniques 3) Peer debriefing 4) Negative case analysis 5) Referential adequacy 6) Member checks 7) Thick description 8) Dependability audit 9) Confirmability audit 10) Reflexive journal c) Can't tell
42. Any gaps in the coherence of the methodology?	a) No b) Yes Describe: c) Can't Tell

ABSTRACT

Design principles are universal and may be translated onto the newest trends and emergent technologies. In this research study, the authors combined the perspectives provided by two sources to create a set of recommended design principles for technology-enhanced learning environments. One source was the *How People Learn* framework (Bransford, Brown, & Cocking, 2000). The second source was a series of interviews conducted with pacesetters in the field of educational technologies. With the knowledge gained from these two sources, the authors created our own set of design principles. These principles may be used to guide evaluation, instructional design efforts, or best

practice models for exemplary use of educational technologies in the classroom.

INTRODUCTION

Hundreds of millions of dollars have been spent in recent years to improve and maintain technology infrastructure for schools. Now policymakers and the public want to know what impact this technology has had on student learning. To answer that question, states and school districts need parameters for evaluating their technology-related activities and using the data to guide their decision making. However, researchers have cautioned against drawing inappropriate cause-and-effect conclusions based on experimental studies (Olson & Wisher, 2002; Russell, 2001). What scientific

DOI: 10.4018/978-1-60960-503-2.ch803

cally based evidence is available on the impact of educational technology often is focused on the degree to which a particular technology leads to changes in learning or teaching (Lawless & Pellegrino, 2007). In fact, a better way of judging the impact of new technologies is to examine how they are used and the context in which the use occurs (Schifter, 2008; Zhao, Byers, Pugh, & Sheldon, 2001).

Instructional designers and researchers have stressed the need for robust design principles to guide the production of products and programs (e.g., Kali, 2006; Kali, Spitulnik, & Linn, 2004; Underwood et al., 2005). In this research we also chose to emphasize design principles because they are universal, and they translate to the newest trends and emergent technologies. To do so, we set out to combine the latest research perspectives with the most current leadership perspectives. We began by summarizing key perspectives of the How People Learn (HPL) framework for learning environments. The HPL framework is widely respected and provides recommendations that can be applied to the design of technology-enhanced learning environments. We interviewed pacesetters in educational technologies and reported emerging themes based on the thoughts of those pacesetters. These sources provided the foundation for creating our own set of recommended design principles for technology-enhanced learning environments. This approach combined the best of the past with fresh perspectives from the present.

IMPORTANT PRINCIPLES ABOUT LEARNING AND TEACHING

The National Academy of Sciences *How People Learn* book synthesized decades of research on how people learn to develop a framework for understanding the connections between cognition and instruction (Bransford, Brown, & Cocking, 2000). This report is widely embraced as a seminal work for educators and researchers alike. In fact,

How People Learn (HPL) is becoming widely accepted as a theoretical framework, and that is how we use it here. That work provided the theoretical foundation for designing and conducting the interview study of the pacesetters.

Although the HPL framework provides many important teaching and learning implications, we highlight four of the principles that have particular importance in the design of technology-enhanced learning environments. Each has a solid research base as well as important implications for how teachers teach. Each principle also helps designers think about technology's role in the design and delivery of effective learning environments.

One important principle about the way people learn is that “students come to the classroom with preconceptions about how the world works” (Bransford et al., 2000, p. 14), which include beliefs and prior knowledge acquired through various experiences (e.g., Lin, 2001; Pressley et al., 1992). This learning principle suggests that students start to make sense of the world at a very young age. In many cases students already hold multiple conflicting views before learning new information, as a result, they create their repertoire of views without reflecting on their existing knowledge. This principle implies that designers of effective technology-enhanced learning or instruction should build on students' preconceptions and learning styles, allow decision making, and foster students' multiple intelligences.

Another HPL principle is that “to develop competence in an area of inquiry, students must have a deep foundation of factual knowledge, understand facts and ideas in the context of a conceptual framework, and organize knowledge in ways that facilitate retrieval and application” (Bransford et al., 2000, p. 16). Numerous studies comparing performance by experts and novices have shown that experts not only obtain richly structured knowledge bases that allow them to plan a task, notice patterns, generate reasonable arguments, and draw analogies to other problems,

but they also exhibit more organized conceptual frameworks that allow for greater transfer.

This learning principle suggests effective learning environments are knowledge centered and based on developing richly structured information foundations. Instructional designers should center the learning environment on what is taught, why it is taught, and what competence or mastery looks like.

A third principle from the HPL framework is that “a metacognitive approach to instruction can help students take control of their own learning by defining goals and monitoring their progress in achieving them” (Bransford et al., 2000, p. 18). Most educators agree that metacognition is one of the most important cognitive skills among intelligent human activities. Good teachers provide the time, space, and materials necessary to promote metacognitive skills such as self-regulated learning. Reciprocal teaching, for example, is a technique designed to improve students’ reading comprehension by helping them explicate, elaborate, and monitor their understanding as they read (Palinscar & Brown, 1984). This learning principle suggests designers must incorporate metacognitive activities into the subject matter that students are learning in order to improve understanding and help students transfer learning to new settings and events.

The fourth principle of the HPL framework is that “learning is influenced in fundamental ways by the context in which it takes place. A community-centered approach requires the development of norms for the classroom and school, as well as connections to the outside world, that support core learning values” (Bransford et al., 2000, p. 25). Learning is a collaborative process in which students actively construct and receive explanations and ideas and negotiate meanings. Such collaboration can help students engage in deeper cognitive processing, such as clarifying thinking, reorganizing information, correcting misconceptions, and developing new understanding. This principle suggests that designers must

incorporate a collaborative mechanism in the design process for students to experience cognitive conflicts, hear different perspectives, and ultimately accomplish the learning tasks with the help of their peers or experts.

METHOD

Participants

For this study we identified key pacesetters in educational technologies from a multitude of specialties. These pacesetters were also directly or indirectly at the forefront of the newest initiatives. We sought representation from the following categories at the highest level of management or peer reputation: the U.S. Department of Education Educational Technology Office, program officers for federal educational technology initiatives, grant awardees, state government technology directors, educational technology professional organizations, educational technology futurists, gaming and simulation experts, educational technology journal editors (both peer-reviewed and trade journals), and university professors. We wanted a widely representative group to eliminate single-field bias. The pacesetters’ diversity added depth to the information and insights we collected from them. Their experiences, from both their personal use of various technologies and the individual circumstances of their experience, informed their perspective.

Procedure

We began our research by recruiting three educational technology experts as advisors and developing a list of possible interview participants. These advisors have been involved in large educational technology initiatives and represent broad perspectives: national initiatives, curriculum development, teacher professional development, professional organizations, and the academic

Table 1. Interview questions

<i>Question 1. What makes an educational technology or its use exemplary?</i> This question sought the criteria that experts consciously or subconsciously use to rate educational technologies. We phrased the question to show that the choice of technology and the way it is used matter.
<i>Question 2. Based on your criteria from question 1, identify which technologies on the list below you would consider exemplary. Please note that this list is not exhaustive.</i> Here we wanted to prompt the interviewee to provide perspective on a wide range of technologies. We were concerned that without the list interviewees might not think broadly or that many of them would focus too narrowly on topics that were highly salient at the time, such as videogames or the latest social networking site. By the same token, we also were concerned about skewing their perspective by providing a list. To address this concern, we eschewed a categorization scheme for now and listed the items in random order.
<i>Question 3. Now that you have identified which technologies from the list that you feel are exemplary, please select at least three of those technologies to discuss with us. We would like two types of information about each technology: Identify the features you like about that technology, and give the advantages and disadvantages of using that technology.</i> We wanted to focus the discussion on the design features that make a technology or its use particularly effective. From this information we hoped to generate a list of <i>exemplars</i> , which are discussed elsewhere in this special issue.
<i>Question 4. In your opinion, which technologies show the most future promise for educational use?</i> We wanted to focus on the idea of “promise” here. Perhaps there are existing technologies that are underutilized or could be ported over to education. Perhaps there are some that have had an impact in other areas, such as business, which should be considered for educational uses. Perhaps some are being used in extraordinary ways somewhere but have received little publicity.

world. The research team teleconferenced with these advisors multiple times. We sought consensus on the study method and interview items.

We also conducted interviews with three people not on the research team to test the item wording and length of interview. We then made minor revisions to the protocol. The group consensus and initial interview process were themselves informative to our overall research study. Table 1 shows the final four questions with a rationale for each.

Recruitment consisted of calling or e-mailing participants to request interviews. When a candidate agreed to participate, we sent a follow-up e-mail to confirm participation, scheduled an interview, and mailed or e-mailed a cover letter, consent form, and the interview protocol. We interviewed 18 pacesetters; however, two declined to consent. Therefore, this paper features the perspectives and insights of 16 pacesetters. We conducted the interviews by phone; the calls typically lasted about 40 minutes. One team member took notes, while another guided the interview and asked the questions. Interviewees also had opportunities to comment about topics or technologies not included in the interview protocol. For each interview the notes were typed into summary format, and both team members

revised them until it was agreed that the summary fairly represented the conversation. In many cases the interviewee either e-mailed or faxed follow-up details.

Data Analyses

The interviews consisted of four questions. In the present article we report on the findings for questions 1 and 4. The results for questions 2 and 3 are described elsewhere in this special issue. From the interview data we conducted a content analysis to identify thematic patterns for each question. We first did this vertically within individual cases before moving across cases, using the constant comparative technique outlined by Miles and Huberman (1994). Then we refined analytic categories and tested for reliability between coders and used the categories to examine data from all interviews.

RESULTS

Pacesetters generally provided detailed, specific comments about what makes an educational technology or its use exemplary. They typically reiterated their initial comments from various angles

throughout the interview. Here we present the seven major themes that arose from the interviews along with pertinent comments from pacesetters.

Technology Theme 1: Create a Learner-Centered Environment

Technology itself is not an answer in education. The technology must have a purpose, such as to enhance teaching or learning or to promote problem solving. Pacesetters considered a technology exemplary if it resulted in substantial gains for the learner. To that end, technology that emphasizes a learner-centered environment and allows learner control has a significant potential to result in more substantial learner gains, making the technology exemplary. Pacesetters also recommended that the focus be on the learning, not the technology. Furthermore, pacesetters said technology that employs experiential or situated learning has significant impact on increasing student learning, motivation, and retention of content. Additionally, they considered technology that supports individualized learning and fits students' needs as highly effective. Here are some comments from pacesetters:

To get at what helps people learn, use four broad areas: Who is the learner, how do they learn, what are their intellectual capabilities, and what are their strengths and weaknesses? If we're going to envision a future of technology and learning, we should use this framework for thinking.

Technology is exemplary if you can tie it to student achievement. There are a lot of tools thrown out into the classroom, but if you can't tie it to student objectives, it's meaningless. A tool without a task has no context using technology. Until we can help schools with methodology, it is ineffective.

Good educational technologies engage learners (scaffold learners) toward meaningful problem solving. Exemplary technology use is a function

of the alignment between the specific problem-solving/reasoning and the technology tool used to assist that reasoning. Exemplary lessons with technology would be those which allow students to make discoveries for themselves, such as a scientist would.

When you talk about exemplary learning, you aren't really talking about the technology at all... It's when the technologies are applied to certain circumstances that makes all the difference. For instance, in some cases the laptop is effective; in some cases it's not. It depends on many factors, such as the school districts and principals. We should be looking at what is going on in the classroom—get away from the discussion on technology, and focus on teaching and learning.

Experimental educational technologies are the new paradigm in learning, as they are interactive. The outdated 20th century paradigm involves passive technologies where you click on something and read information.

Technology Theme 2: Support Engagement, Interactivity, and Motivation

Educational technology must be engaging, interactive, and motivating. Pacesetters said engagement was extremely important for getting students interested in further learning. Thanks to videogames and communication tools, technology already is prevalent in many students' lives, and can be highly motivating and conducive to student learning. Likewise, interactive technology that allows students to exchange work, ideas, and data and that also allows for multiple platforms provides exemplary educational experiences, pacesetters said. Students who use technology to see and analyze real-time data are much more engaged and interested in what they are learning. Here's what pacesetters said:

Education technology moves away from text-based to engaging game and simulation education.

I think technologies that allow kids to experiment in a dynamic environment are exemplary. Kids can “push” in one place and “see what happens” in another place. It’s not static. Google Maps are an exemplary technology because they are not static and you can experiment.

Technology provides firsthand experience rather than reading (the material) from a textbook, and therefore becomes a more memorable and exciting learning experience. Students are more likely to remember and retain this information. When students see real-time information and real events happening, they are much more engaged and interested in what they are learning about. More learning takes place, students remember more, and dig deeper. Students are actually learning more in the situated learning perspective.

Technology Theme 3: Promote Ease of Use and Cost Effectiveness

Pacesetters said exemplary technology is easy to use and versatile. Several reasoned that a technology that works consistently and is simple to implement would naturally reach a larger audience. Cost is also a consideration. Cost includes production, training, use, maintenance, and the need for updates. Several pacesetters said technology must be “lower end” enough to work in the school and within the school’s resources. One pacesetter said the iPod was an exemplary educational technology:

The iPod is ...a technology that has gained success because of pervasive use and ... it could be easily adapted to the classroom...Ease of use is an important feature for exemplary technology because it can make a big impact when it is used on a widespread basis.

Technology Theme 4: Provide Assessment

Exemplary technology features automated ongoing assessment and formative feedback embedded in the technology for quicker and more sophisticated reinforcement. Learners should be able to receive feedback and assessment in all contexts or lessons, pacesetters said. An exemplary technology works for teachers too, the pacesetters noted. If teachers can integrate a technology effectively into their teaching—even if that means a realistic amount of professional development—the technology ultimately has a better chance of impacting student achievement. Add to that teachers’ ability to combine a technology with another in their teaching, and you’ve got an exemplary technology, pacesetters said. Here’s what one pacesetter—a technology expert representing a state department of education—said:

...feedback needs to be quicker and can be quicker via use of technology and to also get more sophisticated feedback. If we’re going to envision a future of technology and learning, we should use this framework for thinking. Add up everything, but if it doesn’t help someone learn, even if it’s great, it doesn’t really make someone better or help them learn. So we need quick assessment and feedback.

Technology Theme 5: Support Social and Community Building

An educational technology that incorporates a high degree of social and community-building opportunities is effective, pacesetters said. This type of tool lets students access current data and information and build a social network around their learning task. The pacesetters predict technologies that effectively use communication and collaboration will have a significant impact on education. Communication technologies that enable students to access information and resources from global

intelligence pools will quickly revolutionize how students work through academic courses, obtain information, and collect their own data. Students will communicate with mentors and peers in other countries, unconstrained by geography. Social networking technologies will provide students with invaluable expertise and support as they take advantage of greatly increased options for attending classes and as they make better use of distance human interactions and artificial intelligence. Here are some insights from pacesetters:

The vast number of interactions made possible through technology, including application sharing, tools for chat rooms, bringing people together for sharing models, and roles, and addressing the different aspects of community coaching are exemplary features of educational technologies.

The social and community building aspect is an overall advantage of technology. Social network is crucial to learning. Technology that connects people is what's needed to get learning communities going.

Technology Theme 6: Promote Scalability, Utility, Dissemination, and Portability

Pacesetters said scalability, utility, dissemination, and portability are important criteria for exemplary educational technology. A technology should be able to handle a large number of students and reach a large audience, but it should also adapt easily to other contexts and across different platforms. Future educational technology must be portable too, pacesetter said, so students can take a tool with them outside of school to learn anywhere, any time. Here are some other pacesetter comments:

Some technologies have one primary use, and the user can't get beyond that one use. An example of this is using a graphing calculator to graph a mathematical equation. This technology doesn't

apply to other contexts; if there are a dozen ways in which the technology can be used, there will be more educational opportunities.

The content delivery platform will always change; there will always be new software and new hardware. The educational assets should not go obsolete when you go from a tablet to a handheld. Ideally, what you have in your educational initiative is a set of learning experiences that cuts across different technologies.

Technology Theme 7: Foster Knowledge Construction/Integration

Embedding components of knowledge construction within a technology has potential for helping students develop a deeper conceptual understanding of the material they're learning. Pacesetters said knowledge construction tools could promote immersive environments in which students not only create their own environments or genres, but share them with other students. Here are some comments from pacesetters:

Argumentation tools and virtual reality technologies are potentially effective approaches to developing a deeper conceptual understanding.

Technologies that have potential as concept builders and problem-solving scaffolders would be future exemplary technologies. Immersive environments have this potential as well as knowledge construction programs such as STELLA or Wikis.

The technology is enabling multiple paths to exploring information. Computer offers you interesting ways to do research- structure information.

StorySpace is a hypermedia construction program. This is a non-linear and promotes student construction of their understanding. If the technology is non-linear, students can make more links to the concepts involved.

DESIGN PRINCIPLES FOR EXEMPLARY EDUCATIONAL TECHNOLOGIES

In this section, we describe six design principles that resulted from clustering learning principles from HPL with the technology themes from pacesetters. In Table 2 we illustrate the connection between HPL, pacesetters, and design principles. Examples for each design principle are also included.

The Technology-Based Instruction Should Promote Learner-Centered Experiences

According to Callahan and Switzer (2001), technology plays an important role in facilitating quality education. They also wrote that the very first dimension of facilitating a quality education is that students should be at the center of their own learning. Pacesetters agreed in theme 1. Thus, designers should pay close attention to the knowledge, skills, and attitudes that students bring to their understanding of knowledge. How much the technology impacts students and their learning depends on the instructional strategies that accompany its use (Russell, 2001; Summer-ville & Reid-Griffin, 2008). To create a learner-centered environment, designers must integrate effective instructional strategies and recognize students' prior knowledge, skills, and attitudes and a variety of approaches to their own learning (Trinidad, 2003).

The Technology-Based Instruction Should Scaffold Knowledge Construction

According to the theory of HPL, learning occurs when a learner actively builds meaningful cognitive representations and mental models. An educational technology should help students make sense of new materials. For example, a technology-

supported argumentation tool engages students in constructing scientific knowledge claims, evaluating the claims constructed, and establishing the objectivity of scientific explanation (Duschl, Ellenboger, & Erduran, 1999).

The Technology-Based Instruction Should Support Problem-Solving and Metacognitive Skills

Technology can provide numerous representational tools that expand and strengthen human cognitive capacities such as problem solving. The problem-based learning framework uses a real-world problem to create a cognitive connection to complex, real-world problem solving. To that end, instructional designers should incorporate meaningful problems with appropriate goals central to subject matter concepts.

The Technology-Based Instruction Should Support Assessment

Technology that facilitates cycles of ongoing assessment is considered exemplary. An online threaded discussion forum, for example, lets students post their work where they can get feedback from a wider range of critics, reflect on what they've learned, and compare their work with peers' products. Such technology supports ongoing assessment, has the potential to promote meaningful learning, and contributes significantly to teaching and learning for understanding (Wiske, 2006).

The Technology-Based Instruction Should Provide a Community of Learning

Communication and collaboration are two important components that an exemplary educational technology offers students. For instance, students use digital media and environments to communicate and work collaboratively, includ-

Table 2. Illustrative connections between HPL, pacesetters, and 21st century educational technology design principles

Important Principles from HPL	Pacesetter Perspectives	21st Century Educational Technology	
		Design Principles	Examples of Learning Environment Features
Build on student preconceptions and learning styles: Students come to the classroom with preconceptions about how the world works.	Emphasize a learner-centered environment: Technology should allow students to investigate and make discoveries for themselves.	The technology-based instruction should promote learner-centered experiences.	Support learners' preconceptions, prior knowledge, beliefs, and experiences. Offer learners choices. Foster learners' multiple abilities. Reinforce multiple distributed intelligences. Support both visual and verbal learners. Encourage learners to investigate personally relevant problems.
Support development of richly structured knowledge foundations: Students must have a deep foundation of factual knowledge, understand facts and ideas in the context of a conceptual framework, and organize knowledge in ways that facilitate retrieval and application.	Foster knowledge construction/integration: Technology should provide multiple paths for students to explore information.	The technology-based instruction should scaffold knowledge construction.	Enhance organized content knowledge. Provide knowledge construction or organizational tools. Create a cognitive conflict that contradicts learners' intuition. Encourage learners to reconsider their repertoire of ideas. Enable manipulation of factors in models and simulation.
Provide metacognitive activities: Students should take control of their own learning by defining goals and monitoring their progress in achieving them.	Support engagement, interactivity, and motivation: Technology should use real-time data and live events to encourage students to be more engaged and interested in what they are learning.	The technology-based instruction should support problem-solving and metacognitive skills.	Promote self-regulated learning. Help learners engage in expert-like thinking processes. Provide ample times for decision making. Provide learners with opportunities to practice real-world situations. Present options for learning skills in a virtual world for application to real-world situations. Allow the transfer of pragmatic learning changes to real-world environments. Support learners in articulating complex scientific ideas.
Encourage cognitive conflicts and hear different perspectives: Learning is influenced in fundamental ways by the context in which it takes place.	Support social and community building: Technology should allow students to build a social network around their learning task.	The technology-based instruction should provide a community of learning.	Support social/community building. Facilitate communication and collaboration among learners or with experts. Allow multiple platforms of communication. Employ multiple social activity structures. Enable multiple ways to participate in online discussions. Provide opportunities for learners to serve as instructors of their peers. Scaffold the development of classroom norms.
n/a	Promote scalability, utility, dissemination, and portability: Technology should be able to handle a large number of students, reach a large audience, and adapt easily to other contexts and platforms. Promote ease of use and cost effectiveness: Technology should be easy to use and affordable for the general public.	The technology-based instruction should support versatility.	Support utility. Allow dissemination. Allow learners to learn everywhere. Incorporate features for ease of use. Reach a large audience. Provide multiple opportunities for use. Enable virtual navigation for exploring complex physical systems.

		Design Principles	Examples of Learning Environment Features
n/a	Provide assessment. Technology should offer ongoing feedback and automated assessment to enhance student achievement.	The technology-based instruction should support assessment.	Support assessment. Provide feedback. Provide subsequent review. Enable just-in-time evaluation. Remedy weaknesses or skill deficits. Enable learners to evaluate the work of their peers.

ing from a distance, to support their own learning and contribute to the learning of others. Such processes also encourage students to develop cultural understanding and global awareness when they communicate and work with students from other cultures.

The Technology-Based Instruction Should Support Versatility

Although HPL does not explicitly address versatility, several pacesetters said educational technologies should be widespread, easy to use, and portable.

DISCUSSION

In conducting this study, we were faced with the familiar question of how to define educational technology and the relative importance of a technology versus its use. The pacesetters provided us valuable perspectives. In future research we must grapple with how educational technology research is actually used for decision making. One end of the spectrum proposes it is really not about the technology, it is solely about the context. Studies from this perspective are fundamentally so context bound that you can't generalize their findings. The other end of the spectrum portrays a tidy world in which an input equals a measurable output and how dollars are spent can predict with certainty the outcomes achieved. Although the *No Child Left Behind*-like need for accountability prefers the latter, reality may be closer to the former.

The interviews yielded many intriguing themes, the most often cited being the importance of engagement and interactivity in a technology. Implementation variables such as cost, ease of use, and teacher receptivity and adoption were also important. Pacesetters gave input on how exemplary technologies enhance teaching and learning, with problem solving and collaboration

being notable. Moreover, community networking and social networking technologies were most often cited for future education impact. As some sociologists accuse technology of isolating students and decreasing social skills, our findings make it increasingly apparent that students (and teachers, mentors, and educational technology leaders) recognize that technology has the power to bring people together and that collaboration via technology can greatly enhance learning.

CONCLUSION

Wager (1992) claimed that “the educational technology that can make the biggest difference to school and students is not the hardware, but the process of designing effective instruction” (p. 454). Our pacesetters delivered a similar message: It is not technology *per se* that improved student outcomes, but rather how the technology was used and integrated into instructional processes. The pacesetter interviews support the importance of the classroom context and the role of teachers rather than the technology itself.

In this study we searched for answers as to what constitutes good practice in the use of educational technology. Continued research will refine those answers. We recommend conducting ongoing dialog among the experts who see students and teachers on a day-to-day basis. We think their unique perspectives would further the knowledge base we’ve laid out. Future studies could also substitute an online survey for the live interviews. Regardless of the approach, we think the study of best practices in educational technology must be ongoing. After all, in the time it took you to read this chapter, a new technology has likely been developed or used in a different way by an educator.

KEY TERMS AND DEFINITIONS

Design Principle: A descriptor or characteristic which can be used by educators and designers to structure the content and features of an education technology and its implementation into curriculum.

Pacesetter: A person who is a leading influence in his or her field of study or work.

Educational Technology: The use of technology to improve teaching, learning and the school environment.

Learning Environment: Place or setting where learning occurs; not limited to a physical classroom and includes virtual settings in which learning takes place.

Instructional Design: A systematic approach to the design and development of instructional materials and products using objectives, teaching strategies and evaluation to meet learning needs.

Metacognition: The study of thinking and learning.

Criterion: The standard by which an evaluation is made

How People Learn: A book by the National Academies Press which describes a framework for understanding the learning sciences.

Rapid E-Learning in the University

Ivy Tan

University of Saskatchewan, Canada

Ravi Chandran

National University of Singapore, Singapore

DEFINITIONS OF RAPID E-LEARNING

Rapid e-learning (REL) is a phrase in common use since 2003. This article defines REL, describes types of REL authoring tools, discusses management and instructional issues surrounding REL in corporate and academic settings, and summarizes the experience of the National University of Singapore (NUS), an early adopter of the concept of REL since 2004.

Almost all current literature on the topic focuses on REL applications in corporate e-learning. There is very little academic research into issues surrounding REL because this is a recent development. At this stage of implementation of REL, the literature on the topic is limited. The following three definitions are commonly used:

1. Josh Bersin defined REL as a category of on-line training content, which can be developed in weeks, can be authored by subject matter experts (SMEs), and maintains instructional focus and quality (Bersin & De Vries, 2004). REL tools leverage on common software such as PowerPoint and then convert that to Flash or other formats for Web delivery with options to add audio and simple quiz. Content is published, edited, and republished by the SMEs with little or no assistance.
2. Patti Shank, President of Learning Peaks, broadened the definition to include rapid instructional design, development, deployment, and evaluation (Shank, 2006). REL is no longer just synonymous to the rapid authoring and development of content, but also to the streamlining of the entire project management process and production cycle.

DOI: 10.4018/978-1-60960-503-2.ch804

3. Another possible definition of Rapid E-learning is when the phrase is used to indicate how rapidly e-learning is being adopted or embraced by an organization. (Tan, Lee & Goh, 2004).

The definitions by Bersin & Associates and Patti Shank, which include process and product, are widely accepted as the main definitions of REL.

TOOLS FOR CONTENT AUTHORING

Rapid e-learning tools can be classified into two types of applications: synchronous, real time, and asynchronous, any time software. Synchronous applications include virtual classroom tools like WebEx, Centra, Elluminate, Breeze Live, Interwise, and other software in this category. Presentations recorded during live lectures are reused in an asynchronous setting.

Examples of asynchronous applications include Breeze Presenter and Articulate, which convert PowerPoint slides with audio narration into Flash animations with options to include videos, animations, progress tracking, and assessment quizzes. Software such as Camtasia, Captivate, and Qarbon Viewlets capture screens along with mouse movements and clicks.

Contribute, a scaled down version of Dreamweaver, allows SMEs to author and edit HTML pages in an interface that resembles Microsoft Word. Wikis and blogs can also be classified as REL tools because they enable SMEs to publish and edit content in asynchronous mode.

MANAGEMENT ISSUES

In Spring of 2004, Josh Bersin & Associates surveyed 228 e-learning developers, mostly from the corporate sector in the United States, concerning challenges faced. Results showed that the greatest challenge was limited financial resources, followed

by tight deadlines. Time and cost savings are main reasons why organizations embrace REL. According to Bersin and De Vries (2004), a course developed under the traditional production cycle with a timeframe of 3-11 weeks costing between \$5,000 to \$30,000 per instructional hour to produce with a team consisting of the SME, instructional designer, programmer, graphic artist, video and sound editors, and so forth, can be produced in less than 3 weeks with little or no budget and developed by the SME with professional guidance and templates.

The traditional production cycle:

Needs Analysis → Instructional Design → Development with technical team → Deployment → Evaluation

The REL production cycle:

Needs Analysis → Rapid Instructional Design and Development → Rapid Deployment → Rapid Evaluation

The main difference between the two production cycles is that the instructional design and development phases in the traditional cycle are being combined. The SME is responsible for hands on development of the final e-learning product with little or no help from the programmer and graphic artist. The final product can be rapidly published with the click of a mouse button. Questionnaires with predefined categories are used to ensure that evaluations are carried out rapidly and efficiently. From a management perspective, REL frees up developers' time and they can be assigned to projects that require their skills. It also solves the problem of instructional designers needing access to SME time.

INSTRUCTIONAL ISSUES

The instructional issues discussed here encompass type, or level of learning, content change, instructor control, and quality.

The first issue to consider when considering use of REL tools is the type of learning required. Blooms taxonomy classifies cognitive learning outcomes into six cognitive levels arranged in the following hierarchy: knowledge, comprehension, application, analysis, synthesis, and evaluation. REL supports learning at the knowledge and comprehension stage and can be implemented effectively when PowerPoint is used to deliver content. As we move up the Bloom's taxonomy, REL is not a good option because REL tools lack sophisticated capabilities to assess student learning beyond setting up simple quizzes. The tools cannot author games, complex interactivities, and simulations. It is difficult to use REL to assess if a student is able to apply a learned skill to a new situation. In certain disciplines, understanding of abstract concepts is classified as "knowledge," level 1 on the Bloom's taxonomy, but this is best taught through simulations. Developments of such courseware will not be rapid. Patti Shank (2006) said that REL is best suited for level 1 of the Bloom's taxonomy and for information broadcast, news, and updates.

The second issue is how frequently content changes. Maintenance cost is significantly reduced when SMEs are independently able to record or edit content using REL tools.

The third issue to consider is the autonomy of instructors and the control they exercise in determining content and methods of delivery for instructional material and courses. This is probably more frequently addressed in the academic setting than in the corporate setting. For example, some SMEs are not comfortable with the use of technology. In addition to writing content, the SME plays an active role in development and editing, which could be overwhelming, adding to pressure and workload. New SMEs teaching a course for the first time and not familiar with content authored by someone else may not be able to rapidly record a presentation with audio.

A fourth issue to consider is the quality of instructional materials. This is both a technical and

a pedagogical issue. In projects requiring studio quality sound and video, traditional methods are recommended.

The Role of Instructional Designers in REL

With REL, the role of instructional designers is slightly changed. Instructional designers act as guides and facilitators, helping SMEs write and develop content using REL tools. REL is usually used to author content in small chunks of reusable learning objects (RLOs). The design of the course containing a sequence of RLOs, assessment, tracking, forum discussions, deployment, course evaluation, and revisions still require traditional instructional design skills. Hence, the role of the instructional designer is not diminished with the use of REL. When REL processes and methods are properly applied, it is possible to produce high quality courses for both blended and distance learning.

Worksheets, Checklists, and Templates

A research report on REL released in June 2006 by the eLearning Guild showed that 72% of respondents to the research survey who use REL tools also use templates to facilitate rapid design and the streamlining of the production process.

Instructional designers and project managers have always used worksheets and templates in the traditional production cycle, such as the ADDIE model. De Vries (2006) has successfully demonstrated how worksheets and templates can efficiently streamline the production process. Bersin calls this a "development toolkit" consisting of templates and guidelines on the use of color, font, lines of text per page and so forth. De Vries's toolkit consists of analysis and module development worksheets which enable instructional designers to work together with the SME to author content quickly in a framework guided by pedagogy.

De Vries also designed a set of development, deployment, and evaluation checklists consisting of project management tasks to help instructional designers work more efficiently.

AN EARLY ADOPTER: THE NATIONAL UNIVERSITY OF SINGAPORE

The National University of Singapore (NUS) is a traditional research university with about 30,000 students. Students attend on-campus lectures. E-learning focuses on blended learning rather than distance learning. The Centre for Instructional Technology (CIT) at the NUS was set up in 1999 with the mission to provide a supportive environment for the exploration, development, and application of digital technologies to enhance teaching and learning.

In January 2004, the courseware team began a pilot project involving the use of Macromedia Breeze Presenter. The software enables faculty to enhance their PowerPoint presentations with multimedia content with ease. By installing a plug-in onto the user's PowerPoint software, audio narrations and quizzes can be added. The presentation is saved as a Flash movie on a Web server. These presentations can be classified as a group of Learning Objects created with Breeze. The learning objects can then be accessed online without launching PowerPoint and can be played on any PDA, PC, and Macintosh.

There were three main reasons for implementing REL at the university. The first reason is cost effectiveness. The courseware team had been developing multimedia courseware since 1999, adopting the traditional production model that involves a team of content experts, instructional designers, programmers, and graphic artists. While this method produced high quality courseware, the cost of maintaining and updating courseware is high. REL could reduce maintenance cost.

The second reason was to provide an efficient software solution to the instructors, which would hopefully result in greater buy-in to e-learning. The team observed that professors are not prepared to get involved in the development of complex courseware. Because PowerPoint is used extensively by instructors, an easy to use software that enhances the features of PowerPoint is more practical for most instructors rather than the service of a team of software developers.

Third, the CIT team hoped to build a repository of Breeze created learning objects quickly and efficiently. Learning objects could be shared, packaged, used, and re-used by different instructors. With these in mind, the CIT introduced the concept of rapid e-learning (REL) in January of 2004. Because REL is not suitable for every project, traditional courseware development remains a core service and REL compliments that. In addition to Breeze Presenter, the centre implemented the e-learning XHTML editor (eXe) and Centra, which can also be classified as REL tools. This case study on REL focuses on the use of Breeze Presenter as the REL tool.

Breeze Presenter was introduced to faculty through newsletters, road show demonstrations, direct approach to selected faculty, and workshops. For the first few sessions, an instructional technologist guided faculty members as they prepared their learning objects with Breeze. Instructors were able to work independently after one or two guided sessions. Formal instructor surveys were not conducted on the use of REL, partly due to the popularity of the software and its smooth integration into the e-learning infrastructure of the university. However, regular qualitative feedback from instructional technologists working with professors on Breeze Presenter is very positive. Instructors embrace it because they have no problems learning the software, the user interface has not changed much since 2004, and Breeze enables them to add simple interactivity to PowerPoint presentations without technical assistance. Instructors like this

Table 1. What students like about Breeze

Reasons for liking Breeze Presentations	Percent
Ability to access presentation at low bandwidth	38.20%
Breeze characteristics such as design, layout, and UI	18.70%
Ability to selectively learn	19.50%
PowerPoint slide layout, graphics, and lecturer's presentation	11.40%
Other issues	2.50%
Dislikes Breeze	1.60%
No comments	8.10%

sense of independence and flexibility. As of July 2006, more than 800 learning objects have been created with REL. Instructors use these learning objects to complement classroom lectures, tutorials, and supplementary lessons.

The CIT team conducted student surveys in June 2004, and 200 students responded (see Table 1).

As Table 1 indicates, 38.20% liked Breeze because they can access the presentations using a low bandwidth Internet connection. 19.50% of respondents liked it because they can selectively learn, Breeze presentations come with standard toolbars that allow users to navigate between slides, view slide notes, control audio and video, play, pause, and stop the presentation and search the presentation for key words. 9.7% of students either dislike Breeze or have no comments. It would be interesting to find out more about the opinions of these students through qualitative feedback. 11.40% of respondents liked the slide layout and lecture presentation style. This figure measures content delivery and indicates that there is room for improvement in the design of PowerPoint slides and content presentation. It is also indicative that there are students who do not prefer lecture style presentations. The NUS team believes that there is a place for REL authoring tools in the university. Table 2 shows the IT infrastructure that supports e-learning. REL holds equal status to custom courseware.

Table 2. The e-learning IT infrastructure of the National University of Singapore

-Virtual Classroom and eMeetings	-Plagiarism -SELF	-Teaching Facilities Centre
Webcasts, Podcasts, Video Conference, Video Production and Events Coverage		
Custom Courseware		Rapid E-Learning
Learning and Content Management System and repositories of learning objects		
Client Consultation and Support		

The popularity of Breeze Presenter indicates that instructors find REL tools useful for performing certain tasks that once required the service of professional staff. Some professors became comfortable with using IT and continued to develop complex custom courseware after using Breeze. REL tools have increased the productivity of the CIT by increasing output and shortening production time. REL presentations require minimal maintenance support. The centre expects REL to become even more popular in the near future. Its place in the e-learning ecology of the university appears to be secure. The pilot project achieved positive results in all three areas except that cost savings cannot be confirmed because the initial cost of implementation and software licensing was too high.

CHALLENGES OF REL IN THE UNIVERSITY

Instructional designers will not dispute the usefulness of worksheets, checklists, and templates of the type suggested by De Vries (2006). These are essential in REL. However, the e-learning environment in a large university is different from that of an industrial corporation. While it is feasible to use project management worksheets and checklists in the university context, templates are almost impossible to implement. In a traditional research university, professors make the final decision as to

how a course is to be designed and taught, whereas instructional designers are restricted to offering suggestions. Imposing templates designed to ensure quality instructional design may be viewed as intrusive and could create tensions with faculty.

Other constraints on the use of REL in the university environment arise from the basic problem of quality. Poor presentation skills result in poor quality learning objects, no matter how sophisticated the technology employed. The university must find other ways to improve the quality of PowerPoint presentations without imposing templates. Fortunately, there are workshops designed to help instructors prepare PowerPoint slides and improve their presentation skills; it is important for SMEs interested in creating e-learning with REL tools to become well-versed on proper course design techniques (Boehle, 2005). By working with instructors, instructional designers can guide and make suggestions as to how a presentation can be improved without implementing templates. In this manner, both the specific skill sets of SMEs and instructional designers are maximized to create an optimal e-learning experience.

REL promises to reduce cost of production by shortening the production process and reducing the number of professional staff needed. The CIT is not able to confirm any cost reductions. The most recent eLearning Guild's research report on REL (2006) also could not conclude that REL reduces cost. In that report, 49% of respondents claimed REL reduces production cost, whereas 19% found the cost remained the same and 32% found it cost more. More research is needed to determine the reasons for this contradiction to cost reduction claims. The CIT found the cost of software licensing to be high. Moreover, there is a yearly software maintenance fee. For cost savings to be achieved, REL software must be reasonably priced, and some tools remain expensive.

The eLearning Guild's research report (2006) was unable to affirm that quality has not been sacrificed, despite the use of templates, worksheets, and checklists for quality control. In fact, the majority

of respondents indicated that quality—as defined by look and feel, interactivity, learner retention, and behavior—either remained the same or decreased when compared with courses authored by traditional methods. Similarly, the NUS experience also points to a need for some form of quality assurance. When asked what it takes for REL to succeed, 83% of respondents in the eLearning Guild's 2006 survey replied that the involvement of instructional designers was paramount. Therefore, when the latter become more involved, it is realistic to assume that processes and methods will become fine-tuned and that quality issues will be mitigated.

All the same, SMEs are embracing REL because the tools are easy to use and they can perform basic tasks without assistance. Students like the easy-to-access, self-paced presentations.

FUTURE TRENDS AND CONCLUSION

Despite challenges, REL development promises time and cost savings, and increased productivity. In 2003, Larstan Business Reports, conducted a survey of 85 Fortune 500 companies and more than 80% of respondents reported that REL strategies would make a significant contribution to training efforts in their organization. The eLearning Guild REL report (June, 2006) showed that demand for REL among its members increased from 70% in 2005 to 82% in 2006. The report claimed that REL is currently the fastest growing trend in e-learning project management and authoring. This trend is expected to continue.

REL software that can author complex games and simulations beyond the current one-way transmission of content is on the horizon. Currently, application developers are responding to demand in the market for new and better authoring tools. It is widely expected that desktop applications like Microsoft Office will become available online in the near future. When this becomes reality, online versions of REL tools are likely to follow. It may eventually become common to integrate

REL authoring tools into Learning and Content Management Systems, further integrating content development and knowledge management.

KEY TERMS AND DEFINITIONS

ADDIE: Abbreviation for analyze, design, develop, implement, evaluate. A step by step structured procedure that helps instructional designers

use instructional material to create learning objects or e-learning courses.

Blended Learning: A combination of physical classroom instruction and online component of the course. Online components may supplement lectures and tutorials or they may consist of part of the curriculum which was previously taught in the physical classroom.

Bloom's Taxonomy: Classification system of the cognitive domain by Benjamin Bloom in 1956. Learning outcomes are categorized into six levels: Knowledge, Comprehension, Application, Analysis, Synthesis, and Evaluation.

Distance Education: A course that is delivered without requiring students to attend lessons in a physical classroom.

LMS and LCMS: The learning content management system, or LCMS, allows users to share, search and reuse content (learning objects) for lessons. Learning objects can also be exported for use in another LCMS. LCMS manages content. The learning management system (LMS) manages the course and contains course information, assignments, schedules, and so forth. Today, commercial LMS includes the LCMS component and hence, LMS usually also means LCMS.

Rapid E-Learning (REL): A category of online training which can be developed in weeks, can be authored by subject matter experts (SMEs), and maintains instructional focus and quality.

Reusable Learning Objects (RLOs): Small chunks of content in digital form. RLOs are tagged with information, stored in a repository, shared, and reused for teaching. Several learning objects put together form a lesson.

SME: Subject matter experts or content writers.

Tools: Software used to perform certain tasks or to create something in e-learning. When used in the context of an LMS, it means a feature in the LMS that enables users to perform a specific task.

INTRODUCTION

This article presents the essence of the Innovative Production Machines and Systems (I*PROMS) Network of Excellence. It gives the rationale for networks of excellence, outlines the scope and structure of I*PROMS, and summarizes its program of activities.

RATIONALE FOR NETWORKS OF EXCELLENCE

Manufacturing is a significant wealth generation sector, accounting for over 20% of the Euro-

pean Union's (EU's) gross domestic product. To compete successfully in the global market, the European manufacturing industry needs to be underpinned by well focused advanced production research. Because of the breadth of the field, commercial considerations, and the multinationalism of the EU, production research activities within it have been naturally fragmented.

There is the potential to coordinate precompetitive research for common benefit. Under its Sixth Framework Programme (FP6), the EU has introduced networks of excellence as a new "instrument" to overcome fragmentation of European research and help shape the conduct of research in Europe. The operation of these networks is based on a joint program of activities aimed principally

DOI: 10.4018/978-1-60960-503-2.ch805

at integrating the research activities of the network partners while also advancing knowledge on the topic.

THE I*PROMS NETWORK OF EXCELLENCE

The EU FP6 network of excellence for Innovative Production Machines and Systems (I*PROMS) was inaugurated in October 2004. I*PROMS integrates the production research activities of 30 research centers from 14 countries in Europe: MEC, Cardiff University (UK) (coordinator), Profactor (Austria), Czech Technical University in Prague (Czech Republic), VTT (Finland), CETIM (France), ENIT (France), INRIA (France), Robosoft (France), IAO Fraunhofer Institute (Germany), IPA Fraunhofer Institute (Germany), IPK Fraunhofer Institute (Germany), Schneider Electric (Germany), TUC (Germany), University of Hannover (Germany), University of Patras (Greece), Dublin City University (Ireland), CRF (Italy), FIDIA (Italy), University of Naples Federico II (Italy), PIAP (Poland), University of Minho (Portugal), Fatronik (Spain), Tekniker (Spain), TNO (The Netherlands), Sakarya University (Turkey), University of Warwick (UK), University of Cambridge (UK), University of Manchester (UK), University of Newcastle (UK), and University of Oxford (UK).

I*PROMS addresses production research in an integrated manner to help shape this research area and overcome fragmentation. By creating an EU-wide research community concentrating on future manufacturing concepts, processes, and systems, I*PROMS acts as the main research hub within the EU for the whole area of production machines and systems.

I*PROMS adopts the knowledge-based “autonomous factory” vision for delivering increased competitiveness for manufacturing in 2020. The network focuses on intelligent and adaptive production machines and systems that meet dynamic

business and value drivers through advanced information and communication technology.

I*PROMS promotes the development of common concepts, tools, and techniques enabling the creation and operation of flexible, reconfigurable, sustainable, fault-tolerant, and eco- and user-friendly production systems. Such systems should react rapidly to changing customer needs, environmental requirements, design inputs, and material/process/labor availability to manufacture high quality, cost-effective products.

THE CLUSTERS IN I*PROMS

I*PROMS addresses six manufacturing challenges: concurrent manufacturing, integration of human and technical resources, conversion of information to knowledge, environmental compatibility, reconfigurable enterprises, and innovative manufacturing processes and products. Work on those themes is prosecuted by four interconnected clusters (see Table 1): advanced production machines (APM), production automation and control (PAC), innovative design technology (IDT), and production organization and management (POM).

The following sections give an outline of the I*PROMS clusters and their scopes. Further information can be found in Pham, Eldukhri, Peat, Setchi, Soroka, Packianather, et al. (2004); Pham, Eldukhri, Setchi, Soroka, Packianather, Thomas, et al. (2004); Pham, Eldukhri, Soroka, Zlatanov, Packianather, Setchi, et al. (2005), and <http://www.iproms.org>.

Advanced Production Machines (APM) Cluster

Advanced production machines are the workmen of the factory of the future. These include machines for processing new/nano/smart/high-performance materials, micromanufacture (MEMS) machines, rapid manufacturing machines (rapid prototyping and rapid tooling), and manufacturing robots (sta-

*Table 1. Manufacturing challenges addressed by I*PROMS research clusters*

Manufacturing Challenge	Network Clusters			
	<i>APM</i>	<i>PAC</i>	<i>IDT</i>	<i>POM</i>
Concurrent Manufacturing	X	X	X	X
Integration of Human and Technical Resources		X	X	X
Conversion of Information to Knowledge		X	X	X
Environmental Compatibility	X		X	
Reconfigurable Enterprises	X	X		X
Innovative Manufacturing Processes and Products	X			

tionary and mobile). In addition to the challenging “stand-alone” research issues connected to these technologies, this cluster also considers two key issues that require cross-technology cooperation, multifunction machines, and reconfigurable machines.

Production Automation and Control (PAC) Cluster

Production automation and control represents the foremen of the factory of the future, responsible for overseeing the machines and for communicating between machines and management. The scope of the PAC cluster includes self-adaptive control, flexible/reconfigurable manufacturing, adaptive quality systems, agent-based distributed architectures, (machine) knowledge management, and human-machine interaction. The major research issue identified for this cluster is collaborative agent-based (or holonic) manufacturing automation and, related to that, self-adaptive control and human-machine interaction. There is considerable interaction between this cluster and the APM cluster in making these machines more “intelligent” and between this cluster and the production organization and management cluster in controlling these machines within the overall autonomous factory environment. It is the combination of these cluster areas that will ultimately provide the overall flexible/reconfigurable autonomous factory.

Innovative Design Technology (IDT) Cluster

Innovative design technology relates to the designers of the factory and products of the future, conceiving novel, customizable, value-added products, and the factory machines and systems required to manufacture them. The coverage of the IDT cluster includes product knowledge management, computer-aided innovation, and advanced computer-aided manufacture. It is with appropriate IDT that concurrency through the product life cycle, as well as across the extended enterprise, can be achieved, with huge potential impact on time-to-market and product development, manufacturing, maintenance, and disposal costs. Two key areas of work are identified: virtual product design technology and design complexity.

Production Organization and Management (POM) Cluster

Production organization and management concerns the management of the factory of the future. It covers advanced process control, enterprise/manufacturing simulation, (human) knowledge management, and human-computer interaction at the organizational, enterprise level. This cluster deals with the management of operations ranging from innovation, planning, organizing, scheduling, and controlling of production processes as well as the management of the interface with the ex-

tended enterprise and other supporting functions. Two key themes are identified: fit manufacturing enterprises (both individual and extended) and integration of human and technical resources enabling effective collaboration between man and machine. This includes effective human-computer interaction by means of multimodal/multimedia knowledge-based user interfaces with active knowledge access and adaptive, dynamic knowledge presentation.

I*PROMS ACTIVITIES

The work of the I*PROMS network and its clusters is laid out in a comprehensive joint program of activities (JPA). The JPA comprises the following components:

- A set of integrating activities aimed at structuring the way the participants carry out research on the topics considered. These activities include defining common research priorities within the scope of I*PROMS; creating and operating joint research platforms; preparing joint bids to government and industry for research grants; creating communication and collaboration facilities; training network researchers; and developing synergistic links with existing research capacities within the EU.
- A program of jointly executed research to support the network goals. The research undertaken by the four I*PROMS clusters covers a broad range of topics including new processes for new materials, miniaturization, mechatronic modules, nanotechnology, modeling and simulation, product life cycle planning, flexible manufacturing systems, process integration, new process control and sensors concepts, intelligent manufacturing process/near-net shape

processes, and substitution of harmful substances.

- A set of activities designed to spread excellence, including training of manufacturing engineers; promoting mobility and exchange of researchers from outside the network; transferring knowledge to teams external to the network through networking activities; networking with other research networks; transferring technology through Web-based advisory services; interacting with national and European Commission (EC)-funded technology transfer projects for industry including small and medium enterprises (SMEs); organizing events to increase public awareness and understanding of I*PROMS-related science and technologies; publishing the network's vision for the factory of the future; developing a program of industrial workshops, seminars, and conferences; and collaborating with other related centers of excellence outside of the network to ensure that knowledge and excellence is spread widely.

ACKNOWLEDGMENT

I*PROMS is funded by the European Commission under its Framework 6 Programme.

Chapter 8.6

Aesthetic Decisions of Instructors and Instructional Designers

Patrick Parrish

University Corporation for Atmospheric Research, USA

ABSTRACT

The same qualities that make works of art beautiful, meaningful, or at times even transformative in our lives also underlie our best learning experiences. This study sought to better understand the relationship between art and instruction by looking at how aesthetics underlie the design decisions of teachers and instructional designers. Five instructional designers and teachers were interviewed about a course or online learning product they had recently designed. The interviews explored the design decisions they had made based on how they imagined learners would experience the instruction at its beginning, middle, and ending. Participants discussed the introduction of tension to enhance engagement, worked to achieve a coherent experience for learners through narrative

qualities, and demonstrated concern for the immediacy of their learners' experiences, discussing the expected thoughts and feelings of learners at each stage of the course or module.

INTRODUCTION

The primary purpose of all education and training professions is to make sure learners take away useful knowledge and skills. But some practitioners also realize that the way to ensure that deep learning will happen is to help learners become engaged in a process of self transformation. For this reason, many instructional providers focus on crafting learning *experiences*, not simply conveying content and assessing learning. For example, some instructional providers place “increased emphasis on the qualitative immediacy of experience, on its unity and wholeness, on its

DOI: 10.4018/978-1-60960-503-2.ch806

emotional underpinnings, on the temporal unfolding of events” (Jackson, 1998, p. 181), and put care in developing details of their instruction that may seem, on the surface, only peripherally related to its subject matter, and only minimally implied by standard instructional strategies. This chapter will show that some instructional providers use approaches that can best be described as *aesthetic* in their work to heighten the learning experience,.

Instructional design, coming from a tradition of applying scientific and engineering principles to instruction, can be seen as conflicting with the traditional craft-orientation of most educators (Rose, 2002). However, even in the work of many instructional designers there exists an artistic thrust that guides the design of products considered of high quality by clients and learners. This study will demonstrate that in the minds of the instructional designers who participated, the same qualities that make works of art beautiful, meaningful, and at times transformative also underlie the most successful learning experiences. The goal of this study was to understand the relationship between art and instruction by looking at the ways in which aesthetics underlie the design decisions of teachers and instructional designers. Its purpose is not to diminish the value of science for instruction, but to reconsider aesthetics as a core foundation for instructional practice, alongside science. In fact, the study relies on social scientific approaches in its attempts to uncover the underlying aesthetics of instructional practice.

AESTHETIC EXPERIENCE

In common parlance, *aesthetics* describes our experience of and passion for creating art, but John Dewey saw it as applying more broadly as a kind of everyday experience (1934/1989). Dewey argued that aesthetics described a prevalent and essential kind of experience, one that is particularly heightened and felt to be especially meaningful—one flush with transformative potential. It is this kind

of experience that artists seek to create or recreate in their work. In this sense, aesthetic experience can exist not only in our engagement with the arts, but in all activity, perhaps especially in activities involving learning. But the concept of *aesthetics* has had many interpretations, and Dewey’s is by no means representative. This section will first briefly describe some competing aesthetic theories before outlining his Pragmatist theory. This theory is worth significant discussion because it is important to move beyond clichéd and superficial conceptions of art and aesthetics in order to see its application to learning and instruction.

Aesthetics is commonly used in at least two senses, both of which are applicable to this study. In one sense, *aesthetics* describes the strategies or principles employed by artists in creating their work. Essays like Aristotle’s *Poetics* (trans. 1984) primarily explore this aspect. But *aesthetics* is also the name for the philosophical tradition that explores the impact of the arts on our lives, why we call some things art and not others, the relationship of artists to their work, and why humans have a passion for creating and engaging with works of art even when they have no apparent practical value. This philosophical tradition, especially in recent history, has led to many different interpretations. Some have said that art is our way of making certain things in our world “special” or distinct from everyday experience—an attempt to celebrate our humanity or to attach increased human meaning to things (Dissanayake, 1995). Connor (1999) points to another school of thought that suggests that the function of art is to create a useful distraction for the miseries we encounter, or to provide a cathartic mechanism for working out “issues and anxieties which... cannot be addressed directly” (Functionalist theories of the aesthetic, para. 3). Others have claimed that *art* is merely a classification of artifacts defined by social institutions as suitable for public appreciation (Dickie, 1989). In other words, this view holds that aesthetics exists only as a socially created convention, and that artists are simply skilled crafts

persons with attached celebrity, but without additional purpose. This attempts to explain the recent predilection for innovation and the emergence of radically non-traditional examples of modernist and postmodernist art. But Berleant (1991) takes a less cynical tack and posits “engagement” as the common quality that connects all the artifacts we call art, a quality that puts his theory most in line with that of Dewey, as shown below. In his view, works of art are designed to engage us in an exploration of meaning—an essential and defining human endeavor. Connor (1999) concludes that the concept of aesthetics may be of no use given its “protean and unpredictable essence,” (The fallacy of counter-aesthetics, para. 6). However, this protean essence lends further credibility to Dewey’s conception of aesthetics as a pervasive kind of experience that emerges from diverse activities.

John Dewey (1934/1989) proposed that aesthetic experience grows out of the rhythmic alternation of disruption and order, the “struggles and achievements” (p. 19), in our lives. In other words, art emerges from the rhythms of everyday experience and epitomizes our nature as beings establishing and achieving goals. As Dewey put it:

Life consists of phases in which the organism falls out of step with the march of surrounding things and then recovers unison with it—either through effort or by some happy chance. And, in a growing life, the recovery is never mere return to a prior state, for it is enriched by the state of disparity and resistance through which it has successfully passed. . . . Here in germ are balance and harmony attained through rhythm. (p. 14)

With little effort one can see that Dewey was describing the process of learning as the source of aesthetic experience. The rhythms and tensions that lead to aesthetic experience with works of art are parallel to those found in transformative learning experiences.

The rhythms of aesthetic experience give it inherent narrative qualities. Whether a work of art takes the form of painting, sculpture, architecture, drama, dance, fiction, or film, our experience of it follows a fundamental pattern in which we perceive the object or situation and over time, through engagement with it, come to sense its meaning or unity. This is the basic pattern of any narrative—a beginning that includes confrontation with an indeterminate situation or object, gradual unfolding of its nature through observation and engagement, and a final consummation that results in meaning or coherence. For this reason, aesthetic learning experiences lend themselves to narrative analysis (see McEwan & Egan, 1995), as the themes that resulted from this study demonstrate, with their attention to *beginnings, middles, endings, character, tone*, and the relationships of the “reader” and “author” to the “text.”

A necessary ingredient for the aesthetic experience of art is “the contribution we ourselves make, a contribution that is active and participatory” (Berleant, 1991, p. 4). Dewey suggests that in order to understand art,

. . . one must begin in the raw; in the events and scenes that hold the attentive eye and ear of man, arousing his interest and affording him enjoyment as he looks and listens. . . . The sources of art in human experience will be learned by him who sees how the tense grace of the ball-player infects the onlooking crowd; who notes the delight of the housewife in tending to her plants . . . ; the zest of the spectator in poking the wood burning on the hearth and in watching the darting flames and crumbling coals. (1934, p. 4-5)

In choosing these examples, Dewey posits active engagement as a necessary quality of aesthetic experience. Rather than the commonly offered aesthetics of passivity or *disinterestedness*, in which objects are enjoyed for appearance, but not for utility or understanding (Cooper, 1995), Dewey and Berleant propose an aesthetics of en-

gement. *Engagement*, in a pragmatist sense, can be defined as intellectual, emotional, or physical investment in an activity in anticipation of future consequences (the opposite of disinterest). Just as artworks can be designed to draw in readers or viewers to puzzle out a plot or to sympathize with characters, to walk through buildings or around a sculpture, or to have a vicarious somatic experience in watching a dance, learning experiences can be designed aesthetically to stimulate similar forms of engagement. For example, instructional designers might attend to the compelling stories inherent in the content they teach; to the imaginative qualities of learner activities; to the details of attractive and intuitive classrooms, texts, and computer interfaces; to the use of evocative language, examples, and illustrations; to the natural tensions and emotions that emerge during the learning process; and to the pacing of instructional activities.

Finding a connection between art and instruction is not in itself new. Authors have theorized about the artistic nature of teaching, drawing strong parallels between the activities of teaching or instructional design and those of performing or creating works of art (Davies, 1991; Eisner, 1998; Sarason, 1999). For example, teachers and IDs can sometimes be so skillful and graceful in crafting a learning experience that it can be appreciated or experienced as aesthetic. Teaching and creating instructional materials is also, like art, often a spontaneous, improvisational activity, and not dominated by prescriptive models. Indeed, the ends of instruction are never fully predetermined, but emergent. Wang (2001) more directly proposed that teachers should emphasize the aesthetic aspects of learning experiences, particularly in bringing out the unexpected, uncertain, or ambiguous aspects of their content areas to engage students. Expanding on Jackson's (1998) work, Wong, Pugh, & The Dewey Ideas Group (2001), have applied Deweyan concepts to call for creating significant anticipation in learners within inquiry science learning through the use of

compelling ideas and stories. The study described here, however, differs in its investigation of instructional practice to learn the extent to which teachers and IDs intuitively think like artists in making instructional decisions.

This study looked beyond instructional theories and models to examine how teachers and IDs in diverse settings applied strategies to enhance learning engagement and influence attitudes toward instructional content. It examined the design and implementation decisions used by participants in their work on a specific course or instructional product, such as the sensory qualities of the classroom and learning materials; the use of narrative structures in learning activities; the creation of tension, anticipation, and dramatic impact; the pacing of activities; the pattern of activities; and methods of creating closure. In addition, in order to discern relationships between their underlying values and these decisions, the study sought to understand some of their guiding values for instruction, what they considered general goals for instruction, and how they characterized learners and their relationships to them in the teaching/learning process.

PROCEDURES

Data Collection

This study applied grounded theory research methodologies (Strauss & Corbin, 1998) to discover possible aesthetic bases for decisions made by teachers and IDs. A series of interviews with five participants was used to develop the set of themes leading to this report. Applying purposive (Krathwohl, 1998) and theoretical (Creswell, 1998) sampling methods, participants were chosen based on other's judgments of their high levels of expertise. Participants were known to demonstrate great care in the quality of their instruction, care deeply about learning experience, and have the ability to articulate insights

into their practice. Participants were chosen also to represent varied arenas of practice, including both teachers and instructional designers. This range of participants was desired to ensure a broad focus on learning, rather than narrowing in on one delivery mode. The products they had created were all large components of instruction, either entire courses or self-paced modules of two or more hours of student contact time. This criterion was applied in order to capture how these practitioners perceived an evolution of learning engagement during the experience. Participants (and their projects) included

- **AF**, a member of the math faculty at an urban community college (a Calculus I course taught face-to-face)
- **BI**, an instructional designer working within a for-profit organization that creates custom and off-the-shelf training for corporate clients (a computer-based learning program on quality improvement)
- **CI and DI**, both instructional designers with a not-for-profit organization with government sponsors, specializing in weather-related education and training. The two had divergent audiences—middle-school students (hurricane science and safety) and professional weather forecasters (ocean-effect snowstorms), respectively—for their projects, both of which were online learning modules to be used individually or in small groups.
- **EF**, an adjunct faculty member (also a practicing instructional designer) for an online Master's degree program in Instructional Technology (an instructor-led online learning course on instructional strategies)

Note that AF and EF are faculty at a college or university—"F" for faculty. BI, CI, and DI are instructional designers—"I" for instructional designer. Each participant had recently taught the course or developed the instructional product

they discussed, so the decisions and experience of the teaching or development process were fresh in mind. The course materials or products were available to examine as a secondary data source.

While participants were briefed ahead of time with the general purpose of the research, with the exception of the final question the interview questions did not directly ask participants to consider the concepts of art or aesthetics (see Appendix A, Sample Interview Questions). Instead, they were designed to prompt participants to think about how learners might experience the instruction, repeatedly asking what learners might be "thinking and feeling" during the course of instruction and what they had done as designers of the experience to influence those thoughts and feelings. I considered myself an active participant in the interview process (Holstein & Gubrium, 1995), and at times the interview took on characteristics of a discussion between two practitioners. The study followed a method similar to that of phenomenological researcher Aanstoos (1985), who used think-aloud protocol to uncover actual thinking processes of chess players, rather than those predicted by cognitive theory. While think-aloud protocol is typically impractical for processes with a long time-scale, such as instructional design and teaching, focused reflection on a specific course or product (with the product at hand, when possible) achieved a similar outcome.

Data Analysis

In keeping with grounded theory research methods (Strauss & Corbin, 1998), transcriptions for each interview were initially open-coded at a high degree of detail, the unit of analysis varying from phrases to entire paragraphs, depending on the concept expressed. During open-coding and "axial coding" (Strauss & Corbin, 1998), the initial set of 50 codes were collapsed into the 11 categories reported here.

FINDINGS

Differences between participants were apparent, as anticipated given their varying professional orientations and places of practice. For example, the teachers could rely on being able to read student feelings during instruction, and could accommodate and adjust prior design decisions to changing student perceptions. They worked toward an engagement substantially built on a high degree of trust, using language that implied, “I’m here, I care about you” (Participant EF) and making students realize that “it’s not me against them . . . that I’m on their side” (AF). In contrast, the instructional designers of self-paced products realized that even with their efforts to anticipate reactions to the instruction, they might still be missing the mark with a large percentage of learners. It appeared deeply frustrating to them that they would likely never see the faces of learners to know the instruction’s impact:

My problem is that I don’t know any learners. I’m so far away from them. I wish I could watch them, I wish I could interview them, but I don’t know any of them. The only one I know is myself, and the only learning style I know is my own. (Participant BI)

Even with this substantial difference between teachers and IDs, very similar concerns for the learner experience and high degrees of empathy emerged from the interviews and similar design solutions were described. These are reported below, organized into general themes of Guiding values, Instructional goals, Opening qualities, Narrative flow, Identity, Tension, Limits, Middle qualities, Climax or turning point, Ending qualities, and Teaching as art.

Guiding Values

When asked about guiding values for their work, participants spoke of the necessity to connect with

the individual needs of learners and to keep them engaged and interested because doing so will help learners develop useful skills and knowledge to take away from the experience.

(CI) Learning is not easy. It takes work. . . . So I feel like I’ve got to get the learners to put in effort or they’re not going to get anything for their time. . . . We’re in an information overload society . . . and every moment you’re choosing. . . . If we make something, we better make it good, . . . valuable, well crafted, self-contained, and engaging and appealing.

(AF) Everybody learns differently. . . . My job is to present the material in all sorts of different ways so those thirty people sitting there aren’t going to change their style to match me.

(BI) I think the instructional designer is sort of the advocate for the learner. . . . We’re kind of the conduit or intermediary between the knowledge and the learner.

Instructional Goals

Several participants made clear statements that their instructional goals are more than information transfer and skill development. They included affective, transformative goals, such as developing a deeper respect of the content area, an appreciation for its importance and value, and even its “elegance.” This additional appreciation requires modeling the behaviors of those who value the content and apply it with success.

(BI) The other thing we try to do is . . . create a back story, a dramatic back story . . . about a group of people working through the process. . . . It needed to be a real story. Something that made sense. . . . It’s all about modeling.

(AF) That’s one of the things I try to portray to students, that I do enjoy teaching it, and love the

math and it's exciting, and I'm trying to get them to feel that excitement with me. We'll talk about something that's happening and I'll say, "Isn't that cool? Isn't that neat the way it works? . . . It doesn't always work, but I try to pull them in."

(AF) And I want them to have gotten the best education they can so they are ready to move on. But it's almost just as important to me for them to finish the semester and not be quite as afraid of mathematics as they were at the beginning.

(DI) Meaningfulness. And then there's this aesthetic integrity that you can sense in something. Balance. And something about timing, pace, that it's . . . the right kind of pacing you know when you find it. . . . They will go through it and at the end of it they'll say that was worth my time, that meant something to me, that's something that I can use, that's something I can carry forward with and apply in my life.

These instructional goals, combined with the fact that learners are frequently multi-tasking adults with competing demands in their lives, necessitate engagement strategies. Education (or professional development) is only one of these demands on students' time. Students may come to the instruction with few experiences of academic success, and they may see instruction as intimidating rather than inviting. They may come with a limited desire for what the course has to offer, perhaps because it is required rather than chosen.

(DI) The other stuff I can't have any influence over. So as engaging and attractive as that [computer] interface is—it's what's going to key them in initially and create that relationship. . . . A lot of the thinking behind this is based on visits I had to the office [of representative learners], watching people at work, and [seeing] how tight their schedules are and how much multi-tasking there is.

(BI) You know, we see all the stats about how people don't make it [through self-paced instruction]. When I'm thinking about the person, I'm just trying to capture their interest for whatever moment I have them.

Opening Qualities (Hooks, Novelty, Comfort)

The opening of an instructional event is considered critical by each of the participants. It is the opportunity to create a lasting impression and set the tone of the relationship with the learner. It needs to have some kind of hook that draws learners in and encourages them to stay engaged.

(BI) We're always looking for a hook, [an] emotional, intellectual, dramatic hook to get the learner into what's going on.

(EF) It's real important to me that there's a conversational tone that says I'm here, I care about you. I want us to learn from each other. I think about that heavily. Students new to online learning are nervous about it. I'm trying to make it more comfortable.

(AF) I'm hoping that they're sitting there and thinking, "This isn't as scary as I thought." And interested enough to think, "I better come back tomorrow because who knows what she's going to do next."

Narrative Flow

All the participants discussed using narrative elements to create a flow to the instruction and to keep learners engaged through the end. This took many forms, from simply referring to the course as an "adventure" (AF) or facilitating a series of activities that comprise a process of "building things," (EF) to actually centering the instruction on a case, scenario, or "back story" (BI, CI, DI) that learners work through.

(AF) I always try to talk about it with the excitement of, “It’s a journey and this is where we’re going to be going, and we’re going to be discovering these things.”

(DI) By the time they get to question six [in the case study], they’re really caught up. The event is taking place now, there’s [an] ocean-effect [snowstorm]. There are some quirks about how the atmosphere is setting up, there’s some banding that’s not really explained well. So hopefully they’re engaged enough to want to continue . . . that the idiosyncrasies of the case itself will continue to hold their attention throughout all nine questions.

Identity

Participants recognized that learning includes a process of transforming identity and asked learners to assume a new identity within the instruction. In some cases, this was a request to suspend disbelief and take part in a narrative, to have learners identify with a fictional person with an immediate need of the knowledge they themselves are attempting to develop. In others, it was a more direct request to envision their own potential new identity. In both cases, the request can be seen as an attempt to make learners’ identities more malleable, preparing them for the transformation that is one goal of the instruction.

For example, in EF’s online course about instructional strategies, not only do students apply what they’re learning in designing a product of their choosing (often they are practicing professionals or interns, and the class project is for a real audience), but they are told that the course instructors have followed the same process in designing the course the students are currently taking. In this way, the students identify at several levels: as professionals given the opportunity to enhance their craft by following a new model, as IDs in a community of practice sharing reflections on their

profession, and as learners experiencing designed learning activities with a critical perspective.

For DI, transforming identity meant drawing the learner into the scenario using second-person voice—“You are sitting down to your shift,” as if the learner *was* the forecaster in the case study. As the scenario proceeds, the learner has to make decisions and use data identical to those the actual forecaster would have used at the time, furthering the identification.

In the products created by BI and CI, as well, learners are asked to participate directly in a situation in which the instructional content has to be applied, but the narration is more explicit. In CI’s case, the learner is the house guest of a fictional family in Florida, welcomed at the front door of their home, and asked by the family to help prepare for the potential of the coming hurricane. For CI, one of the primary goals of the module is to “connect with people’s lives,” and to show that “people in this place . . . know about hurricanes.” In this way, learners identify with the family in ways that help them “connect that science means something in people’s lives.”

For BI, the identification is not quite as direct, but the story is more complex. Many dramatic situations are presented in the “backstory” in which characters work through problems of practice that require the skills the learners are being taught. Frequently, learners are asked to help the characters analyze their situation or make decisions. BI spoke of the difficulty in creating a narrative that learners would relate to. “If it’s not real or compelling, then it has a tendency to hurt the content, even if the content is true.”

In AF’s case, like that of EF in part, learners are encouraged to identify with the instructor rather than a fictional character. One goal of AF’s teaching is to have students develop a positive attitude toward math, and this is achieved by demonstrating that attitude.

Tension (Withholding)

In some cases, the opening engagement of the instruction is maintained through careful use of tension. Some participants even speak of withholding information in order to create expectation and curiosity. For CI, this is inherent in the narrative structure associated with the approaching hurricane: “Maybe there’s interest and anticipation on when the hurricane’s going to hit . . . That was sort of our goal, to have a little suspense.” Tension was also introduced through game-like elements—forcing learners to explore the fictional location to find the available resources. For DI, tension is also inherent in the case study approach, but there is a small element of misdirection included as well. As the case unfolds, learners would “be confronted with the nuances and why they blew the forecast” (why the weather event misled them, which is likely for this case). Similarly, the “backstory” in the instructional product designed by BI contains a mystery that is solved only by following the story closely, and is revealed only near the end. “There are all kinds of red herrings that are laid out throughout. . . . [The characters] model the content itself in that you don’t want to jump to conclusions. You want to measure, analyze, re-measure. You want the learner to experience that. You draw them into the misdirection.”

The teachers in the study (AF and EF), in contrast to the designers, were more reluctant to introduce tension. As AF puts it, “I think there’s probably more than enough there already.” However, even AF creates a gentle tension with the frequent unexpected activities, like mathematical “sing-alongs.” EF’s original course design began with activities that were likely quite new to the learners, and for which limited guidance is provided. “We are clear in what we want them to build [a design document], but we are not obvious in describing it to them.” EF recalled a comment she had heard from a colleague that justified this treatment: “When you have someone teaching you, you have to suspend your own judgment and

just go where [the teacher] is going”. However, in a follow-on interview, EF spoke of how the course had been redesigned “to make it more coherent, to have it make more sense to people.” In the redesigned course, EF and the co-instructor provided a “roadmap” that better explained where students were headed and why. As a result, no one had dropped the online course at the midpoint, where several students had dropped out in previous incarnations of the course. Perhaps with the nature of online instruction, with its frequently larger transactional distance, and perhaps with the complex nature of mathematical content (for AF), added tension simply places excessive demand on learners.

Limits (Student Acceptance, Practical Constraints)

While all the participants strove to develop engagement, they also realized that some situational factors were beyond their control. For example, students have limited capacity or willingness to suspend disbelief during instruction. In addition, practical constraints mean that efforts can only go so far before budget, development team consensus, and the necessity to cover sufficient content limit them. Artists face similar constraints in working with their materials or developing projects for specific locations.

(DI) Initially I was hoping I could set more of a roll, use a tone that you are on shift, playing the whole game of a case scenario. That’s the first sentence, “You are sitting down to your shift.” I was hoping to sustain that tone, but working with subject matter experts, that tone went away.

(CI) Right off the bat there’s maybe pretty high engagement. Then . . . maybe when they get to this [computer] screen they may be disappointed. Then there’s this worksheet thing, and this inherently means work, so the average student is thinking, “Oh, we’re going to have to do a worksheet?”

Middle Qualities (Growing Comfort, Boredom, Pattern, Routine)

Participants noted varying qualities about the middle instruction events. Some noted that the middle marked a potential growing comfort with the instruction and a willingness to see it through. If the teacher has been successful, he or she will also have gained the trust of learners by this point, and will have created an environment where reaching the end appears achievable. However, some noted that the limitations of engagement strategies rise prominently in the middle, and that it can be a challenge to sustain engagement—the “second act” challenge also faced by authors of novels, plays, and films (Tierno, 2002). If engagement is difficult to sustain, the use of pattern and routine can help learners keep on task, or the instruction might move more quickly into the climax or turning point (discussed in the next theme), or increase anticipation for that climax through careful “plot” revelations or hints.

(BI) If they've been through it all, they know the team [in the back story] and they know the problem. Maybe they're interested. Then hopefully they're starting to get interested in some of the tools. How you can actually measure quality in a service environment. They're starting to get intrigued about what they could do [in their own workplace].

(AF) I think they're feeling pretty comfortable [by the middle]. I think they've figured out by now that it's not me against them. . . . They're much more trusting, and they're believing a lot more of what I do. . . . I think they look back at the beginning of the course and think, “I don't know why I was so scared.”

(DI) [By the middle] I think they'll be thinking that these guys really tried to make it look as if we're really in the midst of a true [weather] forecast. . . . The engagement might be a little less than I

was hoping. . . . [but] I think once they get used to the amount of data at their fingertips, they'll be engaged with the analytical aspects of this.

(CI) By the time they get [to the middle] they know there's a story, they know there's a hurricane coming, they know the routine—they know the drill of the dog thing, then you do the computer thing. They sort of know what to expect.

Climax, Turning Point

None of the participants had difficulty in pointing to a climax or turning point within the instruction. This point may have been either a surprise or puzzle that added an interesting twist, an “Aha” moment, or a low point that was overcome, making the rest of the experience seem easy in comparison. In narrative terms, this is the denouement, the “untying” of the story complication(s). In learning experiences, the aha moment may occur at different times for different learners, but it may be associated with the same sort of content revelation. Some designers specifically attend to this and attempt to build opportunities for such revelations into their designs.

(AF) In a math class, that point in the semester you would call a climax . . . I think is more related to a [difficult] concept. . . . You see this again and again, this struggle point. . . . And that's kind of a low point of the semester. . . . But I do see a lot of students at this point go, “It's not as hard as I thought.” It's a kind of Aha moment.

(BI) [The climax] is when they actually measure and find out what the problem is [in the backstory].

(CI) [In the scenario] we had the electricity go off [when the hurricane strikes]. It breaks up the whole structure and the pacing. And it's timed with how hurricanes [actually] disrupt things.

(DI) There's the juggernaut in there of the [precipitation] banding taking place [in the snow event]. . . . I still think there's no way that you'd ever be able to forecast banding at that level. . . . But I don't see that as a bad thing . . . if it sparks somebody's interest to go research something else. . . . In retrospect, these cases are great to look at, because they are intriguing.

(EF) I'd say [the climax] is when they have to use all the work we've done in the beginning to design a blueprint for their own course. They actually have to pull in everything. And the ones who are able to do that have major Aha's.

Ending Qualities (Closure vs. Open-Endedness)

Participants spoke of mixed goals in providing closure for the instruction. First, there is the goal of providing a solid conclusion to the “story of the course” (EI) by reaching a logical ending. There is also the goal of drawing the entire experience into a unified whole, showing how all the parts of the course were necessary for reaching its intended conclusion. At the same time, there is a desire to keep the end somewhat open, to indicate that the end is another beginning, or that the course is just the starting point for deeper, more important learning to take place.

For AF, while the last Calculus I class session is a time for celebration, with an awards ceremony for those who have gotten “As” on all their tests, there is also the fact that the final few days of the course were spent on Calculus II content, giving students a preview of where they may be heading next. CI felt strongly that the instructional design was faulty in that it didn't provide enough linkage back to the classroom, where the teacher and students could carry forward with other related activities. For EF, the course ends with a reflection and becomes a rite of passage, where learners are told, “Welcome to the group of instructional designers who think through learning.” For BI

and DI, the end of the back story and the end of the severe weather case provide natural closure to the instructional experience.

Teaching as Art

When asked for their opinions about the artistic aspects of teaching and instructional design, each of the participants had well formed thoughts on the matter, indicating that they had considered this question before.

(AF) Watching someone do the teaching process well is like watching a Broadway show. . . . I think the feeling that you get is emotionally similar to looking at great art or hearing great music.

(BI) I think great art changes perception. And . . . great instruction should change perception as well. I don't know that it's been done, but I think that it's possible that great instructional design could be an art form.

(CI) I feel that teaching is a spontaneous, creative art. Teachers think they have a plan, and they have strategies, and the content, but they're in the moment too. There's an aesthetic value in and of itself. I think it's important. It makes learning real.

(DI) You know you've got all these theories . . . but it's a very creative process to actually take your content and put it into a structure. . . . And that's a very creative thing, where you're blending theory with aesthetics and common sense and some usability ideas.

(EF) It's artistic because I can impact people's lives and their emotions. It's artistic because there is no one solution.

Note that different notions of art are reflected in these comments. Some participants express the view of art as based in creativity, spontaneity, and individual judgment—in contrast to traditional

approaches to instructional design as perhaps overly scientific and formulaic. But either in the comments above or as noted in other findings, most also connect the artistic nature of instruction to its transformative potential, its ability to change ways of thinking, emotions, and in the end, the lives of learners.

The Story of a Learning Experience

One of the more significant conclusions to be drawn from the findings is that teachers and instructional designers can and do think about the learner's experience in aesthetic terms, even if they might not be naturally inclined to use those terms explicitly. Taken together, the findings provide a rich description of the aesthetic qualities to be found in learning experiences. Based on the themes that emerged from this study, one can imagine the story of an aesthetic learning experience as it unfolds. The composite picture below is based on beliefs expressed by participants and describes the impacts of the many aesthetic decisions they might make in any instructional situation. It is not intended as a model of learning, but as a story derived from practitioner experience that suggests guidelines for instructional decision making.

As learners enter a formal instructional situation, they may do so with a wide variety of anticipatory feelings. They may be fearful, skeptical that the experience will be worthwhile, ambivalent but willing to trust the instructor (at least for a time), or ideally, optimistic and highly motivated. Each of these initial feelings is either justified or modified by their experience at the start of the course or first engagement with a self-paced product, coloring their attitude as they proceed. Because negative feelings can interfere with learning by reducing either engagement or expectations, the instructor or designer typically has included a strategy to minimize negative impressions. If so, learners may lose their negative feelings (or improve upon their neutral ones) and become engaged with the instruction, either through enjoyable and familiar

activity, unique or pleasant sensory experiences, or the creation of a sense of drama, mystery, or anticipation.

By the middle of the experience, if things have gone well, learners may have forgotten their fears and skepticism. They may experience an increased feeling of belonging and trust, but the reality that learning is hard work has also set in. The beginning phase may have gone by quickly, but the end is still far away and a substantial amount of work remains to be accomplished. The role of the instructor or ID in the middle phase is often simply to make the experience as bearable as possible by providing a routine pattern to the activities and clarity in the instructional communications. Inevitably, some of the luster and newness of the experience is lost, and only if learners maintain sufficient trust in the experience and are sufficiently willing to "suspend disbelief" to continue the temporarily crafted relationship of student and instructor will their engagement stay intact.

Finally, the ending approaches, typically in a fluster of activity. The sheer exhaustion that accompanies the conclusion of this final activity, if kept in balance, adds emotional intensity to a feeling of consummation and restored order. The instructor or ID can provide further closure by creating opportunities for learners to reflect on what they've learned, helping to tie the preceding learning activities into a unified whole by showing how they were each necessary to get to this endpoint. Perhaps there is also a ritual of closure that points out how far learners have come, and there may be reference to the fact that life goes on beyond the experience, but that the future will forever be touched by it, adding significance to the parting.

Trust comes up frequently in the above account because it was stated or strongly implied by participants as a necessary condition for effective learning. Similarly, others have pointed to trust as an intrinsic aspect of artistic endeavors. Cavell's (1976) advice to artists could also be advice for teachers and instructional designers who respect

the individual intentions of their students. He tells artists that they must necessarily take chances, but also to remember that

... you are inviting others to take them with you. And since they are, nevertheless, your own, and your invitation is based not on power or authority, but on attraction and promise, your invitation incurs the most exacting of obligations: that every risk must be shown worthwhile, and every infliction of tension lead to a resolution, and every demand on attention and passion be satisfied—that risks those who trust you can't have known they would take, will be found to yield value they can't have known existed (p. 199).

CONCLUSION

Two essential qualities of aesthetic experience are its *immediacy* and an *anticipation of consummation* (Dewey, 1934/1989). *Consummation* is an experience of unity or coherence in which it becomes apparent that “all the varied parts are linked to one another, and do not merely succeed one another” (p. 55), it. In cognitive terms, consummation is achieved by the integration of knowledge. Dewey also claims that “what is not immediate is not esthetic” (p. 119), suggesting that aesthetic experience is not achieved in reflection only, it arises from a situation in which the immediate details stand out as compelling in themselves. The participants in this study demonstrated that they were concerned with both of these essential qualities in designing learning experiences for their students.

One prominent aesthetic decision made by these practitioners was to use tension to enhance engagement and increase anticipation. Learners may naturally experience tension by confronting complex content in their attempt to fulfill a desire to complete the course successfully, and instructional providers can use and manage this tension to achieve successful results. Instructors and IDs

can impose tension by finding dramatic conflict within the content or by purposefully withholding and releasing information at a controlled pace (see the above comments on tension in the Findings section). The participants also worked to achieve a coherent experience for learners, using narrative or other techniques to reveal how the contents of the course fit together. The dramatic structure of several of the instructional designs inherently created anticipation of a consummation. Finally, a concern for the immediacy of their learners was demonstrated by their abilities to empathize with learners and imagine their thoughts and feelings at each stage of the course or module. They demonstrated clear concern for many details of the learning environment that would help create a rich, immediate (*un-mediated*) experience for learners.

Instructional designers have recently increased their contemplation of the artistic nature of their work (Visscher-Voerman & Gustafson, 2004; Hokanson, Hooper, & Miller, 2008; Hokanson & Miller, 2009). However, their explorations sometimes begin with rather limited stereotypes about the nature of art. One of these stereotypes is that an artist is focused on attractive and pleasurable qualities. Yet any careful survey of the art that surrounds us in books, films, theater, and even the visual arts will demonstrate that artists seek something more substantive than to bring pleasure. They challenge us. Another stereotype is that artists use their own judgment as final arbiter of quality, with little care for their audiences. To the contrary, artistic merit relies more on empathy than insular inspiration. Art is a social phenomenon; meeting needs in all cultures and in all historic periods by helping people understand the dimensions and demands of experience. A final stereotype, arising primarily within the modernist and postmodernist historic periods of rapid change, is that art necessarily includes innovation and experimentation, with little concern for productive outcomes—concerns that are best left to those in other roles of society. However, every artist is con-

cerned with one critical productive outcome—the aesthetic experience of those who appreciate his or her work. Innovation (in technique, material, or subject matter) is but one potential starting point for achieving this. While bringing aesthetics into the discussion of instructional design practice is intended to broaden the concerns of practitioners, the result of using limited notions is to ignore the deeper connections between art and instruction.

This study sought to demonstrate that aesthetics plays a significant role in instructional practice, beyond these superficial views of art and artists. A true instructional artist is less concerned with innovation or attractive products as she is with designing compelling experiences that lead to transformative learning.

FUTURE DIRECTIONS FOR RESEARCH

This study focused on the design of whole courses or large modules that likely take more than one session to complete. It would also be useful to look at smaller and larger scales of learning experiences for ways in which aesthetic principles come into play. What is the pattern of aesthetic experience for individual lessons or class sessions? In what ways do even smaller scale activities play out? What is the role of feedback in adjusting the “qualitative immediacy” during instruction? At the other extreme, one might ask how larger scale experiences, such as degree programs, display aesthetic qualities. These questions are only touched upon in this study and deserve further investigation.

In addition to the descriptive results reported here, further research on aesthetic practice in teaching and instructional design could lead to sets of guidelines for instructional practice. Identifying aesthetic strategies in current practices and finding those that appear to create the desired outcomes can lead to a catalog of aesthetic strategies for instruction. Educators may be able to expand upon and more clearly describe these strategies

by finding comparisons to the strategies applied by artists. For example, Parrish (2009) explores the potential contributions of literary theory to describing learning experiences and deriving aesthetic principles for designing them.

APPENDIX A

Sample Interview Questions

1. How did you come to be a teacher/instructional designer? What drew you into the profession?
2. How long have you been in the profession? In what capacities have you worked?
3. Tell me about any guiding values or philosophies you hold about your practice. In particular, how do you view your relationship with and responsibility to your learners?
4. How did you come up with the concept for this design? Are there any models or sources that influenced you? Are there any specific products or experiences that led you to this design? Were you influenced by any models or metaphors NOT from instructional sources?
5. Tell me how you view the content of your module/course. For example, is it a set of well defined rules, or is it more complex and open to interpretation? How do you want the learner to engage with and to think about this subject matter?
6. Tell me a story about an imaginary student who might use this module or be enrolled in this course. Make it a typical student, not an ideal one.
 - a. How does the student enter into the module/course? What catches their attention first? What are they thinking and feeling as they begin?
 - b. As they are near the middle of the module/course, what is their experience? What do they remember about the beginning? What do they anticipate about the end? What are they thinking and feeling now?
 - c. Is there a turning point or climax that the student reaches during the course? Describe it(them).
 - d. As they conclude, what are they thinking and feeling? What impression are they left with? What is most memorable about the module/course?
7. Use a metaphor to describe how learners experience the course. For example, you may think about the module/course as either as a physical space the learners are exploring, such as a building, a city, or a park. What catches their eye as they first enter? How do they move through it? How do they exit?
8. Think about the level of tension or engagement of learners as they work through the module/course. How does it change over time? Where does it change? What is that level at the very end?
9. Now think about what it is about your course/module design that creates an initial impression or mindset in the learner. How do you use language to influence the impression or mindset of learners? Visuals? Color? Interactivity? Are there any surprises, conflicts, or disruptions that you purposefully want the learner to experience? How do you want learners to deal with or resolve these? What have you done in the final parts of the course/module to create a lasting impression? How do you “wrap up” the experience for the learner so they can feel a sense of accomplishment?
10. People experience time differently depending on the situation and how they are engaged with it. How do you think learners experience “course/module time” when taking this course/module? How does that experience of time change over the duration of the course/module?
11. In general, in what ways do you think that instructional design/teaching could be described as an artistic process?

Chapter 8.7

The Pervasiveness of Design Drawing in ID¹

S. Todd Stubbs

Brigham Young University, USA

Andrew S. Gibbons

Brigham Young University, USA

ABSTRACT

This chapter is a survey of the literature of ID to look at the breadth and usage of design drawings in this discipline to better understand the emerging use of VIDLs to improve designs. To conduct this research, we sampled several ID textbooks, ID journals, software, and case studies looking for examples of design drawing. Design drawings found were then categorized using Gibbons' (2003) seven ID layers as a taxonomy to understand the drawings' purposes. We did not find the same pervasiveness or level of self-awareness as found in other design fields. Examples of design drawings were found, but were somewhat rare. Furthermore, we discovered that those examples we found tended to document only two of Gibbons' seven layers, indicating narrow applica-

tion. We believe this gap represents a serious shortcoming in ID, indicating a lack of tradition, skill, and standards for visual representations of design except in limited ways. At present, design drawing is a rare but growing phenomenon in ID, which, when fully understood and implemented, can only benefit the practice of ID.

INTRODUCTION

This chapter applies a layered concept of instructional design (ID) architecture described by Gibbons and Rogers (in press) to a taxonomy of design drawings described by Stubbs (2006) to produce a refined category system for describing the use of drawing and sketching in ID. The value of doing so is dramatized by Stubbs, who compares the use of design drawing in ID to its use in other design fields, detecting a large disparity. If

DOI: 10.4018/978-1-60960-503-2.ch807

Stubbs' analysis is correct, then designers in other fields have a much richer tradition of the use of drawing in design and a literature that shows a much higher level of self-awareness in the use of drawings during design than most instructional designers would expect.

Design drawing might be considered the primitive of visual instructional design languages (VIDLs). In this chapter we hope to understand where we are with this basic form of VIDL to better understand where we are going.

Though instructional designers excel in the use of drawings of many kinds in their *produced* designs, it would appear that they lag behind other design fields in exploiting the value of drawings and sketches while *designing*.

This deficit has important consequences for the economics, quality, and quantity of instructional designs. Whereas other design fields have begun to capitalize on the power of computers as a design tool, instructional designers seem to be more at the mercy of the tools and design interfaces created for use by others who have more vibrant economies, such as Web and software design. Early attempts to create tools to express designs in the instructional designer's vernaculars appear to have been swallowed up in the success of other design fields, notably the Web and Web development tools (Fairweather & Gibbons, 2000). Only recently has interest in the authoring of learning objects revitalized interest in design interfaces that emphasize ID structures, a trend that we hope will persist and broaden.

The value of the computer to design lies in its ability to take part in routine and mundane decision-making. Successes in computer-aided design have come largely from the ability to describe a design problem (or some portion of a design problem) in terms that can be translated into computer languages. For instance, the design of an architectural column can be translated into sub-problems for the design of the capital, the shaft, and the column base (Mitchell, 1990). If only the shaft sub-problem could be expressed in

computer terms, then that portion of the design could be given computer support, and the remaining sub-problems would depend entirely on human decision-making. By the same reasoning, if only portions (sub-problems of sub-problems) of the design of each of the capital, shaft, and column base could be expressed in such terms, then the design of each of these would require human effort and decision-making, supplemented by some degree of computer assistance. This is the principle today of popular development systems for Web and software design. The involvement of the computer—which is capable of making numerous routine decisions very rapidly and dealing with representation issues at the same time—creates an economic lever. More quantity at higher quality can be produced more rapidly—cheaper, better, faster. And as languages for problem description and solution improve and become more nuanced, the quality and sophistication of the designs improves. This is exactly what has happened to the design of computer chips over the past thirty-five years. Chips designs today are created to human specifications with human decision-making concentrating mainly on high-level design issues. As a result the economics of computer chip design have changed so that a return to hand-drawn circuit design would be an expensive luxury.

This chapter addresses how ID problems can be described in terms of design languages (some portion of which may be translatable into computer languages). It begins by describing research by Stubbs (2006) on the use of design drawing by instructional designers. Stubbs conducted a review of ID literature, and categorized the drawings he found there according to the layers described by Gibbons and Rogers. Stubbs discovered the disparity we have already mentioned between the level of interest in design drawing in ID and other fields of design (see chapter III). He found that, though in the field of design studies there is strong interest in design drawing, there is not a corresponding interest and self-awareness of the use of drawing in the literature of ID.

According to Stubbs:

The general design studies literature has both theoretical and empirical studies on the subject of design drawing. In this literature, design drawing is considered an important, even vital part of design thinking. It is thought of as a design language, which comes in a variety of distinguishable forms, and accompanies and contributes to the design process as it progresses through various stages of development. Studies in this literature show how the intentional ambiguity of design drawing provides space to the designer for creativity and innovation, invoking a kind of dialogue between the designer and the design, which is deemed essential to the design process.... By contrast, the literature of ID has nothing like this level of consideration for design drawing. Instead, the few available articles in the literature of ID touching on design drawing are about proposed notation systems. Evidence of design drawing in the practice of ID as seen in the literature finds that, when it does appear, it is most often concentrated in two aspects of ID identified with Gibbons' content and strategy layers.... To say that there were no examples of design drawing in ID would be hyperbole. However, considering how little was found and how narrowly focused it was, it prompts the question, "What might ID be missing by its lack of attention to this language, so valued in other fields of design?" (p. 85–86. See also chapter III).

Stubbs notes McKim's (1980) observation "that designers with versatility and skill in graphic languages have an advantage, which may apply to instructional designers as well" (p. 134). McKim postulates that "not only [will designers]...find more complete expression for their thinking but also [they will be able to] re-center their thinking by moving from one graphic language to another" (p. 134). On this basis, Stubbs proposes that design drawing in ID "deserves a thorough examination" and presents the typology of design drawings,

described below, that distinguishes six types of drawing that commonly appear in the literature of the field. Only one of these six types is considered design drawing.

Next, the chapter uses the layered ID architecture proposed by Gibbons and Rogers (in press) to categorize design drawings by function. This architecture draws on concepts from many design fields, showing that designs in those fields have a layered architecture that decomposes design problems in functional terms. Baldwin and Clark (2000) describe how this principle of decomposition lies at the economic center of the modern computer industry, making possible design modularity. Gibbons and Rogers demonstrate that layering applies to instructional designs as well, with the benefit that the problem thus described can be solved in terms of existing design languages, most of which are derived from instructional theory or proven design practice.

EVIDENCES OF DESIGN DRAWING IN ID

The experience of many instructional designers strongly suggests that design drawing is a part of ID. However, this chapter will show that ID does not appear to have the same tradition for design drawing, especially during the early phases of design, as is found in other design fields. For this review, evidence of design drawing in ID was sought in several sources: a sampling of ID textbooks, journals, software, and case studies were examined. The ID literature for research about design drawing in ID was also searched. With some notable exceptions, very little was found.

To facilitate the study of design graphics, a typology was created to identify the types of graphics found in ID literature. This section describes this typology as a means to categorize graphics of interest to this study. Gibbons' instructional design layers are then used to provide further

sub-categorization of one of the types of graphics found in the literature.

A Typology of Images

A variety of types of illustrations can be found in the literature of ID. Some are design graphics, but many are not. This typology of images has been devised to aid in distinguishing those that are from those that are not. A sampling of the literature of ID was scanned for graphics, and then those graphics found were categorized into one of five types based on their apparent intent:

1. **Design graphics:** Design graphics illustrate some aspect of the design of a specific piece of instruction for the purpose of planning or building that instruction.
2. **Content graphics:** Content graphics are part of the instruction delivered to learners that aid or support learning.
3. **Reporting graphics:** These graphics are used to illustrate or report the outcomes of research.

4. **Illustrations of ID models:** Graphics of this sort are illustrations that represent processes of design or construction of instruction. Diagrams of the popular ADDIE or ISD processes fall into this category.
5. **Instructional models & learning models:** These graphics include illustrations of the components of instructional theories or learning theories and the relationships among them. They are sometimes not differentiated from ID models (type 4).

The principal difference among these types is intent; the surface form may not be the discriminator. For example, it is possible to imagine a graphic, whose intent is unclear without the accompanying explanation. The mere existence of a diagram with circles and boxes connected with lines would not be enough to determine a graphic's purpose.

Let's examine each of these different types of graphics found in the research literature.

Figure 1 is an example of a type 1 graphic. It is clearly related to some specific piece of

Figure 1. An example of a type 1 graphic from ETR&D (Kalyuga & Sweller, 2005) (Copyright © 2005, The Association for Educational Communications and Technology [AECT]. Used with permission.)

instruction, charting the flow of procedures for training a specific piece of content. It may have been created to help a programmer or developer understand what was supposed to happen in this instruction.

Notice the specific content in the graphic in Figure 1. Type 1 graphics have information, either in the diagram or in the accompanying context, that ties them directly and clearly to the design of a specific piece of instruction. They may refer to specific content, as does Figure 1. They illustrate the structural elements, flow, process, information chunking, or some other aspect of the specific instructional design. To determine if a graphic is of type 1, ask, “Was this graphic representation created to assist in the creation of specific instruction?”

Type 2 illustrations are distinguished from type 1 by being part of the content of the instruction, rather than part of the design. That is, they are presented to the learner. Figure 2 was part of the content of experimental instruction trying to determine the difference in value between using mimetic icons versus standard square icons in a content graphic.

Computer screen shots of finished computer assisted instruction (CAI) are common illustrations in the sources reviewed. These screen shots

should be considered type 2. To decide if something is type 2, ask, “Was this graphic representation part of what was presented to learners during instruction?”

Type 3 graphics are used to illustrate the outcomes of research. They are often employed to help make statistical results more transparent to the reader. Bar graphs, pie charts, line graphs, etc., are common, though they are not limited to these. They are distinguished from type 1 because they illustrate the results of evaluation or research rather than the proposed design of a piece of instruction. Figure 3 is a typical example of type 3 graphic which supports a report on outcomes of research.

To determine whether a graphic representation belongs to type 3, ask, “Does this graphic help report the results data or other outcome of the evaluation or research?”

Type 4 diagrams are used to illustrate models of design processes, what Reigeluth (1993) calls an “instructional-design process” (p. 13). Figure 4 shows Dick and Carey’s model for the systematic design of instruction—a classic example of an illustration for a design process. The purpose of type 4 graphics is to help the reader understand a design process model, i.e., how to design or create instruction.

Figure 2. An example of two type 2 graphics from ETR&D (Griffin & Robinson, 2005) (Copyright © 2005, The Association for Educational Communications and Technology [AECT]. Used with permission.)

Figure 3. An example of a type 3 graphic from ETR&D (Liu & Bera, 2005) (Copyright © 2005, The Association for Educational Communications and Technology [AECT] Used with permission.)

To clarify whether a diagram belongs to type 4, ask, “Does this graphic illustrate a design process or theory about how instruction ought to be designed?”

Finally, type 5 diagrams illustrate instructional models and learning models. Figure 5 is an example of a type 5 diagram. Note that it describes or illustrates a general principle of teaching or learning and is not specific to a particular piece of instruction nor does it describe a process by which instruction is created. This type of diagram would normally be illustrating an instructional theory or learning theory.

Design theories and models (type 4) are often confused or conflated with learning and instructional theories and models (type 5). May (2006) distinguishes between design theories and learning or instructional theories by noting that design theories pertain to how someone designs an instructional product to achieve certain objectives, whereas learning theories pertain to how someone receives, processes, and remembers information. Though similar in some respects to type 4, design process model diagrams, type 5 diagrams can be distinguished from the others by asking, “Does

Figure 4. From Dick, Carey, and Carey, *The systematic design of education*, 5th ed. (Published by Allyn and Bacon, Boston, MA. Copyright 1985 by Pearson Education. Reprinted by permission of the publisher.)

Figure 5. An example of a type 5 graphic from ETR&D (Copyright © 2005, The Association for Educational Communications and Technology [AECT] Used with permission.)

this graphic illustrate a theory of learning or a theory of instruction?”

While this typology covers the majority of illustrations one might expect in research about instructional design, other kinds of images occasionally occur. For example, a photograph of the principal of a school where an intervention took place, is probably not easily placed into any of the types proposed.

Extending the Typology of Type 1 Design Graphics with ID Layers

Once graphics have been established as type 1, design graphics, is possible to extend the typology to identify and distinguish them from each other. This sub-level of categorization provides the ability to see how widely design drawings are used throughout the design process.

This sub-categorization is accomplished by adapting a concept put forth by Gibbons (2003) called instructional design layers. Gibbons has observed that instructional design often takes place as the design of several interrelated layers. Design of each layer can be considered separately from the other layers, providing an important

modularization to the design effort. The design of each layer is expressed in design languages, and these languages define the scope of designers’ thinking. Gibbons’ instructional design layers are:

- Content
- Strategy
- Control
- Message
- Representation
- Media-logic
- Data management

At the content layer, the designer defines the units of content segmentation, determines the method of content capture, and defines the kind of content elements that will be gathered. The design problem in the strategy layer consists of several interrelated sub-problems concerned with structures of time, goals, sequence, activity, physical setting, and social relationships are decided. The design problem within the control layer is the means of communication of messages from the learner to the source of the learning. The message layer determines the types of instructional messages, how they are composed, and how they are generated. The representation layer is the selection of media types, the selection of media, its generation, and the rules governing its structure and display. The design problem within the media-logic layer involves the description of execution structures that enact the representation and interactions. The design problem at the data management layer is to plan the capture, storage, analysis, aggregation, interpretation, and reporting of data produced during instruction.

To determine the pervasiveness of design drawing in ID, this typology and its extension of type 1 graphics by ID layers has been applied to a number of sources to discover and analyze examples of design drawing in ID. These sources are discussed below.

ID LITERATURE SAMPLING

A sampling of common texts in the field of ID was searched for images. Images found were then filtered through the typology above to identify examples of design drawings, type 1, in the texts. The texts included in this review are common, well-known textbooks about instructional design. Included in this review are the following textbooks: *The Systematic Design of Instruction* (Dick & Carey, 1990), *Principles of Instructional Design* (Gagné, Briggs, & Wager, 1992), and the two volumes of *Classic Writings on Instructional Technology* (Ely & Plomp, 1996). An argument could be made to bring in other texts not included here, but these are an adequate representative sample for our purposes.

The original edition of Dick and Carey's book from the late 1970s is the source of the first "Dick and Carey model" of instructional design known to nearly every instructional design student of the last thirty years. This model is particularly helpful to inexperienced or beginning instructional designers because it provides a complete systematic approach to the process of instructional design. (This review uses the 1990 edition of the text.)

The familiar blue and violet book by Gagné, Briggs, and Wager (1992) can be found on the bookshelf of nearly every instructional designer trained in the 1990s. Its presence on the bookshelves of colleagues often means that it was purchased as a class textbook, but it was kept for its ongoing value as a reference. This textbook provides a rational basis for much of the practice in instructional design, based in cognitive psychology and information processing theory.

The two-volume set from Ely and Plomp (1996) is a collection of classic literature in the field of ID. As such, it has value for both its historical reach, and the breadth of coverage. These volumes of classic articles reveal some of the roots of the field of instructional technology in audio/visual production and distribution, about which many of the papers are concerned.

For the purpose of this review, three respected ID journals were also scanned for graphics. Graphics found were categorized by the types above to discover any type 1, design graphics. The journals surveyed included: *Educational Technology Research and Development* (ETR&D), *Interactive Learning Environments* (ILE) and the *Journal of Educational Technology Systems* (JETS). It was felt that this combination of journals gave a sufficiently broad cross section of the field to effectively represent graphic communication in ID research literature.

ETR&D is a bi-monthly research publication of the Association for Educational Communications and Technology (AECT). It contains sections on both research and development, as well as book reviews, international reviews, and research abstracts. AECT has a historical connection to schools and libraries (especially audio/visual departments) and has good relationships with the faculty and students from universities that have degrees in instructional technology. AECT is an international organization, but its roots are American, and the majority of its members are from the United States. Articles in ETR&D tend to reflect this orientation. For this study we looked at all the graphics in volume 52 (2004), one full year.

ILE is an international journal published in Europe about the impact of technologies (the Internet, groupware, multimedia, etc.) on education, training, and life-long learning. The journal includes articles that cover both tools and organizational support required for authoring and implementing courseware. ILE is published three times a year; one publication contains two volumes. We reviewed volume 12, numbers 1 and 2 (a single publication), volume 13, numbers 1 and 2 (also a single publication), and volume 13, number 3. This covers roughly a year and one third.

JETS is published by Society for Applied Learning Technology (SALT). This quarterly journal deals with systems in which technology and education interface with special emphasis given to the use of computers as a component

of education systems. Members of SALT tend to come from the ranks of government and military, industry, and education, in that order. JETS reflects this priority in the types of articles it contains. For purposes of this study volume 33 (2004-5), covering one year, was reviewed.

Instructional design software was also considered. Since the early days of multiple slide projectors driven by cues on a sound track, multimedia has been explored as an instructional medium. Since the computerization of these tools, there have been graphic user interfaces among instructional multimedia authoring tools. PCV3 from Control Data and forms of visual PILOT (a computer-assisted instruction language; the acronym stands for programmed instruction, learning, or teaching) are examples of these. Of all these systems, Authorware enjoyed a unique position by being popular as a general-purpose multimedia authoring system as well as an instructional design solution, in spite of the fact that it was expressly developed to serve the needs of ID. Though they are very popular with instructional designers, Macromedia Director and Flash, are not reviewed for this study because they are general-purpose multimedia authoring tools, though they are used extensively in the production of instructional materials.

Authorware was selected for discussion in this section because it is by far the most popular ID-specific tool and it uses a graphic user interface that mimics traditional flowcharting familiar to instructional designers and others.

It may be argued that ID textbooks and journals would not be a fruitful source of ID graphics because they are mostly concerned with general theory and broad explanations. If that were true, then one particular kind of study would be more apt to provide evidence of design drawing in instructional design: case studies.

Indications that cases may be a fruitful source of examples of design drawing in ID can be found in a popular set of competencies for instructional designers called "Competencies and Skills for Instructional Designers" (Analysis & Technol-

ogy, 1995) of this list of competencies suggests that instructional designers be competent in the ability to:

- Develop flowcharts to identify learning events at the frame specific level using standardized symbology
- Develop storyboards using a template appropriate to the needs of the project

Case studies may be found in journal articles, dissertations, and books. For purposes of this study, one book of ID case studies, plus five additional case studies were reviewed.

The book of ID case studies reviewed is *The ID Casebook: Case Studies in Instructional Design* (Ertmer & Quinn, 2003) which is a compilation of 36 instructional design cases for use as practice by beginning instructional designers. Five additional case studies, four dissertations and one research article, were also reviewed. Most of the additional case studies were found by searching Doctoral research in educational technology (2005) as well as Digital Dissertations (University Microfilms) and ISI Web of Science (Institute for Scientific Information), searching for the term "case study" in the title of instructional design articles and dissertations. Case studies were considered that seemed to cover the instructional design of materials, rather than other cases (such as those about educational programs or processes), as it was thought that these would be the most productive sources of design drawing. The article is by Gastfriend, Gowan, and Lane (2001) and the dissertations include Ludwig-Hardman (2003), Hall (2004), and Twitchell (2001). Another dissertation, May (2006), was recommended by a colleague.

Although drawing as a method of design has been discussed in general literature of design studies since the 1960s and before (Jones, 1970), it has only recently become the object of study in ID. Initially, the search for ID literature about design drawing was frustrating—particularly with automated search tools. Any attempt to combine

terms like “drawing,” “graphic,” or “representation” with “instructional design” or “instructional technology” invariably resulted in research titles that had to do with the use of visual media in designed materials (type 2), not for their design and development (type 1). However, by careful screening, a few studies were identified that seemed relevant. These are: some articles authored by Gilbert Paquette and others (Paquette, 1996; Paquette, Aubin, & Crevier, 1994; Paquette, de la Teja, Lundgren-Cayrol, Léonard, & Ruelland, 2002; Paquette, Léonard, Lundgren-Cayrol, Mihaila, & Gareau, 2006; that design language is presented here in Chapter 2.3) about proposed graphic notation systems for ID; and, an article by Figl and Derntl (2006) which discuss visual instructional design languages (VIDL). One of the VIDLs discussed in Figl and Derntl is Botturi’s E²ML. we will also discuss Botturi’s (2003) dissertation on E²ML in detail.

Results of ID Literature Review

Textbooks

For this literature review, three textbooks, Dick and Carey (1990), Gagné, Briggs, and Wager (1992), and Ely and Plomp (1996) were reviewed. All the graphics and illustrations in these textbooks were classified according to the typology discussed earlier into one of five types (or miscellaneous if they did not seem to fit any of the categories). This classification is presented in Table 1.

In two of the books, design drawings predominate, taking 42% in Dick and Carey (1990)

and 62% in Gagné, Briggs, and Wager (1992). In Ely and Plomp (1996), design process model diagrams—type 4—lead, but with only 33% of the total. The difference in dominance of type 1 in the first two books versus type 4 in the last book can be explained by the differences in the purposes for which the books were written. The textbooks by Dick and Carey, and by Gagné, Briggs, and Wager are both intended as textbooks for the beginning designer. As such, they provide basic instructional design process information for guiding the novice instructional designer in her beginning work. This explains the prevalence of instructional design examples represented by these design drawings. Ely and Plomp, on the other hand, is a collection of miscellaneous papers from various sources brought together because of their seminal value to the field of ID. Because many of these papers propose instructional design models, the prevalence of type 4 model graphics should not surprise us.

The beginning of each chapter of Dick and Carey starts with a duplicate of the diagram of their model, with that chapter’s step highlighted. Because the same diagram is repeated each time to aid in navigating the book, these model graphics were only counted once. Also, Dick and Carey contains a relatively large number of graphics categorized as “miscellaneous.” Most of these miscellaneous graphics are depictions of proposed elements of their notation system for skills analysis. As such, they do not fit neatly into any of the categories.

The preponderance of design drawings or graphics in both Gagné, Briggs, and Wager, and in

Table 1. Types of graphics found in three ID textbooks

	Type 1 Design	Type 2 Content	Type 3 Report	Type 4 Process	Type 5 Instr'l	Misc
Dick & Carey	28	2	6	6	9	15
Gagné, Briggs & Wager	16	4	1	4	1	0
Ely & Plomp	2	7	4	12	4	7

Dick and Carey was unexpected. Closer inspection of these graphics reveals that nearly all of these type 1 design graphics occur in the first third of both books, and all of them are examples of skills analyses. Each book sets forth a slightly different notation system for illustrating the results of skills analysis.

Viewing the skills analysis drawings through Gibbons' (2003) instructional design layers, discussed earlier we found that all the type 1, design graphics, in Dick and Carey, and in Gagné, Briggs, and Wager, fall within the content layer. As such, they are an important use of design drawing in their own right, but represent only a small fraction of the potential uses of design drawing in ID.

In summary, examples of design graphics in these textbooks are common, but limited to only one of Gibbons' seven layers of instructional design: content. If design drawing itself were considered an important aspect of instructional design work by these authors, we would have expected to examples illustrating other of Gibbons' design layers represented in this sample literature. Interestingly, content or skills analysis is often used as the starting point for instructional design, so the use of graphic as an aid to the start of instruction is noted.

Journals

For this literature review, three ID journals were reviewed. They are *Interactive Learning Environments (ILE)*, *Educational Technology Research and Development (ETR&D)*, and the *Journal of Educational Technology Systems (JETS)*. All the

graphics and illustrations in selected issues were classified according to the typology discussed earlier into one of five types. This classification is presented in Table 2.

The three journal titles that were sampled for this study show some variation from the results of the textbooks.

In these journals, many articles demonstrated or discussed specific instructional design projects. As a result, type 2 graphics (screen shots from instructional computer programs and other illustrations of content) predominated: in *ILE* 56%, in *ETR&D*, 31%, and in *JETS*, 48%.

In *ETR&D*, the balance between research and development articles is reflected in the balance between type 2, content graphics (31%), and type 3, report graphics (29%). *JETS* is similarly balanced between type 2 and type 3.

Type 1 graphics, while not the least common, are always in the minority. In *ETR&D* they were the smallest category, 2%; they are the third smallest category in both *ILE* at 14% and, in *JETS*, at 9%.

In summary, even more dramatically than in the textbooks analyzed, these numbers indicate the relatively light value placed on type 1, design graphics, in the journal literature of ID. Instead, we find a preponderance of type 2, content graphics, often, captured computer screens or graphics, used to illustrate reports about specific products.

Software

Authorware is the ID multimedia authoring software reviewed in this study. The original Authorware, called Course of Action, was created by

Table 2. Types of graphics found in three ID journals

	Type 1 Design	Type 2 Content	Type 3 Report	Type 4 Process	Type 5 Instr'l	Misc
ILE	11	46	7	14	3	0

JETS	5	30	26	2	0	0

programmer and instructional designer Michael Allen who had been working on Control Data's PLATO courseware. It was his intent to build a system that would require little or no programming to produce instructional courseware. (Wikipedia: Authorware)

To build a presentation in Authorware, the designer drags pre-defined behavior icons from a palette of behaviors onto a design window. Once in the design window, a behavior's specific attributes can be set. The behavior icons in the design window are connected into a visual flowchart called a flowline, which determines the sequence in which the behaviors are executed. Figure 6 shows several design windows with flowlines in them. Also note the palette of behaviors on the left side of the figure. Behaviors include display, motion, erase, navigation, interaction, calculation, movie, and others. The available behaviors have changed over the life of the product. When an Authorware presentation is executed, the behaviors play out their actions on the presentation window (not shown).

It is surprising that Authorware is one of the few ID products that uses a visual approach to design. The dragging of behaviors to the design window and connecting them into a *flowline* is a

good example of a visual metaphor. Authorware's iconic, visual interface allows designers and authors to work more efficiently. The visual metaphor excels at providing the author the ability to see the flow of media-logic and to catch logical errors in thinking.

However, much of Authorware's functionality is not accessed visually, but by means of dialog boxes for specifying the attributes of behaviors and in other non-graphic ways, including a complete scripting language inside the application. Viewed through Gibbons' layers of ID we find that the flowline—the most graphic aspect of Authorware—is limited to Gibbons' strategy layer and media logic layer because it allows the designer to define the sequence of instructional events, and it directly affects the logic of execution. Visual means are also provided for composing the screen presented to users (the representation layer) but each screen must be composed separately—there is no way to compose families of screens through the visual interface (though it might be scripted in the scripting language). There are also ways to add control elements to the screen (addressing the control layer), but, except for their placement on the screen, the manipulation of these screen controls is not performed through the visual

Figure 6. Authorware presentation's behavior palette (far left) and several flowlines

interface. Authorware does have some built-in student tracking capability (supporting the data management layer), but more than basic functions of this capability require scripting. Authorware has no provision for the content layer, or for the message layer to be addressed by the designer.

Case Studies

Of the six sources for case studies reviewed, only two illustrated significant examples of design drawing. In the other four, there was little or no evidence of type 1 design graphics (though several of them did have examples of types 4 and 5—graphics supporting instructional design process models and instructional or learning models).

The first source of ID case studies examined was Ertmer and Quinn's *The ID Casebook: Case Studies in Instructional Design* (2003). Ertmer and Quinn contains only one illustration of type 1, shown in Figure 7. It is the results of a skills inventory for flight attendants. Like the design graphics found in the textbooks, it addresses Gibbons' content layer.

Of the five additional case studies chosen, the research article (Gastfriend, Gowen, & Layne, 2001) and two of the dissertations (Hall, 2004; Ludwig-Hardman, 2003) contained no examples of design drawing at all.

The dissertation-case study by Twitchell (2001) contains in an appendix a copy of the design document for the courseware about which the case is written. Included in this design document are several instances of design drawings and representations. Here is a sampling:

1. A structural perspective: component parts (a venn-diagram-like illustration, with a circle and squares representing instructional components), p. 199.
2. A data-flow diagram, p. 200.
3. A logic & data-flow diagram, p. 202.
4. Several tables containing important data.

5. A rough screen shot of the initial screen, p. 214.
6. Several other rough (wire-frame?) screen shots, pp. 10, 11.
7. A flowchart of instructional logic for a drill, p. 234.
8. The instructional flow of the program, p. 237. (see Figure 8)
9. A screen shot (more refined than previous screen shots, but still not final) + pull-down menu items, p. 240.
10. Additional screen shots, pp. 242, 244, 245, 247, and 249.

These figures comprise a fairly broad representation Gibbons' ID layers. For example, the rough screen shots (items *e*, *f*, *i*, and *j*) are intended to guide the developer in the production of user-interface screens. As such they are clearly illustrative of the representation layer in the abstract, but probably also contain elements of the content and message layers as well. Item *a* is a broad view of the strategy layer as it applies to the entire piece of courseware; *g* is an example of a narrow view of one component of the courseware at the strategy layer. Item *h*, shown in Figure 8,

Figure 7. Simplified job map for level 1 flight attendants (Ertmer & Quinn, 2003, p. 68). Reprinted by permission of Pearson Education, Inc., Upper Saddle River, NJ)

Figure 8. Program instructional flow from Twitchell (2001)

illustrates aspects of both the strategy layer as well as the media-logic layer.

Another example of a case study is a dissertation by May (2006) which analyzed the use of Gibbons' (2003) model-centered instructional design theory by a team of instructional designers tasked to design an instructional simulation. May carefully transcribed design sessions, and analyzed photographs of the rough design sketches drawn on the white board during design sessions. One of these photographs is shown in Figure 9. Many of the features of design drawing, are apparent in May's study.

May's study was unique among the case studies that we encountered in the depth to which he analyzed the design process. Parallels between the general field of design and ID became clear in May because of his careful and thorough reconstruction of events and words. May's study is a wonderful window on the ID process in gen-

eral and model-centered instructional design in detail.

To summarize, only two of the case studies reviewed gave insight in the role of design drawing in ID. The fact that we found so few speaks to the point that design drawing is not commonly discussed in ID as it is in the general design literature.

ID Literature about Design Graphics: VIDLs

Our search uncovered three important sources of research on the topic of design drawing in ID. They are an article by Figl and Derntl (2006), a dissertation by Botturi (2003), and the research of Paquette, et al. (Paquette, 1996; Paquette, Aubin, & Crevier, 1994; Paquette, Léonard, Lundgren-Cayrol, Mihaila, & Gareau, 2006). These three sources are reviewed below. They are part of an increased interest in visual ID Languages (VIDLs)

One example of this increased interest is the report of Figl and Derntl (2006), comparing the value of three VIDLs for the design of blended learning courses. What all these VIDLs have in common is their connection to the concept of learning objects and the SCORM (sharable courseware object reference model) standard. The three VIDLs compared are E²ML (educational environment modeling language), PCeL (Person-centered e-learning), and EduWeaver.

E²ML, a VIDL by Botturi (2003) is a semi-formal modeling notation for creating and documenting instructional designs. Its notation is similar to the unified modeling language (UML) used in object-oriented computer programming, substituting learning objects for computer-code objects. PCeL is founded on the person-centered philosophy of Carl Rogers (1983) but related to Alexander's (1979) concept of architectural pattern languages. PCeL includes a library of instructional patterns, modeled in UML activity diagrams, which serve as templates for the creation of instructional instantiations. EduWeaver is a Web-based courseware design tool that uses a

modeling framework for grouping and sequencing learning objects into cohesive lessons, modules, and courses into its own visual format.

Of these three, Botturi's E²ML can notate the widest variety of instructional constructs (see also Chapter VII). Botturi (2003) describes the intent of E²ML as a kind of blueprint for instructional designs, allowing all stakeholders in an instructional design effort the ability to agree on details of design. His goals for E²ML are to provide a notation system that will visually support design and development, document a design, and support evaluation.

While Chapter VII of this handbook presents a more lightweight version of E²ML, its original presentation, in 2003, proposes a wider set of inter-related diagrams. One of the principal strengths of E²ML is indeed the many varied types of diagrams that can be used for various purposes. This flexibility comes from adapting a majority of UML's views to instructional design purposes. Botturi proposes several types of ID diagrams, shown in this list of diagrams (Botturi, 2003, p. 82) below:

1. Goal definitions
 - a. Goal statement

Figure 10. An example of an E²ML goal mapping diagram showing dependencies (Botturi, 2003, p. 94)

- b. Goal mapping
- 2. Action diagrams
- 3. Resource lists
 - a. Role and actor list
 - b. Location list
 - c. Tool list
- 4. Overview diagrams
 - a. Course breakdown statement
 - b. Dependencies diagram
 - c. Activity flow

Figures 10, 11 and 12 are examples of a few of these types of diagrams. Figure 10 is an example of a goal map (item 1b on Botturi’s list, above), showing dependencies among instructional goals. It was produced following the specifications of the QUAIL model, a sub-model of the original E²ML specification. The symbols on the diagram labeled “G1,” “G2,” etc., represent different goals, Figure 11 is an example of an action or activity diagram (item 2 from Botturi’s list). Note the goals which this instructional action is supposed to address, listed along the right side. Figure 12 is an activity flow diagram (item 4c on the list above), “A1,” “A2,” etc., are the identifiers for specific activities and the diagram shows their order of occurrence. All of the various types of representation in E²ML are related to design, and fall under type 1.

While E²ML’s many types of diagrams give it broad coverage, nearly every diagram can be related to Gibbons’ strategy layer in one way or another. However, most diagrams also contain

elements for multiple layers and integrate those layers together. For example, the goal mapping diagram (item 1b from Botturi’s list of diagrams above; see Figure 10 for an example) as well as his dependencies diagram (item 4b from Botturi’s list) address Gibbons’ content layer as well as the strategy layer. E²ML’s action diagrams (item 2 from Botturi’s list; see Figure 11 for an example), sophisticated tables of information, document some aspects of Gibbons’ control layer, as does the activity flow diagram (item 4c from Botturi’s list; Figure 12 is an example). Despite the preponderance of connections to the strategy layer, many of these diagrams integrate support for other layers as well.

Figure 11. An E²ML action diagram (Botturi, 2003, p. 98)

Figure 12. An example of an E²ML activity flow diagram, (Botturi, 2003, p. 103)

Botturi's goal for E²ML is that it serves as a means for detailing instructional designs with a high level of specificity like the finished blueprints in architecture, or the detailed orthographic projection drawings in engineering. E²ML is being used to provide unified curricula among schools in Switzerland with different languages and cultures. Its high level of specificity allows it to do this. E²ML portrays the final, detailed outcome of design thinking, not the process by which it occurred, much like the design document examples found in Twitchell's (2001) case study discussed above. E²ML diagrams provide a level of detail that supports collaboration as well as detailing, documenting, and communicating a fully developed instructional design (as a language of design).

Paquette (1996; see also Chapter 8) created a graphic notation system, with supporting software, called MOT (an acronym for the French

term *Modélisation d'Ojets Typés*). MOT includes symbols (see Figure 13) for abstract knowledge classes (concepts, procedures, and principles), as well corresponding individual facts (examples, traces, and statements). Similarly, lines (arrows) connecting the symbols also come in a number of types. MOT's abstract knowledge classes correspond to object-oriented programming *classes* and individual facts correspond to the *instantiations* of the classes.

Because MOT can be used for both abstract classes as well as specific instantiations, it is able to describe both models (types 4 or 5) and instances of instruction (type 1). Figure 14 shows an example of a generic cognitive skill model ("Simulate a process") on the left, and an activity structure based on this general skill ("Choose a multimedia production process") on the right. Figure 14 does not show a third level of specific-

Figure 13. The integrated vocabulary of the MOT representation (Paquette, Léonard, Lundgren-Cayrol, Mihaila, & Gareau, 2006)

ity with specific instantiations of the classes in the general skill diagram, using the second set of symbols. The level of specificity it adds to the common hierarchical flowcharts of skills analyses, such as those found in Dick and Carey (1990), and in Gagné, Briggs, & Wager (1992) make it a good augmentation to these diagrams of content layer material.

Examples of MOT from Paquette's writing most often document Gibbons' content layer (for example, knowledge analyses), and strategy layer (for example, instructional activities). With MOT's primitives, this notation system can be applied to virtually any general notation task that uses containers and arrows, such as Laseau's (1986) bubble diagrams and networks. Because of its basic structure, MOT might be used to il-

lustrate other layers of design if those layers can be illustrated abstractly.

MOT's basic approach also makes it flexible enough to serve the various stages of design. As noted, Paquette and his colleagues have created software for creating MOT diagrams, but virtually any diagramming software that allows custom symbols (such as Visio or Omnigraffle) would be capable of implementing MOT. In addition, MOT's symbol set and concept are simple enough that they could be the basis of hand-drawn design drawings.

Figure 14. A MOT diagram showing both a meta-knowledge representation and a learning scenario (Paquette, Léonard, Lundgren-Cayrol, Mihaila, & Gareau, 2006)

SUMMARY OF DESIGN DRAWING IN ID

Our purpose in this chapter has been to understand the usage and breadth of design drawings in ID. These visual representations of instructional design are closely related to VIDLs. In other design fields, the use of graphics, sketches, or drawings in design is highly developed widely studied (see, for example, Robbins' (1998) book *Why Architects Draw*.)

We began with a review of ID literature to see if we could observe a similar tradition in ID. To conduct this review, we sampled several ID textbooks, ID journals, software, and case studies looking for examples of design drawing. We learned to distinguish design graphics from four other types of design drawings typically found in the literature (content graphics, reporting graphics, illustrations of ID models, and instructional and learning models). With design graphics identified, we categorized them using Gibbons' (2003) seven ID layers as a kind of taxonomy to understand the purposes for which these design drawings were created. These layers are: content, strategy, control, message representation, media-logic, and data management.

We did not find the same pervasiveness or level of self-awareness as found in other design fields. Examples of design drawings were found, but were somewhat rare. Furthermore, we discovered that those examples we found tended to document only two of Gibbons' seven layers: content and strategy (with some exceptions) indicating narrow application. We believe this gap represents a serious shortcoming in ID, indicating a lack of tradition, skill, and standards for visual representations of design except in limited ways.

It is widely held that a common visual language for conveying design ideas has facilitated progress in many other fields of design. The lack of such a medium in ID may be a roadblock to improving the practice of ID. This book represents a possible groundswell of interest in the subject of

visual design languages for ID. At present, design drawing is a rare but growing phenomenon in ID, which, when fully understood and implemented, can only benefit the practice of ID.
