Contents

Volume I

Section I. Fundamental Concepts and Theories

This section serves as the groundwork for this comprehensive reference book by addressing central theories essential to the understanding of instructional design. Chapters found within these pages provide a tremendous framework in which to position instructional design within the field of information science and technology. Insight regarding the critical integration of global measures into instructional design is addressed, while crucial stumbling blocks of this field are explored. The chapters comprising this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the instructional design discipline.

Chapter 1.1. Taxonomies for Technology	1
<i>Richard Caladine, University of Wollongong, Australia</i>	
Chapter 1.2. Preparing Teachers to Teach Online.....	8
<i>Gregory C. Sales, Seward Incorporated, USA</i>	
Chapter 1.3. Reflective E-Learning Pedagogy.....	18
<i>Leah Herner-Patnode, Ohio State University, Lima, USA</i>	
<i>Hea-Jin Lee, Ohio State University, Lima, USA</i>	
<i>Eun-ok Baek, California State University, San Bernardino, USA</i>	
Chapter 1.4. Higher Education's New Frontier for the E-University and Virtual Campus	34
<i>Antonio Cartelli, University of Cassino, Italy</i>	
Chapter 1.5. Learning Activities Model.....	41
<i>Richard Caladine, University of Wollongong, Australia</i>	

Chapter 1.6. What Factors Make a Multimedia Learning Environment Engaging: A Case Study.....	51
<i>Min Liu, University of Texas at Austin, USA</i>	
<i>Paul Toprac, Southern Methodist University, USA</i>	
<i>Timothy T. Yuen, University of Texas at Austin, USA</i>	
Chapter 1.7. Quality Learning Objective in Instructional Design	71
<i>Erla M. Morales, University of Salamanca, Spain</i>	
<i>Francisco J. García, University of Salamanca, Spain</i>	
<i>Ángela Barrón, University of Salamanca, Spain</i>	
Chapter 1.8. Instructional Design Methodologies	80
<i>Irene Chen, University of Houston – Downtown, USA</i>	
Chapter 1.9. Contemporary Instructional Design	95
<i>Robert S. Owen, Texas A&M University-Texarkana, USA</i>	
<i>Bosede Aworuwa, Texas A&M University-Texarkana, USA</i>	
Chapter 1.10. Instructional Design Methods Integrating Instructional Technology.....	101
<i>Paula Jones, Eastern Kentucky University, USA</i>	
<i>Rita Davis, Eastern Kentucky University, USA</i>	
Chapter 1.11. Using Design Patterns to Support E-Learning Design.....	114
<i>Sherri S. Frizell, Prairie View A&M University, USA</i>	
<i>Roland Hübscher, Bentley College, USA</i>	
Chapter 1.12. Visual Design of Coherent Technology-Enhanced Learning Systems: A Few Lessons Learned from CPM Language.....	135
<i>Thierry Nodenot, Université de Pau et des pays de l'Adour, France</i>	
<i>Pierre Laforcade, Université du Maine, France</i>	
<i>Xavier Le Pallec, Université de Lille, France</i>	
Chapter 1.13. History of Distance Learning Professional Associations	162
<i>Irene Chen, University of Houston Downtown, USA</i>	
Chapter 1.14. Using Games to Teach Design Patterns and Computer Graphics	173
<i>Pollyana Notargiacomo Mustaro, Universidade Presbiteriana Mackenzie, Brazil</i>	
<i>Luciano Silva, Universidade Presbiteriana Mackenzie, Brazil</i>	
<i>Ismar Frango Silveira, Universidade Presbiteriana Mackenzie, Brazil</i>	
Chapter 1.15. Using Video Games to Improve Literacy Levels of Males.....	192
<i>Stephenie Hewett, The Citadel, USA</i>	

Section II. Development and Design Methodologies

This section provides exhaustive coverage of conceptual architecture frameworks to endow with the reader a broad understanding of the promising technological developments within the field of instructional design. Research fundamentals imperative to the understanding of developmental processes within instructional design are offered. From broad surveys to specific discussions and case studies on electronic tools, the research found within this section spans the discipline while offering detailed, specific discussions. From basic designs to abstract development, these chapters serve to expand the reaches of development and design technologies within the instructional design community.

Chapter 2.1. Planning for Technology Integration.....	207
<i>Henryk R. Marcinkiewicz, Aramco Services Company, USA</i>	
Chapter 2.2. Bringing Reality into the Classroom.....	219
<i>Antonio Santos, Universidad de las Americas Puebla, Mexico</i>	
Chapter 2.3. Model-Facilitated Learning Environments: The Pedagogy of the Design.....	238
<i>Glenda Hostetter Shoop, Pennsylvania State University, USA</i>	
<i>Patricia A. Nordstrom, Pennsylvania State University, USA</i>	
<i>Roy B. Clariana, Pennsylvania State University, USA</i>	
Chapter 2.4. Developing Learning Communities: Improving Interactivity of an Online Class	255
<i>Pawan Jain, Fort Hays State University, Hays, USA</i>	
<i>Smita Jain, University of Wyoming, Hays, USA</i>	
Chapter 2.5. Developing Prescriptive Taxonomies for Distance Learning Instructional Design.....	270
<i>Vincent Elliott Lasnik, Independent Information Architect, USA</i>	
Chapter 2.6. Drawing Circles in the Sand: Integrating Content into Serious Games.....	288
<i>Matt Seeney, TPLD Ltd., UK</i>	
<i>Helen Routledge, Freelance Instructional Designer, UK</i>	
Chapter 2.7. A Model for Knowledge and Innovation in Online Education.....	302
<i>Jennifer Ann Linder-VanBershot, University of New Mexico, USA</i>	
<i>Deborah K. LaPointe, University of New Mexico Health Sciences Center, USA</i>	
Chapter 2.8. A Large-Scale Model for Working with Subject Matter Experts	317
<i>Judith A. Russo-Converso, CSC, USA</i>	
<i>Ronald D. Offutt, Northrup-Grumman Information Technology, USA</i>	
Chapter 2.9. Instructional Challenges in Higher Education Online Courses Delivered through a Learning Management System by Subject Matter Experts.....	330
<i>George L. Joeckel III, Utah State University, USA</i>	
<i>Tae Jeon, Utah State University, USA</i>	
<i>Joel Gardner, Utah State University, USA</i>	

Chapter 2.10. Functional Relevance and Online Instructional Design.....	342
<i>Glenn E. Snelbecker, Temple University, USA</i>	
<i>Susan M. Miller, Kent State University, USA</i>	
<i>Robert Z. Zheng, University of Utah, USA</i>	
Chapter 2.11. Self-Regulated Learning: Issues and Challenges for Initial Teacher Training.....	359
<i>Manuela Delfino, Institute for Educational Technology - Italian National Research Council, Italy</i>	
<i>Donatella Persico, Institute for Educational Technology - Italian National Research Council, Italy</i>	
Chapter 2.12. Individualized Web-Based Instructional Design.....	375
<i>Fethi Inan, Texas Tech University, USA</i>	
<i>Michael Grant, University of Memphis, USA</i>	
Chapter 2.13. The Virtue of Paper: Drawing as a Means to Innovation in Instructional Design	389
<i>Brad Hokanson, University of Minnesota, USA</i>	
Chapter 2.14. LDL for Collaborative Activities	403
<i>Christine Ferraris, Université de Savoie, France</i>	
<i>Christian Martel, Pentila Corporation and Université de Savoie, France</i>	
<i>Laurence Vignollet, Université de Savoie, France</i>	
Chapter 2.15. Development of Game-Based Training Systems: Lessons Learned in an Inter-Disciplinary Field in the Making	431
<i>Talib Hussain, BBN Technologies, USA</i>	
<i>Wallace Feurzeig, BBN Technologies, USA</i>	
<i>Jan Cannon-Bowers, University of Central Florida, USA</i>	
<i>Susan Coleman, Intellignet Decision Systems, Inc., USA</i>	
<i>Alan Koenig, National Center for Research on Evaluation, Standards and Student Testing (CRESST), USA</i>	
<i>John Lee, National Center for Research on Evaluation, Standards and Student Testing (CRESST), USA</i>	
<i>Ellen Menaker, Intelligent Decision Systems, Inc., USA</i>	
<i>Kerry Moffitt, BBN Technologies, USA</i>	
<i>Curtiss Murphy, Alion Science and Technology, AMSTO Operation, USA</i>	
<i>Kelly Pounds, i.d.e.a.s. Learning, USA</i>	
<i>Bruce Roberts, BBN Technologies, USA</i>	
<i>Jason Seip, Firewater Games LLC, USA</i>	
<i>Vance Souders, Firewater Games LLC, USA</i>	
<i>Richard Wainess, National Center for Research on Evaluation, Standards and Student Testing (CRESST), USA</i>	

Chapter 2.16. Bridging Game Development and Instructional Design	464
<i>James Belanich, U.S. Army Research Institute for the Behavioral Social Sciences, USA</i>	
<i>Karin A. Orvis, Old Dominion University, USA</i>	
<i>Daniel B. Horn, U.S. Army Research Institute for the Behavioral Social Sciences, USA</i>	
<i>Jennifer L. Solberg, U.S. Army Research Institute for the Behavioral Social Sciences, USA</i>	

Chapter 2.17. Lessons Learned about Designing Augmented Realities	480
<i>Patrick O'Shea, Harvard University, USA</i>	
<i>Rebecca Mitchell, Harvard University, USA</i>	
<i>Catherine Johnston, Harvard University, USA</i>	
<i>Chris Dede, Harvard University, USA</i>	

Section III. Tools and Technologies

This section presents an extensive treatment of various tools and technologies existing in the field of instructional design that practitioners and academics alike must rely on to develop new techniques. These chapters enlighten readers about fundamental research on the many methods used to facilitate and enhance the integration of this worldwide phenomenon by exploring software and hardware developments and their applications—an increasingly pertinent research arena. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of instructional design.

Chapter 3.1. Cognitive Architecture and Instructional Design in a Multimedia Context.....	496
<i>Renae Low, University of New South Wales, Australia</i>	
<i>Putai Jin, University of New South Wales, Australia</i>	
<i>John Sweller, University of New South Wales, USA</i>	

Chapter 3.2. Simulating Teaching Experience with Role-Play	511
<i>Scott J. Warren, University of North Texas, USA</i>	
<i>Richard A. Stein, Indiana University-Bloomington, USA</i>	

Chapter 3.3. Impact of Podcasts as Professional Learning: Teacher Created, Student Created, and Professional Development Podcasts	527
<i>Kathleen P. King, University of South Florida, USA</i>	

Chapter 3.4. Modelling Spoken Multimodal Instructional Systems.....	541
<i>Niels Ole Bernsen, NISLab, University of Southern Denmark, Denmark</i>	
<i>Laila Dybkjær, NISLab, University of Southern Denmark, Denmark</i>	

Chapter 3.5. Applying the ADDIE Model to Online Instruction	566
<i>Kaye Shelton, Dallas Baptist University, USA</i>	
<i>George Saltsman, Abilene Christian University, USA</i>	

Chapter 3.6. E-Learning with Wikis, Weblogs and Discussion Forums: An Empirical Survey about the Past, the Presence and the Future.....	583
<i>Reinhard Bernsteiner, University for Health Sciences, Austria</i>	
<i>Herwig Ostermann, University for Health Sciences, Austria</i>	
<i>Roland Staudinger, University for Health Sciences, Austria</i>	
Chapter 3.7. Integrating Blogs in Teacher Education	607
<i>Yungwei Hao, National Taiwan Normal University, Taiwan</i>	
Chapter 3.8. iPods as Mobile Multimedia Learning Environments: Individual Differences and Instructional Design	620
<i>Peter E. Doolittle, Virginia Tech, USA</i>	
<i>Danille L. Lusk, Virginia Tech, USA</i>	
<i>C. Noel Byrd, Virginia Tech, USA</i>	
<i>Gina J. Mariano, Virginia Tech, USA</i>	
Chapter 3.9. Telementoring and Project-Based Learning: An Integrated Model for 21 st Century Skills.....	639
<i>Joyce Yukawa, St. Catherine University, USA</i>	

Volume II

Chapter 3.10. Developing Educational Screencasts: A Practitioner's Perspective	665
<i>Damien Raftery, Institute of Technology Carlow, Ireland</i>	
Chapter 3.11. Teaching IT Through Learning Communities in a 3D Immersive World: The Evolution of Online Instruction.....	679
<i>Richard E. Riedl, Appalachian State University, USA</i>	
<i>Regis M. Gilman, Appalachian State University, USA</i>	
<i>John H. Tashner, Appalachian State University, USA</i>	
<i>Stephen C. Bronack, Appalachian State University, USA</i>	
<i>Amy Cheney, Appalachian State University, USA</i>	
<i>Robert Sanders, Appalachian State University, USA</i>	
<i>Roma Angel, Appalachian State University, USA</i>	
Chapter 3.12. The MOT+Visual Language for Knowledge-Based Instructional Design.....	697
<i>Gilbert Paquette, Télé-université Université du Québec à Montréal, Canada</i>	
<i>Michel Léonard, Télé-université Université du Québec à Montréal, Canada</i>	
<i>Karin Lundgren-Cayrol, Télé-université Université du Québec à Montréal, Canada</i>	
Chapter 3.13. poEML: A Separation of Concerns Proposal to Instructional Design.....	718
<i>Manuel Caeiro-Rodríguez, University of Vigo, Spain</i>	

Chapter 3.14. SEAMAN: A Visual Language-Based Tool for E-Learning Processes.....	742
<i>Gennaro Costagliola, University of Salerno, Italy</i>	
<i>Filomena Ferrucci, University of Salerno, Italy</i>	
<i>Giuseppe Polese, University of Salerno, Italy</i>	
<i>Giuseppe Scanniello, University of Basilicata, Italy</i>	
Chapter 3.15. coUML: A Visual Language for Modeling Cooperative Environments.....	758
<i>Michael Derntl, University of Vienna, Austria</i>	
<i>Renate Motschnig-Pitrik, University of Vienna, Austria</i>	
Chapter 3.16. Modeling Learning Units by Capturing Context with IMS LD	789
<i>Johannes Strobel, Purdue University, USA</i>	
<i>Gretchen Lowerison, Concordia University, Canada</i>	
<i>Roger Côté, Concordia University, Canada</i>	
<i>Philip C. Abrami, CSLP, Concordia University, Canada</i>	
<i>Edward C. Bethel, Concordia University, Canada</i>	

Section IV. Utilization and Application

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective instructional design programs and processes. This section includes over 30 chapters which review certain utilizations and applications of instructional design, such as Internet citizenship and expanded access for the visual and auditory impaired. Further chapters show case studies in Africa and Australia, and the impact of globalization and standardizing languages for instructional design. The wide ranging nature of subject matter in this section manages to be both intriguing and highly educational.

Chapter 4.1. Wireless Computer Labs	809
<i>Lawrence A. Tomei, Robert Morris University, USA</i>	
Chapter 4.2. Personalised Learning: A Case Study in Teaching Clinical Educators Instructional Design Skills	817
<i>Iain Doherty, University of Auckland, New Zealand</i>	
<i>Adam Blake, University of Auckland, New Zealand</i>	
Chapter 4.3. Creating Supportive Environments for CALL Teacher Autonomy	840
<i>Renata Chylinski, Monash University, Australia</i>	
<i>Ria Hanewald, La Trobe University, Melbourne, Australia</i>	
Chapter 4.4. Learning Object Based Instruction.....	861
<i>Alex Stone, VLN Partners, LLC., USA</i>	

Chapter 4.5. Teaching Technology to Digital Immigrants: Strategies for Success.....	870
<i>Danika Rockett, University of Maryland Baltimore County, USA</i>	
<i>Tamara Powell, Kennesaw State University, USA</i>	
<i>Amy Massey Vessel, Louisiana Tech University, USA</i>	
<i>Kimberly Kimbell-Lopez, Louisiana Tech University, USA</i>	
<i>Carrice Cummins, Louisiana Tech University, USA</i>	
<i>Janis Hill, Louisiana Tech University, USA</i>	
<i>Richard Hutchinson, Kennesaw State University, USA</i>	
<i>David Cargil, Louisiana Tech University, USA</i>	
Chapter 4.6. Internet Citizenship: Course Desing and Delivery Using ICT.....	880
<i>Henry H. Emurian, University of Maryland – Baltimore County, USA</i>	
<i>Malissa Marie Carroll, University of Maryland – Baltimore County, USA</i>	
Chapter 4.7. The Real World Buffalo: Reality TV Comes to a Charter School	888
<i>Marion Barnett, Buffalo State College, USA</i>	
<i>Kim Truesdell, Buffalo State College, USA</i>	
<i>Melaine Kenyon, Buffalo State College, USA</i>	
<i>Dennis Mike, Buffalo State College, USA</i>	
Chapter 4.8. Research on the Effects of Media and Pedagogy in Distance Education.....	904
<i>Lou Yiping, Louisiana State University, USA</i>	
Chapter 4.9. Application of E-Learning in Teaching: Learning and Research in East African Universities	914
<i>Michael Walimbwa, Makerere University, Uganda</i>	
Chapter 4.10. Asynchronous Online Foreign Language Courses.....	928
<i>Leticia L. McGrath, Georgia Southern University, USA</i>	
<i>Mark Johnson, University System of Georgia, USA</i>	
Chapter 4.11. The Application of Sound and Auditory Responses in E-Learning	936
<i>Terry T. Kidd, University of Texas School of Public Health, USA</i>	
Chapter 4.12. The Influence of Visual and Temporal Dynamics on Split Attention: Evidences from Eye Tracking	944
<i>Florian Schmidt-Weigand, University of Kassel, Germany</i>	
Chapter 4.13. Leveraging Libraries to Support Academic Technology.....	963
<i>Heather Jagman, DePaul University, USA</i>	
<i>Melissa Koenig, DePaul University, USA</i>	
<i>Courtney Greene, DePaul University, USA</i>	

Chapter 4.14. Student Decision Making in Technology Application	972
<i>Ali Ahmed, University of Wisconsin - La Crosse, USA</i>	
<i>Abdulaziz Elfessi, University of Wisconsin - La Crosse, USA</i>	
Chapter 4.15. Transforming a Pediatrics Lecture Series to Online Instruction	984
<i>Tiffany A. Koszalka, Syracuse University, USA</i>	
<i>Bradley Olson, SUNY Upstate Medical University, USA</i>	
Chapter 4.16. A Collaborative Approach for Online Dementia Care Training	998
<i>Colla J. MacDonald, University of Ottawa, Canada</i>	
<i>Emma J. Stodel, Learning 4 Excellence, Canada</i>	
<i>Lynn Casimiro, University of Ottawa, Canada</i>	
<i>Lynda Weaver, SCO Health Service, Canada</i>	
Chapter 4.17. Gaming and Simulation: Training, and the Military	1006
<i>Sheila Seitz, Windwalker Corporation, USA</i>	
<i>Courtney Uram, James Madison University, USA</i>	
Chapter 4.18. Leveraging the Affordances of an Electronic Game to Meet Instructional Goals	1023
<i>Yuxin Ma, University of Louisiana at Lafayette, USA</i>	
<i>Douglas Williams, University of Louisiana at Lafayette, USA</i>	
<i>Charles Richard, University of Louisiana at Lafayette, USA</i>	
<i>Louise Prejean, University of Louisiana at Lafayette, USA</i>	
Chapter 4.19. A Video Game, a Chinese Otaku, and Her Deep Learning of a Language	1039
<i>Kim Feldmesser, University of Brighton, UK</i>	
Chapter 4.20. Narrative Development and Instructional Design	1069
<i>Douglas Williams, University of Louisiana at Lafayette, USA</i>	
<i>Yuxin Ma, University of Louisiana at Lafayette, USA</i>	
<i>Charles Richard, University of Louisiana at Lafayette, USA</i>	
<i>Louise Prejean, University of Louisiana at Lafayette, USA</i>	
Chapter 4.21. Teacher Gamers vs. Teacher Non-Gamers	1085
<i>Christopher L. James, Russellville City Schools, USA</i>	
<i>Vivan H. Wright, University of Alabama, USA</i>	
Chapter 4.22. Dance Dance Education and Rites of Passage	1104
<i>Brock Dubbels, Center for Cognitive Studies, Literacy Education, University of Minnesota, Department of Curriculum & Instruction, USA</i>	

Section V. Organizational and Social Implications

This section includes a spacious range of inquiry and research pertaining to the behavioral, emotional, social and organizational impact of instructional design around the world. From case studies in Africa to studies of gaming on developmentally disabled and learning disabled children to plagiarism and community collaboration, this section compels the humanities, education, and IT scholar all. Section 5 also focuses on hesitance in some faculty members' integration with instructional design, a growing issue among those involved with education who are already forced to "wear many hats" at the higher education level. With more than 20 chapters, the discussions on hand in this section detail current and suggest future research into the integration of global instructional design as well as implementation of ethical considerations for all organizations. Overall, these chapters present a detailed investigation of the complex relationship between individuals, organizations and instructional design.

Chapter 5.1. Culturally Negotiating the Meanings of Technology Use.....	1133
<i>Deepak Prem Subramony, Utah State University, USA</i>	
Chapter 5.2. Cross-Cultural Learning Objects (XCLOs).....	1159
<i>Andrea L. Edmundson, eWorld Learning, Inc., USA</i>	
Chapter 5.3. Technology Integration Practices within a Socioeconomic Context: Implications for Educational Disparities and Teacher Preparation.....	1169
<i>Holim Song, Texas Southern University, USA</i>	
<i>Emiel Owens, Texas Southern University, USA</i>	
<i>Terry T. Kidd, University of Texas School of Public Health, USA</i>	
Chapter 5.4. Assistive Technology for Individuals with Disabilities.....	1183
<i>Yukiko Inoue, University of Guam, Guam</i>	
Chapter 5.5. Cognitive-Adaptive Instructional Systems for Special Needs Learners	1191
<i>Bruce J. Diamond, William Paterson University, USA</i>	
<i>Gregory M. Shreve, Kent State University, USA</i>	
Chapter 5.6. Animated Computer Education Games for Students with ADHD: Evaluating Their Development and Effectiveness as Instructional Tools	1211
<i>Kim B. Dielmann, University of Central Arkansas, USA</i>	
<i>Julie Meaux, University of Central Arkansas, USA</i>	
Chapter 5.7. Barriers to and Strategies for Faculty Integration of IT	1228
<i>Thomas M. Brinthaup, Middle Tennessee State University, USA</i>	
<i>Maria A. Clayton, Middle Tennessee State University, USA</i>	
<i>Barbara J. Draude, Middle Tennessee State University, USA</i>	
Chapter 5.8. Social Psychology and Instructional Technology	1237
<i>Robert A. Bartsch, University of Houston - Clear Lake, USA</i>	

Chapter 5.9. Addressing Emotions within E-Learning Systems.....	1245
<i>Valentino Zurloni, CESCO, University of Milan - Bicocca, Italy</i>	
<i>Fabrizia Mantovani, CESCO, University of Milan - Bicocca, Italy, & ATN-P LAB,</i>	
<i>Istituto Auxologico Italiano, Italy</i>	
<i>Marcello Mortillaro, CESCO, University of Milan - Bicocca, Italy, & CISA -</i>	
<i>University of Geneva, Switzerland</i>	
<i>Antonietta Vescovo, CESCO, University of Milan - Bicocca, Italy</i>	
<i>Luigi Anolli, CESCO, University of Milan - Bicocca, Italy</i>	
Chapter 5.10. Behaviorism and Developments in Instructional Design and Technology	1259
<i>Irene Chen, University of Houston Downtown, USA</i>	
Chapter 5.11. Harnessing the Emotional Potential of Video Games	1282
<i>Patrick Felicia, University College Cork, Ireland</i>	
<i>Ian Pitt, University College Cork, Ireland</i>	
Chapter 5.12. Students' Attitudes toward Process and Product Oriented Online Collaborative Learning.....	1300
<i>Xinchun Wang, California State University, Fresno, USA</i>	

Volume III

Chapter 5.13. Plagiarism and the Community College.....	1320
<i>Teri Thomson Maddox, Jackson State Community College, USA</i>	

Section VI. Managerial Impact

This section presents contemporary coverage of the social implications of instructional design, more specifically related to the corporate and managerial utilization of information sharing technologies and applications, and how these technologies can be facilitated within organizations. Section 6 is especially helpful as an addition to the organizational and behavioral studies of section 5, with diverse and novel developments in the managerial and human resources areas of instructional design. Typically, though the fields of industry and education are not always considered co-dependent, section 6 provides looks into how instructional design and the business workplace help each other. The interrelationship of such issues as educational design, quality improvement, work ecology, teacher self-confidence, technology skills, and professional development are discussed. In all, the chapters in this section offer specific perspectives on how managerial perspectives and developments in instructional design inform each other to create more meaningful user experiences.

Chapter 6.1. Prevention is Better than Cure: Addressing Cheating and Plagiarism Based on the IT Student Perspective.....	1341
<i>Martin Dick, RMIT University, Australia</i>	
<i>Judithe Sheard, Monash University, Australia</i>	
<i>Maurie Hasen, Monash University, Australia</i>	

Chapter 6.2. Structuring a Local Virtual Work Ecology for a Collaborative, Multi-Institutional Higher Educational Project: A Case Study	1364
<i>Shalin Hai-Jew, Kansas State University, USA</i>	
Chapter 6.3. Motivation and Multimedia Learning	1393
<i>Renae Low, University of New South Wales, Australia</i>	
<i>Putai Jin, University of New South Wales, Australia</i>	
Chapter 6.4. Making E-Training Cost Effective through Quality Assurance	1413
<i>Lichia Yiu, Centre for Socio-Eco-Nomic Development (CSEND), Switzerland</i>	
<i>Raymond Saner, Centre for Socio-Eco-Nomic Development (CSEND), Switzerland</i>	
Chapter 6.5. Using the Interpersonal Action-Learning Cycle to Invite Thinking, Attentive Comprehension	1423
<i>Bob Zimmer, The Open University, UK</i>	
Chapter 6.6. Synergy: Service Learning in Undergraduate Instructional Technology Courses	1446
<i>Jacqueline M. Mumford, Walsh University, USA</i>	
<i>Elizabeth Juelich-Velotta, Walsh University, USA</i>	
Chapter 6.7. Knowledge Transfer in G2G Endeavors	1465
<i>Luiz Antonio Joia, Rio de Janeiro State University, Brazil</i>	
Chapter 6.8. Policy Issues Regarding the Instructional and Educational Use of Videoconferencing	1472
<i>Joseph Bowman, University at Albany/SUNY, USA</i>	
<i>Felix Fernandez, ICF International, USA</i>	
<i>Sharon Miller Vice, University at Albany/SUNY, USA</i>	
Chapter 6.9. Improving Teachers' Self-Confidence in Learning Technology Skills and Math Education through Professional Development.....	1487
<i>Taralynn Hartsell, The University of Southern Mississippi, USA</i>	
<i>Sherry S. Herron, The University of Southern Mississippi, USA</i>	
<i>Houbin Fang, The University of Southern Mississippi, USA</i>	
<i>Avinash Rathod, The University of Southern Mississippi, USA</i>	

Section VII. Critical Issues

Section 7 details some of the most crucial developments in the critical issues surrounding instructional design. Importantly, this refers to critical thinking or critical theory surrounding the topic, rather than vital affairs or new trends that may be found in section 8. Instead, the section discusses some of the latest developments in cognitive load, social constructivist and pedagogy theories, as well as new approaches in faculty development, learning with visualizations, and implications of anonymity online. This section also asks unique questions about the role of business intelligence in developing countries and in linguistic confusion across cultures. Within the chapters, the reader is presented with an in-depth analysis of the most current and relevant issues within this growing field of study.

Chapter 7.1. Theories and Principles for E-Learning Practices with Instructional Design	1504
<i>Maria Ranieri, University of Florence, Italy</i>	
Chapter 7.2. Humanistic Theories that Guide Online Course Design	1514
<i>MarySue Cicciarelli, Duquesne University, USA</i>	
Chapter 7.3. Commodity, Firmness, and Delight: Four Modes of Instructional Design Practice	1520
<i>Brad Hokanson, University of Minnesota, USA</i>	
<i>Charles Miller, University of Minnesota, USA</i>	
<i>Simon Hooper, Penn State University, USA</i>	
Chapter 7.4. Performance Case Modeling	1537
<i>Ian Douglas, Florida State University, USA</i>	
Chapter 7.5. Can Cognitive Style Predict How Individuals Use Web-Based Learning Environments?	1553
<i>Martin Graff, University of Glamorgan, UK</i>	
Chapter 7.6. Multimedia, Cognitive Load, and Pedagogy.....	1564
<i>Peter E. Doolittle, Virginia Polytechnic Institute & State University, USA</i>	
<i>Andrea L. McNeill, Virginia Polytechnic Institute & State University, USA</i>	
<i>Krista P. Terry, Radford University, USA</i>	
<i>Stephanie B. Scheer, University of Virginia, USA</i>	
Chapter 7.7. Instructional Game Design Using Cognitive Load Theory	1586
<i>Wenhao David Huang, University of Illinois, USA</i>	
<i>Tristan Johnson, Florida State University, USA</i>	
Chapter 7.8. Faculty Development in Instructional Technology in the Context of Learning Styles and Institutional Barriers.....	1607
<i>Robson Marinho, Andrews University, USA</i>	
Chapter 7.9. On the Role of Learning Theories in Furthering Software Engineering Education.....	1645
<i>Emily Oh Navarro, University of California, Irvine, USA</i>	
<i>André van der Hoek, University of California, Irvine, USA</i>	
Chapter 7.10. Theoretical and Instructional Aspects of Learning with Visualizations.....	1667
<i>Katharina Scheiter, University of Tuebingen, Germany</i>	
<i>Eric Wiebe, North Carolina State University, USA</i>	
<i>Jana Holsanova, Lund University, Sweden</i>	
Chapter 7.11. Teaching Social Skills: Integrating an Online Learning System into Traditional Curriculum.....	1689
<i>Graham Bodie, Purdue University, USA</i>	
<i>Margaret Fitch-Hauser, Auburn University, USA</i>	
<i>William Powers, Texas Christian University, USA</i>	

Chapter 7.12. Conversation Design in the Electronic Discussion Age.....	1714
<i>Gregory MacKinnon, Acadia University, Canada</i>	
Chapter 7.13. E-Social Constructivism and Collaborative E-Learning.....	1730
<i>Janet Salmons, Vision2Lead, Inc., USA & Capella University, USA</i>	
Chapter 7.14. Ethics in Interactions in Distance Education.....	1744
<i>Paul Kawachi, Open Education Network, Japan</i>	
Chapter 7.15. Implications of Anonymity in Cyber Education	1755
<i>Bobbe Baggio, Advantage Learning Technologies, USA</i>	
<i>Yoany Beldarrain, Florida Virtual School, USA</i>	
Chapter 7.16. An Ontological Approach to Online Instructional Design	1771
<i>Robert Z. Zheng, University of Utah, USA</i>	
<i>Laura B. Dahl, University of Utah, USA</i>	
Chapter 7.17. Lost In Translation: Improving the Transition Between Design and Production of Instructional Software.....	1793
<i>Eddy Boot, TNO Human Factors, The Netherlands</i>	
<i>Jon Nelson, Utah State University, USA</i>	
<i>Daniela De Faveri, Università della Svizzera Italiana, Switzerland</i>	
Chapter 7.18. Pask and Ma Join Forces in an Elementary Mathematics Methods Course.....	1806
<i>Jean Morrow, Emporia State University, USA</i>	
<i>Janet Holland, Emporia State University, USA</i>	
Chapter 7.19. Assessing 3D Virtual World Learning Environments with the CIMPLe System: A Multidisciplinary Evaluation Rubric1	1817
<i>Sean D. Williams, Clemson University, USA</i>	
<i>Deborah M. Switzer, Clemson University, USA</i>	

Section VIII. Emerging Trends

The final section explores the latest trends and developments, and suggests future research potential within the field of instructional design while exploring uncharted areas of study for the advancement of the discipline. Introducing this section are chapters that describe some of the most recent issues in technology-assisted education, followed by new topics on adult education and virtual inquiry. Of special note to those looking for the design portion of instructional design, two of the final chapters discuss aesthetics and new practices in instructional design. These and several other emerging trends and suggestions for future research can be found within the final section of this exhaustive multi-volume set.

Chapter 8.1. Contemporary Issues in Teaching and Learning with Technology	1840
<i>Jerry P. Galloway, Texas Wesleyan University, USA & University of Texas at Arlington, USA</i>	

Chapter 8.2. New Directions in the Research of Technology-Enhanced Education.....	1847
<i>Robert N. Ronau, University of Louisville, USA</i>	
<i>Christopher R. Rakes, University of Louisville, USA</i>	
<i>Margaret L. Niess, Oregon State University, USA</i>	
<i>Lauren Wagener, University of Tennessee, USA</i>	
<i>David Pugalee, University of North Carolina, USA</i>	
<i>Christine Browning, Western Michigan University, USA</i>	
<i>Shannon O. Driskell, University of Dayton, USA</i>	
<i>Susann M. Mathews, Wright State University, USA</i>	
Chapter 8.3. Emerging Edtech: Expert Perspectives and Design Principles	1880
<i>Ching-Huei Chen, Center for Educational Technologies®, Wheeling Jesuit University, USA</i>	
<i>Manetta Calinger, Center for Educational Technologies®, Wheeling Jesuit University, USA</i>	
<i>Bruce C. Howard, Center for Educational Technologies®, Wheeling Jesuit University, USA</i>	
<i>Anna Oskorus, TiER 1 Performance Solutions, USA</i>	
Chapter 8.4. Rapid E-Learning in the University	1892
<i>Ivy Tan, University of Saskatchewan, Canada</i>	
<i>Ravi Chandran, National University of Singapore, Singapore</i>	
Chapter 8.5. The Innovative Production Machines and Systems Network of Excellence.....	1899
<i>D. T. Pham, Cardiff University, UK</i>	
<i>E. E. Eldukhuri, Cardiff University, UK</i>	
<i>A. Soroka, Cardiff University, UK</i>	
<i>V. Zlatanov, Cardiff University, UK</i>	
<i>M.S. Packiananther, Cardiff University, UK</i>	
<i>R. Setchi, Cardiff University, UK</i>	
<i>P.T.N. Pham, Cardiff University, UK</i>	
<i>A. Thomas, Cardiff University, UK</i>	
<i>Y. Dadam, Cardiff University, UK</i>	
Chapter 8.6. Aesthetic Decisions of Instructors and Instructional Designers.....	1904
<i>Patrick Parrish, University Corporation for Atmospheric Research, USA</i>	
Chapter 8.7. The Pervasiveness of Design Drawing in ID	1921
<i>S. Todd Stubbs, Brigham Young University, USA</i>	
<i>Andrew S. Gibbons, Brigham Young University, USA</i>	

Preface

Instructional design integrates the burgeoning field of Information Technology with the global development of educational theory and practice. Through development and analysis of cognitive load and learning design theories, and ADDIE, Gagne, and constructivist models, instructional design has advanced greatly since its inception during World War II.

The constantly changing landscape of instructional design makes it challenging for experts and practitioners to stay informed of the field's most up-to-date research. That is why Information Science Reference is pleased to offer this three-volume reference collection that will empower students, researchers, and academicians with a strong understanding of critical issues within instructional design by providing both extensive and detailed perspectives on cutting-edge theories and developments. This reference serves as a single, comprehensive reference source on conceptual, methodological, technical, and managerial issues, as well as providing insight into emerging trends and future opportunities within the discipline.

Instructional Design: Concepts, Methodologies, Tools and Applications is organized into eight distinct sections that provide wide-ranging coverage of important topics. The sections are: (1) Fundamental Concepts and Theories, (2) Development and Design Methodologies, (3) Tools and Technologies, (4) Utilization and Application, (5) Organizational and Social Implications, (6) Managerial Impact, (7) Critical Issues, and (8) Emerging Trends.

Section 1, ***Fundamental Concepts and Theories***, serves as a foundation for this extensive reference tool by addressing crucial theories essential to the understanding of instructional design. Chapters such as *Contemporary Instructional Design* by Robert S. Owen and Bosede Aworuwa and *Instructional Design Methodologies* by Irene Chen lay a foundation to some of the more basic and essential fundamentals of the field. Other chapters such as *History of Distance Learning Professional Associations*, also by Irene Chen, give detailed, yet brief summaries of the history of the instructional design developments. Also of note, the final two chapters in section 1, *Using Games to Teach Design Patterns and Computer Graphics* by Pollyana Notargiacomo Mustaro, Luciano Silva, & Ismar Frango Silveira; and *Using Video Games to Improve Literacy Levels of Males* by Stephenie Hewett give introduction to a few video and serious game applications in the instructional design field.

Section 2, ***Development and Design Methodologies***, presents in-depth coverage of the conceptual design and architecture of instructional design, focusing on aspects including online course materials and education, augmented and virtual realities architectures, and methodological frameworks for Web based instruction. Designing and implementing effective processes and strategies are the focus of such chapters as *Planning for Technology Integration* by Henryk R. Marcinkiewicz, and *Lessons Learned about Designing Augmented Realities* by Patrick O'Shea, Rebecca Mitchell, Catherine Johnston, and Chris Dede.

Section 3, ***Tools and Technologies***, presents extensive coverage of the various tools and technologies used in the development and implementation of instructional design. This comprehensive section includes such chapters as *iPods as Mobile Multimedia Learning Environments* by Peter E. Doolittle,

which detail software and hardware developments (respectively) and their applications in the field of instructional design. Additional chapters on MOT+Visual, poEML, SEAMAN, and coUML describe some of the newest modifying languages and tools at the disposal of instructional designers. And perhaps of the most vital note to higher educators is the broad discussion over a few chapters on videoconferencing and its quintessential and technical role in pedagogy.

Section 4, ***Utilization and Application***, describes how instructional design has been utilized and offers insight on important lessons for its continued use and evolution. Due to the breadth of this section's subject matter, section 4 contains the widest range of topics, including chapters such as *Application of E-Learning in Teaching, Learning and Research in East African Universities* by Michael Walimbwa and *Internet Citizenship* by Henry H. Emurian and Malissa Marie Carroll. This section is also filled with international case studies and applications of new technologies in higher learning institutions. Also of note in section 4 is the treatment given to developments in course design for foreign language instruction, some of the most recent and relevant publication on the vital subject matter.

Section 5, ***Organizational and Social Implications***, includes chapters discussing the organizational and social impact of instructional design. Overall, these chapters present a detailed investigation of the complex relationship between individuals, organizations and instructional design. The first 8 chapters of section 5 are about the challenges of culture on the ever expanding and diversifying global higher education system. *Behaviorism and Developments in Instructional Design and Technology* by Irene Chen, and *Addressing Emotions within E-Learning Systems* by Valentino Zurloni, Fabrizia Mantovani, Marcello Mortillaro, Antonietta Vescovo, and Luigi Anolli are examples of some of the psychological or behavioral impacts on instructional learning, developing the influence emotion and mental response have on learning styles and pedagogy. And aside from cultural and psychological adaptations of instructional design, there are also spots of interest in *Plagiarism and the Community College* by Teri Thomson Maddox.

Section 6, ***Managerial Impact***, presents focused coverage of instructional design as it relates to improvements and considerations in the workplace. In all, the chapters in this section offer specific perspectives on how managerial perspectives and developments in instructional design inform each other to create more meaningful user experiences. Typically, though the fields of industry and education are not always considered co-dependent, section 6 provides looks into how instructional design and the business workplace help each other. Examples include *Structuring a Local Virtual Work Ecology for a Collaborative, Multi-Institutional Higher Educational Project* by Shalin Hai-Jew; and *Improving Teachers' Self-Confidence in Learning Technology Skills and Math Education through Professional Development* by Taralynn Hartsell, Sherry S. Herron, Houbin Fang, and Avinash Rathod. Section 6 is especially helpful as an addition to the organizational and behavioral studies of section 5, with diverse and novel developments in the managerial and human resources areas of instructional design.

Section 7, ***Critical Issues***, addresses some of the latest academic theory related to instructional design. Importantly, this refers to critical thinking or critical theory surrounding the topic, rather than vital affairs or new trends that may be found in section 8. Instead, the section discusses some of the latest developments in cognitive load, social constructivist and pedagogy theories, as well as new approaches in faculty development, learning with visualizations, and implications of anonymity online. Within the chapters, the reader is presented with an in-depth analysis of the most current and relevant issues within this growing field of study. Chapters such as *Commodity, Firmness, and Delight* by Brad Hokanson, Charles Miller, and Simon Hooper show stylistic and business-savvy industry improvements, while *Ethics in Interactions in Distance Education* directs some of the latest scholarly publication on morality and its online legislation and execution. This section also asks unique questions about the role of business intelligence in developing countries and in linguistic confusion across cultures.

Section 8, *Emerging Trends*, highlights areas for future research within the field of instructional design, while exploring new avenues for the advancement of the discipline. Beginning this section is *Contemporary Issues in Teaching and Learning with Technology* by Jerry P. Galloway, detailing some of the most recent issues plaguing the IT side of online higher education. Closing out the book are two fascinating chapters of recent developments. First, in Patrick Parrish's *Aesthetic Decisions of Instructors and Instructional Designers* comes a study of the effects of visual and graphic depiction on pedagogy and effectiveness. Second and finally, *The Pervasiveness of Design Drawing in ID* by S. Todd Stubbs and Andrew S. Gibbons closes out the book, with a last look at an instructional design topic that has recently found trending importance. These and several other emerging trends and suggestions for future research can be found within the final section of this exhaustive multi-volume set.

Although the primary organization of the contents in this multi-volume work is based on its eight sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. Furthermore to ensure that the scholar, researcher and educator have access to the entire contents of this multi volume set as well as additional coverage that could not be included in the print version of this publication, the publisher will provide unlimited multi-user electronic access to the online aggregated database of this collection for the life of the edition, free of charge when a library purchases a print copy. This aggregated database provides far more contents than what can be included in the print version in addition to continual updates. This unlimited access, coupled with the continuous updates to the database ensures that the most current research is accessible to knowledge seekers.

As a comprehensive collection of research on the latest findings related to using technology to providing various services, *Instructional Design: Concepts, Methodologies, Tools and Applications*, provides researchers, administrators and all audiences with a complete understanding of the development of applications and concepts in instructional design. Given the vast number of issues concerning usage, failure, success, policies, strategies, and applications of instructional design in organizations, *Instructional Design: Concepts, Methodologies, Tools and Applications* addresses the demand for a resource that encompasses the most pertinent research in instructional design development, deployment, and impact.

Section I

Fundamental Concepts and Theories

This section serves as the groundwork for this comprehensive reference book by addressing central theories essential to the understanding of instructional design. Chapters found within these pages provide a tremendous framework in which to position instructional design within the field of information science and technology. Insight regarding the critical integration of global measures into instructional design is addressed, while crucial stumbling blocks of this field are explored. The chapters comprising this introductory section, the reader can learn and choose from a compendium of expert research on the elemental theories underscoring the instructional design discipline.

Chapter 1.1

Taxonomies for Technology

Richard Caladine
University of Wollongong, Australia

INTRODUCTION

For over 3000 years from Homer, Moses and Socrates onwards, the teacher in direct, personal contact with the learner, has been the primary means of communicating knowledge...until the fourteenth century, when the invention of the printing press allowed for the first time the large-scale dissemination of knowledge through books. (Bates, 1995)

Today there is a range of technologies available to those who design learning events, from the old and simple to the new and complex. Key attempts have been made to develop theoretical frameworks of learning technologies and have been reported in the literature of higher education, human resource development, and instructional

design. These three fields are not discrete and some overlap occurs. For example, commentators in the field of instructional design state that their designs are provided for learning in many contexts including schools, higher education, organizations, and government (Gagné, Briggs, & Wager, 1992; Reigeluth, 1983). In many cases the theoretical frameworks are intended to guide the selection of learning technologies but often the conceptualizations have not kept pace with technological change.

There are many definitions of taxonomy and most of them refer to systems for the classification and organization of things. Carl Linnaeus developed the most well known taxonomy during the expansion of natural history knowledge in the 18th century. It is the scientific system for the classification of living things and has the basic structure of organism, domain, kingdom, phylum, class, order, family, genus, and species.

DOI: 10.4018/978-1-60960-503-2.ch101

It has been argued (Wikipedia, 2005) that the human mind uses organizational structures to naturally and systematically order information received and hence makes sense of the world. A taxonomy is clearly an organizational structure and it follows that as the Linnaean taxonomy assists those investigating the life sciences; a taxonomy of learning technologies can help users and investigators of learning technologies. Further it is suggested that taxonomies of learning technologies are appropriate tools to assist in the design of learning events that include technologies.

BACKGROUND

The Linnaean taxonomy has a deep hierarchical structure which reflects the number and diversity of living things. It is reasonable to expect that a taxonomy for learning technologies will be smaller due the smaller number of learning technologies. Just as new species are added to the Linnaean taxonomy as they are discovered, a taxonomy of learning technologies must be adaptable to cater for learning technologies of the future. A taxonomy of learning technologies is therefore a framework that classifies or organizes learning technologies.

There have been a number attempts to classify or organize learning technologies and while their classification frameworks are logically sound they have not always been developed to assist in the design of learning events that use technology in the most effective and efficient manner. Also, there is a considerable range in the depth of approach or rigor. However, all of the approaches either divide technologies into categories, either by intention or as a result of categorization by other criteria.

Leshin, Pollock, and Reigeluth (1992) present a classification scheme for “media” that is based on attributes in which learning technologies are grouped into five “systems.”

- Human-based system (teacher instructor, tutor, role-plays, group activities, field trips, etc.)
 - Print-based system (books, manuals, workbooks, job aids, handouts, ect.)
 - Visual-based system (books, job aids, charts, graphs, maps, figures, transparencies, slides, etc.)
 - Audiovisual-based system (video, film, slide-tape programs, live television, etc.)
 - Computer-based system (computer-based instruction, computer-based interactive video, hypertext, etc.)

They state that the “systems” share the characteristic of carrying “a message (information) to a receiver (learner)” and that some “systems” can “process messages from the receiver” (Leshin et al., 1992, p. 256). Writing in the field of instructional design, Leshin, Pollock, and Reigeluth use their classification as a starting point from which technology-based learning events can be designed: “Now through the process of message design you will tailor your instruction to a particular medium or set of media.” (Leshin et al., 1992)

The approach taken to the classification of learning technologies by Leshin, Pollock, and Reigeluth provides little or no insight into the application of the technology, and is not much more than a labeling system. As they were writing prior to the development of the World Wide Web, the classification system did not include learning management systems or online technologies. They could easily be added to the last category of computer-based systems, but this adds little to the understanding of them or to their application to learning in an appropriate way.

Also writing in the literature of instructional design, Romiszowski (1988) classifies “media” by the sensory channels they support and provides examples such as telephone for the auditory channel, video for the “audio/visual” channel, chalkboards for the visual channel, and devices

or models for the “tactile or kinesthetic” channel. Romiszowski’s approach is slightly more informative than that of Leshin, Pollock, and Reigeluth as he makes the conceptual connection between technologies and “sensory channels.” However his system of classification provides little insight into the characteristics of the technologies which lead to the matching of them to learning activities in an appropriate manner.

Others in the field of instructional design take an even less rigorous approach to the categorization or classification of learning technologies. Reiser and Gagné (1983) argue that a “number of kinds of categories can be devised for the classification of media” and that “frequently employed categories include audio, print, still visual and motion visual, and real objects.” They elaborate that the reasons for categorizing “media” are generally associated with their selection and that their application can be optimized through matching their characteristics to the task:

A particular type of medium can best present a task having a similar classification. For example the learning of a task that requires differentiation of visual features can best be done with a visual medium (Reiser & Gagné, 1983, p. 13).

While Reiser and Gagné’s categorization of “media” is appropriate for the selection of technologies as adjuncts to classroom teaching from the technologies available in the early 1980s, it does not have much to offer the selection of learning technologies as central elements of learning events and does not easily expand to address technologies developed after their conceptualization was published.

Some other commentators have taken a more interpretive approach to the categorization of learning technologies. Contrary to the descriptive classification approaches, Laurillard (2002) categorizes learning technologies through the use of “pedagogical categories” and argues that “there

are many attempts in the literature to categorise and classify the forms of media, none of which is very illuminating for our purpose here” (pp. 77-78).

Laurillard continues with the argument that “educational media” should be classified in terms of the categories and extent of learning processes they support and provides the four categories: “Discursive, Adaptive, Interactive and Reflective.” Laurillard’s categories provide limited insight to the nature and characteristics of learning technologies when used outside of the “teaching strategy.”

In a similar fashion to Leshin et al., Romiszowski, and Reiser and Gagné, Bates classifies learning technologies in two ways. First, according to the “medium they carry” and he states:

“In education the five most important media are:

- Direct human contact (face-to-face)
- Text (including still graphics)
- Audio
- Television
- Computing” (Bates, 1995, p. 32)

Second, Bates distinguishes between technologies that are “primarily one-way and those that are primarily two-way, in that they allow for interpersonal communication” (Bates 1995).

Bates, writing about open learning and distance education in higher education, where in the past communications between learners and between learners and facilitators have been difficult due to the absence or lack of face-to-face opportunities, describes one and two-way technologies for four of the “five most important media.”

Other approaches to the classification of learning technologies are designed for large distance education institutions which have large instructional design resources.

One approach by an organization with instructional design resources (Sun Associates, 2001) is to divide technologies into the categories:

- Tutorial technologies
- Application uses of technologies
- Exploratory technologies
- Communications technologies

This approach is helpful but it does not provide an insight to the nature of the technology, rather, it is suggesting how the technologies should be used. For example, under communications technologies no differentiation is made between videoconference, which is two-way, and Web searching, which is one-way.

Another approach (Bruce & Levin, 1997) divides the technologies into the categories of:

- Media for inquiry
- Media for communication
- Media for construction
- Media for expression

Bruce and Levin's taxonomy further subcategorizes technologies and while theoretically helpful, could be confusing, as the basic differentiation between one-way and two-way is not apparent. They include document preparation as a subcategory of media for communication. It can be argued that all education is (or should be!) communicative and this category does not help to tease apart the appropriate uses of the different technologies.

By far the most exhaustive approach to the development of a taxonomy for learning tech-

nologies is that taken by Tomei (2005). The intention of his work is to provide a "desktop reference for the analysis, design, development, implementation and evaluation of technology based instructional materials" (Tomei, 2005, p. xx).

Tomei expands upon the work of the educational psychologists who developed the commonly known "cognitive, affective and psychomotor domains of teaching" (Tomei, 2005). He argues that a technology domain exists as "the newest domain for teaching [that] addresses technology first and foremost as its own viable content area" (p. 11).

The technology domain is a hierarchic structure containing from the lowest to highest, five levels: literacy, collaboration, decision making, infusion, integration, and tech-ology (Tomei, 2005). The taxonomy is not one of learning technologies *per se*, rather it is a taxonomy of knowledge of, skills with, and attitudes to technology. It serves as an excellent framework within which curricula may be developed to provide students with opportunities not only to become adept users of technology but critical thinkers about technology and its impact.

Tomei's is a rigorous work resulting in a theoretical as well as practical contribution to the field.

In many institutions teachers are often asked to design curricula for students who, by virtue of location or time constraints, will use technologies for a significant proportion of their learning. These teachers need a simple yet robust tool to help them understand the technologies they are being asked to use in their teaching while maintaining their research concentration in their own fields.

In 2006, the author presented a new organizational structure, or taxonomy of learning technologies at the Information Resources Management Association Conference (Caladine, 2006). This taxonomy of learning technologies divides learning technologies into broad categories depending on their communications channels. In the top layer of the taxonomy, learning technologies are categorized as one-way or two-way. More descriptive

Table 1. Taxonomy for the technology domain (Tomei, 2005)

Level	Taxonomy Classification	
1.0	Literacy	Understanding Technology
2.0	Collaboration	Sharing Ideas
3.0	Decision Making	Solving Problems
4.0	Infusion	Learning with Technology
5.0	Integration	Teaching with Technology
6.0	Tech-ology	The Study of Technology

titles have been chosen and the one-way learning technologies are labeled as “representational” as they represent things or materials. The two-way labeled as “collaborative” as they facilitate collaborations.

The taxonomy of learning technologies categorizes technologies as representational or collaborative. Collaborative technologies are then divided into the subcategories of “dialogic” or “productive.” Within each of these categories individual technologies can be further described by their synchronicity or asynchronicity.

CONCLUSION

Many attempts and approaches to the categorization of learning technologies are dated and are no longer relevant to the technologies available to those designing learning events.

The taxonomy for the technology domain (Tomei, 2005) departs from the other attempts as it is a hierarchy of knowledge of, skills with, and attitudes to technology. As such it serves as a relevant and useful guide to the preparation of curricula that develop these attributes in students.

A common characteristic of several of the attempts is the basic division of technologies into one-way and two-way (Bates, 1995; Rowntree,

1994). The taxonomy of learning technologies uses this division and adds subcategories to create an organizational structure that is sufficiently robust for general application to technologies used in learning and simple enough to be accessible to busy academics. The taxonomy is designed to provide designers of blended learning courses an introduction to the appropriate uses of learning technologies.

The taxonomy of learning technologies was developed to describe the learning technologies available at the time of writing. It is difficult to predict the near future and impossible to predict the distant future in the field of learning technology. It is hoped that if the taxonomy does not describe future technologies, it will be able to be easily changed to do so.

KEY TERMS AND DEFINITIONS

Asynchronous: Not necessarily occurring at the same time. In asynchronous electronic communications it is reasonable to expect that all communicating parties are not at or near their computer or communications technology. E-mail is an asynchronous technology.

Categorization: Grouping according to the role played.

Classification: Grouping according to similar or like characteristics.

Distance Learning (aka Distance Education): Education in which learners are geographically separated from facilitators.

Education: A structured program of intentional learning from an institution.

Facilitator (aka Facilitator of Learning): The person who has prime responsibility for the facilitation of the learning, rather than terms such as “teacher,” “trainer,” or “developer.”

Flexible Learning: An approach to learning in which the time, place, and pace of learning may be determined by learners. In this chapter this term is used to include the approaches taken by distance learning and open learning.

Higher Education: Intentional learning in universities and colleges.

Human Resource Development: Intentional learning in organizations. Can include training and development.

Instructional Design: The process of is concerned with the planning, design, development, implementation, and evaluation of instructional

activities or events and the purpose of the discipline is to build knowledge about the steps for the development of instruction.

Interaction: Reciprocal between humans and between a human and an object including a computer or other electronic device that allows a two-way flow of information between it and a user responding immediately to the latter's input.

Learner: A generic term to describe the person learning, rather than terms such as "trainee" and "student."

Learning: An umbrella term to include training, development, and education, where training is learning that pertains to the job, development is learning for the growth of the individual that is not related to a specific job, and education is learning to prepare the individual but not related to a specific job.

Learning Activities: The things learners and facilitators do, within learning events, that are intended to bring about the desired learning outcomes.

Learning Event: A session of structured learning such as classes, subjects, courses, and training programs.

Learning Management System (aka Virtual Learning Environment, Course Management

System and Managed Learning Environment):

A Web-based system for the implementation, assessment, and tracking of learners through learning events.

Learning Technologies: Technologies that are used in the process of learning to provide material to learners, to allow learners to interact with it, and/or to host dialogues between learners and between learners and facilitators.

Online Learning: Flexible or distance learning containing a component that is access via the World Wide Web.

Representational Technology: A one-way technology that supports interaction with the material.

Synchronous: Occurring at the same time. In synchronous electronic communications, it is reasonable to expect that all communicating parties are at or near their computer or communications technology. Telephone is a synchronous technology.

Taxonomy: A hierarchical structure within which related items are organized, classified, or categorized, thus illustrating the relationships between them.

This work was previously published in Encyclopedia of Information Technology Curriculum Integration, edited by Lawrence A. Tomei, pp. 833-838, copyright 2008 by Information Science Reference (an imprint of IGI Global).

Chapter 1.2

Preparing Teachers to Teach Online

Gregory C. Sales
Seward Incorporated, USA

INTRODUCTION

The vast majority of today's teachers were never taught using computers. They have no firsthand experience using computers for teaching and learning and they may even believe computers are a threat to their jobs. Helping these teachers to become effective online teachers requires a systematic multi-layered approach to professional development. First, teachers have to be convinced of their institution's commitment to online instruction. Then, they need support and guidance as they move through various levels of understanding and concern about what online learning is and its role and value in education. Finally, teachers need to develop competencies that will enable them to be successful online teachers. This chapter presents a brief background

on the use of technology in education, research on approaches to professional development, and specific information on the competencies required to be an effective online teacher.

BACKGROUND: TECHNOLOGY AND TEACHING

Even in the world's most advanced schools, computers have only been available for a few decades. During that time, huge advances have been made in the technologies available for use in schools, their educational applications, and our understanding of how to use them to promote learning.

In the late 1970s and early 1980s, as computers were just beginning to appear in classrooms, professional development focused on operating the computer and running software packages. This included basic operation and maintenance,

DOI: 10.4018/978-1-60960-503-2.ch102

programming, using productivity tools (e.g., word processors, databases, and spreadsheets) and eventually the use of grade-level appropriate curriculum-specific instructional programs.

By the late 1980s professional development had changed its focus. No longer was the goal to simply make teachers competent users. Rather, it was to help them develop strategies to increase the effective student use of technology for learning. Teachers were exposed to concepts such as the use of collaborative learning in technology-based learning environments. They also began requiring students to use technology for research, data collection, and presentation of findings. Teachers' roles shifted from using technology to teach, to using technology to facilitate learning.

The introduction of the Internet and online resources in the late 1990s presented another change in the use of technology in education. Teachers and students began to browse this virtual library for information and resources heretofore unavailable to them. Computers became a tool for searching, retrieving, manipulating, and sharing information. Teachers began to see the online environment as an information repository that contributed to student learning and through which students could contribute to the learning of others. Teaching strategies began to make use of this rich resource by including online research and reporting activities.

By the early 2000s, use of the Internet for communication had evolved beyond mere text messages to include a full range of media — images, audio, and video. Online distance education began to gain popularity. All levels of education began to see online learning as a vehicle for expanding the reach of institutions and by offering educational services to potential students they could not previously reach. The concept of online education presented yet another opportunity to change the role of teachers. The personal relationship between teachers and students, which was so often a critical component of classroom instruction, took on

an entirely different character. Online distance education courses created instructional environments where teachers and students interacted in a digital world and where they might never meet, speak, or even see each other in person.

Overview

Online distance education (also commonly referred to as distance education, online learning, online teaching, and distributed learning), as the name implies, delivers instruction using a computer network, without requiring face-to-face meetings of students and faculty (Arabasz & Baker, 2003). These online courses, taught in virtual classrooms, are often facilitated by use of the Internet (Spector & de la Tega, 2001), and may be synchronous, asynchronous, or a combination thereof.

Online distance education offers exciting opportunities for learners, teachers, and educational institutions. Internet technology allows distance education to make efficient, content-rich, interactive learning opportunities available to learners at locations and in ways previously not possible. For an increasing number of institutions, this capability is broadening and extending their methods of delivering education. Consequently, online distance education has been the focus of numerous research studies, position papers, standards documents, and guidelines. These documents (e.g., Sales, 2005; Smith, 2005; The Institute for Higher Education, April, 2000; The Higher Education Program, and Policy Council of the American Federation of Teachers, May, 2000; Twigg, 2003a, 2003b), address the relative instructional effectiveness of online learning, educational quality, student needs, institutional support, instructional strategies, costs, required teacher competency, and more.

One report, *Quality On the Line* (The Institute for Higher Education, 2000), studied six institutions actively involved in online education and constructed a list of 24 “benchmarks that

are essential for quality Internet-based distance education” (p.25). These benchmarks represented seven categories:

1. Institutional Support
2. Course Development
3. Teaching/Learning
4. Course Structure
5. Student Support
6. Faculty Support
7. Evaluation and Assessment

Across all levels of instruction, responsibility for achieving these benchmarks is shared by institutions, teachers and their program areas, and students. However, teachers are primarily involved in the Course Development, Teaching/Learning, Course Structure, and Faculty Support benchmarks.

MAIN FOCUS: A MODEL FOR PREPARING TEACHERS TO TEACH ONLINE

Preparing teachers to participate effectively in online instruction (e.g., Course Development, Teaching/Learning, Course Structure, and Faculty Support) requires carefully structuring professional development. The model below (Figure 1) illustrates the critical components such preparation should address.

Functioning both as a model and a hierarchy, Figure 1 suggests online teacher training begin by assessing and addressing teachers’ readiness to change as indicated through their expressions of concern about the impact of online teaching and learning. It then moves into increasing their comfort level with online technologies as they relate to quality of instruction, correlation of online instruction with the values of the institution, and the ease with which they can teach using online instruction. Only after these issues have

Figure 1. Preparing teachers to teach online

been addressed should teacher preparation focus on developing their competencies to teach online.

The remainder of this chapter is devoted to explaining and supporting the elements of this model and the progression it suggests.

Readiness for Change: A Concerns-Based Approach

For many teachers the transition from teaching in a classroom, where they have direct and personal contact with all of their students, to online teaching, where interactions are often restricted to a virtual environment, is a significant change. The process of change often involves exposing teachers to and integrating them in a number of technology-based teaching and learning activities. The goal is to

increase their knowledge, skill, and confidence in the use of educational technology over time.

The level of teacher readiness for online distance education training should be assessed prior to integrating teachers into any formal training experiences. Loucks-Horsley (1996), while studying teacher acceptance of change in science curricula, proposed that teacher readiness for change can be determined by the types of questions or concerns they express about the change or innovation being considered. This concerns-based approach identifies a seven-level hierarchy of teacher readiness (see Table 1).

Teacher concerns move from the lowest level, Awareness, upward. At the lowest stages, stages 0 through 2, the teacher is moving through levels of considering the innovation as a teaching tool. During stages 3 and 4 the teacher's energy is focused on using and refining use of the tool to optimize teaching and learning experiences. The highest two stages, 5 and 6, show teachers moving into the creative realm that extends the innovation further into unanticipated or developed areas. Naturally, different teachers will move through the hierarchy at different rates and many may never reach the upper levels.

Training should be geared to the level of readiness being expressed by a teacher. In a recent project in Oman, Sales (2007) reports seeing teachers express concerns from the lowest levels to the highest. Some teachers, although asked to participate in a pilot of online teacher training,

simply chose to ignore the opportunity (Stage 0). Others expressed their concerns by asking questions about the project's purpose and the amount of time they would need to commit to it (Stages 1 and 2). Even further up the hierarchy, teachers expressed concern about the time it was taking away from other instructional approaches and possible effects on students (Stages 3 and 4). Within Oman's Ministry of Education some of the trainers participating in the project began suggesting modifications and adaptation of the online learning to better reach learners and achieve desired outcomes (Stage 6).

In some situations the full spectrum of concerns may be represented within the population to be trained. In these cases a series of training interventions will likely be required to reach teachers at different levels of concern. Institutions, having limited resources for the integration of an innovation, may need to make decisions about their ability to provide training to teachers at every level.

Characteristics Influencing Adoption of Technologies

There are many political, cultural, economic, ethical, and resource issues that impact teacher ability to prepare for and use online distance education. For example, Sales and Emesiochl (2004) report on a civil service retirement act in the Republic of Palau which forced technology-trained teachers into retirement and flooded schools with untrained

Table 1. Typical expressions of concern about an innovation (from Loucks-Horsley, 1996)

Stages of Concern	Expression of Concern
6. Refocusing	I have some ideas about something that would work even better.
5. Collaboration	How can I relate what I am doing to what others are doing?
4. Consequence	How is my use affecting learners? How can I refine it to have more impact?
3. Management	I seem to be spending all my time getting materials ready.
2. Personal	How will using it affect me?
1. Informational	I would like to know more about it.
0. Awareness	I am not concerned about it.

teachers. Sales (2007) also reports how a number of teachers in the Sultanate of Oman resisted the adoption of online training because they felt it required them to participate in training on their own time, rather than being released from their teaching responsibilities, as they historically have been, to participate in face-to-face training.

Further, an individual's level of readiness as reflected in the concern-based approach (Loucks-Horsley, 1996) to teacher development discussed above, is strongly influenced by his or her personal beliefs as well as the environment in which he or she lives and works. Teachers' perceptions of a specific educational technology and their beliefs about their own ability to use it easily, successfully, and with better results, strongly influence their willingness to consider adoption of that technology.

In their chapter on the adoption of learning technologies, Wilson, Sherry, Dobrovolny, Batty and Ryder (2001), argue in support of the validity of the STORC approach (Rogers, 1995) when applied to technology interventions in education. STORC is an acronym for a set of characteristics considered during adoption of innovations. These characteristics represent attributes or conditions that must be evaluated favorably before an innovation has sufficient appeal to reach a given level of adoption. In addition to the original set of characteristics (simplicity, trialability, observ-

ability, relative advantage, and compatibility), Wilson, et. al. (2001) proposed a condition of support be added, thereby changing the acronym to STORCS (see Table 2).

The categories of characteristics in this approach may be independent of each other, or may have an influence on each other. However, they do not have a hierarchical or ordinal relationship. Rather, the point Wilson and his co-authors make in their presentation of this approach is that the more characteristics present, the greater the likelihood an innovation will be successfully adopted.

Professional development programs must consider teacher responses to each of the question types listed in the STORCS approach. Training interventions should help teachers understand and generate thoughtful and positive answers to these questions. Their affirmation of these questions will significantly influence their approach to, and enthusiasm for, online teaching.

Instructional Design

The EDUCAUSE Center for Applied Research (ECAR) recently sponsored a study to examine the e-learning activities in higher education entitled, *Evolving Campus Support Models for E-Learning Courses*. In a summary of the report's findings, Arabasz and Baker (2003) identified major

Table 2. An adaptation of the extended STORC approach to adoption of an innovation (as presented by Wilson, et. al., 2001)

Category		Characteristic
S	Simplicity	Is the innovation easy to understand, maintain, and use? Can it be easily explained to others?
T	Trialability	Can the innovation be tried out on a limited basis? Can the decision to adopt be revised?
O	Observability	Are the results of the innovation visible to others, so that they can see how it works and observe the consequences?
R	Relative Advantage	Is the innovation seen as better than that which it replaces? Is the innovation more economical, more socially prestigious, more convenient, and/or more satisfying?
C	Compatibility	Is the innovation consistent with the values, past experience, and needs of the potential adopters?
S	Support	Is there enough support to do this? Is there enough time, energy, money, and resources to ensure the project's success? Is there also administrative and political support for the project?

concerns of online teachers related to distance education.

The first concern cited was “lack of knowledge to design courses with technology” (p.4). This concern is supported by Siragusa (2000). He argues that online teachers who do not possess the necessary skills in instructional design are increasingly being encouraged to develop online courses. He states:

Instructional design decisions that lead to the way in which students learn on the Internet are being placed in the hands of lecturers who are only just coming to grips with online learning and the use of the Internet. ... Research and development for online learning has not yet caught up with the pace at which courses are appearing on the Internet. Instructional design principles that were developed for computer-assisted instruction appear to be overlooked by those now developing materials for the Internet. (p.1)

Instructional design is the process of planning for the development and delivery of effective education and training materials. Instructional designers use a variety of models that ensure a careful and systematic process is employed. Effective processes begin with a needs assessment and continue on to examine content/learning requirements, learner needs, the learning environments, delivery systems, tools and resources available for development and delivery, as well as other resources and constraints that will impact the project (e.g. financial resources, time available for the project, talents and experiences of those working on the project, social or political pressures). This information is then used to develop learning outcomes, select instructional strategies and techniques, guide the selection of instructional resources, and development of course content.

When applied in distance education, or other forms of course development, instructional design results in carefully structured and thoroughly

documented plans for the production of the online course materials. These plans provide an opportunity to carefully review content, sequence methods and assessment to ensure the most instructionally sound course is being developed. This documentation also serves as an excellent resource when conducting maintenance evaluations or implementing revisions to the course structure, content, or function.

Concerns are expressed among online teachers and distance education scholars regarding the preparation of teachers to create courses for the online environment. These concerns highlight the need for professional development programs that emphasize the creation of instructional design competencies among those responsible for course production.

Facilitation

Another significant concern of online teachers identified by Arabasz and Baker (2003) was “a lack of confidence in use of technology in teaching” (p.4). This concern is well founded given that online instruction requires teachers to use a variety of tools and techniques which are new to them. One of the recognized keys to the success of online courses is the facilitation of learning by online teachers (Jaques & Salmon, 2006; Salmon, 2000, 2002). This involves online communication with students and the creation online learning environments that require or encourage communications between students.

Stamper and Sales (2001) state that through frequent, timely, and personal communications with online students, teachers create the perception that they are close at hand — a “close apparent” distance. They argue this communication-enhanced relationship helps distance learners feel they are recognized, contributing members of the course. Stamper and Sales go on to suggest that by creating a close, apparent distance, instructors can

increase learner satisfaction with online courses and reduce drop-out rates.

Salmon (2000, 2002) has conducted action research and published on the facilitation of online courses. Her work illustrates to teachers what she believes are critical skills and techniques specific to facilitating online courses. Through effective use of the e-moderating and e-activities behaviors she promotes, Salmon believes online learning opportunities can be optimized.

Facilitation skills are essential competencies to be included in online teacher development. Training should include modeling of techniques that increase communications. Teachers should be encouraged to plan frequent communications and to promptly address specific student needs.

Development

Course development is the actual production of the software version of a course for online delivery and the supporting instructional materials. Where a learning content management system (LCMS) is being used, online course development is likely to involve teachers in populating content presentation templates with text, graphics, photographs, and other instructional resources. Of course, working with the template interface and different media assets that need to be in the appropriate digital formats can be technically demanding. Since most teachers are not software geeks, this often presents a challenge to be addressed through support services or as part of the professional development program.

In the commercial e-learning development world, course production is a team process (Sales, 2002). Subject matter experts work with instructional designers, programmers and Web-developers, graphic artists, animators, database specialists, and media production professionals. Through a collaborative and iterative process, the instructional design is transformed into a functioning online course presentation, complete

with management, record-keeping, and administrative features.

Some efforts to use a team approach have been undertaken in higher education (Wells, Warner & Steele, 1999). Anne Arundel Community College, for example, created an Online Academy to help instructors develop skills needed to prepare and deliver online courses. Even in this effort, however, online teachers are still expected to develop the course “using software he or she is comfortable working with.”

Most institutions expect online teachers to acquire the skills needed to develop and maintain their courses. Arabasz and Baker (2003) report that across all levels of higher education institutions, only 8% of institutional effort directed at online learning is spent on creating e-learning course elements. Instead of investing in course development, institutes are devoting resources to such areas as Web-based development tools, online references and resources, listservs, and help desks.

Each professional development program for online teachers needs to determine its own institutional competency requirements based on the unique combination of delivery system components and support options. At a minimum, teachers need to have a thorough understanding of development options and the vocabulary necessary to communicate with other members of the development team.

FUTURE TRENDS

Legal and Ethical Issues

Numerous legal and ethical issues are associated with online distance education. Copyright law, which has special interpretation when it comes to online courses (Hoffman, 2000), is often seen as the only legal issue of concern. However, Ko and Rossen (2001) in their book on online teaching identify a range of issues including copyright,

acceptable use, plagiarism, and ownership of the newly created course materials. Mpofu (2002) provides a more comprehensive list by including discussions of privacy and licensing/piracy.

Professional development for online teachers must examine all relevant legal and ethical issues. Issues such as copyright and ownership need to be considered from the perspective of how they will influence design decisions. Acceptable use and plagiarism should be covered as they relate to informing students of institutional policies, posting information online for others to access, and evaluating student work. Issues of software licensing and piracy may influence decisions related to development and delivery environments as well as assignments given to students. Finally, the legal and ethical issues associated with data privacy in terms of students' records and personal safety should also be addressed.

CONCLUSION

Professional development to prepare teachers for online distance education must accommodate the unique needs of each individual teacher. Teacher concerns, readiness to adopt new technologies, and an institution's specific policies, systems, and support services all contribute to the need for individualized or custom tailored training experiences.

Institutions and trainers must recognize that development of online teachers requires an ongoing process, not a single event. Professional development programs need to offer a series of graduated experiences that move teachers along a continuum. Taking them from an entry point based on each teacher's unique needs to an exit point based on institutional competency standards.

Professional development programs should engage teachers in activities that move them from their current level of understanding in each of the follow domains.

- **Readiness for Change:** Teacher readiness for change can be determined by the types of questions or concerns they express about the change or innovation being considered.
- **Comfort with Online Technologies:** Teachers' beliefs about their own ability to use it easily, successfully, and with better results strongly influence their willingness to consider adoption of that technology
- **Design:** Analysis, instructional design, creative design, and in some cases interface design. This domain encompasses the skills and processes necessary to take a course from the concept stage to the point where it is ready for production.
- **Development:** Creation of the media assets that support the content (produced during the design phase), production of the software product (through programming or the use of a tool), and quality assurance testing. The development domain begins with the design and ends with a fully functional, error free, course.
- **Facilitation:** Instructor skills and behaviors, and strategies and techniques for course delivery. Facilitation involves taking the completed course and creating a dynamic learning experience for students. This domain involves teachers in presenting content, engaging students, providing feedback, and otherwise creating a positive learning environment online in support of the "automated" portion of the course.
- **Legal and Ethical Issues:** Laws, rules, regulations, policies, procedures, and associated consequences. This domain, as shown in the Competency Model, overlaps the other three domains. Legal and ethical competencies influence teachers' execution of competencies in each of the other domains.

KEY TERMS AND DEFINITIONS

Apparent Distance: The perceived proximity of faculty and students in a distance education environment. Close apparent distance is the term used to describe a relationship that is perceived as positive, supporting, in regular communication—a relationship in which the student and faculty are well known to each other and where communications flow easily.

Competency: A statement that defines the qualification required to perform an activity or to complete a task. Faculty competencies for online distance education identify the qualifications needed to be successful in this job.

Course Development: The actual production of the software version of a course for online delivery and the supporting instructional materials. Faculty involved in the development of online courses are often required to have technology specific knowledge and skills – digitizing, converting file formats, operation of specific software programs, and programming.

Data Privacy: Current United States laws provide protection to private data, including students' performance data. Online distance education environments need to address privacy issues though design of courses and security features built into record keeping systems.

Fair Use: A term defined in the United States copyright act. It states the exemption for schools to some copyright regulations. (This exemption pre-dates many current educational applications of technology and may be not address some online learning situations.)

Instructional Design: The process of planning for the development and delivery of effective education and training materials. Instructional designers employ a systematic process that considers learner needs, desired learning outcomes, delivery requirements and constraints, motivation, psychology, and related issues.

Online Teaching: Delivers instruction using a computer network, usually the Internet, without requiring face-to-face meetings of students and faculty. Courses may be synchronous, asynchronous, or a combination. (also commonly referred to as online distance education, distance education, online learning, and distributed learning)

Piracy: Refers to the illegal or unlicensed use of software.

Chapter 1.3

Reflective E-Learning Pedagogy

ABSTRACT

The number of learning opportunities that are technology mediated (e-learning) is increasing as institutions of higher learning discover the value of technology in reaching larger numbers of students. The challenge for those instructors who implement such technology in higher education is to correctly apply pedagogy that has been successful in student learning to these new delivery methods. In some cases, new pedagogy is being created. For successful facilitation of knowledge to take place, instructors must make students partners in the process, help them learn to reflect about their activities, and focus on course outcomes rather than the technology itself. We will share key e-learning pedagogy from different areas of specialty (mathematics education,

special education, and instructional technology) in higher education.

INTRODUCTION

Dewey (1933, p. 35) says: “While we cannot learn or be taught to think, we do have to learn how to think well, especially how to acquire the general habit of reflecting.”

Institutions of higher education are realizing the value of the tech-mediated approach (E-learning) as a way to engage learners at a distance as well as enhance courses that meet with the instructor in the traditional setting (Edwards, 2005). While technology has made this a viable teaching alternative, the instructor has to make a concentrated effort not to let the technology overwhelm the teaching objectives of the course.

DOI: 10.4018/978-1-60960-503-2.ch103

Instructors must engage the learners as collaborators in the process. New E-learning pedagogy includes discussions of what to do if technology fails and how to address students' concerns about isolation from other learners. This means constructing a new way of thinking and reflecting on their own instruction, while maintaining the traditional emphasis on course objectives.

When examining E-learning through the lens of constructivism it is important to understand the motivation of those involved, both the instructor and the students (Vygotsky, 1987). When students are asked to engage in problem solving that is relevant to their culture, true learning is constructed (Santmire, Giraud & Grosskopf, 1999). Students in teacher education programs must examine their own culture and learn to reflect on their knowledge, skills, and dispositions. The instructor may use this reflection as a way to evaluate growth both in terms of the E-learning environment and the course content. In this chapter, we will discuss 1) roles of the instructor and the student in E-learning, 2) key pedagogical approaches to increasing students' ownership in E-learning, and 3) reflection as a means of evaluating a student's growth in E-learning.

BACKGROUND

Learning from a distance is not new. For well over 100 years, universities have offered alternatives to visiting the main campus for classes. The first of these, in the United States, were offered by Pennsylvania State University in the form of correspondence by mail courses in 1892 (Shearer, 2004). There is always a demand for access to university classes close to home. Many institutions offer distance as well as face to face instruction. In 2000–2001, 90 percent of public 2-year and 89 percent of public 4-year institutions offered distance education courses (National Center for Education Statistics, 2003). A technology-medi-

ated (E-learning) course is one that may incorporate a variety of technology-based educational strategies: synchronous and asynchronous collaborative communication, project/activity-based learning, and web-based interaction and feedback (Edwards, 2005). It may take place in a wholly online environment or in a combination of online and face-to-face interactions. Technology has made E-learning an attractive option, but technology does not insure successful implementation of coursework (McVay, Snyder, & Graetz, 2005).

According to Russell (1999), there are over 200 studies on technology for distance education that report no significant difference in student learning when technology, instead of traditional classroom approaches, are used to deliver course instruction. This research shows that students achieve similar outcomes despite different uses of media. So the value of technology-mediated learning needs to lie in convenience to the students, not in trying to boost their achievement over peers receiving typical instruction.

E-learning is essentially different from traditional education in that it requires changes in pedagogical approaches (Miller & King, 2003; Moore & Kearsley, 1996). One of the most frequently pointed out concerns about E-learning is the sense of isolation and lack of human contact among its users (Baek & Barab, 2005; Baek & Schwen, 2006; Hara & Kling, 2000). When students do not fully interact with the instructor and other classmates, they do not have ample opportunity to learn content. Interaction among the class community members is vital to the success of E-learning (Moore & Kearsley, 1996; Palloff & Pratt, 2001).

A great deal of research supports constructivist and student-centered pedagogical approaches (Anderson, 2004; Baek & Barab, 2005; Baek & Schwen, 2006; Bonk, Kim & Zeng, 2006; Carr-Chellman, Dyer, & Breman, 2000; Miller & King, 2003) as ways of increasing students' ownership and responsibility, which contribute

to the improved quality of learning. One of the methods that has been successful in E-learning courses is a collaborative learning community approach (Islas, 2004; Palloff & Pratt, 2001). Specific pedagogical approaches to implement the community approach include making students partners in the learning process and helping them to engage in collaborative inquiry and to learn to reflect about their activities (Baek & Barab, 2005; Baek & Schwen, 2006; Duffy & Kirkley, 2004; Palloff & Pratt, 2001).

If instructors are expected to provide students with a learning environment that engages students in real world problem solving using their own experiences and working with others, instructors also need to experience a similar opportunity, in which they can actively search for meaning in content and apply personal experiences (Knox, 1986). Having ownership of their learning, instructors will be more likely to reflect critically on their own teaching practices and may then generate new knowledge and attitudes toward teaching and learning. Teacher education programs and practices are becoming focused on the need to help teachers become more reflective about their teaching. Reflection helps us examine questions and explore our underlying assumptions, values and beliefs while it moves us into more uncomfortable zones to inform our practice (Al-Mahmood & McLoughlin, 2004; Brookfield, 1995). Therefore, reflection can not only help students understand underlying principles of practice (Dewey, 1933), but also assist instructors to measure students' growth.

Instructors must examine how their roles will change in the E-learning environment. They can do this by exploring new ways to approach course instruction using technology, and by researching the approaches that increase student learning within this environment. The final step in the process is to evaluate the effectiveness of the course by looking at students' growth. Traditional methods of assessment can be supplemented by

the instructor's and students' reflection about their growth as professionals and in the classroom.

DIVISION OF ROLES IN E-LEARNING

The techniques for working in an E-learning environment are often different from traditional face-to-face course preparation. The focus for the instructor needs to be on the overall course outcomes and objectives rather than technology issues (Bannan & Milheim, 1997; Rieber, 1993; Su, 2005). In a traditional format, the instructor assigns individual and group activities, welcomes some further communication during office hours and receives the completed assignment in person on the assigned date. When the instructor introduces technology into the course and eliminates some or all of the face-to-face interaction, then numerous other opportunities for dialogue and feedback must be present (Su, 2005). This communication can take many forms and the knowledgeable instructor evaluates and changes her methods of communication depending on the type of course, the type of student, and the type of technology that works best for each class.

COMMUNICATING WITH THE STUDENTS

The instructor in the E-learning environment must be committed to engaging students in communicating about the course content (Su, 2005). These interactions can take a variety of forms. The instructor may be seen by the students via video conference. Verbal communication can take place between students at multiple sites and the instructor. The instructor may also hold online office hours in a chat room or require chat room participation at certain times during the week. The instructor may also verbally communicate via phone. All of these are examples of real time synchronous communi-

cation, requiring everyone involved to participate at the same time. Asynchronous communication is more common in E-learning. The instructor will post assignments, questions and announcements. Students will respond whenever they access the computer. The instructor does need to be aware that the asynchronous nature of most online learning can create anxiety among the students, because no instructor is present (Sherry, Cronje, Rauscher, & Obermeyer, 2005). This anxiety can be mitigated by a clear and organized syllabus. The instructor must also respond frequently to communications from students, and above all, the instructor must model the type of information that is expected for satisfactory information exchange (Seaton, Einon, Kear, & Williams, 2004).

When implementing an E-learning course it is important to have a plan before the instructor starts the course, as well as contingency plans in case technology fails. Videoconferencing allows students at numerous locations to have access to the course in real time. It is helpful to have a facilitator present at each location that receives the broadcast. This person can help the instructor plan before the course starts. A facilitator can also help the instructor design the room layout and discuss the best utilization of the available equipment. The facilitator can also plan for breaks in the transmission and troubleshoot if connections fail. If no facilitator is present at the locations receiving the broadcast, then students should have a detailed class summary to follow in the event transmission is lost and they have to resort to alternative activities with their time.

ORGANIZATION AND FACILITATOR ASSISTANCE

Research from a distance learning class illustrates the need for constant communication between participating sites. Two regional campuses that are part of a large midwestern university in the

United States needed a course on working with students with special needs. The administrators at both sites agreed that having the course at the same time and conducted by one instructor would be efficient and cost effective. The study sought to compare the distance learning experiences of two groups of undergraduate education students. The data was collected at the end of the course using student evaluations. The first time this course was taught, a facilitator was present at both campuses. The instructor presented one week at one campus and the next week at the other campus. The alternative campus received the course via video conference. Twice during the ten week quarter the connection failed. The first time it was reconnected fairly quickly, but the second time the whole class time was lost. The instructor could communicate with the class in front of her, but the facilitator at the other campus did not know what to tell the other class. He was concerned with trying to fix the connection, so he did not answer the phone when the instructor called with an alternative assignment. The second time this course was held as a distance learning course, everyone involved was more prepared. The facilitators agreed to answer the phone quickly when a connection failed and the instructor agreed to have an agenda with alternative assignments available for each class period. The students were emailed the agenda prior to class each week. When the connection did briefly fail, everyone was prepared and the students felt that the class time was not wasted. The fact that both sites had a facilitator that worked to fix the technology problems immediately also created an atmosphere of cooperation and the feeling that the students' time was valued.

The results of the student evaluations support having a facilitator who was available at both sites and a more organized approach to foreseeing and solving technology issues (see Table 1). The student evaluations were not as concerned with technology and were not as negative for the second class. The use of a knowledgeable

technology facilitator was an important factor in the second course, which was perceived as more successful by the participating students. If the course is held online the instructor can still use the support of a technology facilitator. This form of technology support can be utilized for preplanning the course and deciding what aspects of available online tools will best meet the instructor's objectives. The instructor may need extra training in the use of discussion boards or chat rooms. They will also need to understand the procedures students need to follow to upload assignments. It is beneficial for the instructor to have the ability to troubleshoot some common technical issues. For example, when students upload to a web-based course, created in a format

like WebCT© or Desire2Learn©, the document will appear to upload, but if any extra characters (*, ', #) appear in the document name, it will not always successfully upload, which results in the instructor not being able to grade the document in a timely manner. The facilitator can help the instructor learn solutions for these common issues and be available as tech support when students run into more complex problems. This results in the students feeling supported throughout the course and allows them to focus more on content than the actual technology (Sherry, Cronje, Rauscher, & Obermeyer, 2005).

Table 1. Comments Related to Technology in the Distance Learning Course ©2007, Leah Herner-Patnode. Used with permission

Quarter	Theme	Comments
Spring 2005	What aspects of the teaching or content of this course do you feel were especially good?	What changes could be made to improve the teaching or content to meet the objectives of this course?
	Notes WebCT were <u>great</u> . (2)	I really didn't like the TV-web thing across campuses because I felt like I was distracted more and struggled with understanding the content when Dr. H was at Marion.
	WebCT was great	The technological issues were quite distracting. I think our class was the right type for good distance learning.
	Being able to reach you through email	Have two separate courses instead of sharing the same class time with another class through video conference.(2)
	Having Midterm online	We do not have the technology to facilitate class over a feed like this.
		Don't do online course. It's very distracting to the one that doesn't have the professor there.(2)
		The distance learning is a huge pain. I also never really understood what all the assignments entailed. The field word was a lot to be expected also.
		Do not do it over the web. There were too many problems trying to get connected to Marion. (4)
		I didn't really like the distance learning. (2)
		No technology. It was horrible and distracting. (2)
		Can't think of anything but it was weird having a distance learning class.
Spring 06	Course very organized. Outstanding encouragement of student participation. (3)	Format of class made it difficult to feel engaged or interested in material.
	Liked open discussion forum and testing format.	Pretty boring, going over on-line notes not necessary.

AWARENESS OF STUDENT NEEDS

The instructor must be aware of the areas of need demonstrated by each group of students. It is beneficial to discuss the technology expectations along with course objectives (Chickering & Erhmann, 1996). One example of using web-based course tools would be to have the syllabus state that all work is required to be posted in the web-based course dropbox using Microsoft Word. The upload is required by the start of class on the day the assignment is due, and students are responsible for checking to make sure their work is successfully loaded. The syllabus also states that students are required to check for updates posted in the announcement section and access their student email. By making these requirements a part of the official syllabus, students will view them as a natural part of the course expectations.

TECHNICAL SUPPORT

The ability to access technical support is important. Students who are new to technology may have an increased need for extra instruction. This can be accomplished by open hours in computer labs operated by course facilitators, or general university tech support, by utilizing peers, or by making appointments for face-to-face assistance with the instructor. Once the student feels confident with the technology, the student can focus on the course content. When students are frustrated about technology they tend to persevere on that issue and it distracts them from the course objectives. Some student evaluation comments from the first time the distance learning class was taught illustrate this point. When students were asked to list changes that could be made to improve the teaching or content to meet the objectives of the course, there were a number of students who could only focus on the technology (see Table 1). Of the forty-four comments from students for this quarter,

twenty-two referred to the technology aspect of the course versus the course content. Compare this with the Spring 06 comments when out forty comments only six related to the technology, and four of the six were positive. When the technology issues were addressed more effectively, both in terms of planning and student support, the final course evaluations showed improvement in the rating of the instructor. The course content did not change from Spring 2005 to Spring 2006, but the final evaluations were an average of 4.2 on a 5 point scale in all categories for Spring 2006 versus a 3.7 for the previous course when the students felt more uneasy about technology. If the instructor, with the help of technical support, wants students to focus on course content, then she has to create a comfort level with technology that helps them see technology as a tool that enhances, rather than hinders the overall course presentation. Once the instructor defines her role and the role of her students it is important to increase the students' ownership of the course content.

PEDAGOGICAL APPROACHES AND LEARNERS' OWNERSHIP

Increasing students' ownership and responsibility will lead to quality work. A vital way in which to increase learners' ownership and responsibility is the collaborative learning community approach (Baek & Barab, 2005; Baek & Schwen, 2006; Islas, 2004; Palloff & Pratt, 2001). Most salient pedagogical approaches include making students partners in the learning process, helping them to engage in collaborative inquiry and to learn to reflect about their activities (Duffy & Kirkley, 2004; Palloff & Pratt, 2001). Let us discuss these approaches in detail, with examples.

Students as Partners

In the process of inviting students as partners, it is important to consider a new power relationship and dynamics between the instructor and the students and to keep a balance between pre-planned teaching activities and emergent learning activities. Even though macro-level activities can be designed by the instructor, their realization in reality is uncertain. The instructor needs to be flexible enough to allow emergent learning agendas, which give students opportunities to negotiate meaning anew. Learning can take forms quite contrary to what the instructor intended (Baek & Barab, 2005). This implies that planned procedures and structural elements should be intertwined with students' emergent activities and needs in the design. The main considerations are providing minimal structures and allowing for opportunities in which students can contribute in defining their own learning activities. When the instructor works with adult learners such as teachers, the instructor needs to link class activities to students' interests by asking and capitalizing on learner-generated issues (Duffy & Kirkley, 2004). The structure and activities need to be flexible enough to create a learning environment that involves facilitating an intellectual curiosity utilizing students' own experiences. For example, main discussion topics and venues can be planned in advance, but this should be kept minimal, so that the culture of the class community can be filled by the day-to-day professional experiences of the students.

Collaborative Inquiry-Based Learning

Inquiry-based learning is an instructional approach that emphasizes students' active quest for meaning. It is a way of exploring the world through the process of asking questions, investigating, and making decisions to solve problems. Inquiry-based learning may take many different forms.

First, as a pedagogical term, it includes various instructional models and approaches to facilitate higher-order thinking skills, using inquiry as a main conduit. Second, as a more generic term, it involves critical reflections on the learning processes on the part of learners themselves (Baek & Barab, 2005). Inquiry-based learning is established when learners take the lead in the learning process, thereby enhancing meaningful learning (Brown & Campione, 1994; Cognition & Tech. Group at Vanderbilt 1997; Collins, Brown, & Holum, 1991; Van Zee, Hammer, Bell, Roy, & Peter, 2005). Inquiry activities increase students' engagement and understanding, and also teach the scientific process (Polacek 2005).

Inquiry usually takes the form of processes. Dennen (2005) suggests that different stages of discussion - initiation, facilitation, conclusion, feedback - can be utilized in the process of inquiry. Lim (2004, p. 633) introduces the elements of the inquiry process (Figure 1) which are: Ask, Plan, Explore, Construct, and Reflect. These elements interact with Share activities via discussion and collaboration. The inquiry process can be implemented by individual students or in a collaborative team and is more recursive and circular than linear as it evolves.

- *Ask*: This element presents a real-world, authentic situation, scenario, or case in which students can relate their experiences to topics in instruction. Depending on the level of the students, the level of difficulty and terminology in the scenario will be varied.
- *Plan*: This element helps students to develop investigation strategies to find information in order to answer the generated questions. In a team project, the tasks and roles need to be defined as a part of the Plan.
- *Explore*: The students engage in the process of investigating the problem by collecting relevant information. The process

Figure 1. Display of inquiry-based learning (©2007, Leah Herner-Patnode. Used with permission)

of exploration will include the use of various resources such as GIS, Probeware, forensic, and educational games.

- **Construct:** The students analyze what they have found, and synthesize and build their own knowledge relative to the original question, based on the information obtained during the 'Exploration' Incorporating the concept of learning-by-design, learners will construct their knowledge via projects using Podcast, Wiki and Blogs.
- **Reflect:** The students have opportunities to reflect on their conclusion as well as on the entire inquiry learning process. Students' understanding on the topic/problem will be assessed.

The instructor needs to help students to create their own meaning while engaging in the collaborative learning process. Students need to be actively involved in social enterprise as members of the learning community and to have opportunities to produce objects that show their understanding from the collaborative inquiry (Wenger, 1998). In order to successfully facilitate collaborative inquiry, the instructor needs to provide a supporting structure that effectively supports the learning process, sustains student engagement, and helps

students maintain focus on the performance objectives (Duffy & Kirkley, 2004).

In order to facilitate collaborative team inquiry, a number of team members will be evenly distributed among the weeks. It is important to emphasize that the main purpose of the collaborative inquiry is not to simply reduce the amount of work each individual needs to do, but to create synergy which can be difficult to achieve when working alone. Each week, for example, one of the teams serves as "hosts" of the online community; the team's responsibility is to foster communication in the online community and to facilitate students' learning. In order to foster online dialogues, the team shares the roles of initiator, supporter, and wrapper.

During the collaborative inquiry process, the instructor needs to scaffold the collaborative critical thinking to encourage challenging perspectives, and to provide a supporting environment (Duffy & Kirkley, 2004). In the inquiry process, the instructor needs to encourage students' individual and collective reflection/feedback on their participation and learning. Specific instructions and examples on good/active/responsible participation and non-examples are useful. Providing opportunities to reflect and evaluate their learning will help them increase ownership in their learning. It is useful to create rubrics for students to evaluate their own participation and learning/outcomes

as well as other teams' learning/outcomes. Later, students need to explain and defend the results of their inquiry. If the instructor invites students' voices in the development of the rubrics, it will help students develop ownership in their learning.

Student Participation in the Course Improvement

Along the same vein with the mentioned approaches, it is important to have students' participation in the course improvement. The instructor needs to structure frequent discussions about what is working with the course and what can be improved. A specific forum such as a name of a *Café*, *our learning community*, and *our voice*, can be dedicated to the discussion in which learners freely post their experience about the course. When the majority of community members want to modify a direction of a certain activity to better support learning, it needs to be seriously considered and possibly incorporated into the course design within the extent to which it does not cause confusion. In the next section, we will discuss a way of assessing students' learning in E-learning.

REFLECTION AS A MEANS OF EVALUATING A STUDENT'S GROWTH

"Reflection leads to self knowledge and this is fundamental to the development of our professional practice", says Kuit, Reay & Freeman (2001, p. 139). This chapter views reflection as a means of learning and a tool for assessment. In order to understand why and how reflection demonstrates a student's learning, this section focuses on several different emphases in the study of reflection and ways of assessing reflection.

Emphases in the Study of Reflection

Reflection as Process. "[Reflection] is what a teacher does when he or she looks back at the teaching and learning that has occurred, and re-constructs, reenacts, and/or recaptures the events, the emotions, and the accomplishments. It is that set of processes through which a professional learns from experience" (Shulman, 1987, p. 19). This view focuses on reflection as a reactive process, which is part of learning through teaching. Reflection as a process should be seen as a spiral procedure (Hannary, 1994; Lee, 2000), which produces informative useful knowledge for our future decisions and action (Killion & Todnen, 1991).

Reflection in Practice. When teaching, instructors frequently encounter an unexpected student reaction and attempt to adjust instruction to take into account such a reaction. According to Schön (1983, 1987), reflection can be seen in two time frames: reflection-on-action, which can occur before and after an action and reflection-in-action, which can occur during the action. Both reflection-in and reflection-on-action help reflective practitioners to develop and learn from their experience. This view supports "integration of experience with reflection and of theory with practice" (Osterman, 1990, p. 135).

Reflection in Context. Schön's (1983, 1987) portrayal of reflection has been criticized, because it does not explicitly include any social processes within a learning community. The critics claim that although reflection can be individualized, it can also be enhanced by communication and dialogue with others. Therefore, instructors and students should be encouraged to consider their own practice as well as the social conditions of their practice. This idea of reflection has led to work on the issue of social practice (Solomon, 1987), which includes consideration of ethical, moral, and political principles (Colton & Sparks-

Langer, 1993; Kemmis, 1987; LaBoskey, 1993; Valli, 1992; Zeichner & Liston, 1996).

Reflection in E-learning. When reflecting during the E-learning process, the focus will be on teaching and learning practices in a clearly different way and under new environmental conditions. The main difference between reflection in the E-learning environment and reflection in the general education setting is the communication mode. In the traditional setting, students reflect verbally or in writing (Lee, 2000), whereas students in the E-learning setting reflect through the written communication mode, when they are in discussion boards and chat rooms. It is clearly a new way of talking to each other. These new forms of communication and new environments for learning by using Internet technologies have the potential of collaborative reflection (Bain, 2000; Churchill, 2005).

Reflection to Measure a Student's Growth

Reflection is now seen as a general professional skill. Teacher educators and curriculum developers have been endeavoring to develop systematic criteria to assess one's reflection, as do E-learning instructors. As mentioned earlier, E-learning requires changes in pedagogical approaches (Miller & King, 2003; Moore & Kearsley, 1996) and new methods to assess student learning and performance. This section introduces reflection as an assessment tool to measure student beliefs, knowledge, and disposition. The following areas are ways to measure a student's growth by evaluating the reflection taking place in the E-learning setting.

Content of Reflection. Different issues are considered by different individuals while they have experiences in the same context (Goodman, 1994; Lee, 2005; Sparks-Langer et al., 1991; Taggart, 1996; Van Manen, 1977; Valli, 1992; Zeichner & Liston, 1996). Since each individual screens a

given situation using his/her own filter, there are differences in the content of reflective thinking by individuals. Reviewing content of reflection provides the information about which issues should be addressed and discussed in preservice teacher education and professional development programs.

Attitudes of the Reflector. Dewey (1933) claims that the necessary attitudes for reflection are open-mindedness, responsibility, and wholeheartedness. An individual who is open-minded does not attempt to hold the banner for one, and only one perspective, and does not look to other perspectives with argumentative delight (LaBoskey, 1994; Van Manen, 1991). An attitude of responsibility involves careful consideration of the consequences to which an action leads. Responsible teachers ask themselves why they are doing what they are doing and consider the ways in which it is working, why it is working, and for whom it is working (LaBoskey, 1994). Wholehearted teachers regularly examine their own assumptions and beliefs and the results of their actions and approach all situations with the attitude that they can learn something new. According to Goodman (1991), wholeheartedness enables preservice teachers to work through their fears of making mistakes, being criticized, disrupting traditions, and making changes. Thus it provides a basis for action and growth.

Depth of Reflective Thinking. Lee (2005) proposed three levels of reflective thinking, Recall (R1), Rationalization (R2), and Reflectivity (R3). R1 and R2 are considered reactive and R3 is regarded as proactive. At the R1 level, one describes what they experienced, interprets the situation based on recalling their experiences without looking for alternative explanations, and attempts to imitate ways that they have observed or were taught. At the R2 level, one is looking for relationships between pieces of their experiences, interpreting the situation with rationale, searching for "why it was," and generalizing their

experiences or introducing guiding principles. At the R3 level, one approaches his/her experiences with the intention of changing/improving in the future, analyzes his/her experiences from various perspectives, and is able to see the influence of his/her experiences/actions in other situations.

Attributes of Reflective Practitioners. In E-learning, students sometimes do not have opportunities to demonstrate their growth in practice, due to the lack of interaction with the instructor and other classmates. However, it is still essential to discuss best practices, such as the characteristics of an effective teacher and effective instructional approaches, through a discussion board or reflective statements. The differences between reflective teaching and teaching that is not reflective are discussed by many teacher educators (Gipe et al., 1991; Pollard & Tann, 1994; Taggart, 1996; Zeichner & Liston, 1996). Table 2 compares the differences between technicians and reflective practitioners in approaching a situation. Teachers as technicians and teachers as reflective practitioners approach a situation in different ways. This summary provides ideas for practice that teacher educators must encourage preservice and in-service teachers to carry out (See Table 2).

The reflective practitioners described by researchers are people who make decisions; have an understanding of people; are concerned with the human, as opposed to the technical, aspects of problems; and have a need for affiliation and

a capacity for warmth. They are also spontaneous, curious, adaptable, and open to new events and changes.

FUTURE TRENDS

E-learning is a rapidly growing instructional approach. Almost every institution offers some form of E-learning opportunity to its students. This will continue to grow and evolve as a viable means of instruction. To make sure E-learning is as effective as the best traditional courses, universities have to support instructors in learning about facilitating an E-learning course and the unique pedagogy involved. Continued research on best practices should be disseminated to the higher education community.

The learner-centered collaborative community approach has been considered as a viable way to increase students' ownership in E-learning. It is congruent with the result of a higher-education survey (Bonk, Kim & Zeng 2006) about the future prediction of pedagogical approaches for E-learning. It identified that group problem-solving and collaborative tasks, and authentic cases and scenario learning will be the most widely used instructional approaches in E-learning courses. In order to facilitate the learner-centered environment, the instructor needs to be a co-learner and

Table 2. Differences between technicians and reflective practitioners ©2007, Leah Herner-Patnode. Used with permission

Teacher as Technician	Teacher as Reflective Practitioner
• Locates problems entirely in the students and their actions • Looks for a program or technique to fix the deviant behavior of students • Does not attempt to examine the context of the classroom • Does not seriously question the goals or values embedded in her/his chosen solution • Accepts the problems as given and tries to solve them	• Examines teacher's own motivations and the context in which the problem occurs • Looks for distinct ways to pose the problem and attempts to get a different perspective on the students and the issues involved • Questions teacher's own beliefs and orientations • Is responsive to the unique educational and emotional needs of individual students • Questions personal aims and actions • Constantly reviews instructional goals, methods, and materials

partner in the practice of reflection about teaching and learning.

In the coming years, the technologies that are viable in E-learning will rapidly increase in number. Examples of such technologies will include wireless technologies, peer-to-peer collaboration tools, sharable learning/content objects, simulations and games, virtual worlds, and intelligent agents. The instructors need to be proactive in learning relevant technologies and consider appropriate pedagogical approaches that capitalize on emerging technologies for E-learning.

As mentioned earlier, reflective thinking and reflective practice are now considered as general professional skills. In the context of E-learning, teacher educators should endeavor to find ways of facilitating collaborative reflection, which will strengthen a collaborative learning community and collaborative inquiry in an E-learning course. Another area to which greater attention must be paid is in developing criteria to systematically assess reflection skills. By doing so, teacher educators can not only get evidence of students' growth but also collect insightful information that will improve the quality of an E-learning course.

CONCLUSION

In this chapter, we have discussed the roles of the instructor and student in E-learning, key pedagogical approaches to increase students' ownership in E-learning, and facilitating reflection using E-learning activities. The evolution from instructor as giver of knowledge to instructor as facilitator and collaborator is a difficult route for higher education to follow. The move away from traditional course delivery often changes the role of the instructor. The instructor needs to have an organized approach with access to technology support, so that the focus can be on learner outcomes rather than technology issues (Bannan & Milheim, 1997; Rieber, 1993; Su, 2005). Communication is

important in the E-learning setting and can take many forms. A good instructor gauges what works best for content delivery and utilizes the most effective form of communication with the students. An instructor who understands student needs and accommodates those who need help will provide a course that is organized and prepared for technical difficulties, and whose students will gain a good perception of the overall content. Research supports constructivist and student-centered pedagogical approaches (Anderson, 2004; Baek & Barab, 2005; Baek & Schwen, 2006; Bonk, Kim & Zeng, 2006; Carr-Chellman, Dyer, & Breman, 2000; Miller & King, 2003) as a means to increase students' ownership and responsibility of the quality of their learning. If the instructor wishes to model the role of reflective practitioner, then the instructor needs to examine E-learning pedagogy carefully while constructing a course that requires critical thinking and reflection skills. It is in this way that we move towards using technology as a tool that effectively meets course objectives.

KEY TERMS AND DEFINITIONS

Asynchronous Communication: Communication between two or more parties is not synchronized or happening in real time. The person communicating can submit her questions

and statements at any time and other people in the class can see the communication when they choose to read it.

Collaborative Inquiry: It is the active quest for meaning. It involves a process of asking questions, investigating, and making decisions to solve them as a way of exploring the world. This may take many different forms. As a pedagogical term, it includes various instructional models and approaches to facilitate higher-order thinking skills, using collaborative inquiry as a main conduit. As a more generic term, it involves critical reflections by learners themselves on their learning.

Distance Learning: Coursework does not take place in the traditional manner with the instructor working face-to-face with the students. Students communicate with the instructor via technology.

Learner-Centered Approach: A pedagogical approach that respects learners' diverse needs and places learners' voices in the center of the course design. It emphasizes learners' ownership through

learners' active search for meaning in content and application of personal experiences.

Learning Community: A curricular structure consists of a group of learners. It encourages learners to actively participate and to contribute to the process of learning. The instructor typically serves as a co-learner and partners in reflective practice about teaching and learning.

Reflection: Dewey (1933, p.7) identified reflection as one of the modes of thought: "active, persistent, and careful consideration of any belief or supposed form of knowledge in light of the grounds that support it and the future conclusions to which it tends"

Technology Mediated Course: A course that may incorporate a variety of technology-based educational strategies: synchronous and asynchronous collaborative communication, project/activity-based learning, and web-based interaction and feedback.

Chapter 1.4

Higher Education's New Frontier for the E–University and Virtual Campus

Antonio Cartelli
University of Cassino, Italy

INTRODUCTION

Technologies entered in education since their first appearance and were used both for improving the efficacy and efficiency of traditional teaching and for creating new teaching-learning opportunities (Galliani et al., 1999). The definition “educational technologies” was coined in the 1950s to describe the equipments to be used in teaching-learning controlled environments. The introduction of the computer in teaching led to the definition of “new educational technologies” to mark the overcoming of traditional systems like audio-visual media (i.e., cinema, radio and television) with the new digital medium.

In the 1970s the Association for Educational Communications and Technology (AECT) formulated the definition of instructional technology as

“... the theory and practice of design, development, utilization, management, and evaluation of processes and resources for learning. ... We can think about it as a discipline devoted to techniques or ways to make learning more efficient based on theory but theory in its broadest sense, not just scientific theory”.

The Internet in the 1990s introduced further elements of innovation in the use of technologies for education with an exponential growth of instruments and resources leading to the transition from face to face (f2f) teaching to online teaching-learning experiences.

The Internet more than other technological experiences entered in the educational systems all over the world and is today marking a revolution in continuous education and lifelong learning.

Universities, like many other institutions, have been fully invested from the innovation in teaching-learning processes and often participated

DOI: 10.4018/978-1-60960-503-2.ch104

in the transformation of distance education in on line education. Among the best examples on this regard are the Open University and the Phoenix University online, where people can earn they degrees fully online.

After delay, Traditional universities are concerned today with the use of technologies for the improvement of the efficiency of their courses, the monitoring of students' careers and the access to continuous education opportunities.

In what follows a survey of the Italian situation as an example of the more general European context will be analyzed and the research funded from European Commission will be reported.

ITALIAN UNIVERSITIES AND E-LEARNING

European universities have met the challenge of modernisation by introducing e-learning activities in their organization. The governments also encouraged the establishment of e-learning in higher education by supporting the digitization of the infrastructures of their institutions.

The ELUE project (E-Learning and University Education) belongs to the initiatives approved and funded from the European Commission for the promotion of e-learning and aims at the diffusion of e-learning in the university in Finland, France and Italy. The study reports the results of a joint survey carried out on the universities of the respective countries by the Conference of Italian University Rectors (CRUI), by the *Conference des Presidents d'Université Française* (CPU) and by the Finnish Virtual University (FVU).

The project belongs to the set of initiatives designed to foster the creation of an European Area of Higher Education (as referred to from the European Community action in the Bologna Process) and its main ideas and aims can be summarized as follows:

- The systematic analysis of e-learning experiences and their sharing could help in the achievement of a progressive convergence of the university systems in the individual countries towards the establishment of a unique European model,
- The collection and the dissemination of statistical information on the state and role of e-learning in the universities of the countries involved in the project are the main information to be shared. The project also aimed at the individuation of elements useful in identifying, understanding and implementing an observatory on e-learning evolution in the universities.

The results of the investigation were published in 2006 and are available online on the Website of the CRUI (2006).

In what follows some data on the participation in the survey of the Italian universities is reported and the information considered relevant for what follows is discussed.

In Table 1 the percentage in the distribution of Italian universities in the survey is shown.

When limiting to the universities participating in the survey (59 on 77) it emerged that only 64% among them (i.e., 49% of total number of universities) stated that they had an e-learning policy. Figure 1 depicts the percentage of universities reporting the presence of an e-learning policy.

It has to be noted that assuming 51% of the universities without an e-learning policy is real-

Table 1. Participation of the Italian university system in the survey

	Universities	%
Universities which filled in the questionnaire	59	76.6
Universities which didn't fill in the questionnaire	18	23.4
Total	77	100.0

Figure 1. Percentage of the universities reporting the presence of an e-learning policy

istic because the lack of an answer to the survey is widely synonym of a lack of policy on e-learning.

Furthermore the presence of ICT centres has been investigated and 84% of the universities answering to the survey declared the existence of at least one structure of this kind (i.e. 64,37% of the Italian universities). In Figure 2 is reported the graphic of the distribution. This datum has to be completed with the number of ICT centers in the Italian universities as reported in Table 2.

The only remark on the data in Table 2 is the lack of completeness of the same data, because

Figure 2. Percentage of the universities reporting the presence of an ICT center

Table 2. Distribution of e-learning centres in Italian universities

Number of e-learning centers	Absolute value	%
One	26	33.77
Two	14	18.18
More than three	19	24.68

it cannot be automatically deduced that universities which did not answer to the survey did not have one or more e-learning centre (they could have them in the faculties or in other structures).

At last when asked to indicate if research activity was made on e-learning and ICT use in the university only 49% among them declared they had this activity in their agenda (i.e., 37,55% of the universities).

Figure 3 reports how universities make or plan to make research on e-learning and ICT use in education in the Italian universities which answered to the survey.

It is clear from the data reported until now how complex is the context of the e-learning presence in Italian traditional universities where e-learning is present in single structures and is object of study and research but is not an integral part of the university management strategies in teaching.

Figure 3. Percentage of the university research on e-learning

It is beyond the scope of this chapter a detailed discussion of the results of the ELUE project but to have a more complete panorama of Italian situation some further information is needed.

In Italy a special law, the so called Moratti-Stanca Law (from the names of two Minister of the former government who proposed it), recently introduced (2003) Telematics Universities and stated:

- a. The rules and duties those universities are subjected to,
- b. The creation of a Committee all Telematics Universities are submitted to for the approval and the accreditation,
- c. Whatever distance education strategy the University uses for its courses it has to guarantee and verify the presence of the students at the ending examinations (both in single courses and final theses).

Until now eight Italian institutions have been accredited as telematics universities and the National Council for University (CUN, 2005) recently published a document stating what follows:

- The Law suggests the introduction of e-learning strategies at different levels in traditional universities together with the creation of new structures (telematics universities), but except a few requests only accreditation for new telematics universities have been asked for,
- Telematics universities do not make research adequately neither in e-learning and distance learning strategies and application nor in the scientific fields of the courses they propose,
- There is great anxiety for the use of distance learning and e-learning in medical professions (both in initial and in-service training),
- The introduction of e-learning in traditional courses is affected from the problem of the

e-tutor presence/absence, which has not been adequately solved.

E-LEARNING IN EUROPEAN UNIVERSITIES AND THE EUROPEAN COMMISSION INITIATIVES

The previous paragraph shows how complex the Italian situation is as regards e-learning and its use in the universities. In other European countries the situation is similar to the Italian one also if the numbers are different from country to country. To give impulse to the e-learning policies in the universities of the corresponding countries the European Commission promoted many workshops and conferences and supported with grants many e-learning projects. Actually the main aspects the European Commission is working on are concerned with:

- The cooperation among high education institutions on the planning of joined curricula involving different universities, including the agreements for evaluation, validation and recognition of the acquired competences (on a national basis),
- Large scale experiences on virtual mobility together with the physical mobility,
- The development of innovative study curricula based both on traditional learning methods and on line methods.

To the whole set of the above aspects in the context of the e-learning program the European Commission gave the name of *European Virtual Campuses* (notwithstanding the absence of a well settled definition of virtual campus).

In what follows the reports from the European Commission on virtual campuses will be analyzed in a great detail due to the relevance they have on the e-learning development plan.

In the consultation workshop held in Brussels on 23rd November 2004 (EC, 2005a) three definitions emphasising different aspects of a virtual campus were proposed:

- *Collaborative perspective*, denoting ICT-based collaboration of different partners supporting both learning and research in a distributed setting,
- *Enterprise (economic) perspective*, denoting an ICT-based distributed learning and research enterprise.
- *Networked organization perspective*, denoting an environment which augments and/or integrates learning and research services offered by different partners.

At the workshop held in Brussels on 11th October 2005 (EC, 2005b) to explore the issues associated with Virtual Campuses (VCs), one of the four key themes of the EU's eLearning Programme, the need for a critical review of existing projects in this area was identified. The workshop identified a range of issues that affected the successful implementation and deployment of VCs and their long-term sustainability.

Among the conclusions of the European commission is that if e-learning and VC initiatives are to be sustainable within the EU, then it is vital that stakeholders understand how new models of teaching and learning transform the institution and how they can be used to enhance the flexibility and inclusiveness of the European education system.

The starting point for the revision work has been the set of the projects funded from the Education, Audiovisual & Culture Executive Agency (EACEA). The list of the projects as they were approved and funded in three different years is reported in Table 3.

It has to be noted that in the 2006 call for proposals within the eLearning Programme, the EACEA stated that two priorities had been retained for the call:

Table 3. List of EACEA virtual campuses projects in 2004, 2005 and 2006

2004 virtual campuses projects
REVE – Real Virtual Erasmus
eLene-TT e-Learning Network for Teacher Training
ELLEU E-learning per le Lingue e le Letterature Europee
E.A.S.Y Agency for EaSY Access to Virtual Campus
E-LERU Creation of LERU (League of European Research Universities) virtual campus
eTTCampus European Teachers and Trainers Campus
VICTORIOUS Virtual Curricula Through Reliable InterOperating University Systems
MASSIVE Modelling Advice and Support Services to Integrate Virtual Component in Higher Education
VIPA Virtual Campus for Virtual Space Design Provided for European Architects
Virtual COPERNICUS-CAMPUS
2005 virtual campuses projects
eduGI Reuse and Sharing of e-Learning Courses in GI Science Education
eLene-EE Creating Models for Efficient Use of Learning – Introducing Economics of eLearning
E-MOVE An Operational Conception of Virtual Mobility
E-Urbs European Master in Comparative Urban Studies
EVENE Erasmus Virtual Economics & Management Studies Exchange
EVICAB European Virtual Campus for Biomedical Engineering
PLATO ICT Platform for Online learning and Experiences Accreditation in the Mobility Programme
VENUS Virtual and E-Mobility for Networking Universities in Society
2006 virtual campuses projects
VCSE: Virtual Campus for a Sustainable Europe
eLene-TLC eLearning Network for the development of a Teaching and Learning Service Centre
PBP-VC Promoting best practices in virtual campuses

1. Systematic critical review of existing virtual campus projects or experiences, including their valorisation in terms of sharing and transfer of know-how, with an eye to sup-

porting deployment strategies at a European level,

2. Support for the dissemination or replicable solutions to help set up virtual campuses at European level and to establish a community of decision-makers.

The above list does not exhaust the e-learning initiatives in Europe and, what's more, do not include the many e-learning experiences all over the world. It is beyond the aims of this work the detailed analysis of all the e-learning experiences and of the great deal of virtual campuses projects, but the following examples can help in better understanding the e-learning impact on education:

- Virtual campuses involving universities in regions which had no or less contacts for a long time have been planned and carried out (like the Baltic Sea Virtual Campus where universities from Poland, Estonia, Latvia, Russia, Finland, and so forth cooperate in the development of master programs)
- Virtual campuses based on the use of virtual reality environments are available on the Net (the Nanyang University in Singapore is one of the most interesting examples on this regard),
- International scientific institutions like ESA (European Space Agency) and NASA (USA Space Agency) created virtual campuses for employers' training and for cooperation among scientists all over the world.

CONCLUSION AND FUTURE TRENDS

The experiences reported in the former paragraphs give a snapshot of the changes induced from ICT in High Education and confirm (whenever the need for a demonstration was required) that:

Figure 4. Synthesis of the different e-learning experiences in today universities

- Times and spaces of high education are rapidly changing,
- Deep organizational changes are needed to face the requirements for high quality continuous education,
- Digital literacy is a need for actual and future generations.

Until now it can only be deduced that a lot of experiences, involving at different levels e-learning instruments and strategies, are available and they are well summarized in the image from P.C. Rivoltella (2004) in figure 4.

KEY TERMS AND DEFINITIONS

Blended Learning: The combination of at least two different approaches to learning. It can be accomplished through the use of virtual and physical resources, i.e., a combination of technology-based materials and face-to-face sessions used together to deliver instruction.

Bologna Process: European reform process aiming at the creation of an High Education European Space within 2010. Actually it includes 45 countries and many international organizations. It pursues the organization of the national High

Education Institutions so that: (a) curricula and degrees are transparent and readable, (b) students can make their studies wherever they want in Europe, (c) European High Education can attract extra-European students and (d) an high quality knowledge base for the social and economic development of Europe is made available.

Brick and Click University: A definition of university which is derived from a business model (bricks-and-clicks). In that model both offline (*bricks*) and online (*clicks*) activities and presences are integrated.

Instructional Technology: A growing field of study based on the use of technology as a means to solve educational challenges, both in the classroom and in distance learning environments. Resistance from faculty and administrators to this technology is usually due to the fear in the reduction of human presence in education it is hypothesized to induce.

Lisbon Conference: Held in January 2000 (in Lisbon) and underlined the aim of making the European Union the most competitive and dynamic society of the world, based on innovation and knowledge.

Virtual Learning Environment (VLE): A software system designed to help teachers in the management of educational courses. The system can often track and monitor the students' operations and progress. It is often used to supplement face-to-face classroom activities.

Virtual University: Sometimes called *telematics university* is an organization that provides higher education on the Internet. Among these organizations there are truly "virtual" institutions, existing only as aggregations of universities, institutes or departments providing courses over the Internet and organizations with a legal framework, yet named virtual because they appear only on the Internet.

Chapter 1.5

Learning Activities Model

Richard Caladine
University of Wollongong, Australia

INTRODUCTION

The design of learning is probably more accurately described as the design of learning activities as it is the activities that are designable compared to learning which is the desired outcome of the activities. While the term “instruction” may be out of favor with some commentators, as it implies a teacher-directed approach, “instructional design” has been used for some years to describe the design of the things learners and teachers or trainers do to facilitate learning.

Instruction is a set of events that affect learners in such a way that learning is facilitated. Normally we think of events as external to the learner – events embodied in the display of printed pages or the talk of a teacher. However, we also must

recognize that the events that make up instruction may be partly internal when they constitute the learner activity called self-instruction. (Gagné, Briggs, & Wager, 1992, p. 3)

Courses of study, subjects, or training programs are generally too large to be matched to a particular technology or technological element of a learning management system. Distance education courses are generally characterized by a “package” of several technologies (Bates, 1995) or a “combination of media” (Rowntree, 1994), indicating clearly that more than one technology is generally used. In online learning or e-learning where a learning management system (LMS) is used for a course, subject, or program, the question remains of how to undertake the matching of each technological element of the LMS to subsections of the course, subject, or program.

DOI: 10.4018/978-1-60960-503-2.ch105

The learning activities model (LAM) is based on an investigation of approaches to the categorization and classification of learning activities and reconceptualizes them in such a way as to facilitate the matching of them to learning technologies.

With a small number of notable exceptions (Gagné et al., 1992; Laurillard, 2002) there is little reference in the literature to explicit methods of classification and categorization of learning activities for the purpose of matching them to learning technologies. However, several commentators provide tacit classification as a by-product of discussions for other purposes.

BACKGROUND

The approaches to the theorization of learning activities can be grouped into four categories:

- Some commentators classify learning activities for purposes other than the selection of learning technologies.
- Others do not overtly categorize or classify, yet provide tacit conceptualizations while achieving other ends.
- Yet others simply list methods or examples of learning activities in the absence of a more detailed conceptual framework.
- A fourth approach is to provide categories of learning activities that may ultimately assist in the selection of learning technologies in a way that is appropriate for the learners, the material, the context, and the budget.

By investigating other aspects of distance education, Bates (1995), Taylor (2002), and Rowntree (1994) imply a classification of learning activities. Bates' descriptions of learning technologies as one-way or two-way implies that there are one-way and two-way learning activities and it follows

that learning activities that utilize technologies in these ways can be classified as:

- Interactions with the material using the one-way technologies, and
- Interactions between people using the two-way technologies.

Taylor (2001) provides corroboration of this tacit conceptualization in the description of the generations of distance education, where technologies are categorized as providing "highly refined materials" and/or having "advanced interactive delivery." Further, Rowntree (1994) implies a similar tacit categorization of learning activities by categorizing "media" as those for human interaction and those for interaction with materials. It is not surprising that learning activities can be categorized as interactions with materials and interactions between people as this is reflected in many learning experiences.

THE LEARNING ACTIVITIES MODEL

The learning activities model is a theoretical framework that can be used as an analytical tool and to assist designers of learning events. It is premised on the argument that categories of activities that are subdivisions of the learning process can be matched to techniques, technologies, and methods as part of the design process.

Provision of Material

Traditionally, the predominant approach to undergraduate university teaching consisted of a presentational style. Most lectures were primarily concerned with the provision of material, as learning seemed to be equated with the acquisition of knowledge as opposed to the development or construction of it by students. A similar approach occurred in human resource development and

many programs have been conducted in venues where a trainer presents material to a group of trainees. The material was provided by the words the professor or trainer spoke and the words written on the board, overhead projector, screen, or handout. The material provided in traditional presentations like this resulted in notes and memories that learners took away from the training room or lecture theatre.

The first category of the learning activities model (LAM) consists of activities concerned with the provision of material and is referred to as “provision of materials.” Materials may be provided in the classroom, training room, or lecture theatre where they are part of the learning process. Alternatively, in distance education, flexible learning, e-learning, or online learning materials may be provided away from designated learning venues. Materials can be provided in a number of ways, including:

- The voice of the presenter or facilitator in a training program, lecture, tutorial, seminar, laboratory, study group, or residential school
- Visual aids to the above
- Printed materials, for example, prescribed texts, references, and manuals
- Other printed materials such as training notes study guides, lecture notes, and handouts
- Other media, for example, radio and television programs, audio and video, Internet resources, Web pages, multimedia, streams, podcasts, and Web casts.

Interactions

The provision of material alone is generally not considered sufficient to produce the desired outcomes of a learning event. For learning from materials to occur learners have to interact with it and, clearly, in many learning events other types

of interactions occur. These other interactions can be identified through a brief analysis of the history of distance learning and flexible learning as practiced in higher education and human resource development.

Correspondence courses represent one of the earliest forms of distance learning. In correspondence courses, learners interact with printed materials that are sent to them through the mail. Sometimes there are opportunities for limited interaction with the facilitator in the form of comments and corrections on assignments and assessments. Usually there are few, if any, opportunities for interaction between learners. When technology was added to correspondence courses, and the term “distance learning” (or “distance education”) was applied to it, there was greater opportunity for interaction between learners. However, in many cases this was limited due to the high cost of conferencing technology or other communication technology.

Distance learning presents a clear comparison to face-to-face learning where there usually are many opportunities for learners to interact with facilitators and with other learners. Three discrete categories of interaction can be identified. They are:

- Interaction with materials,
- Interaction with the facilitator, and
- Interaction between learners.

The term “interaction” has been used in preference to “interactive” or interactivity. Apart from the grammatical constraints, this is done to avoid confusion that can occur with the term “interactive.” “Interaction” in several dictionaries is defined as action on each party or reciprocal action. There are usually two definitions of “interactive,” one that describes things that interact and another that describes computers that react immediately to the input or commands of the operator. So that there is no confusion between

what is meant here by interactive and the computer definition of interactive, the use of interaction is retained, and defined as reciprocal action. This is broader than, but includes, the interactivity of computer programs. For example, a conversation in which each party tries to change the attitude of the other can be described as an interaction. Interaction is essentially a two-way process allowing information to flow back and forth between learners, facilitators, and other people or things. For example, when a learner (or for that matter any viewer) watches a broadcast of a television program, material is provided to them. If they make a video recording of the program and replay it, pause, rewind, and replay parts of it, the process gains an aspect of the two-way, and to a limited degree they interact with it.

The three categories of interaction are clearly identifiable in learning although not all categories are present in all learning events. The first category of interaction, and the second category in the learning activities model (LAM), is interaction with materials.

Interaction with Materials

As well as the different categories of interaction that can be identified in learning events there are different levels of interaction that can be present within each category. Obviously there are many levels and styles of interaction and although the interaction of the learner or viewer in the example of the videotape (above) is rather basic, it serves to help achieve the desired learning outcomes through the removal of the ephemeral nature of the broadcast once the program is encapsulated in a video recording. "Interaction with materials" is the second category in the learning activities model (LAM) and some examples of activities in this category include:

- Looking up a definition in a reference book,

- Pausing and replaying sections of a video or audio recording,
- Searching the Internet or World Wide Web, and
- Interacting with computer aided learning packages (e.g. multimedia).

In face-to-face learning, the boundary between the provision of material and interaction with it can be difficult to distinguish. In a presentation, material is provided by the voice of the presenter and by any visual aids used. By definition interaction with the material only happens when a learner does something with it. In flexible learning, the boundary between provided material and interaction with it is usually clearer than in traditional face-to-face learning. Often the material is recorded and provided by a technology and in such cases the boundary is defined by the boundary of the technology.

Interaction with the Facilitator

Interaction with the teacher or trainer plays an important role in many learning events and for simplicity's sake this person is referred to as the "facilitator." The role of the facilitator in traditional face-to-face learning will be different to their role in flexible learning. In flexible learning the role can include some or all of the following:

- Design of materials,
- Consultation with learners,
- Assessment of learners' work,
- Answering learners' questions, and
- Provision of materials.

In some contexts, for example, in-house training in a small company, these activities might be undertaken by one person. In traditional face-to-face learning at a university it could be a team consisting of the presenter, a coordinator, and one or more tutors. In flexible learning, learning

Learning Activities Model

events can be the result of single or team efforts. The teams can consist of academics who provide the content material, tutorial staff who answer learners' questions and assess their work, as well as instructional designers, administration, and other infrastructural staff.

In a face-to-face learning environment, learners interact with facilitators by ways like interjecting in a presentation or asking questions during a consultation with the facilitator in the facilitator's office or elsewhere. An example of interaction with the facilitator in higher education can be a discussion taking place between a teacher and student in a tutorial or seminar. An example of interaction with the facilitator in training could be the discussion between a participant and the trainer in an in-service workshop. Tutorials, consultations, and workshops traditionally have been face-to-face meetings; however, interaction with the facilitator can happen in flexible learning through the use of technologies like electronic mail, audio conferencing, videoconferencing and online discussion. While face-to-face interaction is obviously synchronous, the technologies used for interaction may be either synchronous or asynchronous. Some examples of the techniques and technologies that can be used in interactions with the facilitator are:

- Questions and answers in lectures (synchronous)
- Questions and answers in workshops (synchronous)
- Tutorial discussion (synchronous)
- Phone calls (synchronous)
- E-mail (asynchronous)
- Letters (asynchronous)
- Facilitator/learner consultation (face-to-face) (synchronous)

Generally, interaction is a valued quality of learning. The author was a member of the Education Committee of the National Tertiary Education Union (NTEU), the peak academic industrial union in Australia, which developed a policy statement that echoes this sentiment:

NTEU recognises the increase of flexible teaching and learning in tertiary education and while the benefits of flexible teaching and learning are also recognised it must be remembered that education is an interactive process, at the heart of which lies the relationship between student and teacher. (National Tertiary Education Union, 1997, p. 12)

In many Australian universities, it is part of teachers' duty statements to be available for a number of hours per week for student consultation. Also many teachers cultivate an attitude of questioning in their students, hence engendering a learning style that is highly interactive. In human resource development interaction is also valued and considered vital to learning:

All collaborative learning theory contends that human interaction is a vital ingredient of human learning. (Kruse & Keil, 2000, p. 22)

Interacting with the teacher or trainer is the third category of the learning activities model (LAM) and is referred to as "interaction with facilitator."

Interaction Between Learners

Interaction between learners can be formal or informal. The most formal would be in events such as student presentations in tutorials or participant interaction in workshops. Other examples of formal interaction between learners occur where they work as a group or team on a project

for assessment. Less formal interaction between learners can occur at any time or place where they talk about their learning.

The third type of interaction and the fourth category of the learning activities model (LAM) is interaction between students, trainees, or participants and is referred to as “interaction between learners.”

These last two categories (that is interaction with the facilitator and interaction between learners) are both dialogic. Dialog can have different attributes depending on the technology it is mediated by. For example, e-mail is generally limited to text while a videoconference can include body language and vocal attributes. Dialog here is defined as a conversation and is not limited to a duolog.

The Fifth Category of Learning Activities

The first four categories of the learning activities model describe the learning process as consisting of provided materials, interactions with materials, interactions with the facilitator, and interactions between learners. This is not a complete description of all learning activities, rather it is a description of the activities that can be planned and undertaken in order to facilitate learning. There are a number of things that learners do in order to learn or as part of the learning process that the designer of the learning event can facilitate but generally cannot control. These activities do not fit into the first four categories of the learning activities model and include activities such as:

- Learners’ informal reflection on what they have heard or read,
- Formal or structured reflective practice,
- Critical thinking,
- Refining ideas, opinions, and attitudes,
- Comparing new to existing knowledge and experiences, and

- “The penny dropping” or sudden realizations that are apparently not stimulated.

As these activities are outside of the categories mentioned so far, and so that the model can represent all learning activities; a category for these activities is added to the learning activities model. This is the fifth category and is referred to as “intra-action,” a term coined by the author to describe action within. The opportunities for intra-action can be maximized through thorough and appropriate design of the learning activities, and environment. However, as learners bring their own psychological baggage to their learning and as it is ultimately dependent on them, the activities in the intra-action category cannot be prescribed or guaranteed.

The Learning Activities Model

The five categories described are brought together to form the learning activities model (LAM). This model is a theoretical framework of learning activities has theoretical and practical applications and is represented graphically in Figure 1.

In Figure 1 the space enclosed by the circle represents the total of all activities that happen during the process of learning and can be applied to complete programs of structured learning in a range of granularity. At a coarse granular level the model can be used to analyze and describe the approach taken to learning by an institution or organization and the listing of activities for each category of the model would reflect the approach. At a finer level of granularity the model can be applied to courses or programs or to subjects. At the finest level of granularity the model can be applied to short discrete learning events such as using a set of instructions to perform a task. The five categories of the model, provision of materials, interaction with materials, interaction with the facilitator, interaction between learners,

Learning Activities Model

Figure 1. The learning activities model

and intra-action are indicated by the segments or “piece of pie” shapes.

It is not suggested that all categories of the model need to be present for learning to occur or that there is a relationship that always correlates the presence of more elements with increases in the effectiveness and efficiency of learning. Some successful learning events may use all five categories, and others may use only one or two. There are many factors to be considered in the design of the number of categories of the model to include in learning events. For example, while interaction between learners is generally considered desirable in learning events it may be reduced or not occur where the number of learners is small; the duration of the learning event is short and flexibility of time is desired. In such cases it would be conceivable for no interaction between learners to occur during the process of learning.

The model provides a framework within which the activities of learning events can be mapped and can be used as a tool for the design of learning events. The following examples are provided to illustrate the model in general terms and to demonstrate the applicability of the model to commonplace learning environments.

THE MODEL EXEMPLIFIED

This group of examples concerns a simple, everyday learning event: preparing and cooking food from a recipe for the first time. The desired

learning outcome can be easily, although subjectively, measured as the successful production of the food. The first example is the simplest, containing only two categories of learning activities. In subsequent examples further categories of the model are added expanding and developing the activities of learning. In the simplest case of the example, the learner is the person preparing the food and they interact with the learning materials. The learning materials are the recipe and other relevant information, for example, a conversion chart for weights and measures. We all know that food can be prepared this way and that the results can be anywhere in the spectrum of taste. So it would be reasonable to suggest that effective learning can happen this way.

Example 1

The materials are already on hand and not provided as part of the learning event. The facilitator (assuming the facilitator is the person who prepared the recipe and instructions) is not present and the learner works alone. The activities include interaction with the materials (the materials being the recipe book, not the ingredients) and an intra-action (where the intra-action is the comparing and critical evaluation of the process with recipes prepared earlier and other experiences). This is represented graphically in Figure 2.

Figure 2. Example (1) Interaction with materials and intra-action

Example 2

In the second example the learner prepares the food in much the same way but this time the materials include a videotape of a television program, and through the recorded program activities in the category of provision of material are introduced. As well as interacting with the recipe some limited interaction with the videotape (i.e., replaying, pausing, etc.) is possible as well. The graphical representation (Figure 3) is the same as in the earlier example with the addition of the provision of material category.

Example 3

In the third example the learner prepares the food in much the same way interacting with the materials including the television program. However, the learner is not alone. The learner works and interacts with another learner, discussing aspects of the food preparation, sharing information, experiences, knowledge, and reactions. Hence the category of onteraction between learners is added and the graphical representation is presented in Figure 4.

Example 4

In the fourth example, the learner is a member of a face-to-face cooking class. The learner still

Figure 3. Example (2) Provision of materials, interaction with materials and intra-action

Figure 4. Example (3) Provision of material, interaction with material, interaction between learners and intra-action

Figure 5. Example (4) All categories

interacts with the materials and the other learners, and material is provided by the words spoken by the facilitator. The category of interaction with the facilitator is introduced as opportunities exist for learners to question and interact with the facilitator. In this example, all five categories of learning activities are present.

The examples of the cooking class show how the model can be used to analyze existing learning events in a general everyday learning environment. The category intra-action has been included in each example and as mentioned earlier this category is one that the learner controls rather than the facilitator or designer and is included here as an indication that it is possible for activities in this category to take place in these examples.

CONCLUSION

The learning activities model (LAM) has been developed for two purposes. First, it provides a theoretical framework for analysis of learning activities, and second, it assists facilitators and designers of learning events in the design process by subdividing learning events or programs into categories of activities. It can be used in a formative way to analyze a proposed learning event or program or in a summative way to assist in the revision of an existing learning event or program. The learning activities model (LAM) can also be used to compare different methods and modes of achieving learning goals.

There are some things that the learning activities model (LAM) cannot, and is not intended to, do. It will not prescribe the best mixture of activities to use for a particular learning event or content area. It is not sensitive to the cultural and demographic make-up of learners. The facilitator is usually the expert on the content and the facilitator or designer should have created a profile of the learners and hence they are best placed to match the activities of the model with the content and the learners.

KEY TERMS AND DEFINITIONS

Categorization: Grouping according to according to the role played.

Classification: Grouping according to similar or like characteristics.

Distance Learning (aka Distance Education): Education in which learners are separated from facilitators.

Education: A structured program of intentional learning from an institution.

Facilitator (aka Facilitator of Learning): The person who has prime responsibility for the facilitation of the learning; rather than terms such as “teacher,” “trainer,” or “developer.”

Flexible Learning: An approach to learning in which the time, place, and pace of learning may be determined by learners. In this chapter this term is used to include the approaches taken by distance learning and open learning.

Higher Education: Intentional learning in universities and colleges.

Human Resource Development: Intentional learning in organizations. Can include training and development.

Instructional Design: The process of is concerned with the planning, design, development, implementation, and evaluation of instructional activities or events and the purpose of the discipline is to build knowledge about the steps for the development of instruction.

Interaction: Reciprocal between humans and between a human and an object including a computer or other electronic device that allows a two-way flow of information between it and a user responding immediately to the latter’s input.

Learner: A generic term to describe the person learning, rather than terms such as “trainee” and “student.”

Learning: An umbrella term to include training, development, and education, where training is learning that pertains to the job, development is learning for the growth of the individual that is not related to a specific job, and education is learning to prepare the individual but not related to a specific job.

Learning Activities: The things learners and facilitators do, within learning events, that are intended to bring about the desired learning outcomes.

Learning Event: A session of structured learning such as classes, subjects, courses, and training programs.

Learning Management System (aka Virtual Learning Environment, Course Management System and Managed Learning Environment): A Web-based system for the implementation, assessment, and tracking of learners through learning events.

Learning Technologies: Technologies that are used in the process of learning to provide material to learners, to allow learners to interact with it, and/or to host collaborations between learners and between learners and facilitators.

Online Learning: Flexible or distance learning containing a component that is accessed via the World Wide Web.

Representational Technology: A one-way technology that supports interaction with the material.

Timothy T. Yuen

University of Texas at Austin, USA

ABSTRACT

The purpose of this study is to investigate students' engagement with a multimedia enhanced problem-based learning (PBL) environment, Alien Rescue, and to find out in what ways students consider Alien Rescue motivating. Alien Rescue is a PBL environment for students to learn science. Fifty-seven sixth-grade students were interviewed. Analysis of the interviews using the constant comparative method showed that students were intrinsically motivated and that there were

11 key elements of the PBL environment that helped evoke students' motivation: authenticity, challenge, cognitive engagement, competence, choice, fantasy, identity, interactivity, novelty, sensory engagement, and social relations. These elements can be grouped into 5 perspectives of the sources of intrinsic motivation for students using Alien Rescue: problem solving, playing, socializing, information processing, and voluntary acting, with problem solving and playing contributing the highest level of intrinsic motivation. The findings are discussed with respect to designing multimedia learning environments.

DOI: 10.4018/978-1-60960-503-2.ch10+

INTRODUCTION

In order for technology to positively impact classroom learning, students must be motivated to use the technology in addition to learning the content presented with that technology. Literature on motivation and classroom learning has shown that motivation plays an important role in influencing learning and achievement (Ames, 1990). If motivated, students tend to approach challenging tasks more eagerly, persist in difficult situations, and take pleasure in their achievement (Stipek, 1993). Studies have indicated strong positive correlations between intrinsic motivation and academic achievement (Cordova & Lepper, 1996; Gottfried, 1985; Hidi & Harackiewicz, 2000; Lepper, Iyengar, & Corpus, 2005). This suggests that motivational problems or lack of effort is often a primary explanation for unsatisfactory academic performance (Hidi & Harackiewicz, 2000).

Students' lack of interest in mathematics and science has been cited as one of the primary reasons contributing to U.S. students lagging far behind other high-performing countries in math and science, especially at the middle-school level (National Science Board, 1999). According to Osborne, Simon, and Collins (2003), research has indicated a decline in attitudes toward science from age 11 onward. Other researchers have also found that as children become older, their intrinsic motivation to learn science tends to decline (Eccles & Wigfield, 2002; Gottfried, 1985; Lepper, Iyengar, & Corpus, 2005). Therefore, in order to help students succeed in learning math and science, instructional technologists must create technology enhanced learning environments that can motivate students and facilitate learning.

In an effort to meet this goal, we have designed and developed a multimedia enhanced problem-based learning (PBL) environment for six-grade science, *Alien Rescue* (Liu, Williams, & Pedersen, 2002). This program has been used by thousands of middle school students in multiple states. Our

previous research examining the impact of this multimedia PBL environment has primarily focused on its cognitive effects such as its use on acquiring science knowledge and problem-solving skills (Liu, 2004; Liu & Bera, 2005; Li & Liu, 2008), cognitive tools and cognitive processes (Liu, Bera, Corliss, Svinicki, & Beth, 2004), and its effect on reducing cognitive load (Li & Liu, 2007). Studies on *Alien Rescue* have shown it to be an effective learning environment for science knowledge and problem-solving (Liu, 2004, 2005; Liu & Bera, 2005).

As we continued to work with students and teachers in different classrooms, it became apparent that students often considered their experience with *Alien Rescue* "fun" and enjoyed using it. The following quote from a teacher captured the essence of this observation:

Kids are talking about science outside of the classroom. They talk about *Alien Rescue* in the halls and they talk about *Alien Rescue* after school. All of the sixth graders are doing this, and so some of them have friends in different class periods that are working with *Alien Rescue*. They will say, "what did you find out today or have you found where this alien can go?" I think that the most exciting thing is that they are talking science outside of the classroom; I think that is the most impressive thing.

This sentiment led us to ask questions regarding the affective effects of *Alien Rescue*. Why did students like using *Alien Rescue*? What did they find interesting? How did it compare to other school activities they usually do in the classroom? The purpose of this study is to investigate sixth-graders' affective experiences, specifically motivation, as they were using *Alien Rescue* and to find out in what ways *Alien Rescue* was motivating to these students. Our guiding research question was:

How does a multimedia enhanced problem-based learning (PBL) environment, Alien Rescue, motivate students to learn science?

BACKGROUND

Using Multimedia to Enhance the Delivery of Problem-Based Learning

Problem-based learning emphasizes solving complex problems in rich contexts and aims at developing higher order thinking skills (Savery & Duffy, 1995). According to Savery and Duffy, PBL environments have three primary underlying constructivist propositions: (1) understanding is in our interactions with the environment, (2) cognitive conflict is the stimulus for learning and determines the organization and nature of what is learned, and (3) knowledge evolves through social negotiation and by the evaluation of the viability of one's understanding (Savery & Duffy, 1995). In PBL environments, the focus of learning is not only the knowledge outcome, but also the process by which students become self-reliant and independent.

The benefits of PBL, such as the activation of prior learning, self-directed learning, and motivation, have been documented in medical education and with college and gifted students (Albanese, & Mitchell, 1993; Gallagher, Stepien, & Rosenthal, 1992; Hmelo & Ferrari, 1997; Norman & Schmidt, 1992; Stepien, Gallagher, & Workman, 1993). However, literature has also indicated that implementing complex and ill-structured learning environments such as PBL in K-12 classrooms has been challenging (Airasian & Walsh, 1997).

Multimedia-enhanced PBL environments provide a new and different means that can assist students to develop problem-solving skills, to reflect on their own learning, and to develop a deep understanding of the content domain (Cognition and Technology Group at Vanderbilt, 1997), and if designed well, can also be more motivating to students than text-based delivery methods. Multimedia technology can enhance the PBL delivery through its video, audio, graphics, and animation capabilities as well as its interactive affordances

to allow students to access information according to their own learning needs and present multiple related problems in one cohesive environment (Hoffman & Richie, 1997).

Motivation as an Important Factor for Learning

For preschool children, learning is fun. There are no motivational problems for learning in these years (Cordova & Lepper, 1996). Their motivation is manifested by their choice of behavior, latency of behavior, intensity of behavior, and persistence of behavior, and is accompanied with cognitive (e.g. goal setting) and emotional reactions (Graham & Weiner, 1996). Motivation is often considered to be a necessary antecedent for learning (Gottfried, 1985; Lepper, Iyengar, & Corpus, 2005) and is a function of expectancy of attaining a goal that is valued (Klinger, 1977; Pintrich & Schunk, 2002; Weiner, 1991). When students are intrinsically motivated to learn something, they may spend more time and effort learning, feel better about what they learn, and use it more in the future (Malone, 1981; Okan, 2003). An activity is said to be intrinsically motivating if people engage in it 'for its own sake' and if they do not engage in it for extrinsic reasons or motivators (Malone, 1981). Extrinsic motivators, such as external rewards and punishments, can destroy the continuing motivation of students to learn more about subjects outside of class (Greeno, Collins, & Resnick, 1996; Maehr, 1976).

Unfortunately, in later years, instruction in school, rather than being fun, is often boring and dull to students, and students' motivational problems to learn quickly appear: "In a variety of settings and using a variety of measures, investigators have found children's reported intrinsic motivation in school to decrease steadily from at least third grade through high school" (Cordova & Lepper, 1996, p. 715). The problem of motivating students is particularly acute when the subject mat-

ter is science (Tuan, Chin, & Shieh, 2005), from the point of entry to secondary school (Osborne et al., 2003) — when their intrinsic motivation to learn science, interest in science, and attitudes toward science decline (Eccles & Wigfield, 2002; Gottfried, 1985; Lepper, Iyengar, & Corpus, 2005; Stake & Mares, 2001). Thus, promoting intrinsic motivation is critical to help students learn science.

Sources of Intrinsic Motivation for Learning Environments

There are many different perspectives of the sources of intrinsic motivation since it may vary over time, circumstances, and how people view what they are doing (Pintrich & Schunk, 2002). Lepper and Malone (1987) summarized past views of the sources of intrinsic motivation and their characteristics (p. 258):

- Humans as problem solvers: challenge, competence, efficacy or mastery
- Humans as information processors: curiosity, incongruity, or discrepancy
- Humans as players: fantasy involvement using graphics, story, and sound
- Humans as voluntary actors: control and self-determination

These four perspectives on the sources of intrinsic motivation are commonly expressed as challenge, curiosity, fantasy, and control, respectfully (Pintrich & Schunk, 2002). Though listed as separate categories, these perspectives overlap each other. For example, people become curious (i.e. humans as information processors) because of an incongruity in information. This often leads people to want to solve the problem or challenge (i.e. humans as problem solvers) presented by the discrepancy. Each perspective separately cannot sufficiently explain the phenomenon of intrinsic motivation. However, in total, they provide a comprehensive understanding of how learners

can be motivated by a learning environment and its implementation in the classroom, which may reduce the need for the teacher as the source of motivation.

Purpose of the Study and Methodology

To address our research question, we used interviews as our primary data source and the constant comparative method as our analysis technique. We also include descriptive statistics to illustrate specific aspects of the multimedia PBL environment that affect motivation and learning.

A Multimedia PBL Environment: *Alien Rescue*

Alien Rescue is a multimedia enhanced PBL environment for 6th grade science and is designed in accordance with the National Science Education Standards and the Texas Essential Knowledge and Skills (TEKS) guidelines (Liu, Williams, & Pedersen, 2002). The learning objectives include increasing knowledge of our solar system and improving problem-solving skills. It typically takes fifteen 45-minute class periods to complete. *Alien Rescue* presents a complex problem for scientific investigation and decision-making by students. The story of *Alien Rescue* has a science fiction premise that allows students to take on the role of a scientist in charge of finding habitats (e.g., the planets and moons) in our solar system for six endangered aliens by using a rich set of technology enriched cognitive tools. *Alien Rescue*'s cognitive tools include information databases with various media, simulation tools, expert modeling, and charts and a notebook tool.

Participants and Research Setting

One hundred and ten sixth graders from a middle school in a mid-sized southwestern city used *Alien*

What Factors Make a Multimedia Learning Environment Engaging

Rescue as part of their science curriculum for three weeks. The demographics of these sixth graders were approximately 71% White, 15% Hispanic, 10% Asian/Pacific Islander, and 4% African American. About 50.8% were female students and 49.2% were male students.

We observed students' interaction with *Alien Rescue* for the entire duration, and interviewed roughly 50% of the students (n=57). Both individual and focus group interviews were conducted during and after using the program. Focus groups of two to five students were randomly formed as time and seating arrangement permitted. We made an effort to talk to as many students as the time and situation allowed. Altogether, sixty interviews occurred, including ones performed during and after the completion of the program. The time for each interview ranged from 5 to 20 minutes.

Interviews and Analysis

All interviews were audiotaped and transcribed. The interview questions sought to capture students' cognitive and affective experiences during and after using *Alien Rescue*. As recommended by Suchman (1990), these semi-structured interviews occurred as informal conversations that were open-ended but guided by students' activities. Sample interview questions included the following:

- What are you working on now?
- Have you found a planet for the alien species? Which one? Why do you think it is a good home for species X? How did you reach that conclusion?
- Why did you need to launch probes? What did you find out? Do you understand the data? If you find something you do not know, what do you do?
- Which parts did you like or dislike most about *Alien Rescue*? Why?

Interviews after the completion of the program were also semi-structured and conversational, focusing on students' overall experience and impression of the program. The following were eight core questions used as the interview guides:

- What did you think of *Alien Rescue* (AR)? On a scale of 1 to 5 (highest number meaning the best), how do you like AR?
- Which part did you like the most/least about *Alien Rescue*? Why?
- Did you find the problem challenging? Did you like to solve it? Why?
- What have you learned? Did you think that you learned any science content by using *Alien Rescue*? What scientific topics, concepts, or skills have you learned by using *Alien Rescue*? How did you learn?
- How different is working with *Alien Rescue* from working on other school activities? Did you like researching and how was it different from researching in other classes or subjects?
- Did you choose your own team member? How did you work together?
- Did you talk with your peers about *Alien Rescue* outside of class? If so, what did you talk about?
- Would you want to work on programs like *Alien Rescue* in the future? Why?

Transcribed interviews were analyzed using the constant comparative method (Lincoln & Guba, 1985). Relevant information from the students' utterances or incidents was extracted through a systematic set of methodological procedures that inductively generated and connected raw data to codes, codes to categories, and categories to themes (Creswell, 2005). First, the data was examined for evidence or indicators of motivation and/or affect, since these two psychological concepts are considered to be highly linked (Eccles & Wigfield, 2002). The relevant incidents in the transcripts

were coded to describe what the students said about motivation and emotion, a process referred to as “focused coding” (Charmaz, 2006, p. 57). At the next level, the codes were compared with each other and categories emerged at a higher level of abstraction that subsumed these codes. The analyses continued until an “emergence of regularities” (Lincoln & Guba, 1985, p. 350) was reached. The emerged themes were compared with and against conventional intrinsic motivational theory perspectives with the purpose of framing our categories as well as informing existing knowledge.

RESULTS AND DISCUSSION

Findings

Of the approximately 500 paragraphs of text recording the students’ spoken words in the transcript, there were 145 incidents where students spoke of their motivation and affect. A paragraph consisted of as little as one word to as much as several sentences. Some paragraphs contained more than one incident. Of the 145 incidents, 142 incidents expressed positive motivation and affect. Figure 1 summarized students’ expression of motivation and affect. Beyond these 145 incidents of motivation and affect, there were 288 incidents describing the reasons driving their motivation and

affect, such as “I liked researching on the aliens and stuff like finding stuff out.”

After analyzing 288 incidents of students’ motivational drives, eleven themes emerged that influenced the students’ positive motivation and affect while using *Alien Rescue*. The themes for motivation and affect were: authenticity, challenge, cognitive engagement, competence, choice, fantasy, identity, interactivity, novelty, sensory engagement, and social relations. These themes and categories are shown in Table 1, along with the number of incidents and percentages.

Authenticity

Students found situated authentic learning to be motivating and valuable. There were three sub-categories for authenticity: authentic activity, scientific practices, and scientific roles. When asked how different was working with *Alien Rescue* from other school activities, some students responded that the activity was different because it was authentic in nature: “It [*Alien Rescue*] was just like doing something that a real scientist would do.”

In addition, students were motivated by taking on the role of a scientist and performing what they described as scientific practices. Students were able to role-play as a scientist and work within a space station while using the tools afforded by the environment. When asked questions on what they liked about *Alien Rescue*, students’ answers

	Peer Interaction	14

included statements such as: “I liked *Alien Rescue* because how else were you going to learn if you want to be a real scientist because it has a lot of the things you have to do and have to learn how to do” and “I like the program it was neat and... I think it was a good experience if you were going to be scientist some day—it just made you ready for that stuff.”

Challenge

In general, students liked the challenge of using *Alien Rescue* and found it motivating: “I thought it was hard, but it was fun at the same time because it was a challenge and I personally like challenges.” For some students, *Alien Rescue* was “more of challenge, so you can’t give up,” which shows a desire to attempt solving the problem. Other re-

sponses to whether *Alien Rescue* was challenging or difficult included “I think it’s fun and it’s kind of hard” and “*Alien Rescue* gave me a good challenge because it made me exercise my brain more than I would normally if it was an easier game.” However, there were a few instances of students expressing frustration that *Alien Rescue* was too challenging or that there was not enough time to complete it. A student said, “I just think that the reason that it [*Alien Rescue*] could probably be better is because it could have been easier.”

Choice

Students’ feeling of control and choice were important with both positive and negative affective valences. When asked what was liked about *Alien Rescue*, a student replied, “They [probes] were fun because you got to create them and tell them what to do.” Students thought it was fun to explore the program, choose what to do, create probes, and launch them to targeted planets and moons. On the flip side, students did not like losing control, such as when using the expert tool for guidance. The expert tool is a set of video clips in which an expert explains how they would address aspects of the problem and share their problem-solving strategies. Students did not like this and were able to explain exactly why:

Student: well the thing I hate about it [*Alien Rescue*] is the expert.

Group: OH! [agreement from the group]

Student (cont.): He would immediately take control of everything. You can’t get rid of him, he would just stand there and start talking and he would just take control for some reason...

Cognitive Engagement

The students interviewed liked the cognitive engagement that *Alien Rescue* afforded. In fact,

this was the most mentioned reason why they thought *Alien Rescue* was fun. The four main sub-categories expressed by students were learning, problem solving, researching, and thinking. For instance, a student articulated, “...I like the program. It was neat and I learned a lot of terms, a lot of scientific names that I didn’t know before...” When asked why they liked researching on *Alien Rescue*, one student summed it up by saying, “I think that it was fun, doing the research on the planets because you got to figure out different things about the planets and you get to send probes and get information that you don’t know and then you have to research all the aliens and figure out what they need and then try to match them up.” A student appreciated that *Alien Rescue* is “like a puzzle that’s kind of hard to solve but kind of easy at the same time, not easy I should say but difficult. Yeah, and it’s fun and good.” Another student said, “It was neat converting things from Kelvin to Celsius and how you could like figure out their temperatures and stuff.”

Competence/Confidence/ Self-Efficacy

Some students felt competent or confident of his or her knowledge of *Alien Rescue* and his or her recommendations of habitats for the aliens. This may also be considered self-efficacy, which according to Eccles and Wigfield (2002), is a person’s self-evaluation of his or her ability and beliefs about the probability of success in tasks. During engagement with *Alien Rescue*, students attained the feeling of competence and self-efficacy. After completing *Alien Rescue*, this feeling manifested itself as confidence regarding the selection of habitats for the aliens. One student expressed his or her confidence as, “I’m very confident because I really researched, I’m pretty sure that it was right.” Another student said, “I’m pretty confident, well, we are because we think that we researched it a lot and we think that we got it right.”

However, not all the students felt confident about their recommendations. For example, a student who was not expressing confidence because of computer problems said “I was sort of confident on some because the computers we had kept messing up and it erased my notes but we did the best we could and I think that’s all that matters.”

Fantasy

Fantasy was the second major reason, after cognitive engagement, for why students liked and were motivated to use *Alien Rescue*. Fantasy was expressed in terms of empathy for the aliens and space exploration. With regards to aliens, students were motivated by the fictional narrative of saving the aliens’ lives and as students said, “you’ve got to do it to help save the aliens” and “if you miss something the alien will die for that” and “[I like *Alien Rescue*] because [of the] aliens, ‘cause it’s also fun to imagine having them and being friends with them.” Others expressed positive affect for *Alien Rescue* because it was fictional, such as “I thought *Alien Rescue* was pretty cool because you got to actually have some fiction fun in it.”

The science fiction aspect of *Alien Rescue* made one student remark, that in “most other experiments, you don’t have this much fun because you have to do it in real life, this is like science fiction or something.”

Identity/Attainment Value

According to Eccles and Wigfield (2002), the attainment value is the individual’s determination about whether the task confirms or disconfirms the core aspects of the person’s beliefs and self-concepts about his or her self. That is, the task confirms or disconfirms an individual’s self-identity, which is informed by the communities that the student wishes to participate in, whether in school or beyond.

For some of the students, *Alien Rescue* affirmed their identity. These students were motivated to learn science in order to fulfill their desire to become a scientist or space explorer, or both. *Alien Rescue*’s science fiction narrative brought special personal meanings to the activities for some students. For instance, a student said, “I want to one day go out of space and find a new planet plus the ones already discovered and study asteroids and comets because I really like space ‘cause its very interesting”. Another student stated, “And considering the fact that I have been wanting to be an astronaut since I was like three or four years old, this was just like the best program for me...” Another student wanted to “know what it would be like standing on the moon or going to other places” and wanted to eventually “go out of space and find a new planet plus the ones already discovered and study asteroids and comets” because of an individual interest in space.

Interactivity

Students were highly engaged with *Alien Rescue* because of its interactive features. Students’ comments on interactivity can be broken down to activeness, computer-based, feedback, playing, and miscellaneous. Of these, activeness and being computer-based were the most important for these students. When asked, “How different is working with *Alien Rescue* from working on other school activities?,” a student summed up his peers’ comments by saying, “It [*Alien Rescue*] was better because instead of being stuck on the desk, you got to play around with the computer and kind of do whatever you wanted.” Another student who liked “hands-on projects a lot more than reading out of a book” reiterated this point. One student summed up how interactivity evoked positive affect and motivation, saying “...it’s funner because you are not just looking through textbooks you get to actually play around and it’s funner than just sitting there in class.”

However, a few students did not think there was adequate feedback from the program. One student commented on the lack of feedback, "... I think it should tell you if you got it right and show how if they like where they live." In other words, *Alien Rescue* did not present the outcomes of the students' recommendations for the habitats of the aliens, and some students desired this feedback.

Novelty

Students liked to have new and different experiences. This was reflected by their preference for the novelty of *Alien Rescue*, especially since it is computer based, and how it varied from regular classroom instruction. For instance, when asked "On a scale of one to five, one being not very much and five being very much, how much do you like *Alien Rescue*?", a student replied, "I would give it a five because I like doing things that are irregular."

Sensory Engagement

Not only did students find cognitive engagement motivating, but also the engagement of their visual and audio senses. Students enjoyed the multimedia presentation in general (e.g. video scenario of the problem at the beginning of the program, graphics), but the aliens (including 3D alien videos) and probe simulations, in particular. For instance, when students were asked, "Did you like researching and how was it different from researching in other classes or subjects?" one student answered, "[I like *Alien Rescue*] because you have fun and you get to look at the aliens, you get to look at the graphs, you get to look at the pictures and then just kind of go from there" and another student answered, "I like this one part about watching probes."

Social Relations

Interaction with fellow classmates and peers was an important feature of *Alien Rescue*. These interactions took the form of debating within groups on where an alien should go, "one of the things that I liked about the research was working in a group because I think it would have been a lot less fun working by ourselves because I think its fun to talk and, it's actually fun to argue because you are actually getting all that information out and its fun all around."

Not only did the debate occur within groups but also between friends from other groups and peers outside of class:

"Well, I talked about it with my friends, because one of my friends was, 'Oh my gosh I'm totally clueless about this one alien. Do you know where they go?' And I said, 'Well I think they go over there' and she said, 'No, that's wrong they need to go here.' And we would have messed up if it weren't for my friends, because my friend stopped me in the hall and she said, 'guess what we finished Alien Rescue today' and I said, 'That's [habitat] what I chose and she said, 'No, it isn't [right]. Then, I figured it out and so my friend ended up being a little bit wrong and then I had to call Lynn. And then they had a big argument with me because they thought I was wrong and my friends were wrong. I said, 'No I'm right' and then I had to do more research."

Students also found that group interaction afforded them the teamwork needed to solve the problem. As a student pointed out, "when you work in groups, you don't have to do all the research" and the different tasks can be distributed to the appropriate people. As an example, the same student cited the conversion of Celsius to Kelvin problem as being a topic one student may know, but another student may not know. The sense of camaraderie is enhanced by the fact that students

within the same group can help each other since “your partner tells you information that you don’t know.” Unfortunately, not all the members of groups were helpful, as a student stated, “I sort of did work by myself because my partner never helped me.”

GENERAL DISCUSSION

The purpose of this study was to explore the characteristics of a multimedia enhanced problem-based learning environment that intends to provide a rich context for learning science and afford students a motivating experience. The coding and categorizing procedures found eleven key elements that middle-school students considered motivating and/or evoked affect: authenticity, challenge, cognitive engagement, competence, choice, fantasy, identity, interactivity, novelty, sensory engagement, and social relations.

These elements were in congruence with the four sources of intrinsic motivation as discussed in the literature. A new source of intrinsic motivation was revealed through the analysis: humans as socializers - interpersonal relationships, identity, and group membership. Thus, our study was able to expand upon the existing theory on sources of intrinsic motivation with the addition of “humans as socializers” as a fifth source.

Humans as Problem Solvers

Activities are intrinsically motivating when the problems or challenges are personally meaningful. To best promote this motivation, the task should be optimally challenging (Csikszentmihalyi, 1990), and if possible, adaptable to the learner’s ability. As the individual masters challenges in an activity, s/he also attains a feeling of competence, mastery, and self-efficacy for accomplishing that activity. Challenges that are too easy bring on boredom and

challenges that are too difficult evoke feelings of frustration or helplessness.

The results showed that *Alien Rescue* was able to evoke the humans-as-problem-solvers motivation within students. This was the single largest source of intrinsic motivation. This is not surprising since problem-based learning environments often have been found to be intrinsically motivating (Gallagher, Stepien, & Rosenthal, 1992; Hmelo & Ferrari, 1997; Savery & Duffy, 1995), and the core task of a PBL environment is problem solving.

The sources of motivation in *Alien Rescue* that comprised this perspective were: authenticity, challenge, cognitive engagement, and competence. As has been found by other researchers, challenge was a key source of motivation among students (Lepper & Malone, 1987; Malone & Lepper, 1987; Ryan & Deci, 2000). Cognitive engagement was the single most discussed theme by the students in this study. The students were intrinsically motivated in using *Alien Rescue* because it cognitively engaged them to research and learn new concepts and facts, and to think and solve the complex problem presented. Thus, *Alien Rescue* does not only present a challenge but provides an environment in which students valued the learning and thinking processes required to meet the challenge. The rich set of technology-based tools within *Alien Rescue* (Liu & Bera, 2005) supported the learning and thinking processes as well as encouraged interactivity.

In addition, many students knew that they were engaged in authentic activities and understood that solving the problem in *Alien Rescue* required skills that were authentic to the practices and roles of being a scientist. Results suggested that this authenticity was a source of intrinsic motivation, perhaps because it brought more meaning to the problem-solving exercise. Some students found personal meaning because they valued space exploration and science (i.e. identity/attainment value). However, a learning environment cannot

accommodate for all the different, sometimes idiosyncratic, attainment values of students. Instead, the best way to accomplish the inclusion of meaningful activities is to present them in a way that convinces students that the processes employed are authentic in nature.

Finally, some students believed that they found the correct habitats for the endangered species and were confident about their decision. This perceived competence may be viewed as a source of intrinsic motivation and/or the result of intrinsic motivation. *Alien Rescue* scaffolds and reciprocally builds a student's perceived competence as the students proceed to complete the program. This is an important design consideration: students should develop the feeling of self-efficacy as they progress through the learning environment in order to promote intrinsic motivation.

Humans as Players

People play because it is fun. Fantasy involvement using graphics, characters, story, and sound can promote the feeling of play. Fantasy, heightened by using sophisticated multimedia techniques, removes students from everyday (non-play) life, which in turn promotes the feeling that the activity at hand is playing. A playful activity affords the learner to focus on the activity, which drives engagement (Csikszentmihalyi, 1990). However, if the activity is too playful, then the learner may focus on the playing aspects and less on the learning objectives.

Fantasy and interactivity combined, i.e. human as a player, were strong sources of intrinsic motivation for students to use *Alien Rescue*. Fantasy was the second biggest contributor to intrinsic motivation for the students. Fantasy involvement was promoted by using a science fiction narrative that was expressed through multimedia and interactivity. Interactivity is closely aligned with the concept of playing, and in particular, students liked playing on the computer. Results suggested

that the activeness (see Vinter & Perruchet, 2000) and feedback that *Alien Rescue* afforded via computer-based activities evoked positive affect for students. Finally, an indication that the students were experiencing play was that many of them called *Alien Rescue* a computer game and compared it to other games they played.

Humans as Information Processors

We take pleasure in resolving the mystery or disequilibrium and prefer activities that are neither very familiar nor very different (Pintrich & Schunk, 2002). Like challenges, to best promote this motivation is to provide optimal, intermediate levels of surprise and incongruence. Interestingly, curiosity was not explicitly mentioned by students using *Alien Rescue*. Instead, students described being motivated by novelty. That is, they were attracted to novel and different experiences as presented by *Alien Rescue*.

Piaget (1977) theorized that organisms (humans) not only desire experiences that are close to their existing schema, but also radically new experiences that require new cognitive structures or schemata to be accommodated. "Piaget explains how, at times, this process results in a 'reach beyond the grasp' in the search for new knowledge" (Fosnot, 1996, p. 13). Here, it seems that there is some overlap of the metaphor of humans as problem solvers and humans as information processors. Students were not only interested in meaningful challenges but their interest was piqued if the experience was novel to them. This novelty was especially enhanced by the multimedia delivery of *Alien Rescue*. Such use of multimedia effects promotes sensory curiosity (Malone & Lepper, 1987).

Yet, it is interesting that "human as information processors" was not as strong as a source of intrinsic motivation for students using *Alien Rescue* as expected. This could have been because the interpretation and categorization by the researchers

may have unintentionally marginalized this source. For instance, perhaps when students expressed their fondness for designing and using probes to find information about specific planetoids, this was an indication of their need to resolve their curiosity instead of preference for fantasy involvement using graphics. Or maybe it was both.

Humans as Voluntary Actors

The sources of intrinsic motivation from the perspective of ‘humans as voluntary actors’, as stated by Malone and Lepper (1987), are: control and self-determination. People are fond of the feeling that they are in control of their environment. Environments that provide choices and self-direction support the feeling of autonomy, which enhances intrinsic motivation. This motivation is best promoted when the activity provides “a sense of personal control over meaningful outcomes” (Lepper & Malone, 1987, p. 258). Yet, too much control over the outcomes can reduce the meaningfulness of the activity.

The open-ended nature of *Alien Rescue* affords a significant amount of choices. Therefore, it was expected that students would have mentioned choices and control more often than was found. Yet, as an indication of their desire for control, students had a strong negative reaction to the expert-modeling tool, which they felt had confiscated their control.

Humans as Socializers

The theme of social relations was an essential motivating factor of *Alien Rescue* users. Most students found the socializing aspect of working with their peers motivating. Debating and arguing their perspectives about the problem and possible solutions were engaging and fun. Such lively discourse occurred both inside and outside the classroom. Collaboration is an important aspect of PBL environments. Unfortunately, the difficulty in

logistics of performing group assessment in K-12 classrooms often discourages curricula incorporating group work. The results of this study pointed to the need to consider peer collaboration as part of the implementation of learning environments.

Developing and maintaining social relations or socializing is not explicitly stated as a source of motivation in most classical descriptions of intrinsic motivation because it appears to be extrinsic in nature. However, Lepper and Malone implicitly incorporated socializing by including self-determination (Deci and Ryan 1992; Ryan & Deci, 2000) as part of the humans as voluntary actors perspective. Self-determination theory of intrinsic motivation posits that people are innately motivated to seek out optimal stimulation and challenges that meet the needs of autonomy, competence, and relatedness. In self-determination theory, the competence need is the desire to feel capable of acting appropriately in an environment, which overlaps directly with the concept of humans as problem solvers. The autonomy need is the need of humans to feel that they are in control of their environment, as discussed in the metaphor of humans as voluntary actors. Thus, a more accurate portrayal of humans as voluntary actors is that it is about control and autonomy, rather than self-determination.

However, self-determination theory also includes relatedness as a source of intrinsic motivation. Relatedness is the need to feel secure and connected to others in the learning environment. The need for security and connectedness is closely aligned with Maslow’s (1955) theory of hierarchy of human needs of safety and belongingness. In Maslow’s theory, safety needs can be seen in individual’s preference for familiar (e.g. social) surroundings, and belongingness needs involve the need for affectionate relationships and the feeling of being part of a group (Petri, 1981).

In support of the existence of the need to be connected to others and interpersonal relations as a motivator, there have been numerous studies

demonstrating that cooperative learning and group activities, such as those provided in problem-based learning environments, have a positive effect on students' interest, engagement, and motivation (Shernoff, Csikszentmihalyi, Schneider, & Shernoff, 2003). And although not mentioned in the above intrinsic motivation metaphors, Lepper and Malone's (1987, p. 248) taxonomy of intrinsic motivations includes interpersonal motivations, which are promoted by organizing activities with cooperation, competition, and recognition. A fundamental design element of PBL environments is organizing the activity so that learners cooperate to solve a problem, which affords the opportunity to enhance interpersonal relations and motivation.

The innate desire of individuals to establish, strengthen, and maintain interpersonal relations—the sense of belonging to and participating in a social group or community—is aligned with the social constructivist view of motivation (Greeno, Collins, & Resnick, 1996; Wentzel, 1999), which is an underlying theory behind problem-based learning environments. In the classroom, this social group comprises of friends and classmates. The super-motive is the reciprocal process of valuing the social group and the development of one's identity within that social group. Individuals have the innate need to belong to a social group or community where they can develop their self-esteem and attain esteem (via social recognition) from others through participation in that social group or community (Bandura, 1986; Hickey, 2003; Maslow, 1955; Ryan & Deci, 2000). Motivation is the process of negotiation of one's identity and participation in a community in order to attain esteem (Lave & Wenger, 1991).

The Significance of Using Technology in PBL Delivery

Within the context of PBL, the eleven elements that the students found to be motivating about *Alien Rescue* were, to a large extent, delivered and

enhanced with the assistance of technology. Situating the central problem within a science fiction premise, using video newscasts to announce the arrival of the aliens, placing students in the role of a scientist, providing a space station environment for the student to explore, and providing numerous databases of rich information make the learning environment more compelling and engaging for these sixth-graders.

Students' research and problem solving in *Alien Rescue* are assisted with the set of cognitive tools, each with a specific function. These cognitive tools are an important part of enhancing intrinsic motivation. This includes providing tools that students consider are authentic and used in the "adult world" such as the notebook, probe designing, and informational databases about NASA missions, and our solar system. These tools are interactive, supporting fantasy and sensory engagement. They provide necessary cognitive scaffolding during students' problem solving. As students develop more expertise during the process, they feel more confident with their work, which ultimately leads to enhancing students' self-efficacy. The cognitive tools provide students both cognitive scaffolding in assisting them to solve a complex problem, and also motivational scaffolding in making them feel less overwhelmed or helpless. Together with the incorporation of teamwork, students are in control of their own learning, relying less on the teachers, and are encouraged to be self-reliant and independent. The cognitive tools, however, should not be considered to have a one-to-one correspondence to the sources of motivation. Instead, the relationship between the tools and sources of motivations are one-to-many. That is, every tool can afford different sources of intrinsic motivation. For instance, the probe-designing tool supports the fantasy narrative, provides control for the students to test hypotheses and multimedia sensory curiosity while affording the students to continue the process of problem solving. When designing cognitive tools within a learning envi-

What Factors Make a Multimedia Learning Environment Engaging

ronment, designers should consider how tools, individually and collectively, support the sources of intrinsic motivation (See Figure 2).

CONCLUSION

Intrinsic motivation is shown to be highly correlated with the academic success of students, and is thought to be the antecedent to learning. Thus, it would behoove designers of multimedia learning environments to consider incorporating elements that promote the five sources of intrinsic motivation: problem solving, playing, information processing, voluntary acting, and socializing.

The findings of this study showed that students using *Alien Rescue* repeatedly described their experience as fun, interesting, and enjoyable, which are the characteristics of being intrinsically motivated. The two strongest sources of intrinsic motivation for students using *Alien Rescue* are

their participation in problem solving and playing. The students expressed pleasure in engaging cognitive challenges while problem solving and the environment afforded these middle school students the feeling of playing while problem solving. Thus, removing them from everyday life and immersing them in a fantasy appeared to motivate the students to engage in solving a difficult task. The importance of incorporating these sources of intrinsic motivation into designing multimedia learning environments for this age group is obvious.

Other sources of intrinsic motivation such as social relations, curiosity, and choice—though less mentioned in comparison, also merit attention in designing multimedia learning environments. A learning environment that promotes social relations is important because it is not only a source of intrinsic motivation, but peer collaboration is also a way to scaffold student learning through the zone of proximal development (Vygotsky,

Figure 2. Summarizes the motivating characteristics as exhibited in *Alien Rescue* with their corresponding theoretical motivational perspectives

2006). In addition, students are motivated by the novelty of the computer program, as well as with the sensory curiosity afforded by the rich multimedia design. Finally, choice is an essential source of intrinsic motivation and becomes salient to the students who, as shown in this study, had strong negative reactions when it was insufficient or taken away.

Taken together, the eleven elements (authenticity, challenge, cognitive engagement, competence, choice, fantasy, identity, interactivity, novelty, sensory engagement, and social relations) as exhibited in *Alien Rescue* have shown what makes a learning environment engaging to the sixth-graders, and reflect the five sources of intrinsic motivation. Thus, these motivational factors are important for designers to consider in designing learning environments.

FUTURE RESEARCH DIRECTIONS

This study provided some empirical based insights into how a multimedia learning environment can motivate students to learn academic subject matter. One possible future direction of research relates to how to optimize the sources of intrinsic motivation using multimedia. Is it possible to find an optimal level of motivation for a target group of students or is it better to try to develop an adaptable system to accommodate idiosyncratic motivational levels of each student? If the adaptable system approach is taken, how does one measure the student's motivation without interrupting working/playing and confiscating control?

Another possible future research direction is to determine how to enhance the sources of intrinsic motivation of PBL environments, such as *Alien Rescue*. Socializing, evoking curiosity, and choice-making were appreciably less mentioned by students in this study as compared to other sources such as problem solving and playing. How can these secondary sources be enhanced?

Also, will all the sources of intrinsic motivation be enhanced when focusing on improving one or more of the sources' efficacy?

Finally, it is possible to use the five sources of intrinsic motivation as a rubric for evaluating future research on motivational characteristics of multimedia learning environments. Quantitative instruments can be developed to evaluate a wide range of multimedia learning environments to determine which sources were the major contributors for each genre. For instance, how do the results of this study compare to other multimedia enhanced problem-based learning environments? The results from studying each genre of multimedia learning environments can also be compared and contrasted to gain greater understanding of how to motivate students. From this research, we would not only understand how to enhance motivation through multimedia, but we could also be able to add new insights and dimensions to motivational theories as well.

INTRODUCTION

Due to continuous technological advancements, the Web offers diverse applications for e-learning. However, in practice, many times technological development is considered synonymous with improved education. It is very important to take into account the appropriate use of Web development in order to promote knowledge acquisition with a proper selection, delivery and construction of information.

In order to support knowledge management in e-learning, it is critical to take into account the type of information in development. The evolution of the Web towards semantics supports the idea of giving more significance to contents than

to syntax. In this way, the machines can make complex tasks to deliver users the information to meet their needs.

The challenge of defining the type of information to manage for e-learning is a topic that has led to the emergence of new concepts for resource development. One of these concepts is the learning object, which considers resources as independent units that can be re-used for other contexts and educational situations.

However, there are a lot of LOs definitions; the most widespread one is from IEEE LOM (2002) that states the “digital or non-digital entity that may be used, reused or referenced while the learning receives technical support.” However, this concept is too broad to guarantee an efficient resources management. We believe LOs should represent

DOI: 10.4018/978-1-60960-503-2.ch107

at least a single instructional objective and all of the related materials required to support that goal.

In order to manage LOs without interoperability problems, specifications and standards are in development. However, the ability to interchange learning objects is not synonymous of a good quality result. Research about quality LOs is a topic that has had limited focus and there are only a few published works dealing with their quality design.

In today's world, reusable LOs concepts and standards for their treatment represent an advantage for knowledge management systems to whatever kind of business that supports an online system. Users are able to manage and reuse content according to their needs without interoperability problems. The possibility of importing LOs for e-learning aims to increase their information repository, but the learning object quality is not guaranteed.

As stated before, the purpose of this article is to provide an awareness of the elements that should be considered in quality learning objects' instructional design for e-learning systems.

According to this, in the second section we propose our own LOs definition considering different kind of aggregation levels; in this way it is possible to make clear what we understand for LOs and what kind of LOs we are managing. Another important issue is to make clear what is the meaning of quality; for this reason in this section we present our own definition about it.

In order to achieve quality LOs design it is important to take into account their characteristics. The third section defines LOs' characteristics in order to promote quality LOs instructional design.

To achieve this we analyze cognitive theories to promote learning as well as explain issues relating to the LOs characteristics that help to improve their quality for a suitable management. It is because LOs need to be enabled with other ones to build the largest units (didactic units, courses, etc.) possible to deliver selected LOs for students; it means they are part of the whole. In addition, this

work offers recommendations for quality criteria of resources to consider in composing quality didactic units from LOs. Finally, the fourth section points out our conclusions

LOS AND QUALITY CONCEPT

There are new organization models, which need to be encouraged (Cunha et al., 2006). One of the most important is the virtual organization model (Putnik et al., 2006). As a product of Web development, the LOs concept exists (Moreno & Bailly Baillièrre, 2002; IEEE LOM, 2002; Polsani, 2003; Wiley, 2000). LOs have characteristics of being independent units, which are able to be reused in other educational situations.

In agreement with this there are new ways for working and organizational dimensions (Cortés et al., 2006). Knowledge management for e-learning based on reusable LOs means the possibility of accessing specific content according to the learners' needs. To avoid interoperability problems, there are some organizations that are working to develop standards and specifications to manage resources for e-learning systems.

To manage LOs, it is important to respond with what we understand for LOs. We define a LO as a "unit with a learning objective, together with digital and independent capabilities, accessible through metadata to be reused in different contexts and platforms" (Morales et al., 2006).

LOs must have a learning objective because it enables it to direct the contents and material relating to them. Ideally a LO must contain different types of elements, which help to clarify the main idea. In this way learning could be reinforced.

For reusing LOs in many educational levels and contexts, it must include a principal or a few related ideas; in this way teachers are free to decide in which learning context they must be used. It is possible because LOs are not necessarily related to any time, methodology or instructional design.

Independent LOs characterized by one or few related ideas means the possibility to teach some topic by itself, avoiding reusability problems. Accessible through metadata capabilities deliver the LOs characteristics providing different kinds of information about them.

Our proposal is based on IMS specifications, for this reason we refer to metadata considering IMS LOM (Learning Object Metadata) (IMS LOM, 2003), which is a derivation of IEEE LOM (IEEE LOM, 2002). Finally, LOs reusability means the possibility that a LO could be reused many times independent of software and platforms changes. This issue reflects their interoperability and durability characteristics.

IEEE LOM (2002) defines different kinds of aggregation or granularity levels for Los; this means different type of LOs to manage according to their size. However, we think IEEE LOM (2002) definitions are too wide and do not consider educational sense. According to this we suggest the following definitions:

- **Level 1:** The smallest level of aggregation, for example, a picture, an image, a text, and so forth (IEEE LOM, 2002)
- **Level 2:** A lesson with a specific learning objective and a kind of content, practice and evaluation activities
- **Level 3:** A learning module composed by a group of lessons (LOs Level 2), practice and evaluation activities
- **Level 4:** One or more courses composed by a group of modules (LOs Level 3) with different kinds of contents, practice and evaluation activities

The levels mentioned suggest pedagogical components in order to help students to achieve their learning objectives. However this issue is not enough to ensure quality Los.

In order to propose quality LOs design it is important to define what is the meaning of “qual-

ity Los.” According to the RAE (2006) definition, quality is a property or group of properties inherent in a thing, which aims to judge their value. Taking into account this definition and LOs characteristics, we define quality learning objects design as a property or group of properties inherent in a learning objects, which aim to value them as equal, better or worse than other ones.

Quality is a concept that involves other issues for their evaluation, for example, quality criteria, metrics, instruments, and so forth. To achieve a whole quality LOs design, in the next section we are going to mention LOs characteristics that aim to define quality criteria to evaluate their quality for an instructional design process.

LOs INSTRUCTIONAL DESIGN

Different kinds of learning theories exist to explain how learning occurs. However, to apply some design for contents it is necessary to consider some methods depending on learning situations, it is possible through instructional design. Reigeluth and Moore (1999) explain that instructional design is a theory that offers an explicit guide about how to teach to learn.

Instructional design theories are related with the kind of information to try. About LOs some instructional design theories exist. Merrill (1999) proposes the instructional transaction theory directed to mechanized process “is an attempt to extend the conditions of learning and component display theory so that the rules are sufficiently well specified to be able to drive automated instructional design and development.”

This theory describes knowledge in terms of three types of knowledge objects: entities, activities, and processes. Also it identifies a lot of issues like interrelationships among knowledge objects including: components, properties abstractions, and associations between entities, activities, and processes.

Merrill's theory has been criticized about its excess structure because it doesn't facilitate the content developers' work and to put it into practice.

Based on Merrill's theory (1999), Cisco Systems (2004) suggests a guide for reusable learning objects creation. This guide proposes specific structures for any kind of specific learning object. It also provides a help guide and examples for their classification. To ensure solid structures for multi-courses, Cisco Systems provides five levels of hierarchy: course, module, lesson, topic, sub-topic. Each one of these levels has specific elements to structure them.

Cisco System LOs structure is shared by Moreno and Bailly-Baillière (2003), however they suggest taking into account three kind of contents: data and concept, procedure and process and finally reflection and attitude. According to them, the three kinds of contents involve the other ones (Moreno & Bailly-Baillière, 2003). In this way it is possible to simplify the content developers work covering other related types of contents. We think defining three kinds of contents involving another ones is a good idea because each kind of them defines what learners are able to do, because each one of them represents a specific unit of learning together with a specific difficulty level. For example, data and concept refer to basic information about any subject, so they need to be considered at the beginning of a lesson; process and procedure implies a high level of difficulty because it refers to some sequenced steps, which needs to consider previous to basic information (data and concept).

Finally, we would like to suggest "principles" kind of content instead of "reflection and attitude;" this is because principles learning is related with high cognitive levels as induction, deduction, and so forth. Then, this kind of content needs to be considered at the end of a lesson.

Nowadays, LOs instructional design is a topic that is highly discussed. However, according to those mentioned above there are some issues

that must be considered to ensure a quality LOs instructional design. According to this in order to provide an awareness of the elements that should be considered in the quality learning objects instructional design for e-learning systems we suggest some quality criteria into the following LOs components.

- **Overview:** According to Cisco Systems (2004) and Moreno and Bailly-Baillière (2002), a didactic unit needs a general vision in which may be explained general objectives and introduction about the LOs content. Introduction is an important element for any kind of content because, as well as their informative function about the contents, they establish the purpose of the topics and orient learners to what they are expected to learn. On the other side, it is a motivation element that aims to engage the students, letting them know why it is important for them.

An overview must show the LOs objective too. As we explain in the LOs definition, according to LOs reusability characteristics ideally an objective must be simple with one or few related ideas. We suggest that an objective must be directed to learn one kind of content because in this way all the instructional design would be targeted to achieve this specific objective.

Other important issues that must be included in a LOs overview are its own title and the title of the unit of learning; in this way students can know what part of a whole they are trying; the list of topics that aim to relate the topics; the number of hours to be available to achieve the objective that aim to organize the learning; and, finally, keywords that aim to know what related areas are involved with the LOs content.

- **Contents:** One of the most important issues for instructional design is to define what

kind of content we are trying. According to this some instructional design proposals exist (Merrill, 1999; Clark, 1999; Moreno & Bailly-Baillière, 1999; and so forth) in order to define a suitable information or type of knowledge (facts, procedure, process, concept, principle, etc.) The type of content or unit of learning is very important because it responds the answer about what to teach according to a specific cognitive domain.

In general any kind of content must have some quality characteristics taking into account different issues. From a pedagogical point of view, contents must be in line with logic and psychological meaningful: that is to mean, on one side discipline logic (content sequence, methodology, kind of activities, etc.), and on the other side users suitability (level of difficulty, user interests, etc.). Other issues related with any kind of content are the information veracity, data entirely correct, good redaction and orthography, and so forth.

However, taking into account the LOs characteristics it is important that contents do not mention something about the time, for example, this week or this semester... because it could delay its reusability for other educational situations. The same thing must be taking into account for the audience, so phrases related to the kind of users like “dear engineering students...” must be avoided.

- **Practice activities:** Activities may be directed to promote new knowledge acquisition and prepare users for a final assessment. Clark (2002) promotes **practice** and **assessment** activities. The first one has to support students to acquire new knowledge providing feedback, pointing out the most important information, and to prepare them for a final evaluation. The second one must be a final experience together with an approbation or reproval degree. They

are used to verify if the objectives were achieved or not.

Activities may be included into any kind of content during all teaching and learning processes. They help users to know if they must to take the next lesson or a content feedback.

Activities are recommended for any kind of instructional design, however for LOs there are several issue to take into account that are not usually discussed. In general activities are too related with a context. Activities are recommended to acquire new knowledge according to the students' context (culture, interests, etc.).

However activities related with a specific context can causes problems to reuse LOs for another context. To promote LOs reusability we suggest proposing into instructional design some LOs activities that aim to learn the contents independent of the context. For example, some self-assessment activities can help students to remember and, relating concepts between them, some questions about content reflection can help to learn specific contents, and so forth.

In order to avoid contents reusability problems we suggest making some context activities independent of the LOs structure, in this way the LO would have more probabilities to be reused in another context.

Some authors (Zapata, 2005; Del Moral & Cernea, 2006) promote constructivist learning environments for learning objects. They emphasize that activities must be as diverse as possible to attend to different kind of users: case studies, to resolve problems, collaborator work, reflect about situations, and so forth. However, we think a deep reflection about them is necessary before their application to LOs.

Activities are closely related with the kind of contents; if LOs contents are just talking about a basic concept, fact or data, the kind of activities may be directed to reinforce them, for example, relating basic concepts with true or false options, and

so forth. Probably another activity like case study doesn't need this level of complexity. According to this, in order to respond different complexity levels, contents, and cognitive domains, we suggest taking into account three kinds of activities: initiation, restructuring and application.

- Initiation activities classification may be for all LOs, which are designed to teach basic content for a specific subject. An example of this is a quiz.
- Restructuring activities classification may be directed to promote new knowledge acquisition, such as activities that promote questions, investigation, and so forth.
- Application activities may be directed to promote students' experiences in order to achieve their new concepts acquisition. An example of this activity is a case study.

Due to LOs reusability characteristic some authors like Cisco System (2004) and Bailly-Baillièrè (2002) recommend making some sequential activities at the end of a lesson. This is to avoid consistency problems with new LOs adaptation. In this way it is possible to attend the whole of each one of individual LO content.

Web development is directed to the social web, which promotes collaborative tasks that need to be considered for learning. According to this. García-Peñalvo et al. (2007) suggest relating Web tools with different kind of e-activities in order to promote collaborative work.

- **Summary or conclusions:** For whatever kind of teaching and learning process, it is advisable a summary after contents review. For a suitable summary it is advisable to point out the principal ideas and relation between them, in this way it is possible to reinforce the contents and learner progress. Also it is important to relate the contents with another knowledge areas. This may

be done, for example, by diagrams, schemas, conceptual maps, and so forth.

- **Evaluation activities:** As we mentioned above, assessment is a kind of activity that must be a final experience together with an approbation or reproval degree. Their function is to verify if the objectives were achieved or not. An evaluation must take into account each one of the learning objectives and must be directed to any kind of content and their level of difficulty.

As we said before, LOs need to be enabled with other ones to build the largest units (didactic units, courses, etc.) possible to deliver selected LOs for students (Cisco System, 2004; Moreno & Bailly-Baillièrè, 2002). According to the LOs components mentioned above, Figure 1 shows the relation between LOs instructional design components through an ontological model proposing some classification that could be considered for an application profile in order to improve LOs management.

LOs classification suggested above is a way to facilitate LOs management according to instructional design characteristics. Cognitive level aims to define what student skills to develop and what they are able to do. This information is important from a pedagogical point of view to determine their reusability in another educational context.

On the other side, contents classification aims to decide if they are suitable for other educational objectives and aims to determine the contents sequence, because any kind of content defines the specific type of content that LOs contain. This issue is useful to give students specific LOs content they need.

According to the knowledge model proposed, activities are classified by practice and evaluation, as we explained in the first section. Both have the same classification and strategy, however the last one must be evaluated to promote students to another learning stage.

Figure 1. An ontological model for LOs instructional design

LOs normalization is a way to prepare LOs for their management and evaluation, because in this way it is possible to uniform their characteristics promoting their quality criteria. This issue aims to respond to an important question for knowledge management: what to manage?

CONCLUSION

Nowadays LOs are a subject that is highly discussed, but there is not a consensus about their instructional design. This is due to several things, one of which is a big breach between pedagogi-

cal and computer science areas. On one side, from the computer science area there is a high concern about promoting LO characteristics for automated process: reusability, accessibility and interoperability.

Nowadays some specifications and standards are in development as an attempt to solve these problems. As well some researches are focused in development repositories to attend to any kind of LOs aggregation level.

From a pedagogical point of view, researchers complain of a lack of instructional design plan, which aims to direct the LOs content to achieve a learning objective. However, there are some pedagogical issues that are difficult to achieve for automated process.

Nowadays technical and pedagogical issues for quality learning objects design are not easy to solve because it depends of an agreement between them. In a way to help to give a solution we suggested some issues to take into account from instructional design view. We think it is very important to apply some instructional design, because it aims to give LOs educational sense.

The LOs definition we are proposing aims to define some instructional design components, and quality criteria provided aim to create a valid and quality unit of learning. On this basis, it is easier to apply quality criteria for LOs because they have a uniform structure.

This work does not pretend to solve the LOs quality problem, but proposes some ideas to improve their quality into a pedagogical point of view that must be applied both to instructional design and metadata information.

KEY TERMS AND DEFINITIONS

E-Learning: The use of Internet technologies for learning activities to promote a wide display of solutions for improving knowledge and performance.

Instructional Design: Instructional design is the systematic development of instructional specifications using learning and instructional theory to ensure the quality of instruction. It is the entire process of analysis of learning needs and goals and the development of a delivery system to meet those needs. It includes development of instructional materials and activities, and tryout and evaluation of all instruction and learner activities (<http://www.umich.edu>).

Learning Object: A unit with a learning objective, together with digital and independent capabilities, accessible through metadata to be reused in different contexts and platforms.

Learning Objects Repository (LOR): Collections of learning objects that are accessible via Internet. They function like portals with a Web-based user interface, a search service and a catalogue for the resources contained.

Level of Granularity: How much or how little information is included in a learning object. It is related with the LOs size.

Metadata: Coded information about a learning object that aims to describe and manage them in the learning object repository.

Quality Learning Objects: A property or group of properties inherent in a learning objects, which aim to value them as equal, better or worse than other ones.

Reusability: A property of learning objects, which promotes the reuse of them for other educational situations and contexts. It depends on both metadata information and instructional design.

Chapter 1.8

Instructional Design Methodologies

Irene Chen

University of Houston – Downtown, USA

ABSTRACT

Instructional design (ID) is the systematic process of planning events to facilitate learning. The ID process encompasses a set of interdependent phases including analysis of learners, contexts and goals, design of objectives, strategies and assessment tools, production of instructional materials, and evaluation of learner performance and overall instructional design effort. The system approach, developed in the 1950s and 1960s, is rooted in the military and business world and has dominated educational technology and educational development since the 1970s. Currently, there are more than 100 different ISD models, with almost all based on the generic ADDIE model. Other commonly known models include the Dick and Carey model, the R2D2 model, the ICARE model, and

the ASSURE model. These models share three major components: analysis, strategy development, and evaluation. This chapter identifies the different roles and responsibilities involved when developing a typical title and outlines the main steps in the development.

INTRODUCTION

Instructional design (ID) is the systematic process of planning events to facilitate learning. The ID process encompasses a set of interdependent phases including analysis of learners, contexts and goals, design of objectives, selection of strategies and assessment tools, production of instructional materials, and evaluation of learner performance and overall instructional design effort (Gagne, Briggs, & Wager, 1992).

DOI: 10.4018/978-1-60960-503-2.ch108

Instructional design models may be defined as the visualized representations of an instructional design process, showing the main elements or phases of the process and their relationships. The systems approach involves setting goals and objectives, analyzing resources, devising a plan of action, and continuous evaluation and modification of the program (Saettler, 1990). The system approach, developed in the 1950s and 1960s and rooted in the military and business world, has dominated educational technology and educational development since the 1970s.

Currently, there are more than 100 ISD models, but almost all are based on the generic ADDIE model. The more commonly known models are the Dick and Carey model, the ICARE model, and the ASSURE model. These models all share three major common characteristics: analysis, strategy development, and evaluation. This chapter identifies the different roles and responsibilities involved in developing a typical title and outlines the main steps in the development. This chapter also explores ID in terms of definitions, models, and usage.

INSTRUCTIONAL DESIGN, TECHNOLOGY, AND THEORY BACKGROUND

The following key ID terminologies (1996) are explained in “Definitions of Instructional Design”:

- The discipline of instructional design is a branch of knowledge concerned with research and theory about instructional strategies and the process for developing and implementing those strategies.
- Instructional development is the process of implementing the design plans.
- An instructional system is an arrangement of resources and procedures to promote

learning. Instructional design is the systematic process of developing instructional systems and instructional development is the process of implementing the system or plan.

- Instructional technology is the systematic application of theory and other organized knowledge to the task of instructional design and development.

The growth of instructional design is relatively brief when compared with more mature design fields such as architecture. Only during the last century have scholars conducted in-depth research into learning theories, instructional theories, and systematic approaches to instruction. Many researchers analyze how human learning is relevant for the design of educational material (Gros, Elen, Kerres, Merrienböer, & Spector, 1997; Reigeluth, 1999; Schneider, n.d.; Winn, 1997). ID theory provides guidance on the task of designing learning experiences. It also provides a bridge to learning theories and instructional theories. According to Reigeluth, “Instructional theory describes a variety of methods of instruction (different ways of facilitating human learning and development) and when to use—and not use—each of those methods” (Squire & Reigeluth, 2000).

Most researchers agree that instructional materials are concerned with electronic learning environments. Such an environment is a combined system involving tasks, stakeholders, courseware, etc., which is aimed at supporting learning processes. Learning takes place mostly in interaction between learners, courseware products, other tools, and to a lesser degree tutors (human or artificial) (Schneider, n.d.).

The discipline of instructional design concerns research and theory about instructional strategies. Theory background for teaching and learning are presented in the following section.

INSTRUCTIONAL DESIGN PROJECT MANAGEMENT

Developing an instructional project involves skill sets ranging from project management and interface design to sound preparation and programming. Sometimes, budgets and schedules require multimedia developers to juggle more than one role. Design teams represent various fields of expertise (producers, instructors, editors, etc.). Although multimedia tools make it possible for one person to perform every task, few people have the combination of technical, artistic, and management skills necessary to fill every role well. As a rule, teams with a range of expertise best develop instructional design projects. The more a person understands each team crew's role and responsibilities, the better they will perform in these roles.

- Project manager
- Instructional designers
- Content experts/writers/script writer/writer/editor
- Developers/program authors/lead programmer
- Video specialists/camera operator
- Audio/video specialists/sound engineer/audio technician
- Graphic artists/art director
- Testers

The entire instructional design team together has to establish a consistent design for the title by specifying what the navigation system looks like, where information and media appear on screen, and what fonts, colors, and graphical design elements to use.

Time is critical, especially with a team of more than three members working on the same instructional project. Team members need to share expertise, intent, calendars, and internal standards. Designers need to clarify their goals, objectives, content, and evaluation plans to the producers.

Producers also need to focus on the identified audience and objectives and suggest technology options. The instructional design steps save time by focusing the team and serve as the foundation for project development and a roadmap through the process.

INSTRUCTIONAL DESIGN AND TECHNOLOGY PROJECT MANAGEMENT LIFE CYCLE

Every instructional design project is different, but almost all follow these typical project planning, development, and implementation steps:

1. Determine project scope
2. Letter of understanding
3. Contractual agreement
4. Storyboard
5. Prototype
6. Script development
7. Media development
8. Authoring
9. Alpha testing
10. Beta testing
11. Project delivery

Several of the previously mentioned steps can overlap each other. Most projects involve several cycles of media development, authoring, review, and revision. In fact, your project is likely to evolve as your resources change. For example, the content has to be ready before the developers can integrate it into the final project. But writers need to integrate the content and review it on screen in order to edit the content well.

THE APPLICATIONS OF INSTRUCTIONAL DESIGN MODELS

In addition to its concerns with research and theory about learning and instructional strategies, the

discipline of instructional design is also concerned with the process for developing and implementing those strategies. The learning and instruction theories discussed above forms the basic foundation of most of the work that instructional designers do, much as a basic understanding of engineering undergirds the work of architects (Schneider, n.d.). Instructional design theory is also what designers draw on when they need guidance to overcome problems in the design process.

Models help learners to visualize the problem, and then break it down into discrete, manageable units (Ryder, 2006). In instructional design, models can be defined as the visualized representations of an instructional design process, displaying the main phases and their relationships. Each phase has an outcome that feeds the subsequent phase. ID models are visualized representations of an instructional design process, showing the main elements or phases and their relationships. The instructional design models are the instructional designer's primary "tool," which functions as a guide allowing the designer to produce effective, efficient, and consistent instruction (Hinton, n.d.).

Instructional design models can be used in many settings and to varying degrees. Individual instructors creating their own traditional classroom material can benefit from consciously using an instructional design model. Instructional design projects present the same kind of management issues that other types of projects face. Designers need to consider variables that range from how the project should look onscreen to what the personnel, equipment, budget, schedule, and resources allow the project to accomplish. Good project development depends on having a clear picture of the steps involved in the process. Instructional design teams use instructional design models to speed up the process, assist in internal and external communication, and cover all phases of instructional design.

Close alignment of instructional design steps insure that the elements of instruction are all consciously addressed and all the pieces relate to

and support each other. This also ensures that the design is complete and packaged to be transmitted to the clientele prior to instruction. In this way, no phase of instructional design will be forgotten or shortchanged. Instructional design models can help both individuals and design teams work through the process of planning and developing instruction. Consciously working back and forth through the steps of an ID model will add speed and clarity and insure that key instructional principles are addressed. Instructional design models can also be used to assess existing educational material and help in everyday planning.

A variety of models for instructional system design proliferated the late 1970s and early 80s: Gagné and Briggs, and Dick and Carey, to name a few. One possible reason for this phenomenon involves the establishment of formal education and training departments within both public and private organizations. Faced with the computerized technologies of the times, these organizations require a means to quickly develop appropriate methods by which to educate employees in the new business practices ushered into existence by the information age. Another explanation is that businesses, especially consulting organizations, are becoming increasingly required to demonstrate value-added not only to their organization, but to the clients they serve. The evaluation and continuous improvement components of contemporary instructional design models of make far strides from the early develop-and-implement models of the middle of the century in this aspect.

SYSTEMS APPROACH TO INSTRUCTIONAL SYSTEMS DESIGN (ISD)

The system approach, rooted in the military and business world, was developed in the 1950s and 1960s, and has dominated educational technology and educational development since the 1970s.

Instructional design has successfully established a fairly broad knowledge base, with foundations in psychology and other professional practices. The systems approach to instructional design was often accredited to James Finn. Seels (1989) described Finn as the father of the instructional design movement because he linked the theory of systems design to educational technology and thus encouraged the integrated growth of these related fields of study. Finn also made educational technologists aware that technology was as much a process as a piece of hardware (Seels, 1989).

The onset of World War II introduced the huge problem of training thousands of military personnel quickly and effectively. The answer at the time was an enormous influx of mediated learning material: films, slides, photographs, audiotapes, and print materials. In the 1960s, the military was rapidly infusing instructional systems development into their standard training procedures. This period was distinguished by the articulation of components of instructional systems.

The systems approach views a system as a set of interrelated parts, all working toward a defined goal. Examples of systems include the human body and a community. Parts of a system will depend on other parts for input and output. The entire system uses feedback from stakeholders to determine if the goal is achieved. In 1962, Robert Glaser employed the term instructional system and named, elaborated, and diagrammed its components. He also synthesized the work of previous researchers and introduced the concept of “instructional design,” submitting a model, which links learner analysis to the design and development of instruction.

In the field of education, the systems-approach model first focused on language laboratories. The instruction can be viewed as a systematic process in which every component is crucial to achieve the goal of successful learning. These components include the learner, instructor, instructional materials, and the learning environment. The many

components of the system interact to achieve learning. The focus is on what the learner will be able to know when the instruction is concluded.

THE ADDIE MODEL

The ADDIE model has been in use for training development for several decades. Almost all ISD models currently in use are based on the generic ADDIE. The systems approach does not prescribe or promote any particular teaching methodology. No one method will be appropriate for all objectives or for all students. Rather, it is a vehicle that helps teachers to think more systematically and logically about the objectives relevant to their students, and the means of achieving and assessing these (Chen, 2005). These early efforts of ISD in education led to several ISD models that were developed in the late 1960s.

The current version of the systems approach is a process comprised of a series of phases. Sometimes referred to as the ADDIE model, the systems approach of instructional design contains the following major phases: analysis, design, development, implementation, and evaluation.

- Analysis
- Determine the instructional goal
- Analyze the instructional goal
- Analyze the learners and context of learning
- Design
- Write performance objectives
- Development
- Develop instructional strategies
- Develop and select instruction
- Develop assessment instruments
- Implementation
- Implement the system
- Revise the instruction if necessary
- Evaluation

- Design and conduct the formative evaluation of instruction
- Conduct summative evaluation

Each step receives input from the previous step and provides output for the next step. A system is modified if the goal is not achieved. Each component is carefully linked. The ADDIE model is possibly the best known design model, and is frequently used in academic circles.

THE DICK AND CAREY MODEL

Today, Walter Dick and Lou Carey are widely viewed as the torchbearers of the approach with their authoritative book *“The Systematic Design of Instruction”* (1978). While a number of versions of the ISD model exist, the Dick and Carey model is very popular in current instructional design programs.

Dick and Carey’s model, a systems-approach model for designing instruction, is based on the assumption that there is a predictable link between a stimulus and the response that is produced in a learner. It describes the phases of an iterative process that starts by identifying instructional goals and ends with evaluation. This model includes analysis, design, development, formative evaluation, plus needs assessment in a nonlinear relationship (Dick & Carey, 1978). The designer needs to identify the sub-skills the student must master that, in aggregate, permit the intended behavior to be learned, and then select the stimulus and strategy for its presentation that builds each sub-skill.

The following is a list of the elements of Dick et al.’s model explained in *“The Systematic Design of Instruction.”*

1. Determine the instructional goal
2. Analyze the instructional goal
3. Analyze the learners and contexts
4. Write performance objectives
5. Develop assessment instruments
6. Develop instructional strategy
7. Develop and select instruction
8. Design and conduct formative evaluation
9. Revise instruction
10. Use summative evaluation

Establishing an instructional goal or goals is typically preceded by a needs assessment. The needs assessment is a formal process of identifying discrepancies between current outcomes and desired outcomes for an organization. Dick et al. described the performance objectives as a statement of what the learners would be expected to do when they have completed a specified course of instruction, stated in terms of observable performances.

The technique of hierarchical analysis is applied for goals in the intellectual skills domain to identify the critical subordinate skills needed to achieve the goal and their interrelationships. Formative evaluation is used to collect data and information that is used to improve a program, conducted while the program is still being developed. And finally, summative evaluation is conducted after an instructional program has been implemented and formative evaluation completed to present conclusions. The Dick and Carey model describes all the phases of an iterative process that starts by identifying instructional goals and ends with summative evaluation. This model is applicable across a range of context areas (e.g., K-12 schools to business to government) and users (novice to expert).

THE RAPID PROTOTYPING MODEL

Some researchers feel that conventional ISD models place too much emphasis on procedures and not on principles. They argue that conventional ISD models prescribe global tasks such as prepare

the draft version of your instructional material and fail to provide guidance in the selection of appropriate instructional strategies and tactics. As a result, the rapid prototyping methodology has been used in software engineering. Generally, rapid prototyping models involve learners and subject matter experts (SMEs) interacting with instructional designers in a continuous review and revision cycle.

A typical rapid prototyping model uses templates for various types of task for the sake of efficiency. Much time and other resources are saved by focusing on critical content and key steps and producing a lean instructional package. Improvements to this core package are added gradually after it is implemented.

Tripp and Bichelmeyer's rapid prototyping model is a four level process that is intended to create instruction for individual lessons as opposed to entire curricula. The process stages include:

- Perform a needs analysis
- Construct a prototype
- Utilize the prototype to perform research
- Install the final system

This model relies on expert instructional designers to utilize heuristics as well as their past experience and intuition to guide the design (Hoffman & Margerum-Leys, n.d.)

R2D2

Willis (1995) proposed the recursive, reflective, design, and development model (R2D2). This iterative model is based on constructivist theory and has four general guiding principles that apply to the entire ID process: *reflection*, *recursion*, *non-linearity*, and *participatory design*.

Reflection involves critically considering work to date and making changes based on personal analysis as well as feedback from a collaborative

team. The approach stresses the importance of thinking about and revising ideas, plans, concepts, and procedures based on observation and analysis of what is happening in the context of practice (Chen, 1998). The recursive nature of the process involves making the same decisions several, even many, times throughout the design and development process so that initial decisions or designs are not necessarily the "final" ones. Non-linearity refers to the lack of a prescribed sequence of steps in the R2D2 design process. A designer using the R2D2 model can commence the design process with a vague plan and gradually develop, refine, and revise the plan through group interaction. The designer can elect to begin with any number of tasks through task analysis; there is no required "beginning point." The fourth principle, participatory design, refers to the involvement of a design team, which usually includes instructional designers, experts on the subject matter as well as aspects of the instructional process, specialists in graphic design and other supporting fields, and end-users (Chen, 1998). Participatory design means representatives of each type of stakeholder are involved in all aspects of the design and development process. The participatory design approach stresses the need for the team to develop approaches and solutions based on input and feedback from the team.

With R2D2, the ID team is expected to actively reflect on and analyze work to date and regularly revise and rework both the material being developed and the models that underlie its development (see Figure 1).

THE ICARE MODEL

According to its main proponents, Hoffman and Ritchie (1998), the ICARE model is distilled from basic instructional design practice, adapting various systems or "steps of instruction" to what seemed to be particularly useful components for an

Figure 1. A graphical representation of the R2D2 instructional design (ID) model. The model has three focal points (define, design and develop, and disseminate). The nature of this graphic, which has no obvious beginning or ending and constructs an “impossible world” perspective, represents the two Rs of the R2D2 ID model: recursion and reflection (Willis, 1995).

online course. For instance, in converting a course to distant learning units, a conventional 20-credit module is broken down to 20 units worth 9 hours of study each. The model has the following five distinctive but interrelated components that are applied to individual lesson/lecture known as a unit:

1. Introduction
2. Content
3. Apply
4. Reflect
5. Extend

Introduction involves reflection and determination as to how the model fits into the context of the learners' classroom. The next step is connecting the educational material with the learner's real-world environment, and presenting the new material initially with ample explanations for appropriate conceptual scaffolding. Then designers have to apply the material during simulation and providing feedback on the learner's progress, including performance assessment. After these three steps, reflections and extension follow.

THE ASSURE MODEL

This ASSURE model developed by Heinich, Molenda, Russell, and Smaldino provides an acronym to help practitioners remember the steps they must work through (Heinich et al., 2001). It incorporates Gagne's events of instruction to assure effective use of media in instruction. The ASSURE model was modified to be used by teachers in the regular classroom. The ASSURE model applies these six processes that teachers and trainers can use to design and develop the learning environment for their students.

- Analyze learners
- State objectives
- Select instructional methods, media, and materials
- Utilize media and materials
- Require learner participation
- Evaluate and revise

FUTURE TRENDS

Every ID model has some attributes not universally seen in all the others, such as inclusion of context analysis as a function of the design process, sequencing of test development, and the formative evaluation. Because of the limitations of two-dimensional graphic representations and to simplify a discussion of the activities of instructional design, instructional design models have an unintended, yet starkly apparent attribute of being sequential. Designers from every experience level may sometimes follow this sequence; however, more commonly circumstances may cause the designer to modify the sequence of design activities. Many times the steps within a certain phase may occur concurrently.

The growth of instructional design is relatively brief. Only during the last century have scholars done in-depth studies into learning theory and systematic approaches to instruction. Until re-

cently, technologies have limited the number and diversity of learners an instructor could address and involve. New breakthroughs in hardware and software technologies open the doors to new possibilities. Jacobs and Dempsey (2002) present three emerging influences that will impact the future of instructional design: object-oriented distributed learning environments, artificial intelligence (AI), and the fields of cognitive science and neuroscience.

OBJECT-ORIENTED DISTRIBUTED LEARNING ENVIRONMENTS

Objects permit the reuse of code and materials, saving time and resources needed by programmers, and expanding compatibility of applications. While most electronic learning content is currently developed for a specific purpose such as a course or a situational performance intervention, the reusable learning object (RLO) content is modular, freestanding, able to satisfy a single learning objective, and transportable among applications and environments. As organizations make significant investments in digital learning content, they seek greater assurances of portability, platform independence, and longevity, and reusability of digital content (Resnick, 2002). The development and acceptance of “open standards” helps safeguard investments in content development because they enable integration with other campus systems and facilitate content sharing.

Object-oriented distributed learning environments present several new challenges to ID models. There is a growing body of literature relates to game design and larger issues surrounding new media theory. Some of this work has already been applied to education (Aldrich, 2004), but much more could be done to apply gaming and principles of virtual world to instructional design.

ARTIFICIAL INTELLIGENCE (AI)

Artificial intelligence involves the computer working to supply responses to student input from the computer’s database. The development of artificial intelligence will permit control over instructional environments and activities. This is especially apparent in the improvement of course management, which is a key aspect of instructional design. Computers are particularly good at keeping track of information and providing guidance in solving problems. Therefore, learning management systems (LMS) are likely to become more routinely available to learners, instructors, and managers in the future and intelligent tutorials will most likely become common place.

Researchers including Muraida, Spector, and Gros discussed the use of automated instructional design (AID) tools in military courseware development. According to them, AID tools are especially useful in situations where instructional design expertise is lacking and subject-matter experts and others are responsible for developing instruction. AID tools may eliminate some traditional ID tasks such as storyboarding and test generation (Kasowitz, 1998). There are four types of tools that guide users through the ID process: expert systems, advisory systems, information management systems, and electronic performance support systems. Authoring tools are also mentioned as popular mechanisms for supporting the production of computer-based instruction. The strength of AID tools lies in their ability to guide novices and non-ID professionals through the process of creating effective instruction.

COGNITIVE SCIENCE AND NEUROSCIENCE

As discussed in previous sections, historically, instructional design grew out of educational psychology and became integrated with instructional

technology (Dick, 1987; Merrill & Wilson, 2005; Reiser, 2001). Advances in the areas of cognitive science and neuroscience will encourage more accurate monitoring of human learning based on individual activity. A recent special issue of *Educational Technology* (May-June 2004) began a dialogue between researchers associated with two fields: instructional design and learning sciences (Wilson, 2005). The learning sciences (LS) field enjoys higher academic status due to its closer ties to psychology and cognitive science, which are seen as more basic and rigorous disciplines within the academy. On the other hand, ID holds the practitioner advantage. This is a powerful advantage in that ID trains professionals for both academic and non-academic jobs. Instructional designers are seen as having more relevance to everyday concerns of practice, training, education, and commerce (Wilson, 2005).

Within the field of instructional design, researchers and practitioners have observed two constant refrains:

- On the one hand, it is said that ID practitioners rarely work according to theories. They merely work intuitively (Gros et al., 1997).
- On the other hand, it is maintained that much of ID theory is no longer applicable in the current context of rapid change, global communication, and high technology (English & Reigeluth, 1996).

These two prevalent views seem to suggest that there is a tension between theory and practice. According to modern instructional theorist, there has been call for instructional design to shift process driven analysis to learner driven analysis.

Reigeluth (2004) spoke of the “balanced diet” provided by ID’s broad concern for design, development, implementation, management, and evaluation. Wilson (2005) also calls for a more balanced approach by increasing servings of often-neglected aspects of design, particularly

the moral and value layers of meaning, human-computer interface, and the aesthetic side of our work. The foundations or pillars of practice need to go beyond learning theory, and beyond the various ID models depicting the life cycle of design.

Many ID professionals also propose that while most of the current discussions focus on traditional ID models, there is a growing concern both within and without the field about the efficacy of instructional design and its contribution to the learning community. Recent attacks on ISD have devalued it as being archaic, inflexible, and ineffective (Hadley, 2004). While instructional design models are helpful in mapping the intricacies of a design problem, they are sequenced of design decisions without the knowledge required to make them. As a result, models consistently fall short of real-world training problems.

CONCLUSION

As presented, instructional design is a field that affiliates with a number of disciplines including educational psychology, information studies, and instructional technology. It is a discipline that applies theory to practice—learning theory to instructional design practice. Gagné himself said that, “In seeking a way of dealing with multiple objectives other than serially, we perceive a need for treating human performance at a somewhat higher level of abstraction than is usual in most instructional design models.” (1990). There is simply no right way to plan an educational project. However, ID practitioners can borrow the planning techniques and analytical tools, which can be from established models and applied to inform and improve the finished product. This should be part of the toolkit of any competent designer (Hunter, n.d.).

The generic ADDIE process has been the mainstay for many instructional designers over the past two decades. Other than that, instructional design is so eclectic that many researchers in the

field have raged debates for years over basic definition, terminology, and procedures. Some claim that the systems thinking that formed the core of ISD is outdated and inappropriate for instructional design and development; what is needed is more rapid prototyping and user-centered design and development (Spector, 2004). This led many ID researchers and practitioners to consider where we have been and wonder how they have survived.

Key to this merger between learning theories, instructional theories, designers, and technologists is a broad view of technology that included process technologies such as procedures, models, and strategies intended to achieve defined educational outcomes. This allowed instructional designers who saw their efforts largely as an implementation of learning principles to bring their work into line with instructional technology, and use technology-based environments as laboratories for their designs (Wilson, 2005).

As military training and simulation move into the 21st century, ID must look to more mature design fields for direction. Design disciplines such as architecture, musical composition, and automobile design are not characterized by the processes they use, but by the skills of the designer and the craftsmanship of the product. Many researchers argue that the value of instructional design is not found in a process or the models but in a designer (Hadley, 2004). By re-valuing the foundations, we will position ourselves to build fundamentally solid designs, and successfully differentiate ourselves from communities such as learning sciences. The benefit of doing so would be improved learning and more efficient instruction.

KEY TERMS AND DEFINITIONS

Instructional Design: Instructional design, also known as instructional systems design, is the analysis of learning needs and systematic development of instruction. Instructional designers often use Instructional technology as a method for developing instruction. Instructional design models typically specify a method, that if followed will facilitate the transfer of knowledge, skills, and attitude to the recipient or acquirer of the instruction.

Instructional Technology: The use of technology (computers, compact disc, interactive media, software, hardware, video, audio, peripherals, teleconferencing, etc.) to support learning.

Needs Assessment: Used to determine if an instructional need exists by conducting a needs assessment using some combination of the following methods and techniques.

Performance/Learner Analysis: Used to identify learner/trainee/employee characteristics

and individual differences that may impact on learning/performance such as prior knowledge, personality variables, aptitude variables, and cognitive styles.

Project Management: Project management is the application of knowledge, skills, tools, and techniques to a broad range of activities in order to meet the requirements of the particular project. A project is a temporary endeavor undertaken to achieve a particular aim. Project management knowledge and practices are best described in terms of their component processes. These processes can be placed into five process groups: initiating, planning, executing, controlling, and closing—and nine knowledge areas—project integration management, project scope management, project time management, project cost management, project quality management, project human resource management, project communications management, project risk management, and project procurement management.

Rapid Prototyping: The use of rapid prototyping methodologies is to reduce the production time by using working models of the final product early in a project tends to eliminate time-consuming

revisions later on, and by completing design tasks concurrently, rather than sequentially throughout the project. The steps are crunched together to reduce the amount of time needed to develop training or a product. The design and development phases are done simultaneously and the formative evaluation is done throughout the process.

Storyboard: (see figure in Appendix) The process of sketching the content on planning worksheets or with development software. As was true of the flowchart for computer programmers, the storyboard does not have to be a work of art. Graphics can be hand drawn. The idea of storyboarding is to give the production team enough information so each member can take the storyboards and begin to develop his/her portion of the final product. The client and/or the subject matter expert will work closely with the development staff in creating the storyboard.

Task Analysis: Used to determine if it is a training/incentive/organizational problem. That is, identify who has the performance problem (management/workers, faculty/learners), the cause of the problem, and appropriate solutions.

Chapter 1.9

Contemporary Instructional Design

Robert S. Owen

Texas A&M University-Texarkana, USA

Bosede Aworuwa

Texas A&M University-Texarkana, USA

INTRODUCTION

This article discusses the principles of two qualitatively different and somewhat competing instructional designs from the 1950s and 1960s, *linear programmed instruction* and *programmed branching*. Our hope is that an understanding of these ideas could have a positive influence on current and future instructional designers who might adapt these techniques to new technologies and want to use these techniques effectively. Although these older ideas do still see occasional mention and study (e.g., Brosvic, Epstein, Cook, & Dihoff, 2005; Dihoff, Brosvic, & Epstein, & Cook, 2004), many contemporary instructional designers are probably unaware of the learning principles associated with these (cf., Fernald &

Jordan, 1991; Kritch & Bostow, 1998; McDonald, Yanchar, & Osguthorpe, 2005).

BACKGROUND

An important difference between these instructional designs is associated with the use of feedback to the learner. Although we could provide a student with a score after completing an online multiple-choice quiz, applications that provide more *immediate feedback* about correctness upon completion of each individual question might be better. Alternatively, we could provide *adaptive feedback* in which the application provides elaboration based upon qualities of a particular answer choice.

Following is a discussion of two qualitatively different instructional designs, one providing im-

DOI: 10.4018/978-1-60960-503-2.ch109

mediate feedback regarding the correctness of a student's answer, the other providing adaptive feedback based on the qualities of the student's answer. Suitability of one design or the other is a function of the type of learner and of the learning outcomes that are desired.

SOME CLASSIC CONCEPTS OF INSTRUCTIONAL DESIGN AND OUTCOMES

Although the idea of non-human feedback would seem to imply a mechanical or electronic device, other methods could be used. Epstein and his colleagues, for example, have used a multiple-choice form with an opaque, waxy coating that covers the answer spaces in a series of studies (e.g., Epstein, Brosvic, Costner, Dihoff, & Lazarus, 2003); when the learner scratches the opaque coating to select an answer choice, the presence of a star (or not) immediately reveals the correctness of an answer. Examples of the designs discussed next are based on paper books, but they are easily adaptable to technologies that use hyperlinks, drop-down menus, form buttons, and such.

Linear Programmed Instruction

The programmed psychology textbook of Holland and Skinner (1961) asked the student a question on one page (the following quote starts on page 2) and then asked the student to turn the page to find the answer and a new question:

A doctor taps your knee (patellar tendon) with a rubber hammer to test your _____.

The student thinks (or writes) the answer and turns the page to find the correct answer ("reflexes") and is then asked another question.

Questions or statements are arranged in sequentially ordered *frames* such as the previous single

frame. A frame is completed when the student provides a response to a stimulus and receives feedback. Skinner contended that this method caused learning through *operant conditioning*, provided through positive *reinforcement* for stimuli that are designed to elicit a correct answer (c.f., Cook, 1961; Skinner, 1954, 1958).

Skinner (and others who use his methods) referred to his method as *programmed instruction*, which incorporates at least the following principles (cf., Fernald & Jordan, 1991; Hedlund, 1967; Holland & Skinner, 1961; Skinner, 1958; Whitlock, 1967):

- Clear learning objectives.
- Small steps; frames of information repeat the cycle of stimulus-response-reinforcement.
- Logical ordered sequence of frames.
- Active responding by a student who works at his/her own pace.
- Immediate feedback to the response in each frame with positive reinforcement for correct answers.

A technique in programmed instruction is to help the student a great deal at first, and then gradually reduce the cues in latter frames; this is called *fading* (Fernald & Jordan, 1991; Reiff, 1980). If correct responding suggests that a student is learning at a quick rate, *gating* can be used to skip over frames that repeat prior information (Vargus & Vargus, 1991). The programmer is expected to use information about student performance to make revisions; if the student is not succeeding, then it is due to a fault of the program, not to an inability of the student (Holland & Skinner, 1961; Vargus & Vargus, 1991).

Programmed Branching

Crowder (e.g., 1959, 1963) and others (e.g., Pressey, 1963) were critical of Skinner's approach, arguing that students not only learn from know-

ing a correct answer, but also learn by making mistakes. Crowder distinguished between his *automatic tutoring device* and the Skinner-type *teaching machine*, proposing that the automatic tutoring device is more flexible in allowing the student to receive an explanation when an error is made. Crowder (1959, pp. 110-111) provides an example of how this approach could be used in a programmed textbook:

In the multiplication of $3 \times 4 = 12$, the number 12 is called the product and the numbers 3 and 4 are called the

Page 15 quotients.

Page 29 factors.

Page 43 powers.

In this *programmed branching* method of Crowder, the student is taken to one of several possible discussions depending on the qualities of the answer.

While Skinner's design would be expected to work only when stimuli elicit correct answers, Crowder's design allows for mistakes and must be designed to anticipate particular mistakes. Crowder believed that this method caused learning through *cognitive reasoning*. Whatever answer is chosen by the student, the programmed textbook (or machine) makes a *branch* to a discussion associated with issues relevant to the answer that was chosen. This is followed by a return to the same question if the student had made an incorrect choice, or a jump to new a *frame* containing the next question if the student had made a correct choice.

Learning Outcomes

Many issues have been raised over the years about programmed instruction methods. Reiff (1980) discussed several criticisms:

- It does not take into consideration the sequence of development and readiness to learn (e.g., children of different ages or children vs. adults).
- It develops rote learning skills rather than critical thinking skills.
- Students can in some implementations cheat.
- The encouragement to respond quickly could develop bad reading habits.

Crowder's *programmed branching* design, which has received far less attention and study than Skinner's ideas, would seem to answer at least some of these criticisms. Crowder's design provides an explanation to both correct and incorrect answers, so the learner is not rewarded for cheating or working too quickly. Since the explanation is tied to the learner's thinking at the time a choice was made, Crowder's design would appear to be better to develop critical thinking skills, but might not be so good at developing rote learning skills. Crowder's design would appear to be better suited to students who have a greater readiness to learn, while perhaps not so well suited to a student who is at an earlier stage of learning a subject.

The previous discussion suggests that each of these designs is useful, but that each is useful in different kinds of situations and that the *learning outcomes* of each approach might be different. Skinner's teaching machine, for example, might be more useful in situations where students are learning lists and definitions. The automatic tutoring device, on the other hand, might be more useful when the student is already at a higher level of understanding whereby s/he can now use reasoning to derive an answer, or in situations where the student understands that there are degrees of right and wrong without concrete answers. The Skinner-type teaching machine might be better suited to "lower-order" levels of learning, while the Crowder-type automatic tutoring device might be better suited to "higher-order" levels of learning.

Although many ideas have been proposed with regard to a hierarchical perspective on “lower” and “higher” levels of learning, the most well-known, “Bloom’s Taxonomy” (A Committee of College and University Examiners, 1956), originated in about the same timeframe as the ideas of Skinner and Crowder. “Bloom’s Taxonomy” proposes that the objectives of learning lie on a hierarchical continuum: (1) knowledge of terminology and facts, (2) comprehension of translation and paraphrasing, (3) application, (4) analysis, (5) synthesis, and (6) evaluation.

“Bloom’s Taxonomy” is actually only Part I of a two-part work. The previously mentioned first part is known as the *cognitive domain*. Part II (Krathwohl, Bloom, & Masia, 1964) focuses on the *affective domain*: (1) willingness to receive ideas, (2) commitment to a subject or idea, (3) feeling that an idea has worth, (4) seeing inter-relationships among multiple ideas, and (5) the integration of ideas as one’s own.

FUTURE TRENDS

Fernald and Jordan (1991) discussed several reasons as to why programmed instruction might have fallen out of use since the decades of the 1950s and 1960s:

- It was seen to dehumanize the teaching process.
- Educators feared that it might be too effective and threaten their jobs.
- The importance of the learning principles was not understood.
- Applications were often not effectively designed.

Technology, economics, and attitudes have since changed. As economics and student demand push us to use distance education methods, the

first two arguments would seem to become more diminished in the future.

It is hoped that this article assists in diminishing the latter two arguments by introducing instructional designers to the principles discussed in this article and by encouraging instructional designers to create more effective designs with regard to appropriateness for a particular student audience and with regard to the type and level of learning outcomes that are desired. By better understanding the past, we can better affect the future.

Curiously, there has been less attention devoted to Crowder’s ideas of adaptive feedback than to Skinner’s ideas of immediate feedback and reinforcement. We continue see occasional research devoted to related issues, such as issues of immediate vs. delayed feedback (e.g., Brosvic et al., 2005; Dihoff et al., 2004; Kelly & Crosbie, 1997) or of allowing students to keep selecting answers from a multiple-choice set until the correct answer is finally discovered (Epstein et al., 2003). However, we still can only speculate with regard to conditions under which a Skinner-style of instructional design would be better and when a Crowder-style of design would be better. It is hoped that this article generates greater awareness of and use of these designs in new technologies, but also that greater interest in these ideas will stimulate more research into the learning mechanisms associated with them.

CONCLUSION

New technologies such as Web browsers now make it relatively easy for educators with the most modest of skills to present instructional frames in a linear sequential ordering or as branches that are dependent on the student’s selection of answers from a list. In adapting some of these older ideas to newer technologies, we hope that instructional designers will be better equipped to select appropriate methods by considering:

- the student's level of readiness for learning
- the basis for learning when different instructional designs are used
- the qualitatively different kinds of learning outcomes that are possible with different instructional designs

KEY TERMS AND DEFINITIONS

Adaptive Feedback: Immediate feedback in the form of an explanation or discussion that is tailored to the qualities of the student’s answer.

Automatic Tutoring Device: A device that uses programmed branching and adaptive feedback. Learning results from cognitive reasoning.

Cognitive Reasoning: Learning through the process of thinking about an issue; the student learns new ideas and relationships by relating an issue to previously learned material.

Frame: A small piece of information or a statement to which the student is exposed, such as a

page with a single question. In linear programmed instruction, a frame includes a stimulus, a response, and reinforcement (positive feedback).

Hierarchy of Learning: The concept that learning can be sequentially ordered along a continuum from lower-order to higher-order. “Bloom’s Taxonomy” is one of many that have been proposed.

Linear Programmed Instruction: A design whereby a series of frames are presented to the student in a specific sequential order. The student actively responds to stimuli in each frame and receives immediate feedback to that response. Learning results through operant conditioning.

Operant Conditioning: Learning through immediate positive feedback (reinforcement) regarding the correctness of an answer; the student learns to respond in a particular way to a particular question or issue (stimulus). Fading can be used by gradually reducing stimulus cues in subsequent frames when material is repeated.

Programmed Branching: A method whereby the student is taken to one of several possible explanations or discussions depending on the qualities of an answer that is given to a question. Gating is a simple skip of frames that repeat prior information when a student’s answers suggest that the material has been adequately learned.

Teaching Machine: A device that uses linear programmed instruction whereby frames present a question followed by feedback of the correct answer. Learning results from reinforcement of the student’s correct answer.

Chapter 1.10

Instructional Design Methods Integrating Instructional Technology

Paula Jones

Eastern Kentucky University, USA

Rita Davis

Eastern Kentucky University, USA

ABSTRACT

Effective teaching begins with effective planning of instruction. Planned instruction with technology integrated appeals to students and accommodates students' needs. Students expect technology to be utilized to support the learning process because of their acquaintance with a variety of technologies at a very early age. Educators must be aware of the needs and expectations of students and then design courses that integrate technology based on these identified needs and expectations. A critical element required to integrate technology into the learning environment successfully is the instructional design process. The instructional design process provides a framework for systematically planning, developing, and adapting instruction

based on learner needs and content requirements. With the instructional design process, educators evaluate student needs, plan the lesson objectives, design the instructional content, and create assessments. Evaluation and revision of each of the instructional components is continually modified to meet the changing needs of the learners and the advancement of technology.

INTRODUCTION

Educators today integrate technology into the classroom to create various instructional opportunities for students. There are four primary reasons why educators should integrate technology into the instructional process to create new and varied instructional opportunities to support student learning. First, educators need to develop

DOI: 10.4018/978-1-60960-503-2.ch110

and design instruction that will build student understanding. The term “understanding” is best defined through the following three principles:

1. Understanding is a function of learning facts and core principles of a topic
2. Understanding is the product of actively relating new knowledge with prior knowledge and experiences
3. Understanding is a consequence of using and managing intellectual abilities well. (Sherman & Kurshan, 2005)

Developing and supporting student understanding includes keeping the student actively engaged in the instruction while at the same time appealing to students’ various learning styles.

A second reason for educators to integrate technology into the instructional process is because there is a need to plan instruction that will motivate students to learn. According to Sherman et al. (2005), “the lack of interest is generally the number one reason that students give for not learning to mastery level” (p. 11). Technology-based instruction can stimulate students’ interests to explore, discuss, and compare their knowledge with others.

It is important to note that instructional technology, in and of itself, will not directly improve student understanding. In fact, a primary reason that instructors use technology in their instruction is to increase motivation to learn. Motivation is indeed one of the necessary components of learning. According to the self-efficacy theory of motivation (Bandura, 1978; Salomon, 1981), a direct relationship exists between instructional technology (how and when it is used in the teaching process) and student learning because of the motivation factor. Researchers believe a student’s attitudes, beliefs, and values influence their motivation to gain understanding of a topic or discipline (Clark & Sugrue, p. 350). At the same time, the level of knowledge or skills needed

to successfully utilize the technology is also important to the learning process. According to Clark and Sugrue, if students view instructional technology to be within a moderate range of difficulty to use, then they will invest time and effort to learn from this instructional medium. If the students find the instructional medium is too challenging, their motivation to participate and learn is reduced (p. 359).

Third, students expect the use of technology to be a part of the learning process. Students are using technology very early in their lives for non-academic activity; therefore, they are more likely to use technology in all aspects of their lives especially in their educational careers. “Students believe computers are helpful and they will use them more in the workplace,” (Dooling, 2002, p. 22). In addition, Ellis reports that students have very high expectations of technology-supported learning (2004). Educators aware of these expectations will focus on course designs that integrate technology. Therefore, planning instruction with the student’s expectations and needs in mind will help the student to be successful in achieving the instructional objectives.

The fourth reason for integrating instructional technology into the classroom is because educators are searching for new and more effective ways of communicating with students. Students should be provided opportunities to communicate with instructor, with peers and with the content. Understanding of new concepts in the course content is developed through various types of interactions and media.

It is also important to note that integrating technology into instruction is not a “quick fix” that will automatically improve student learning. In fact, the integration of technology into a poorly planned lesson will not transform the instruction into a well-designed or effective instructional opportunity for students. In fact, when technology is integrated into a poorly designed lesson, the learner will many times feel frustrated and

confused. Without the proper support mechanisms in place in schools such as aligned curriculum, appropriate assessment techniques, and ongoing professional development opportunities for teachers, technology integration by itself will not change the fact that students may not achieve the academic goals for the course.

Therefore, the educator's challenge is to plan instruction that integrates technology and ensures that it is an integral and manageable component of instruction. The instructional goal will guide the technology that is used. When technology is combined with a well-planned curriculum that includes appropriate instructional strategies to integrate technology, then student learning (understanding) can be enhanced.

Instructional technology is an integral part of teaching and learning in today's classroom. This chapter will identify and explain some of the key terms related to instructional technology and instructional design. In addition, information will be provided on student expectations for instruction and implications for educators. The purpose of this chapter is to address the following questions:

- What is instructional technology?
- What is instructional design?
- What are the benefits of using instructional design methods?
- Why is the ADDIE model recommended as a beginning methodology for instructional design?
- What are students' expectations of instruction?
- What are the implications in planning instruction that integrates technology?

BACKGROUND

Educators who plan to integrate instructional technology successfully into the learning environment need to be familiar with the instructional design

process. Instructional design is the process and the framework for systematically planning, developing, and adapting instruction based on identifiable learner needs and content requirements (University of Idaho, 2004). "The most widely used methodology for developing new training programs is called instructional systems design" (Kruse, 2004). With this process, educators will carefully evaluate the students' needs, plan the lesson goals, design the instructional content, and create assessments with students' expectations in mind. Therefore, the methods of instructional systems design play a key role in planning effective instruction. The ISD methods should be used to identify the instructional technologies that are needed to help the learners to achieve the goals and objectives of the instruction.

Instructional systems design (ISD) methods are a step-by-step process to help educators evaluate the needs of the students, identify what is to be learned, specify the process through which the lessons will be learned, plan the actual design, develop instructional materials, and evaluate the effectiveness of the instructional components (Hains, 2000). The ISD approach considers instruction from the perspective of the learner rather than from the perspective of the content, (Morrison, Ross, & Kemp, 2001). Morrison et al. (2001) state that through the instructional design model, the following questions are addressed:

- What level of readiness do individual students need for accomplishing the instructional objectives?
- What instructional strategies are most appropriate in terms of objectives and learner characteristics?
- What media or other resources are most suitable to help the student to learn the objectives?
- What support is needed for successful learning?

- What revisions are necessary throughout the instructional process? (p. 4)

The ISD process is based on a set of components working together to achieve a goal with learners' needs in mind. The steps usually involve the following four phases: design, development, evaluation, and revision.

According to the University of Idaho, the design phase includes determining the need for instruction, analyzing the learners' needs, and establishing goals for the instruction. The development phase includes reviewing current content, creating new content, organizing content, and selecting delivery methods. In the evaluation phase, the designer reviews the goals and objectives of the instruction and develops an evaluation strategy. During this phase, students' feedback is collected and analyzed. In the final phase of revision, information from the evaluation phase is implemented to improve the quality of the instructional experience.

The ISD steps are continually evolving based on the needs, success, and feedback received from students and instructors. As noted earlier, there are several sequential steps to be implemented by the instructor in order to move students through levels of understanding and application. There are criticisms that the ISD models are too linear and too inflexible (Kruse, 2004). However, when all of the ISD phases are used interchangeably, the ISD process can prove to be very productive in helping students to achieve the instructional goals. The ISD process should be flexible, allowing the instructor to move freely among the various phases of the design, as dictated by the needs of the learners.

In addition, technology has a very important role in the instructional process. "Technology should be the servant and not the master of instruction. It should not be adopted merely because it exists, or because an institution or faculty fear being left behind the parade of progress without

it" (Gentry, 1995). Therefore, instructors/instructional designers should first identify what it is that the students should learn and then decide if and when it would be appropriate to integrate technology into the learning process.

Instructional Technology Defined

"Instructional technology is defined as the theory and practice of the design, development, utilization, management, and evaluation of processes and resources for learning" (Seels & Richy, 1994, p. 1). To better understand this definition, Hains (2000) describes each of the four components used to define instructional technology as:

1. **Instructional design and development:** The process of specifying conditions for learning and developing the products that focuses on these conditions. This component would include instructional systems design, message design, instructional strategies design, and learner characteristics analysis.
2. **Media utilization:** Includes the selection of the communication medium and the delivery system. Examples of this component would include the use of a course management system like Blackboard™, Angel™, or the use of instructional video and audio components, or even a course Web site with use of e-mail and blogs.
3. **Management:** This component of the term relates to all of the responsibilities associated with the management of the technologies including acquisition, maintenance, delivery of services and management of information.
4. **Evaluation:** Includes using evaluation methods that will provide timely and accurate information to those involved in an education technology design effort.

"The purpose of instructional technology is to affect and effect learning" (Seels et al., 1994, p.

12). It is critical to understand that the main goal of providing instruction is “learning.” The means to understanding and learning is the instruction that is planned. Therefore, the instructor and the instructional designer plans and utilizes instructional technology to help students build upon prior attained knowledge, skills and attitudes, and use technology as a tool to enhance learning.

Instructional Design Defined

Instructional design (also known as instructional systems design) is defined as the analysis of learning needs, identifying instructional goals and objectives, and the systematic development of instruction. Instructional designers will use instructional technology as a method for developing instruction when appropriate to meet the goals of the instruction and to meet the needs of the learners. Instructional design models typically specify a method that if followed will facilitate the transfer of knowledge, develop skills and adapt or encourage attitudes of the learner

In summary, instructional design is the systematic planning of instruction. Instructional design is the process of specifying conditions for learning (Hains, 2000). Instructional design is the step-by-step process used for identifying students’ needs, the design and development of instructional materials, and the evaluation of the effectiveness of the instructional intervention (Kruse, 2004). Planning for instruction is an organized process where instructional materials are thoughtfully created and are planned to deliver instruction that is most effective for the student. The goal is for each student to learn in an environment that provides opportunities for full potential of the student.

Benefits of Instructional Design Methods

According to Kruse, the systemic approach to instructional development has many advantages

when it comes to the creation of technology-based instruction. Some of the advantages noted are: (1) ability to create engaging metaphors or themes, (2) designing learning activities that are effective in meeting the students’ expectations and needs, and (3) the opportunity to engage and possibly motivate learners by the use of technology (Kruse, 2004). Roblyer (2000) adds that instruction can be designed to integrate technology in ways to help the student to remedy identified weaknesses. Once more, the early phases of the ISD process would allow the instructor to become aware of the students’ weaknesses and be able to offer instructional opportunities to address these individual needs.

In addition, designing instruction that provides students the opportunity to build their skills and conduct self-evaluations through the use of technology can be very beneficial. Instruction can also be designed to develop technological and visual literacy (Roblyer, 2000). These skills will better prepare students for high demand jobs in the business world.

Thomas Friedman, in *The World is Flat*, identifies the United States as a global, information-based economy with an increasingly diverse workforce. Therefore, there is a great need for a better-trained workforce who is capable of using technology to improve services, increase quality and raise production. As a result, instruction should focus on using technologies that will prepare students for the workforce.

Embry (2005) reported in one study published in October 2005 by the National School Boards Association (NSBA), 90% of the respondents reported that the use of technology in the classroom has increased educational opportunities for students. This was evidenced by students being more engaged in learning, having a stronger ability to communicate and possessing increased critical thinking skills. Technology is indeed valuable to learners and utilizing appropriate instructional design methods will help to develop a better, well-designed opportunity for learning.

The ADDIE Model

Many instructional design models are based on the ADDIE model. The ADDIE model represents the following components: analysis, design, development, implementation, and evaluation (Kruse, 2004). In Figure 1, the flow of information within the phases is illustrated with the larger arrows. The smaller arrows illustrated how the flow of information can be reversed to the previous phase at any point in the sequence as identified in the instructional analysis conducted in each phase. The ADDIE model of instructional design is recommended as a beginning framework ISD model because it is based upon sound pedagogical principles of instructional development. This model provides the systematic steps needed to ensure that sound and theoretical based instruction is being delivered. When planning instruction, ADDIE provides a process for addressing the instructional challenges and learner needs.

The phases involved in the ADDIE model are defined as follows:

1. **Analysis phase:** Determine the components necessary for the next phases of development. Seek answers to a variety of questions including: Who is the learner? What is the

instructional goal of the lesson? What are the delivery options? What instructional technology, if any, would enhance student learning? What will the students do to determine competency? What is the timeline? What are the online pedagogical considerations?

2. **Design phase:** The systematic method of research, planning, developing, evaluating, and managing an instructional process.
3. **Development phase:** Addresses the tools and processes used to create instructional material. This stage includes story boards, coding, graphic user interface, and creating all multimedia elements.
4. **Implementation phase:** During this phase, an implementation plan is developed. This plan establishes the implementation timeline and procedures for training the facilitators or the learner, and delivering the final product.
5. **Evaluation phase:** A systemic process that determines the quality and effectiveness of the instructional design as well as the final product. Evaluation is an ongoing activity conducted at each phase of the ADDIE model.

Educators, who are familiar with the ADDIE model and use it as the instructional design process, may find they are selecting instructional technology that will support and enhance learning to help student achieve the instructional goal. Instructors are then able to provide a learning environment that will encourage active learning and higher level thinking skills, especially reflection, problem solving, flexible thinking, and creativity (Hopson, Simms, & Knezek, 2002).

The ADDIE model enables standardized development of learning solutions as the educator moves through the five phases or steps. Each step of the process, from the analyses of the learners to the final evaluation of the learner's instructional experience, should be thoroughly planned and monitored to identify solutions for

Figure 1. The ADDIE model

the instructional need. The ADDIE model should be used as a continuous process that allows the educator to monitor and update instructional and assessment components to meet the needs and expectations of the learner. The ultimate goal in applying the ADDIE model, as it is with any instructional design model, is to plan and design instruction that provides the student the content and resources needed to help them to achieve the instructional goals.

Students' Expectations of Instruction

With ISD methods, instruction is planned based on the students' needs and expectations. Therefore, it is important to identify some of the expectations of students today.

In 60 interviews and three focus groups with postsecondary students, the following summarizes the basic instructional needs of learners:

1. Students not only anticipate, but expect technology to be integrated into the instructional process
2. Students see technology as both motivating and challenging
3. Students expect to learn the technology first in order to apply the technology toward learning the subject matter content
4. Students expect their time and resources to be adequately used to help them learn
5. Students expect their instructors to be familiar with the latest technology and be motivated to use technology in their classroom instruction
6. Students expect technology to allow them to have access to the instructor, their classmates and to course information
7. Students expect the convenience of communicating with their instructors by submitting their homework, assignments, and quizzes via technology

8. Students prefer the convenience of using technology at home even though they may not have access to the latest software and hardware required by the instructors

Based on the students' expectations previously listed, it is clear that technology integration into the instructional process is very important. Instructional technology should be utilized as a tool for learning. In the interviews and focus groups students anticipated that they will apply the same skills used in the classroom as they will use in the workplace to analyze, manipulate and summarize information. The use of instructional technology should be more than just drill and practice, tutorial, games and simulations. Educators should plan to integrate instructional technology when it supports the overall goals of the instruction, improves communication, and provides the students greater access to the instructional information and course content.

Advances in technology are changing the dynamics of teaching and learning in education; all educational levels are using technology as a learning tool (Hains, 2000). Today's younger students are also using technology, but they are using it more for non-academic activities (Center for Media Research). The 2005 American Kids Study was conducted to evaluate American children ages 6-11 multimedia and product usage. Approximately 5,400 children responded to the questionnaires sent to households with children 6-11 years old. They were interviewed for MRI's Survey of the American Consumer. The survey period was March 8-August 1, 2005.

As shown in Table 1, it was found that gaming is the top online activity, CD players outnumber MP3 players for music listening. In the American Kids Study, it was reported that during the survey period more than half, 59%, of the 6-11 age group went online in the last 30 days and 8.1% went online every day. Forty-two percent of the respondents played games online, while 23.1%

percent actually worked online for academic reasons. More girls than boys were reported using e-mail and just 2.6% of all of the respondents visited a chat room during the reporting time. Today's students are using technology more in their daily activities. Students are using technology in a variety of ways including entertainment and communications. Even though the numbers are low for younger students, some students are beginning to use technology in their academic interests. This will result in the need to integrate technology in their lessons to help students to research, explore, and find solutions to problems throughout their academic careers.

Implications for Technology Integration

The primary goal of instruction is to make students as successful as possible in learning the content of the course. The benefits of instructional design methodologies for instructors include providing clear and well define instructional components that are well-organized to help the students achieve the goal of the instruction. When the instructional materials are planned well, presented sequentially, designed to address student needs, the students will be more successful in the classroom and the instructor can assess that learning has occurred.

Faculty who are interested in designing instruction using technology reports that ISD methods are beneficial to educators in several ways. These include:

- Instruction is developed more with the students needs in mind. This includes identifying any prerequisite skills that may be lacking and need to be addressed before the student is moved into an academic arena ill prepared.
- Instruction is usually more organized and is sequential because the instruction is planned based on the learning outcome.

Therefore, instructors are able to offer more meaningful instruction.

- Instruction that is well-designed should lead the student to be successful in the assessment. The assessment methods are identified and are based on the goal and objectives clearly stated early in the ISD process.
- Technology is seen as a tool used in the ISD process. Technology is beneficial to help the learner understand and apply the concepts.
- Finally, ISD methods offer continual testing and feedback for each phase of the instruction design process. Therefore, instruction and assessments can be adapted to meet the changing needs of the learners.

When instruction is planned or designed with technology integration, the instructor's role in the learning process will become that of a facilitator of learning. True integration of technology will promote different advantages and disadvantages for the student/learner. According to reports in the NBEA Yearbook 2004, advantages will include: (1) incorporating all five senses of the learner, (2) student comprehension is increased, "Comprehension is raised to 80 percent when one sees, hears, and interacts with instructional materials" (p. 219). This comprehension rate is very high when compared to 20-30% with just site and sound respectively, (3) students have better control of their own learning, (4) cooperative learning can also be an advantage when integrating technology, (5) technology integration offers instructors the opportunity to offer a student more individualized instruction and finally, (6) the use of a variety of communication methods such as bulletin boards, e-mails, online discussion boards, blogs, and chat rooms.

Some of the disadvantages associated with planning instruction that integrates technology include: (1) lack of access to the most advanced

Table 1. Source: Mediamark Research, The American Kids Study, 2005

Selected Findings, 2005 American Kids Study			
	% All Kids	% Boys	% Girls
Online usage			
Gone online in last 30 days	59.0	56.3	61.8
Goes online every day	8.1	7.6	8.7
Online activities in the last month			
Played online games	42.6	40.0	45.4
Did stuff for school/homework	23.1	20.8	25.5
Used e-mail	10.5	7.6	13.6
Used instant messenger	6.5	5.6	7.4
Went to chat rooms	2.6	2.7	2.5
Listen to music via...			
Car radio	74.0	72.0	76.1
CD player	62.8	56.5	69.5
Portable CD player	48.4	44.8	52.3
Stereo	39.5	39.2	39.8
Computer	25.5	23.1	28.1
Walkman that plays tapes/cassettes	8.3	8.2	8.4
Portable MP3 player	4.2	4.3	4.1
MP3 player	4.1	4.2	4.0
Gaming			
Played video, Internet, computer game, last 30 days	84.2	89.3	78.7
Play video, Internet, computer game every day	20.3	28.9	11.1
Things you have in your room			
CD player	59.8	54.1	65.8

DVD player	26.7	27.6	25.6
Computer	16.8	17.9	15.6
Internet access	6.6	7.0	6.1

technology. Despite great strides in incorporating technology into U.S. schools, we still fall short of providing a seamless, convenient, robust, and reliable technology support structure for all

students and teachers (Means, 2002); (2) lack of educator's ability to stay up-to-date on the latest technology; (3) lack of time to devote to planning and designing instruction that integrates technol-

ogy; (4) the technology that is integrated may be too advanced for the learners and that could decrease the students' ability to learn; (5) some course content and instructional activities do not readily lend themselves to the use of technology.

FUTURE TRENDS

The need for flexible learning environments and approaches to teaching reflects a transformation of how instruction will be conducted and delivered in the future. This flexibility will be noticed in areas such as offering distance-learning courses to provide instruction in a variety of locations, as well as providing more mobile and accessible instructional components for students. Time and location are quickly becoming a non-issue when it comes to accessing instructional information. For example, a student may download streamed audio or video lectures and have access to those components through ipods at any time.

Emphasis for the future will be in more online course development, distance education components, ethics in an e-learning environment, instructional materials and the Internet use in the classroom, pedagogical and technological challenges of the Internet, managing and measuring technology based courses, and intellectual property rights with educational delivery (NBEA Yearbook, 2004). In addition to these trends, there will be the challenges of constant technological change, public accountability, competition for students, opportunities for professional development, restricted and decreased funding, and the need to educate all students regardless of their financial status and location.

Furthermore, teaching and learning have evolved to the use of instructional technologies in the educational process across all disciplines. Various disciplines are currently accessing course management systems such as Blackboard™, Web CT™, or Angel™ to integrate technology into the

learning environment with the use of case-based reasoning, electronic portfolios, threaded discussions, reflective journals, and other instructional strategies. Traditional face-to-face instruction will be further enhanced with the use of the course managements systems and the tools they offer. The traditional face-to-face instruction such as lectures, role modeling, simulations, team/group work, will be integrated into the learning environment via the use of technology.

In addition, the acceptance of learning outcomes will be a crucial requirement of the future. Students will need to be able to transfer courses and knowledge to different educational institutions and different learning environments. Therefore, diversity and the evolution of technological savvy students are continuing trends for the future.

CONCLUSION

Effective teaching begins with effective planning. Instructional design represents the systematic planning process for instructional events including technology integration. Planning and integrating technology into the instructional process can indeed provide an opportunity for higher student motivation, increased speed of communication, improve students' technology skills, and ease of access to resources.

Bringing real-world problems into the classroom is a very important asset of technology integration. Problem-solving environments have been developed to help students to better understand the workplace they will be a part of in the near future. Technology integration offers interactivity that makes it easier for students to revisit specific parts of the instruction to explore, test ideas and receive feedback.

Learning through real-world resources that are provided in technologically-rich instruction is not a new idea. For a long time, schools have made efforts to give students concrete experience through

field trips, laboratories, and work-study type programs. Technology integration into the learning environment offers powerful tools for addressing time, money, and resource constraints. Because of the resource savings as well as the opportunity to enrich the student's learning, educators should plan to integrate instructional technology into the instructional process whenever appropriate.

It is also important to understand that the instructor must have an understanding of how people learn and retain information when they attempt to engage the learner through the use of technology. Students expect meaningful learning and the use of technology to develop their critical thinking and problem solving skills. Students also expect their instructors to be familiar with the technology and demonstrate technological skills. Instructors will benefit directly by using course management techniques with technology. At the same time, they will serve as a mentor to their students demonstrating how technology can help in problem solving as well as in managing time and resources.

In addition, instruction will be most effective when it is planned with the students' needs and expectations in mind. The instructional design process can serve as the step-by-step process for educators to design and develop their units of instruction. By using the ISD model, educators will offer more enriching instructional opportunities for students and will plan and prepare to integrate technology into the instructional process where it is most beneficial for the learning outcome.

Finally, a recommendation is for instructors to apply the ADDIE model as the instructional design process when designing instruction that integrates technology. Instructors, then, will be able to provide a complete learning environment that will encourage active learning and higher level thinking skills, especially reflection, problem solving, flexible thinking, and creativity. The ADDIE model is very effective when planning instruction with the use of course management

systems. This model can be just as effective when designing instructional video, audio, text-based, and online instructional components. Each step in the ADDIE model has an outcome that will feed to the subsequent step. Each step is evaluated, then adjustments and improvements made, as the designers continue to move to the desired outcome.

KEY TERMS AND DEFINITIONS

ADDIE Model: A foundational instructional design process that represents five basic components of planning and designing instruction: analysis, design, developments, implementation and evaluation. This instructional design model enables standardized development of learning solutions as the educator and the instructional designer moves through the five phases of development.

Analysis Phase: Determining the needs for instruction, analyzing the learner's needs, and establishing goals of the instruction to begin the design phase.

Design Phase: The designer continues with the subject matter analysis and then moves into the application of instructional strategies according to the content type, the user interface is designed and needed materials are collected.

Development Phase: Production begins with a continued review of the current course content, creating new content, organizing content, selecting delivery methods and technology requirements

Implementation Phase: Create an implementation timeline, establish procedures for training the facilitators or the learners, and make revisions as needed (after the evaluation phase) to prepare the final product.

Evaluation Phase: A systemic process that determines the quality and effectiveness of the designed instruction as well as the final product.

Evaluation is an ongoing process—it occurs throughout the ID process.

Instruction Design Models: Systematic guidelines instructional designers follow in order to facilitate the transfer of knowledge, skills, and attitude to the recipient. The ID models typically specify a method that will create well-planned, logical, attainable, and sequential instruction. ID models are visualized representations of an instructional design process. (Example of ID models include: Dick & Carey Model, ADDIE Model, Kemp Model, ICARE Model, and AS-SURE Model.)

Instructional Design Theory: Guides the practice of the instructional designer and offers explicit guidance on how to better help learners to achieve the instructional goals established for the lesson or instructional activity.

Instructional Designer: An individual who applies a systemic methodology based on instructional theory to design and develop content and curriculum, learning support resources, and delivery and assessment methodologies.

Instructional Systems Design: The analysis of learning needs and systematic development of instruction. ISD is the process and the framework for systematically planning, developing and adapting instruction based on identifiable learner needs and content requirements.

Instructional Technology: Defined as the theory and practice of the design, development, utilization, management, and evaluation of the processes and resources for learning.

Chapter 1.11

Using Design Patterns to Support E-Learning Design

Sherri S. Frizell

Prairie View A&M University, USA

Roland Hübscher

Bentley College, USA

ABSTRACT

Design patterns have received considerable attention for their potential as a means of capturing and sharing design knowledge. This chapter provides a review of design pattern research and usage within education and other disciplines, summarizes the reported benefits of the approach, and examines design patterns in relation to other approaches to supporting design. Building upon this work, it argues that design patterns can capture learning design knowledge from theories and best practices to support novices in effective e-learning design. This chapter describes the authors' work on the development of designs patterns for e-learning. It concludes with a discussion of future research for educational uses of design patterns.

DOI: 10.4018/978-1-60960-503-2.ch111

INTRODUCTION

The instructional design of e-learning course materials directly affects student learning outcomes, but research suggests that many of the instructors developing online courses have not received training in interaction or instructional design (Braxton, 2000; Clark, 1994; Tennyson & Elmore, 1995). Hirumi (2002) found that novice course designers find it difficult to incorporate the types of meaningful interactions needed in online courses. Also, inexperienced educators can have difficulties in the application of learning theories to course design. According to Wilson (1997), theories are written as hard science, and novices require a different type of representation to support their initial learning needs. As further stated in Wilson (1999), "the plurality and multiplicity of models and theories can be daunting to both

researcher and practitioner.” As a result, making the transition from this wealth of information to actual design practice can be difficult for all but experienced educators and instructional designers.

Design patterns have emerged as an approach for capturing design knowledge from theories and best practices in a form that is understandable and useful for novices (Alexander, Ishikawa, Silverstein, Jacobson, Fiksdahl-King, & Angel, 1977). Design patterns and their use in the development of effective learning designs are currently important areas of research.

The purpose of this chapter is to introduce design patterns as a strategy for representing and disseminating instructional design and learning theory research. First, a review of the literature provides a definition for a design pattern and gives the history of design patterns usage and reported benefits in other disciplines. We then examine how design patterns can be used in education to represent and disseminate learning theory research and educator best practices in the context of e-learning design. We discuss our current research with design patterns for e-learning design, which advocates the development of an underlying design framework and support environment for design pattern development and use. Examples of design patterns developed from this work are provided. Finally, we conclude with areas of future research.

BACKGROUND

What Is a Design Pattern?

Design patterns have been defined in the literature in a number of ways. As provided in one of the earliest definitions from the field of architecture, a design pattern “describes a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over, without ever doing it the same way twice” (Alexander et al., 1977).

They further describe a design pattern as “a three part rule, which expresses a relation between a certain context, a problem and a solution” (Alexander, 1979). In a definition almost 20 years later from the field of software engineering, a design pattern is described as a “particular prose form of recording design information such that designs which have worked well in the past can be applied again in similar situations in the future” (Beck, Coplien, Crocker, Dominick, Meszaros, Paulissch, & Vlissides, 1996).

Originating in the field of architecture, design patterns have been used to capture expert knowledge, experiences, and design best practices within many different domains (Alur, Crupi, & Malks, 2001; Borchers, 2001; Gamma, Helm, Johnson, & Vlissides, 1995; Graham, 2003; Tidwell, 2005). A large part of their value is attributed to their ability to serve as a design aid to disseminate this knowledge to a novice designer. Although many formats and templates exist for formulating a design pattern, four elements are typically present:

1. The *pattern name* identifies the pattern and provides a way to communicate about the pattern. Choosing a good name is considered vital as it becomes a part of the design vocabulary (Gamma et al., 1995).
2. The *problem* section describes when to apply the pattern explaining both the design problem that is addressed and the context surrounding it.
3. The *solution* section describes the elements that make up the design to solve the problem. References to other design patterns that support the solution are also typically provided.
4. An *example* section provides specific implementations of the solution. Depending on the discipline, the examples may be textual descriptions or pictures.

Formulating design knowledge in terms of problems and solutions is regarded by some to provide designers with more concrete design

information not readily available in other forms of design knowledge representation such as design guidelines or design principles (Mahemoff & Johnston, 1998a; van Welie, van der Veer, & Eliens, 2000). The objective of most design pattern research is in the development of a collection of design patterns that provide a vocabulary for representing and communicating design knowledge in a field. Different classifications have been used to describe a pattern collection often depending on the degree of structure and connectivity the pattern collection possesses (Appleton, 2000). A *pattern language* is a collection of design patterns that have been connected and interlinked (Alexander et al., 1977). Mahemoff and Johnston (1998a) assert that generativity is the chief benefit of a pattern language. Because the patterns in the language form a cohesive structure, the designer is able to begin with a certain context and work through all of the relevant patterns to generate a design. A *pattern catalog* typically refers to a pattern collection that has a relatively low level of structure and organization. Little cross-referencing exists among patterns, and each pattern gives a relatively independent solution (Appleton, 2000; Schmidt, Johnson, & Fayad, 1996). Derntl and Botturi (2006) also discuss the notion of a *pattern system*, which includes a pattern language and tools to support use of the language. They define a pattern system as “a conceptual system, which consists of the pattern language and some formulation of meta-language features, e.g., instructions about how to use the patterns, the underlying value system and philosophical background, as well as other relevant information and requirements.”

A key question in examining the literature on design patterns is: Why patterns? Three main benefits for pattern usage are often cited: (1) they serve as a *design tool*; (2) they provide for concise and accurate *communication among designers*; and (3) they *disseminate expert knowledge to novices* (Viljamaa, 1997). The reuse of design solutions is one of the most cited rationales for the

use of design patterns (Erickson, 2000). Another cited reason for the popularity of design patterns as discussed in Erickson (2000) is in their ability to provide a “lingua franca,” a common language that can be read and understood by those even outside the design profession the pattern language addresses.

In many disciplines including education, design guidelines and principles have been used to represent design knowledge. It has been argued that guidelines suffer problems involving selection, validity, and applicability (van Welie et al., 2000). Mahemoff and Johnston (1998b) state that design patterns are concrete in contrast to abstract design guidelines and principles and when based on underlying design principles, they can capture the philosophies of good design. Chung, Hong, Lin, Prabaker, Landay, and Liu (2004) describe three ways design patterns differ from other formats such as guidelines and heuristics for capturing and presenting design knowledge:

First, patterns offer solutions to specific problems rather than providing high-level and sometimes abstract suggestions. Second, patterns are generative, helping designers create new solutions by showing many examples of actual designs. Third, patterns are linked to another hierarchically, helping designers address high-level problems as well as low-level ones.

USAGE OF DESIGN PATTERNS

Architecture Design Patterns

Design patterns originated in the field architecture as an approach for improving the design of modern architectural structures (Alexander et al., 1977). The objective was to create a body of knowledge of design solutions to reoccurring problems encountered in architectural design and

to present this knowledge in an understandable and useful form that could be used by architects and the general public. Christopher Alexander and colleagues represented this knowledge in what they termed a “pattern,” a narrative form consisting of textual descriptions and pictures that describe a design problem and its solution. A pattern language consisting of 253 design patterns was developed to support both architects and the public in designing quality architectural structures, a quality they contend was being lost in modern architectural design. The design patterns range from addressing large design issues such as the design of neighborhoods and communities to smaller scale patterns that deal with the design of houses and rooms. The patterns were ordered hierarchically within a pattern language with each pattern referencing the smaller scale patterns that support it and the larger scale patterns that it supports. All patterns are presented in the same narrative structure and format consisting of the following elements:

- The name of the pattern
- A validity ranking indicating the degree to which the authors have confidence in the pattern’s solution
- A picture showing an archetypical example of the pattern
- The context for the pattern
- The problem statement and description
- The solution to the problem
- A diagram of the solution
- References to smaller scale patterns needed to complete the pattern

In one of the volumes of this work, *The Oregon Experiment*, readers are provided with the application of the design patterns in an experiment to redesign the campus of the University of Oregon (Alexander, Silverstein, Angel, Ishikawa, & Abrams, 1975).

Software Engineering Design Patterns

The greatest impact of design pattern usage can be seen within the software engineering community. The goal has been to use design patterns to create a collection of design best practices to support software architecture and design. Gamma et al. (1995), often referred to as the Gang of Four (GoF), published the first influential collection of design patterns in the software engineering community. They developed a catalog of 23 design patterns that capture and present solutions to problems in object-oriented software design. More than a decade later from the GoF text, design patterns and resulting research have a strong presence within software engineering, most notably to support object-oriented software development (Alur et al., 2001; Metsker & Wake, 2006).

The presentation of design patterns changed with their adaptation to software engineering. Gamma et al. (1995) introduced a new format for presenting design patterns (see Table 1). Instead of the narrative format used in architecture, a longer and more explicitly labeled template was used. Another change is the lack of the strict hierarchical ordering that existed in the architecture design patterns. According to Viljamaa (1997), this change can be contributed to the iterative nature of software development, which makes it difficult to impose a hierarchical structuring. Software engineering design patterns also contain software code to illustrate an implementation of the pattern, and due to their technical content, they are not easily understood by users without some software development training.

Design Patterns in Interaction Design

Design patterns have been used within the human–computer interaction (HCI) field to support different levels of interaction design ranging from

Table 1. Software engineering design pattern template (Gamma et al., 1995)

Name and Classification	The name conveys the essence of the pattern and the classification is based on the pattern's purpose in the design process.
Intent	Explains what the pattern does, its rationale, and the design problem addressed.
Also known as	Gives other names for the pattern if any exist.
Motivation	Illustrates the design problem and shows how the pattern solves the problem.
Applicability	Gives the situations in which the pattern can be applied and gives examples of poor designs that the pattern can address.
Structure	Gives a graphical representation of the classes in the pattern.
Participants	Lists the classes and/or objects participating in the design pattern.
Collaborations	Shows the way the objects and classes collaborate.
Consequences	Addresses how the pattern supports its objectives along with the trade-offs and results of using the pattern.
Implementation	Gives the pitfalls and techniques needed when implementing the pattern.
Sample Code	Code fragments on how the pattern might be implemented in C++ or Smalltalk.
Known Uses	Examples of the pattern found in real systems.
Related Patterns	Addresses how the patterns are related and identifies other patterns to be used.

user interface and hypermedia design to social and cognitive design issues (Borchers, 2001; Thomas, Danis, & Lee, 2002; Tidwell, 2005). One objective has been to use design patterns to embody HCI guidelines and design principles, which have been considered by some as not very useful in solving specific design problems (Mahemoff & Johnston, 1998a; van Welie et al., 2000).

Van Welie et al. (2000) introduced a categorization for HCI design patterns based on the kind of design problem the design patterns address. They suggest that just as architectural patterns have the focus of creating quality living environments, HCI patterns need to have a focus, and it should be on usability. They also argue that design patterns should focus on problems of the end users, not necessarily problems of the designers. For example, within education, the student participating in the learning experience would be considered the end user. They state that, "each pattern that focuses on the user's perspective is also usable for designers but not vice versa" (van Welie & Traetterberg, 2000). As shown in the user interface design pattern presented in Figure 1, they include the design principle in the design pattern

and a rationale for how and why the design pattern works. They state that without the rationale section, it is impossible to see whether or why the solution given is good.

Borchers (2001) suggests that the concept of design patterns can be applied to not only architecture, software engineering, and HCI, but can be used to capture design knowledge in any application domain where software is being created. In this research, design patterns were used to capture software and user interface design issues as well as the knowledge from the music domain in the design of interactive musical systems.

There has been no clear consensus on the structure or focus of HCI design patterns. A taxonomy for HCI design patterns has been proposed by Borchers (2000b) along three main dimensions, including:

- *level of abstraction* - Interaction design patterns can address very large-scale issues that comprise a user's complete task or they can address smaller scale, slightly more concrete topics that describe the style of a certain part of the interaction. They

Figure 1. User interface design pattern: Warning (van Welie et al., 2000)

HCI Design Pattern Example

Design Pattern: Warning

Problem: The user may unintentionally cause a problem situation, which needs to be resolved.

Principle: Error Prevention (Safety)

Context: Situations where the user performs an action that may unintentionally lead to a problem.

Forces:

- Work may be lost if the action is fully completed.
- The system can or should not automatically resolve this situation so the user needs to be consulted.
- Frequency of occurrence.
- The number of ways in which the problem can be resolved.
- The likelihood that the user intentionally does the task, e.g. the user wants to do it.
- Some actions are difficult or impossible to recover from.
- Users may not understand why an action could be damaging.
- Users may not understand the consequences or options.
- The severity of the problem if it occurs i.e. how bad is it?

Solution:

Warn the user before continuing the task and give the user the chance to abort the tasks.

The warning should contain the following elements:

- A summary of the problem
- The condition that has triggered the warning
- A question asking the users if continue the action or take on other actions.
- Two main choices for the user, an affirmative choice and a choice to abort.

The warning might also include a more detailed description of the situation to help the user make the appropriate decision. The choices should be stated including a verb that refers to the action wanted. Do not use Yes/No as choices. The choices are answers to the question that is asked. In some cases, there may be more than two choices. Increasing the number of choice may be acceptable in some cases but strive to minimize the number of choices.

Rationale:

By stating the triggering condition, the user can understand why the warning appears. Once that is understood the question leaves the user with only two options. By providing only two options, the choice is made simple for the user: continue or abort. More options make it increasingly difficult for the user to make a decision. By using a verb in the option the user immediately knows what the user is choosing for whereas Yes/No choices require the user remember exactly what the question was. The solution decreases errors and increases satisfaction.

Examples:

This screenshot comes from Eudora 4, if you try to exit the program. It shows that even three choices can be acceptable.

Known Uses: Eudora, Installshield installers (when exiting)

can also deal with low-level questions of user interface design that look at individual user interface objects.

- *function* - Patterns can be classified into those that address mainly questions of (visual, auditory, etc.) *perception* (interface output), and those that deal with interface input, or, more specifically, *manipulation* of some kind of application data, or *navigation* through the system.
- *physical dimension* - Some patterns will address questions of *spatial* layout, while

others deal with issues of *sequence* (discrete series of events, e.g., a sequence of dialogs), or with continuous *time* (such as a design pattern about good animation techniques in the user interface).

Pedagogical Design Patterns

The goals of design pattern research in education have been twofold. One objective has been to use design patterns as a teaching tool to assist students in gaining design skills as in the computer

science education research of Borchers (2002) where design patterns were used to teach user interface design skills to undergraduate students and in similar research where design patterns have been used as a teaching tool for computer programming related courses (Gelfand, Goodrich, & Tammaia, 1998; Nguyen & Wong, 1999; Preiss, 1999). The second and most prevailing objective is in using design patterns to capture knowledge in teaching and student learning to assist in the design of successful learning opportunities for students. This knowledge may be captured from instructional design and learning theories and expert best practices and experiences. Such design patterns are often referred to in the literature as pedagogical design patterns, learning design patterns, or e-learning design patterns when developed for online course design.

The Pedagogical Patterns Project (PPP), which began in 1996 evolved out of this latter objective to use design patterns to capture the knowledge of experienced educators in learning and teaching object-oriented technology (Sharp, Manns, & Eckstein, 2003). The project began by collecting design patterns from various pattern authors, which varied in focus from curriculum issues to teaching and learning specific object-oriented concepts. The example design pattern presented in Figure 2 is from the earlier work of the project and addresses the problem of exposing students to complex programming problems. These earlier design patterns are referred to as proto-patterns because they had not gone through a rigorous review process and were not a part of a pattern language (Sharp et al., 2003).

In the most recent work of the PPP, the effort has changed in scope moving from the collection of proto-patterns that were largely focused on object-oriented teaching to the development of four pattern languages to address various issues of teaching and student learning (PPP, n.d.; Sharp et al., 2003). The four pattern languages include:

1. Patterns for Active Learning – A pattern language that focuses on pedagogy to promote active learning.
2. Patterns for Experiential Learning – A pattern language that focuses on pedagogy that promotes experiential learning.
3. Teaching from Different Perspectives – A pattern language provides some successful strategies to assist teachers in helping learners examine course material from different perspectives.
4. Feedback Patterns – A pattern language provides some successful strategies to assist teachers in providing feedback to students.

A detailed discussion of how the pattern languages evolved from the original collection of proto-patterns is also provided in Sharp et al. (2003). The design patterns have also changed in presentation (see Figure 3) to the format originally used in architecture because they felt it was more informative and provided better support for connecting the design patterns into a pattern language. In this updated form, each design pattern is divided into four sections separated by “****”; the first section establishes the context for the problem, the second section describes the forces and the design problem addressed, the third section presents the solution with consequences and limitations to the solution, and the last section provides examples and additional information concerning the solution (PPP, n.d.). The work of the PPP has not been without criticism regarding the scale, scope, and method for the development of design patterns (Fincher & Utting, 2002). However, there is no consensus in the literature on the format, content, or level of detail of pedagogical design patterns.

Figure 2. Pedagogical design pattern: Fixer Upper (abridged) (PPP, n.d.) ©2000 Joseph Bergin. Used with permission

Examples of Pedagogical Design Patterns	
Design Pattern: Fixer Upper Giving a student or group of students a large artifact that is generally sound but with carefully introduced flaws can both introduce a complex topic early and serve as a way to introduce error analysis and correction. Students are asked to repair and discuss the artifact.	Contributed by Joseph Bergin
Problem/ Issue Too often students work on only "toy" problems because they may not have the experience or skill to build large artifacts from scratch and there is only just so much time. But all realistic problems are large and the day in which small problems were interesting is about past. We want to get students to work on large artifacts without overwhelming them. On another front, students also have difficulty when unexpected errors arise in their own work. Compiler and run time error messages, for example, often leave them lost.	
Audience/Context The pattern can be used in several courses and at several levels. It can be used very early in programming courses and in teaching analysis and design. It can also be used to show the overall structure of a solution methodology.	
Forces We often need to introduce students to a new field requiring mastery of several topics. Students often fail to see how the topics fit together when introduced sequentially. They also often fail to have a grasp of the means of locating and correcting errors. Fixing a larger artifact than can be created by students is generally within their grasp. It gives them a better sense of scale of interesting problems and permits them to integrate a number of issues into the solution of a single problem. Students can benefit from seeing larger problems than they can solve at their current state of development. They also need critical analysis skills and the ability to evaluate programs, designs, etc. (See Lay of the Land and Larger Than Life).	
Solution Give students an artifact, such as a program or design. The artifact proposes to be the solution to a problem, but while generally correct, the instructor has purposely introduced flaws into the program, design, or whatever. The artifact should be fairly large and should contain a number of flaws. Most of the flaws should be simple and obvious to most readers. There should be one or two deeper flaws. Ask the students to find and correct the flaws. Ask them to discuss the nature of the flaws found and the reasons for their changes. Finally, ask them to discuss the overall structure of the artifact and draw inferences from it.	
Discussion/ Consequences/ Implementation This pattern allows students to actively work with larger artifacts than they can develop completely themselves. They benefit since finding flaws in their own work is a valuable skill. In programming, students see lexical, syntactic, and semantic errors. In design, they can see the effect of incorrect partitioning of responsibility. It is important that the overall structure of the artifact be sound. If it is a program it should be well designed and written, with good choice of identifiers. If it is an analysis or design document, its overall structure should be sound with a clear map to the problem statement. The best way to develop such an artifact is to start with an excellent solution to a problem and then doctor it by introducing flaws. There must be different kinds of flaws, but probably not structural flaws if you are dealing with novices. This latter rule can be broken if the artifact is introduced later in the course rather than at the beginning, at a point at which structure is the main issue.	
Example Instances This pattern has been used to teach 1. Beginning programming. Here the artifact is a program illustrating a number of syntactical constructs that have not yet been introduced in class. (It has been used as the first assignment.) The program can be large enough that its structure is not obvious. Two or three classes with several short methods each is about right. One part of the program might be more complex. Together with the driver, there should be three or so pages of code. The errors can be mostly syntactical and lexical, so that the compiler can find them. One or two semantic errors should also be introduced, so that the program does not perform as expected. More serious and perhaps for more advanced students is the failure to fulfill a precondition contract. Ten to fifteen errors is about right if most are easily caught. Even a single class can be introduced that has a flawed public interface. Students can be asked to analyze the consequences of this in relation to the likely current and future use of the class. 2. Introduction to design. Here a problem is presented and a design for the solution. Six to ten major elements in the design is about the right scale. The design should have a few simple flaws, such as missing message paths or missing functionality within a class.	
Contradictions This must be carefully used if student honesty is an issue. It is easy for one student to point to the locations of errors in C++ programs, for example. One way to address this is to use large artifacts that require teamwork. Another is to ask questions concerning the structure as well as the errors. Finally, the students can be asked to examine the artifact before they are given the full set of questions that will be asked about it. Some students are frustrated by such large artifacts. The instructor must be prepared to provide support and encouragement that the real world really is like that and that it is ok to initially (a) be frustrated and (b) lack knowledge.	

HOW EFFECTIVE ARE DESIGN PATTERNS?

An examination of the literature reveals limited empirical data on the effectiveness of design patterns in supporting novice designers and the quality of the designs produced by pattern users. Mostly from within the software engineering community, descriptions of positive experiences with design patterns have been reported (Beck & Cunningham, 1987; Beck et al., 1996; Cline, 1996; Schmidt, 1995). Prechelt, Unger-Lamprecht,

Phillippsen, and Tichy (2002) describe the first controlled experiments with design patterns in the area of software maintenance. They report that design patterns aided users in completing software maintenance tasks faster and with fewer errors.

Borchers (2002) describes his experience with using patterns to teach interaction design to undergraduate students. Design patterns were covered as part of the course content and given to students to use during their first design assignment. He reports that most students were able to relate several design patterns to problems

Figure 3. Pedagogical design pattern from the patterns for experiential learning language: one concept, several implementations (PPP, n.d.)

they were facing with their designs and that the patterns helped the students to retain the design knowledge. Dearden, Finley, Allgar, and McManus (2002) describe a study to evaluate design patterns as a tool for participatory design. They claim novice Web designers were able to produce feasible design sketches of a travel Web site using design patterns and that using the patterns enabled participants without experience in Web design to participate in the design of a Web site. However, no claims were made to the quality of the designs produced by the users due to the limited amount of time participants worked on them and because they were only paper-based sketches. Also from the HCI community, Chung et al. (2004) describe two studies to evaluate the usefulness of design patterns in supporting the design tasks of novice designers in ubiquitous computing. They also evaluated the usefulness of the design patterns in improving communication between designers and

supporting the creation of higher-quality designs. Again not statistically significant, they report the designs created by participants who used design patterns were generally rated higher by judges and that the design patterns helped novice and experienced designers, assisted in communication between designers, and aided designers in avoiding some design problems early in the process.

We believe that data from control studies on design pattern effectiveness is limited due to experimental design difficulties. Spector and Song (1995) discuss the difficulties of measuring the effectiveness of design support methods due to the fact that design-based tasks can be very individualized and quite time consuming to develop. Prechelt et al. (2002) also discuss these challenges and note that difficulty often arises in experiments that attempt to evaluate a specific form of an information source. Because of these challenges, the design of such studies is a nontrivial

task. We have encountered this difficulty within our research (Frizell, 2003, 2006), an issue we discuss in a subsequent section.

DESIGN PATTERNS USAGE IN E-LEARNING

Much of the current research with pedagogical patterns has been in the area of Web-based instructional design or e-learning design. E-learning design can be defined as “the application of learning design knowledge when developing a concrete unit of learning [via an electronic medium], e.g. a course, a lesson, a curriculum, a learning event” (Koper, 2005). Learning design knowledge in this context encompasses beliefs about teaching and student learning derived from a number of sources including educator experiences, best practices, and educational theories. Design patterns have been proposed to capture and disseminate design knowledge from all the aforementioned sources to support both e-learning design and development (Avgeriou, Papasalouros, Retalis, & Skordalakis, 2003; E-LEN, n.d.; Goodyear, 2005; Jegan & Eswaran, 2004; Retalis, Georgiakakis, & Dimitriadis, 2006). Our research lies within this realm and is discussed in the following section.

TOWARDS A PATTERN LANGUAGE FOR E-LEARNING DESIGN

In this section, we describe our research towards the development of a pattern language for e-learning design. We have currently developed 26 design patterns that cover various issues in e-learning design (Frizell, 2003). The focus is to support novices in the design of collaborative and active e-learning environments, which incorporate the support and guidance a student may need to be successful in such an environment. Our research is based on the view that principles from learning theory and instructional design research can

be used to support effective e-learning design, but that this knowledge needs to be captured and presented in a way that supports instructors in its use (Frizell & Hübscher, 2002a). We also advocate that e-learning design patterns should be based on an underlying design framework or philosophy, an issue first discussed by Mahemoff and Johnston (1998a) regarding the development of HCI design patterns. This approach towards the development of design patterns is considered a value-laden approach where the values inform the development of the patterns (E-LEN, n.d.; Fincher & Utting, 2002). The E-LEN consortium notes that e-learning patterns should be used to express educational values and that it is better to be explicit about the educational values than claiming the development of value-free patterns.

PROPOSED E-LEARNING DESIGN PATTERNS

In developing the design patterns, we examined the literature on learning theories and instructional design to identify pedagogical best practices and design principles that support effective learning design. Through this process, we identified 10 design principles that provide a framework for the development of e-learning patterns. The framework presented in Table 2 contains principles that advocate the design of collaborative and active Web learning environments (Bransford, Sherwood, Hasselbring, Kinzer, & Williams, 1990; Brown, Collins, & Duguid, 1989; Jonassen, 1999; Kearsley, 1999; Kearsley & Schneiderman, 1999; Oliver & Herrington, 2000). There is also a focus on providing rich and diverse course content to students (Merrill, 2002; Spiro & Jehng, 1990). Pedagogical principles that emphasize the importance of incorporating structure, support, and guidance into a course’s design are also included in the framework (Gagné, 1985; Kearsley, 1999; Merrill, 2002). In developing the framework, we considered the information content, learning ac-

| 1. Design for interactivity |
| 2. Provide problem-solving activities |
| 3. Encourage student participation |
| 4. Encourage student expression |
| 5. Provide multiple perspectives on content |
| 6. Provide multiple representations of data |
| 7. Include authentic content and activities |
| 8. Provide structure to the learning process |
| 9. Give feedback and guidance |
| 10. Provide support aides |

tivities, and support structures that can be included in a course to enhance student-learning outcomes.

Table 3 provides an overview of the e-learning design patterns that have been developed based on this design framework. The name and a statement of the design intent of each pattern are listed. The design patterns embody the design philosophy represented by the 10 principles listed above and provide novice course designers with a useful way of looking at this often difficult to understand pedagogical information. We do not suggest that this collection of design patterns cover all possible design problems that may arise in course design and while an initial study with users has been conducted (Frizell, 2006), the design patterns can benefit from continued critiquing or shepherding to refine the patterns and to identify additional patterns.

We categorized the e-learning design space based upon the model presented by Oliver and Herrington (2000) for the design of Web-based learning environments based on principles from situated learning theories. Using this model, the design patterns are structured into three distinct but congruent design categories: (1) design patterns that focus on design problems related to course *content*, (2) design patterns that focus on student *learning activities*, and (3) design patterns that focus on providing a *learning support* structure. This categorization allows for the development of e-learning patterns that focus on both the problems students face in being successful in online environments and the problems instructors

face in designing effective online environments. *Content* design patterns assist with design problems related to the presentation and structure of course materials. In developing the design patterns to be included in this category, the focus was on providing rich and diverse course content and on providing structure and guidance in the presentation of course materials. Currently, nine design patterns have been developed to address design problems pertaining to these design goals. *Learning Activity* design patterns provide solutions to problems concerning the creation of collaborative and active e-learning environments. Currently, eight design patterns have been developed that address building learning communities, encouraging student participation, encouraging student expression, and problem solving. *Learning Support* design patterns address problems with providing support to students. The focus was on the creation of design patterns concerned with providing guidance and feedback to students.

Due to space limitations, we present only two of the design patterns in detail. A complete description is available in Frizell (2003). The design pattern shown in Figure 4 named *Information Representation* provides a strategy for providing diverse course content. The design pattern named *Post Requirement* (see Figure 6) provides a strategy for involving students in course activities and addresses the problem of getting all students to participate. A format consisting of six elements—*name*, *context*, *problem*, *solution*, *examples*, and *references*—was chosen to describe each design pattern. We believe this format provides designers with those key features needed to fully understand a design pattern without including too much information so that the pattern becomes difficult to read and follow. The reference section is used to validate the pattern and provides additional resources for those users who are interested in the theory behind the pattern. Borchers (2000a) speaks to the need for patterns to give empirical evidence of their validity without making the pattern unreadable

Table 3. E-learning design patterns (Frizell, 2003)

Content Patterns	Design Goal
• Course Goals	Provide students with course objectives
• Course Layout	Organize course design decisions
• Course Path	Organize and link course content
• Foundation	Help students recall previously learned information
• Information Bridge	Help students make connections between lessons
• Information Chunks	Provide structure to course content
• Information Representation	Provide content in multiple representational forms
• Points of View	Provide students with multiple perspectives on course content
• Syllabus	Inform students of course content and expectations
Learning Activity Patterns	
• Active Student	Encourage student expression and increase student participation by getting them involved in course activities
• Course Interactions	Increase course interactions
• Group Work	Increase course interactions through group activities
• Learning Community	Encourage students to communicate
• Peer Evaluation	Encourage student expression
• Post Requirement	Encourage student participation in group discussions
• Problem Practice	Provide problem-solving activities
• Real World	Provide problem-solving activities in the context of real world usage
Learning Support Patterns	
• Communication Tools	Support student communication
• Discovery Orientation	Support student exploration
• Facilitated Discussion	Support student communication
• FAQ	Provide students with immediate feedback
• Feedback	Give students feedback on course activities and assignments
• Learner Guidance	Provide support to students in understanding and completing course activities
• Moderated Discussion	Support student communication
• Question Time	Provide students with immediate feedback
• Student Input	Gather student feedback on the course

with lots of statistical information. The examples included in the design patterns are obtained from the literature or from existing courses.

FIRST EVALUATION OF THE DESIGN PATTERNS

We conducted a study to investigate the effectiveness of our e-learning patterns in supporting

novices and to gain insight on problems and limitations that may exist in end user's abilities to use design patterns. Our research questions included: Are design patterns effective in supporting the design tasks of novices? Can end users apply the knowledge represented in design patterns more effectively than guideline representation? In this section, we summarize the design and results of the study.

Figure 4. E-learning design pattern example

*E-learning Design Pattern Examples***Design Pattern: Information Representation**

Context: Use when you are presenting complex material to students and you want to maximize their understanding.

Problem: Presenting complex information in only one form (e.g. a textual description) may hinder some student's ability to effectively understand the material.

Solution: Therefore, provide students with opportunities to study complex information in a variety of representational forms. Depending on the type of information, it may be best represented textually through descriptions, analogies, and examples, and/or visually through diagrams, illustrations, or animations. See also the pattern *Points of View*, which also address presenting diverse instructional content to students.

Examples: The following examples illustrate how course concepts can be represented in different ways. The examples are from a research project that examined the effects multiple representations of computer algorithms had on student learning (Hübscher-Younger, 2002).

SELECTION SORT

Pseudocode:

```

SelectionSort (SortArray, ArraySize)
begin
  for I in 1..ArraySize-1 loop
    Pos = I;
    for J in I+1..ArraySize loop
      if SortArray[J] < SortArray[Pos] then
        Pos = J;
      end loop
    if Pos != I then
      temp = SortArray[I];
      SortArray[I] = SortArray[Pos];
      SortArray[Pos] = temp;
    end loop
  end SelectionSort

```

Explanation:

I find that this algorithm is best explained with an example. Let's take an array of size 10 with the following numbers:

63 24 5 17 49 52 19 44 67 12

The algorithm starts from the beginning of the array and searches for the smallest value in the array. In this case, the number 5 is what it finds. It then swaps that number with the number in the first

Methodology

Participants. Twenty-nine computer science graduate students participated in the study. Based on data from the preliminary questionnaire, 45% has some familiarity with software engineering design patterns, while only 17% had some teaching experience mostly as graduate teaching assistants. None of the students indicated having taken any type of education class that focused on teaching and student learning. This suggests the participants were knowledgeable on the subject matter used in the design task (i.e., design of

online C++ programming course), but novices to instructional design.

Procedure. The experimental design was between-groups with the participants being given the same design task to complete. The difference was in the method of design support that was provided to them. One group had access to a Web site containing a subset of the developed e-learning design patterns and the other group had design guidelines. The guidelines were primarily represented as two to three line paragraphs with no accompanying examples. To minimize the effects of having the information not only in different form but also contain different content,

we looked for guideline information that provided content as similar as possible to the information represented in the design patterns. However, there was no optimal way to reproduce the exact same information contained in all the sections of the patterns into a guideline without trying to rewrite the guideline as a design pattern.

The design task for the study consisted of the *selection* and *justification* of useful and applicable design patterns or design guidelines by participants for the design of an online C++ programming course. Participants were asked to provide both *why* they considered the guideline or design pattern useful and applicable to the course's design, and *how* they would use this knowledge to affect the course's design. We chose this design task instead of the design of a course module for evaluation

because we wanted to observe the participants while they interacted with the design patterns. We did not consider the 10–20 hours reported in the literature needed to design a course lesson for evaluation feasible for our study (Thomas, 2000). Spector and Song (1995) also report on the significant amount of time ranging from weeks to months it can take users to produce a course module that warrants evaluation. Based on the design task, the factors considered in evaluating design pattern effectiveness include:

- **Design task results:** An analysis of participant's task results, which includes the number of patterns or guidelines selected, the appropriateness of the selections, the

Figure 6. E-learning design pattern example

Design Pattern: Post Requirement

Context: Use when you want to encourage student participation in course bulletin board discussions.

Problem: Bulletin boards (i.e. threaded discussions) can be used for course communication. However, some students will have a tendency to lurk and read the comments of others, but never contribute to the discussions. Students will still need encouragement to get involved. Such encouragement is especially needed for students who are new to online learning or professionals with busy work schedules (Kearsley, 1999).

Solution: Therefore, make participation in online discussions a requirement of the course. This can be done by giving bonus points as an incentive or making participation a component of the course grade. For many, this will provide the motivation to contribute. Making posting a requirement requires involvement from the instructor as well to facilitate and moderate discussion (Kearsley, 1999). See the Learner Support patterns, *Facilitated Discussion* and *Moderated Discussion*.

Examples: In the following example, students are required to contribute weekly to course discussions. Motivation to participate is provided by making it a component (15%) of the final grade for students.

reasoning given by users for the selection, and the time taken to complete the task.

- **Problems encountered:** Any difficulties observed or reported by users in completing the task.
- **User satisfaction:** A measure of participant's opinions of the design support method after completing the design task. Participants were given a questionnaire after completing the task and asked to rank the method on usefulness, applica-

bility, understandability, learnability, and effectiveness.

The study occurred over a 2-week period with subjects participating one at a time. Participants signed up for 75-minute sessions, but were allowed as much time as needed to complete the design task.

Results summary. Participant's data were studied for any noticeable differences between pattern users and guideline users in the level of

understanding or applicability in the information provided when answering the questions of why an item was selected and on how it would be used. There was no consistency in the data provided that would suggest that one group had a higher level of understanding when compared to the other group. However, several participants from the design guidelines group asked for more clarification on the guidelines and asked the evaluator to provide example usages of the guidelines. One participant from this group commented that more details were needed to help fully understand many of the guidelines. Results from the user satisfaction questionnaire yielded no significant differences between groups regarding the usefulness, applicability, understandability, learnability, and effectiveness of the design patterns or design guidelines.

While data analysis of the results was inconclusive in measuring design pattern effectiveness, and no significant differences were found between design pattern and design guideline usage, users rated the design patterns favorably, reported few problems in understanding the design knowledge presented in them, and indicated the design patterns exposed them to design issues not previously considered. An experimental design that focused on the selection and justification of design patterns by users proved to be insufficient for measuring effectiveness. In future research activities, we intend to explore extensions and possible alternatives to the experimental design used in this first study.

FUTURE TRENDS

Design patterns have emerged as a powerful approach for capturing design knowledge to promote reuse of designs and provide design support to novices. To support wide spread adoption and use of design patterns within education, we highlight three main areas of future research: (1) standardization of the design pattern form in education, (2) the integration of design pattern research with

current research efforts in learning objects, learning design, and learning management systems, and (3) the development of software tools to facilitate the creation, sharing, and use of design patterns. The structure of design patterns and pattern languages and their use within education is still in the exploratory stage. A number of formats and techniques for the development of pedagogical design patterns have been proposed. The design patterns that are currently available also vary significantly in level of detail and focus. Fincher and Utting (2002) have characterized what they term the functional and nonfunctional requirements for pattern languages. However, given the array of what currently exists, further research is warranted on the development of frameworks or models for the development and use of pedagogical patterns. This research must address standards for the structure of pedagogical patterns and criterion for the characteristics that must be present.

Within the education literature, there is a shift towards reuse of design solutions and in addition to design patterns, research into learning objects (Wiley, 2002) and learning designs (Koper & Tattersall, 2005) exists. While there have been some attempts to analyze the relationship among these approaches, further analysis is needed. Several research efforts have also discussed ways software tools may prove beneficial for developing and using design patterns (Budinsky, Finnie, Vlissides, & Yu, 1996; Chambers, Harrison, & Vlissides, 2000; Dearden et al., 2000; Greene, Matchen, & Jones, 2002). Although no formal studies have evaluated the effects of software tools on design pattern usage, tool support may greatly harness the benefits of design patterns. Chambers et al. (2002) found that the problem that may exist in pattern application is in the designer understanding his problem and deciding which design patterns help solve it best. We have explored the combination of e-learning design patterns within a design environment that supports the process of selecting and applying design patterns and have investigated techniques for integrating design

pattern into learning management systems (Fritzell & Hübscher, 2002b; Mondle, 2005). Further research is needed to gain more insight on user experiences with design patterns and to evaluate the designs created with design patterns. This data can benefit the development of pattern support tools and design environments as we gain more insight into the process users follow when using design patterns and how those activities can be effectively supported

CONCLUSION

This chapter has described the concept of design patterns and provided a historical overview of their use in a number of different disciplines to capture and disseminate design knowledge. The use of design patterns has moved from architecture, most notably into software engineering, and also to the HCI and education communities. Software engineering design patterns differ from the original architectural design patterns in that they provide specific implementation details and are best understood by designers with some background in the field. Design pattern research within HCI and education are more closely related to architectural design patterns in that there is a focus on the end user's experience with the product being designed and also specific implementation details are left to the designer. The potential of design patterns and pattern languages within e-learning design is great. Continued research is needed to ensure that design patterns live up to their press, have wide spread adoption and use, and make effective and lasting contributions to the practice and understanding of educational design.

KEY TERMS AND DEFINITIONS

Design Pattern: An approach for capturing, representing, and sharing design knowledge that promotes the reuse of design solutions.

E-Learning: The delivery of educational content through computer and communication technology.

Instructional Design: A process for the design and development of instructional materials and learning activities based on learning theory research.

Learning Design: The use of learning design knowledge to design education.

Learning Management System: A software application that supports the management and delivery of instructional materials and learning activities.

Learning Theory: Philosophies describing the learning process.

Pattern Catalog: A collection of related design patterns.

Pattern Language: A structured collection of design patterns within a particular domain.

Pattern System: A pattern language and tools to support use of the language.

Pedagogical Design Pattern: An approach for capturing, sharing, and disseminating design knowledge concerning teaching and learning.

This work was previously published in Handbook of Research on Learning Design and Learning Objects: Issues, Applications, and Technologies, edited by Lori Lockyer, Sue Bennett, Shirley Agostinho and Barry Harper, pp. 144-166, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 1.12

Visual Design of Coherent Technology–Enhanced Learning Systems: A Few Lessons Learned from CPM Language

Thierry Nodenot

Xavier Le Pallec

Université de Lille, France

ABSTRACT

Visual instructional design languages currently provide notations for representing the intermediate and final results of a knowledge engineering process. As some languages particularly focus on the formal representation of a learning design that can be transformed into machine interpretable

code (i.e., IML-LD players), others have been developed to support the creativity of designers while exploring their problem-spaces and solutions. This chapter introduces CPM (computer problem-based meta-model), a visual language for the instructional design of problem-based learning (PBL) situations. On the one hand, CPM sketches of a PBL situation can improve communication within multidisciplinary ID teams; on the other hand, CPM blueprints can describe the functional

DOI: 10.4018/978-1-60960-503-2.ch112

components that a technology-enhanced learning (TEL) system should offer to support such a PBL situation. We first present the aims and the fundamentals of CPM language. Then, we analyze CPM usability using a set of CPM diagrams produced in a case study in a ‘real-world’ setting.

INTRODUCTION

For several years, the IMS-LD specification (IMS, 2003b) has been the subject of converging theoretical and practical works from researchers and practitioners concerned with Learning Technologies.

The IMS-LD specification is now well documented (Hummel, Manderveld, Tattersall, & Koper, 2004; Koper et al., 2003; Koper & Olivier, 2004) and widely used for the semantic representation of learning designs. A *learning design* is defined as the description of the teaching-learning process that takes place in a unit of learning (Koper, 2006). The key principle in learning design is that it represents learning activities and support activities being performed by different persons (learners, teachers) in the context of a unit of learning. These activities can refer to different learning objects that are used/required by these activities at runtime (e.g., books, software programs, pictures); they can also refer to services (e.g., forums, chats, wikis) used to communicate and collaborate in the teaching-learning process.

Thus, IMS-LD is an educational modeling language that provides a representation of the components of a learning environment in a standardized XML schema that can be executed by compliant e-learning platforms. According to the classification framework defined in Botturi, Derntl, Boot, and Gigl, (2006), IMS-LD is an example of a finalist-communicative language: it is not intended to enable designers to produce intermediate models of the learning design being studied, nor to provide significant methodological

support for designers to build a final representation complying with the IMS-LD specification.

Initially, designers had to use XML editors (like *XMLSpy*) to benefit from all IMS-LD expressive capabilities (levels A, B, C). *Reload*, a tree and form based authoring tool, was the first editor to significantly improve this situation. Chapter XV of this handbook provides an extensive presentation of currently available IMS-LD compliant tools (Tattersall, 2007):

- LD-editors like *Reload* (Reload, 2005), *CopperAuthor* (CopperAuthor, 2005), etc.
- *Visual tools to support practitioners in the creation of IMS-LD compliant designs by means of using collaborative pattern-based templates* (Hernández-Leo et al., 2006).
- Authoring environments for IMS-LD designs like the *ASK Learning Designer Toolkit – ASK-LDT* (Sampson, Karampiperis, & Zervas, 2005).
- Runtime engines able to interpret a LD-scenario like *CopperCore* (Vogten & Martens, 2003).
- learning management systems able to interpret LD scenarios: *dotLRN* (Santos, Boticario, & Barrera, 2005), *LAMS* (Dalziel, 2006), *Moodle* (Berggren et al., 2005), etc.

However, standards like IMS-LD (2003) and IEEE LOM (2002) start from the principle that even though learning theories are not pedagogically neutral, neutral reference models and standards can still be designed: ‘*The aim is not to set up a prescriptive model but an integrative pedagogical meta-model which is neutral since it models what is common with any pedagogical model*’ (Koper, 2001); this assumption promotes the concept of de-contextualized learning objects that can be specified once, and then reused to design learning scenarios relying on instructivist

(acquisition metaphor) or constructivist (knowledge creation metaphor) principles.

This chapter proposes another way to address the design of learning scenarios. On the one hand, we consider that socio-constructivist learning scenarios must be designed in context. On the other hand, we think that even the final results of an instructional design (ID) process should clearly state the mapping between the contextualized activities specified by designers and the functionalities provided by a given learning management system (LMS).

In the first section, we present various on-going research work focusing on languages defined to help designers represent and share ideas about a learning scenario under study. Such languages are called ‘generative-reflective languages’ in (Botturi, Derntl et al., 2006). The second section introduces CPM (cooperative problem-based meta-model) language, a visual design-language focusing on the design of problem-based learning (PBL) situations; we present its syntax and semantics that rely on UML language. Then, we try to understand CPM usability from an analysis of a set of CPM diagrams produced in the framework of a real-world case study. This study illustrates CPM language expressivity; it also states that even though designing PBL situations with CPM notation remains a complex knowledge engineering activity, good practices can concretely improve designers’ efficiency and confidence. Finally, the concluding section summarizes both CPM characteristics and proposals for improvement.

BACKGROUND

In this section, we only focus on current research work that could lead practitioners (teachers, educators, designers) to consider ID languages as adequate tools to explore their problem-spaces, not only to share ideas within a design team, but also to prepare the implementation of coherent technological enhanced learning systems.

Situated learning presupposes that meaning is both incorporated within the learning design as well as being prone to interpretation and shared understanding (Stahl, 2006): “*a blind spot of activity-centered models is their missing ability to describe the relation between the program (the learning design) and its context*” (Allert, 2004).

Thus, modeling coherent social systems for learning requires going beyond selecting and sequencing activities and resources, but also deciding and documenting for what purposes they are being used. This means that roles and activities are to be represented and assessed in context (Derntl & Hummel, 2005). With this purpose in mind, Allert (2005) introduces the concept of second-order learning objects (SOLOs) which are resources that provide and reflect a strategy (generative strategy, learning strategy, problem solving strategy, or decision-making strategy). SOLOs provide means for structuring information or modeling certain aspects of the real world: they represent sets of interrelated concepts that can be used to describe the domain of concern. The use of different SOLOs will thus allow a designer to look at a system from different points of view (e.g., organizationally, structurally, and from social points of view).

Pawlowski (2002), Pawlowski and Bick (2006) introduce the didactical object model (DIN) which extends the aims of current educational modeling languages by introducing specifications for contexts, experiences and acceptance. The concept of reusability is, in this case, extended since it should be possible not only to share scenarios as technical specifications but also to exchange didactical expertise about such scenarios (from the knowledge of their context of use, of concrete experiences reported by the actors involved in its use).

Schneemayer (2002), Brusilovsky (2004), and Paramythis and Loidl-Reisinger (2004) extend the context notion to the environment context which clarifies the real characteristics of the LMS (or any other software) from which the learning situation is being exploited. This leads to an approach for

the engineering of learning situations aiming to specify the learning situation together with the LMS which will later enable students to learn from this situation.

Works of Botturi (2003), Botturi, Cantoni, Lepori, and Tardini (2006) promote the adaptation of fast prototyping for the specific issues of e-learning project development with very particular stress on human-factor management (*i.e.*, the *eLab* model). They developed a visual design language called E²ML (cf Chapter VII of this handbook) to support fast prototyping to enable a developing interdisciplinary team to function (including educators and teachers). Outcomes of the language include better communication within the design team, availability of precise design documentation to evaluate designs and figure out agreed and more feasible solutions.

Despite having quite different objectives, the works that we have listed in this section (including those conducted in the framework of the IMS-LD initiative) share the fact that they address the complexity of ID. Developing future technology-enhanced learning (TEL) systems requires an interdisciplinary team with both pedagogical and technical skills: communication and minimal agreement on means and ends are conditions for success within such a team.

From the point of view of teachers and educators, ID languages can be communication catalysts (Botturi, Derntl et al., 2006) if these actors feel that the concepts of the language are in tune with the characteristics of the learning situation to be described and will enable them to explore, document and share their design decisions with others.

On the one hand, Allert (2005) states that teachers and educators need dedicated languages which reduce complexity by reflecting instruction (and the process of ID) according to specified criteria (p. 41): *i.e.*, formalization, compatibility and interoperability criteria (IMS, 2003b) are to be considered since most educators are now aware that the introduction of technologies in education has important consequences on any design process.

On the other hand, such instructional languages must not neglect didactics, which is the science of learning and teaching; even if in the domain of training (reproductive forms of learning), the learning design is often limited to the planning and sequencing of non-contextualized activities and resources. Pawlowski and Bick (2006) state that designing situated-learning requires languages that can precisely describe the context and the dynamics of the tutoring/learning activities and resources.

Our work on visual ID languages started just before Koper (2001) published his first results on the Educational Modeling Language (the precursor of the IMS-LD specification). From the very beginning, we intended to propose a visual design language that could be useful for both educators and developers of TEL systems. From the point of view of educators, the language requirements were:

1. To enable designers to represent learning-tutoring activities in context.
2. To reduce complexity by reflecting instruction (and the process of ID).

In the following sections, we shall first present the characteristics of the language; then we shall study the language usability from an analysis of its use on ‘real-world’ case studies.

CPM LANGUAGE

CPM stands for **cooperative problem-based learning meta-model**. It is a visual design language that we developed at the LIUPPA Laboratory (Laboratoire Informatique de l’Université de Pau et des Pays de l’Adour, France) as a specialization of UML language. CPM language focuses on the design of problem-based learning (PBL) situations. We decided to work on such a dedicated language because we consider with Allert (2004) and Pawlowski and Bick (2006) that:

1. Pedagogical meta-models are not neutral
2. There is an important need for design languages that specifically address generative learning (learning in context, situated learning).

According to the ID classification scheme defined in Botturi, Derntl et al. (2006), it is a visual (notation level), layered (stratification level), semi-formal (formalization level) language promoting multiple perspectives (more than one view) upon the same entities. In the next paragraphs, we present the aims of the language and the information model captured by CPM language. Fundamentals of both its abstract syntax (the CPM meta-model) and its concrete syntax (the CPM profile) are then discussed. Finally, we briefly present three real-world case studies, which have enabled us to experiment on the usability of CPM language.

Aims of CPM Language

Even though learning by doing activities promoted by a PBL scenario may seem to be natural activities, PBL situations must be scripted. In the context of PBL, the support focuses on mentoring, motivating, creating simulated crises, showing how failures result from poor communication and lack of foresight, identifying and promoting areas in which teams and individuals have to make progress. Thus, PBL is different from traditional instructional methods which emphasize the content: This means the main focus is on the learner and genuine problems (Norman & Spohrer, 1996). Guided by tutors who take only a facilitator role, learners are engaged in active and meaningful cooperative learning. They collaborate with each other by using tools to represent problems, to generate solutions, to discuss different perspectives, to lead experiments and simulations, or to write reports, etc. The driving force is the problem given, the success is the solution of it, and apprenticeship is a condition for success. Thus,

the object of any PBL activity is an ill-structured problem under study and the expected outcomes of a PBL activity are (Miao, 2000):

- Acquiring knowledge and skills which can be transferred to solve similar problems at individual level.
- Constructing shared knowledge and promoting mutual understanding at group level.

To address such objectives, our challenge was to explore UML modeling capabilities for the PBL domain and to adapt the semantics of this language, when required, using meta-modeling techniques.

UML is a standard controlled by the object management group (OMG) which is widely known as a design catalyst within teams of software developers Costagliola, De Lucia, Orefice, and Polese (2002), Ferruci, Tortora, and Vitello (2002). Readers needing a basic understanding of the UML language will find a useful introduction in chapter IX of this handbook.

UML language can be used as a sketch, blueprint or programming language (Fowler, 2005). In sketch usage, developers use UML to communicate some particular aspects of the system being studied. In the blueprint usage, the idea is to build a detailed design for a programmer to use in coding software. Blueprints may be used for all the details of a system or the designer may draw a blueprint for a particular area. In programming language usage, developers draw UML diagrams that are compiled directly into executable code, and UML becomes the source code.

Our studies demonstrated that UML is too general to correctly address PBL domain and interdisciplinary issues (Sallaberry, Nodenot, Marquesuzaà, Bessagnet, & Laforcade, 2002). Yet, UML activity diagrams are explicitly considered in (IMS, 2003a) as useful formalisms to capture requirements and build learning specifications. A UML-based language proved to supply more support to the interdisciplinary team of developers

by means of well known (but debatable) UML features: standard notation, communication power, gateway between models and implementation platforms including software components and services.

Thus, we developed CPM, a specialization of UML language for PBL which we implemented by means of a profiling mechanism (OMG, 1999). This language addresses most of the design process, covering the different stages of conceptual and functional designing. This was a matter of differentiating two target audiences.

On the one hand, *educators and designers* use CPM language to draw models (similar to UML sketches) focusing initial requirements of a PBL situation including the PBL domain, situated roles of learners/teachers, learners skills, predicted obstacles which the educators want learners to overcome, goals and criteria for success within the PBL situation, resources available to learners, etc.

On the other hand, CPM language addresses *instructional engineers*. Their work involves designing a viable solution, in coordinating all the actors involved in the development team. Knowledge of UML is a prerequisite for such engineers who use CPM language to draw various models which capture different points of view or outlooks on the same PBL situation (pedagogical, structural, social, or operational). This set of models makes up the learning/tutoring scenario which can be planned (in terms of steps and learning/tutoring events) but cannot be totally predetermined at design time since PBL addresses generative learning (Allert, 2005). The blueprints they produce are expressed in terms of the concepts appearing in the sketches produced by educators, thus facilitating discussion and agreement.

CPM sketches and blueprints prepare the detailed design stage that involves mapping those agreed CPM models with platform-independent models (PIM), e.g., IMS-LD (Laforcade, 2004) or LMS abstractions (Renaux, Caron, & Le Pallec, 2005). Even though we implemented a toolset to generate Level A IMS-LD compliant models from

our CPM models, abstractions of LMSs are our favourite platform-independent models. The idea consists in mapping conceptual design models with components representing abstract views of the services provided by an LMS: such a mapping leads designers to use the CPM language in order to specialize and contextualize the services supplied by an LMS according to the specificities of the activities to be fulfilled.

The CPM Information Model

CPM relies on an information model depicted in Figure 1 (Nodenot, 2005). It is composed of three blocks:

Block 1 (gray area at the top) deals with the modeling of the situated roles played by the very actors involved in a PBL situation. *Roles* can be assigned to individuals or to groups of actors. All roles do not imply the same knowledge and know-how; according to their learning goals and responsibilities, roles will often use specific *resources* to perform their learning/tutoring *activities*.

Block 2 (gray area at the left) deals with the *work organization* (rules that can constrain the way activities will be conducted by roles). This *work organization*, including collaborative work, can be decided by designers (learning scenario) or it can be in charge of the actors at runtime. When described at design stage, the organization rules may constrain the *activities* and *resources* at the learners'/tutors' disposal. *Activities* can be further detailed in terms of *steps*, enabling designers to elicit the way important learning/tutoring events should be taken into account when they are raised at runtime.

Block 3 (white area at the bottom right) deals with the *resources* used by actors. *Knowledge* can represent activity prerequisites/post requisites, information about what can be learned from available documents, etc. A *language* is useful to the extent it forces actors to use a fixed set of vocabulary when they try to reach agreements in collaborative activities or when they are asked

Figure 1. The CPM conceptual information model

to describe what they know, what they would like to know, etc. *Documents* and *tools* represent contextualized artifacts enabling actors to conduct assigned activities.

The CPM Toolset

From the CPM information model (to be compared with the IMS-LD Information model), we first built the abstract syntax of the language (the CPM meta-model) whereas its concrete syntax was represented through the CPM profile.

The CPM Meta-Model

To construct the CPM meta-model, an interdisciplinary team started with 35 concepts and divided them into two groups. First, concepts were selected which related to the necessity for the educators to produce a PBL situation's conceptual design (using terminology from works by (Develay, 1993) and (Meirieu, 1994) and includes notions like *Learning Goal*, *Obstacle*, *Success Criterion*, etc.). Then, several concepts were identified which are useful to describe a) the learning scenario (its structure and its dynamics) or b) the tool-environment provided to actors to conduct their learning/teaching activities. These concepts are borrowed as often as possible from the IMS-LD terminology (e.g., *Activity*, *Activity-Structure*, *Role*, etc.). They are

located in packages and sub-packages (see Figure 2): the *CPM_Foundation* (defined as a subset of UML 1.5) and the *CPM_Extensions* which adds the necessary concepts needed to describe PBL situations.

Among CPM extensions, cognitive concepts necessary to trace the learning/tutoring behaviors of the actors are included in the *PedagogicalPackage*. This package deals with information used to model the components of a PBLs: misconceptions of the learners, predicted obstacles that a teacher wants the learners to overcome, goals and success criteria of the PBLs, resources available to the learners, etc. The *StructuralPackage* includes

Figure 2. The packages of the CPM meta-model

concepts necessary to describe the PBL scenario and to break it down into simpler learning/tutoring activities. Lastly, the *SocialPackage* deals includes all the concepts necessary to manage co-operative work including sharing of resources and of learning/tutoring activities.

There are interconnections between the concepts within these packages. Figure 3 presents two extracts: on the left, a *Structural Package* extract and on the right a *Social Package* extract. Grey concepts refer to elements from the *CPM_Foundation* package (see UML 1.5).

- *ActivityConcept* particularizes the UML concept of operation; it is a general concept to depict any hierarchy of activities.
- *LearningPhase* is used to sequence a learning scenario; its semantics are close to the *Act* IMS-LD Concept, except that an IMS-LD *Act* can only be broken down into one and only one sublevel. Since it specializes the *ActivityConcept*, the *LearningPhase* concept can be used to describe a scenario with a hierarchy of acts including a hier-

archy of scenes from which different roles will carry out particular activities.

- The *ActivityStructure* and *Activity* concepts are also specializations of *ActivityConcept*; they respectively represent a group of activities and a particular activity assigned to one role. Activity Structures can be of different types (i.e., the *structureKind* meta-attribute).
- The *CollaborativeActivity* concept also specializes the *ActivityConcept*; the meta-model states that such an activity is performed by one and only one role (a role can be assigned to a group of concrete actors). Cooperation is not explicit in our meta-model since we decided to describe cooperation by means of role sharing and resource sharing (i.e., the CPM conceptual information model presented in Figure 1).

The CPM Profile

To enable designers to draw diagrams that are consistent with such a meta-model, we implemented

Figure 3. Interconnections between the concepts of the CPM meta-model packages

the CPM profile. A profile uses the extension mechanisms of UML in a standardized way, for a particular purpose. It merely refines the standard semantics of UML by adding further constraints and interpretations that capture domain specific semantics and modeling patterns.

Like any UML profile, the CPM profile promotes *Stereotypes* which are defined for each specific meta-class of the UML meta-model. Thus, for each concept of the *CPM_Extensions* package, we defined a particular stereotype attached to a specific UML meta-class (the Base meta-class) which the CPM concept directly or indirectly particularizes. We also defined alternatives which are other UML meta-classes to enable designers to use a CPM concept in alternative UML diagrams than those suited to its Base meta-class. For example:

- A *Role* is a stereotype defined for the *UseCases::Actor* meta-class (i.e., Figure 5) (a UML actor is something or someone who supplies a stimulus to the system operations).
- But we also promoted alternative meta-classes (i.e., Figure 6): *ActivityGraphs::Partition* (to enable designers to use the CPM *Role* concept in UML activity-diagrams), *Core::Classifier* (to enable designers to use the CPM *LeaningPhase* concept in UML Class Diagrams).

This mechanism which was already used in OMG(2002a) means that *ActivityGraphs::Partition* and *Core::Classifier* are proxy notations of the *UseCases::Actor* meta-class.

Icons are associated with stereotypes to reduce the designers' cognitive load and to enhance visual appropriation of the CPM models. Tagged values are attached to the different stereotypes; they represent meta-attributes (e.g., *phaseKind*, *structureKind*, *roleKind*, etc.) of the *CPM_Extensions* concepts.

We provided designers with an authoring environment supporting CPM language. This was developed alongside the *Objectteering/UML* CASE tool. This prototype allowed us to verify the coherence between the CPM profile entities (concrete syntax) and the CPM meta-model meta-types (abstract syntax). It also enabled us to store complete case studies (e.g., the SMASH case study) as well as reusable design patterns in the objectteering shared repository. The current release of this CPM language is available within a module that can be integrated in and used with the free-of-charge-version of the *Objectteering/UML Modeler*.

In the next sections, we shall denote a CPM stereotype with the << >> symbol (e.g., the <<activity-structure>> stereotype. A UML metaclass will be highlighted in italics (e.g., the *ObjectFlowState* metaclass). For the purpose of the case studies that we shall be presenting here, model elements which are instances of the CPM stereotypes will appear in italics (e.g., the *Testimonies analysis* <<activity-structure>>).

REAL WORLD CASE STUDIES DESIGNED WITH THE CPM LANGUAGE

Chronologically, we started with the SMASHPBL situation that addresses 10 to 12 year- old pupils who must piece together eye-witness accounts to identify the causes of a bicycle accident. We set up an interdisciplinary team including two teachers, two CPM specialists, and two developers mastering the Moodle LMS. This team used CPM language to formalize the teaching/learning objectives, to imagine and to detail a cooperative learning scenario that could take advantage of available communication tools (chat, forum, etc.). The proposed scenario was then tested in real conditions during four half days within a classroom where groups of pupils assisted by their teacher

had to cooperate according to the constraints of the specified learning/tutoring activities (using dedicated resources—see Figure 3). Dedicated tools (e.g., a dedicated e-whiteboard to help pupils share their understanding of the actors' spatial position when the accident occurred) were then developed to support learners activities; the scenario was then partly implemented for the Moodle LMS.

Proposed by Vignollet, David, Ferraris, Martel, and Lejeune (2006), the PLANET-GAME case study focused on the didactic transposition (see the initial requirements analysis in Figure 2; see also the account in Chapter XII) of a learning game about astronomy. Assisted by a primary teacher, we used CPM language to describe the conceptualization level that 12 year-old pupils can reach and, in the meantime, we selected different scientific properties of these planets: their distances from the sun, their day durations, their year durations, their compositions, their average temperatures, etc. This domain study led us to set more detailed learning/tutoring objectives from which we defined a learning scenario and tutoring strategies (Nodenot & Laforcade, 2006).

The GEODOC case study is an on-the-road project that leads us to formalize CPM scenarios putting the focus on learning/tutoring objectives dedicated to text comprehension as applied to geography. Learning activities which we formalized with CPM language include actual and inferential questions about what is being read (identification and localization of toponyms, topological identification, mapping-out of routes, etc.). This project investigates not only the specialization of LMS services according to formalized learning/teaching scenarios, but also the use of on-the-shelf computational applications in relation with the taught domain (e.g., *Postgis* and *GoogleEarth*).

In the next section, we briefly present the script of a learning scenario and we refer to the figures denoting the CPM diagrams produced in the course of the design of such a scenario. This

will help us give concrete expression of the lessons learned from CPM language.

The Act 2 of the SMASH PBLs: What is this Scenario About?

During *Act 2* (i.e., the IMS-LD terminology), learners (who were previously divided into different groups) have to analyze allocated testimonies. While some groups (that is, *Investigator role 1 to 3*) have access to a limited set, others can read the full set of testimonies (i.e., *Investigator role 4*). The scenario leads all groups (there are several concurrent groups playing *Investigator role 1 to 3* while a unique group of learners plays the *Investigator role 4*) to exchange information about what they learned/understood from the accounts of the testimonies (each group will produce a *belief graph*) and then to write a single *accident report* that all groups must finally acknowledge. The learning scenario is supervised by the *Session manager role* and by a tutor (i.e., the *PoliceChief role*) whose job is to help learners develop an exhaustive analysis of the available testimonies at their disposal.

From a pedagogical viewpoint, such scenario script encourages the groups of learners to confront their own ideas of road safety (knowledge, know-how, attitudes) with the safety rules promoted by road regulations (Highway Code).

In the subsequent text, the reader will find several figures produced with CPM language to specify the *Act 2* learning scenario. The model elements produced during the design process were all stored in the repository provided by the *Objectteering* UML Case tool (i.e., Figure 5) from the set of CPM diagrams produced by the ID Team in charge of the project. Each model element stored in the repository can be used in several diagrams: use-case diagrams, class-diagrams, activity diagrams, state-machines diagrams, etc. Among the different diagrams that were produced

in the course of this project, the following were chosen for this chapter:

- Figure 6 and Figure 7 describe the roles taken by the actors and the coarse-grain activities they performed during *Act 2*.
- Figure 8 describes the resources that *Investigator role 1* can use and produce when performing their dedicated activities.
- Figure 9 details the sequencing of the different coarse-grain activities and the conditions that resources must fulfill to accept transitions from one activity to another.
- Figure 10 and Figure 11 detail the *Testimonies Analysis* <<activity-structure>>.

In the next section, we shall use these figures to elicit the lessons that we learned about CPM language usability. However, from the information given about *Act 2* in this subsection, we strongly encourage the reader to begin by analyzing the semantics conveyed by this set of interrelated CPM diagrams.

Lessons Learned from CPM Language

This section presents the lessons we learned about the usability of CPM language to edit/produce a learning scenario. From the three case studies summarized above, we drew two important lessons:

- Although CPM adopts the jargon that many pedagogues and educational designers already use, producing a set of coherent CPM models for a given case study is still a complex activity.
- Even though most pedagogues are not able to produce a set of CPM coherent models by themselves, both pedagogues and developers can contribute to and benefit from such design models.

Several observations led us to formalize these lessons. To give concrete expression to these observations, we shall rely on CPM models from the SMASH PBL; we shall particularly focus on the *Act 2* learning scenario (the end of the previous section) leading learners to investigate the causes of a bicycle accident from a set of eye-witness testimonies:

Lesson U1: *Although CPM adopts the jargon that many pedagogues and educational designers already use, producing a set of coherent CPM models for a given case study is still a complex activity.*

During the conducted case studies, we noticed that designers encountered difficulties when seeking to organize efficiently the different kinds of model elements that they were eliciting at design time (see Lesson U1, Observation 1). From the analysis of encountered difficulties and observed solutions, we propose a structuring model, which proved useful to organize the different model elements under study within cohesive packages.

We also noticed (see Lesson U1: Observation 2) that without human assistance, most educational designers did not know which notation was the most appropriate to represent their design intents. Yet, when the same educational designers gained experience about both the UML notation and about the CPM meta-model, most could produce expressive yet simple CPM diagrams.

Finally, Lesson U1—Observation 3 shows that designers were sometimes frustrated because they were confusing CPM with a drawing tool: in particular, some did not clearly understand why the provided toolset (editors and wizards) considered some diagrams whose model elements did not conform with the CPM meta-model as erroneous.

Lesson U1, Observation 1: *Relevant model elements must be conveniently organized by designers within packages. CPM diagrams must also be attached to packages.*

Real world case studies that we specified with CPM language had in common that they could not be mastered by a single designer. All the modeling elements could not be represented in the same UML class diagram; learner, tutor roles, learning goals and success criteria had to be contextualized according to the steps of the learning process; both dynamics and structure of resources and activities had to be specified, etc. Relying on our experience in designing such case studies, we argue that in most cases, what is needed is an approach that structures the design of complex learning scenarios at different levels.

Packages are UML constructs which enable the grouping of model elements, making UML diagrams simpler and easier to understand. Packages themselves may be nested within others; they are depicted as file folders and may be Subsystems or Models. When we designed CPM language, we decided to provide designers with two stereotypes (see caption in Figure 5 which extends the *Package* metaclass: the *Learning Process* stereotype to break down the learning process into subprocesses and the *Learning Package* stereotype to group other model elements. In the course of our case studies, we learned efficient ways to exploit these stereotypes for organizing model elements. For instance, Figure 5 describes the packages used in the SMASH PBLs:

This is a snapshot of the browser which enables a designer to edit the SMASH learning scenario. At root level, experience led us to create three learning packages whose model elements are exploited by the *Learning Process* package called the *SMASH Scenario Process*. At the bottom of the figure, worth noting is the *SMASH Scenario* denoted as an activity diagram used to generally describe how the different acts of the *SMASH Learning Process* are sequenced.

The model elements (and graphical views) of these four acts are then detailed within the *SMASH Scenario Process*.

In the snapshot of Figure 5, the details of the *Act 2 Process* were expanded. At this level, it

will be observed that the package structure is the same as the one at root level: Act 2 shows a *Local Roles Package*, a *Local resources Package*, a *Local Learning Roles Package*, and an *Act 2 Scenes Package* which contains all the scenes within Act 2. This structuring promotes the contextualization of roles, learning goals, resources and learning activities. For example, the expanded *Act 2—Local Roles Package* shows different *Actor* stereotypes, which are model elements used during Act 2 to specialize the tutor role and the Learner role (i.e., the *Global Roles Package*).

It is worth noting that this approach is in tune with Derntl & Motschnig-Pitrik (2007), which encourages designers to elicit hierarchies of both learning goals and documents.

Lesson U1, Observation 2: *Among available CPM diagrams, designers must adequately choose those which can help them to produce some simple yet coherent perspectives of the relevant model elements.*

First, let us recall that UML is a language enabling designers to describe an abstraction of a system that focuses on interesting aspects (models) and ignores irrelevant details. A perspective (view) focuses on a subset of a model to make it understandable.

Choosing UML to describe learning scenarios requires rethinking current uses and to elicit new uses of UML diagrams for dealing with the complexity of learning scenarios. From an educational point of view, a learning scenario is a system that must be described in terms of learning roles, learning goals, resources made available to the learners, learning and tutoring interactions/activities, events used to regulate learners' activities, etc.

From previous works (Sallaberry et al., 2002) we predicted the new uses of UML diagrams that CPM language encourages. As stated in the section devoted to the presentation of the CPM profile (see Figure 4), a CPM stereotype such as the <<Role>> Stereotype can extend either the

Figure 4. An extract of the stereotypes provided to designers by the CPM profile

Stereotype	Metaclass	Icon
Activity	Core::Operation

Role	UseCases::Actor	
	ActivityGraphs::Partition	
	Core::Classifier	

Actor metaclass (to represent it in use-case diagrams, or the *Partition* metaclass (to represent it in Activity diagrams) or the Classifier metaclass (to represent it in Class diagrams).

During the course of our experiments, we noticed that designers (educators and computer-scientists) encountered two types of difficulties when trying to map their design intentions with available notation (those provided by the different types of diagrams available). First, most designers were inclined to start from a visual notation (e.g., the notation for class diagrams) and then tried using this specific notation to represent all perspectives of the model being studied, even if such a notation was not convenient for all aspects of the model. Second, we noticed that designers had questions about the notation they would be advised to use, particularly at the beginning of a learning scenario design process.

The case studies we have conducted provide useful answers to these difficulties. Let us focus on the intention, “role models involved in a learning scenario.” If we consider the CPM information model given in Figure 1, designers should address different perspectives for roles. What are these?

How are they involved in the *Work Organization* that the learning scenario promotes? What are their responsibilities in the various (possibly collaborative) activities suggested to be performed in the scenario? What kind of resources do they exploit to carry out such activities? Applied to Act 2 of the SMASH PBLs, Figure 6 and the following are CPM diagrams which focus on the different perspectives listed above.

In Figure 6, SMASH roles specialize the *Class* metaclass. This class diagram shows that the *Learner* role and the *Tutor* role (from the *Global Roles Package*) were specialized to enable designers to denote all actors playing an important roles during Act 2. All roles are played by human beings except the *PoliceChief* role (we chose a detailed view of the *Tutor* role model element to make the *roleKind* tag-value visible). Figure 7 offers another perspective for these SMASH roles:

In this use-case diagram, roles specialize the *Actor* metaclass. This perspective focuses on the activities carried out by roles during Act 2. Each *role* either *performs* activities or *assists* other roles performing those activities. Like in IMS-LD, activities that can be broken down into simpler ones (e.g., *Testimonies analysis*, *Time and document management* or *Production of the investigation reports*) are depicted with the stereotype <<Activity-structure>>.

Figure 8 is another class diagram which designers sketched to focus on the resources used and produced by each role during Act2 (there is a dedicated class diagram for each leaf role that appears in Figure 6). Resources which are produced have the tag-value *output* while others have the tag-value *input*.

The different figures provided in this section clearly show that the different perspectives provided to describe the roles in Act 2 are complementary (all of them can be reached from the model elements browser presented in Figure 5). Other types of diagrams will be presented in Figure 10 (an Activity diagram) and in Figure 11 (a state-machine diagram) to respectively detail

Figure 5. The SMASH PBL browser

the *Testimonies analysis* model element and the beliefgraph model element that appeared in Figure 7 and Figure 8.

These figures also show that UML notations must be understood by designers to enable them to produce simple yet coherent perspectives of the learning scenario being studied. Table 1 provides a synthesis of the practices we noticed during our case studies. To build this table, we took into account only diagrams which appeared in the last version of the design produced for each of our case studies.

The reader may be surprised that we do not recommend the use of the object diagram for the definition of roles and of resources. In fact, experience led us to consider that concrete roles appear only when the scenario is deployed on a platform (LMS) and used by concrete (groups of) learners. It is only at deployment time that the *Investigator role 1* stereotype is instantiated and played by concrete learners. And for similar reasons, the resources produced and used by *Investigator 1* are represented as classes (i.e., Figure 8) and not as objects.

Lesson U1, Observation 3: To succeed in producing a perspective, designers must agree on both the UML notation and the CPM meta-model which

Figure 6. A class diagram representing a hierarchy of SMASH actors

State Machine Diagram	Description of the active classes (resources, roles, learning goals, activities)
Object Diagram	Instances from the domain model (concepts being studied, knowledge and know-how that learners must acquire)

both define the rules that the model elements in a CPM diagram must fulfill.

During our experiments, designers were at first surprised (and a bit confused) that they were constrained by both the rules of UML notations and of the CPM meta-model. On the one hand rules from the UML notations, they could not add, for example, any information about the timeline in the class diagrams being sketched. On the other hand, the CPM meta-model forced them to respect, for example, the following rule: when the <<activity>> and the <<resource>> stereotypes both extend the *Classifier* metaclass (i.e., the class diagram in Figure 8), connection links between such stereotypes must be of type <<Relation>> (the tag-value can either be *input* or *output*). Most designers did not understand such CPM rules, because they did not realize that the same stereotype (e.g., the <<activity>> stereotype) could represent different metaclasses when used in different types of diagrams. For example, in Figure 7, the *Testimonies analysis* model element extends the *UseCase* metaclass while, in Figure 8, it extends the *Classifier* metaclass (i.e., Figure 4 for the available metaclasses of the CPM stereotypes).

The three types of observations presented in this section show that designers need time to gain the necessary experience required to relevantly exploit the CPM language. Our experience also showed that educators can understand the meaning of a set of CPM diagrams but that the (semi) formal nature of CPM language could hinder some educators' commitment in producing such visual designs. They ask for cognitive assistance during the design process: since CPM editors do not allow free drawing, designers require some feedback enabling them to do some opportunistic productions: to-do lists, checklists, wizards, etc.

The first cognitive tools developed were contextual menus that could infer the metaclass to be used from the knowledge of both the diagram type and the stereotype chosen by the designer. In the

framework of our latest project (the GEODOC case study), we also provided designers (educators and computer-scientists) with the best-practices of CPM diagrams and with a set of sample CPM diagrams for each design intent listed in Table 1. Our first experimental results show that such a design team was more efficient (time and design quality) than another team that did not have such documents at their disposal.

But it is already clear that our toolset is still a research prototype that proved expressive capabilities but cannot be distributed to an interdisciplinary team without care and human guidance. Even though the current state of research presented in this section can provide substantial support in understanding PBL scenarios, in designing and documenting new scenarios, it is clear that our approach is specified by rather technically oriented computer science people and a lot of work is still necessary to transform educators into CPM autonomous designers.

Lesson U2: *Even though most pedagogues were not able to produce a set of CPM coherent models, both pedagogues and developers can contribute to and benefit from such design models.*

Through educational expressivity of CPM diagrams, Lesson 1 pinpointed some difficulties encountered by designers who used the CPM toolset. In this section, we present some methodological principles which can help an ID team control the design process complexity.

In the course of the conducted case studies, we first observed that, at any level of the learning scenario analysis (conceptual design, functional design), designers might produce simple yet expressive CPM diagrams (i.e., Lesson U2, Observation 1): it is a matter of focusing on one and only one perspective at a time.

We also noticed that a correct stratification of the learning scenario was important (i.e., Lesson U2, Observation 2) to ensure a smooth transition

between the perspectives drawn during learning scenario conceptual design and those drawn to address the functional design of a TEL system that could manage such a learning scenario at runtime.

Both observations will lead us to elicit a design process in tune with CPM language characteristics.

Lesson U2, Observation 1: *Complexity of models can be mastered by designers using the following rule: Design only what is necessary for a given purpose and recognize overdesign.*

Our experience is that most pedagogues can concretely draw various CPM diagrams if they keep in mind that each diagram should focus on one perspective that remains simple and expressive. Consider the *Testimonies analysis* model element which appears in Figure 7 and in Figure 8. None of these perspectives provides information about the activity sequencing planned during *Act 2*. Adding such an information within Figure 7 is difficult since use-case diagrams are not suited to the description of activity sequencing: in general, UML specialists add OCL constraints (OMG, 2002b) to address such difficulty. Drawing another perspective focusing on such activity sequencing is much easier as stated in Figure 9:

In this figure, the reader will notice all activities and all activity-structures that already appeared in the *Act 2* use-case diagram presented in Figure 7: these model elements are grouped together according to the scene during which they are performed by these actors. The information flows between states as *ObjectFlowStates*: these represent some events that should be true either at the beginning (prerequisite) or at the end (post-requisite) of each scene. These different scenes (e.g., the *Act 2- Scene 2 process*) are structuring model elements that can also be easily located in our SMASH Browser (i.e., Figure 5).

We consider that such a diagram can also illustrate what over-design means. At the conceptual design level where educators play the most important role, it would be useless to try to represent exception-handling in such a predicted learning scenario. At runtime, such a script can raise many exceptions (potentially meaningful for educators) that need to be managed (particularly those in relation with *the Time and document management* <<activity-structure>>). But adding exception handling in such a diagram would be likely to complicate the perspective and could mask the key ideas of the scenario, which were already spotted in Figure 9.

Figure 9. An activity diagram describing the sequencing of the activities performed during *Act 2*

As a consequence, we consider that educators relying on CPM for conceptual design should strive for an 80% solution: at this stage, visual design should be used to represent the intermediate and then the final results of the design, thus providing means of communication between educators and computer scientists. All diagrams presented above are still intermediate results of design which helped educators clarifying and sharing their initial ideas.

CPM activity diagrams are other important perspectives to consider because they are a (natural) bridge between the use-case diagrams (which are useful to represent educational roles, goals and activities) and the class-diagrams (that developers need to implement required functionality on a learning platform). During our experiments, such diagrams represented an interesting communication trade-off between our business logic experts (educators and interaction designers) and information technology experts (software designers, learning platform specialists, etc.).

For example, Figure 10 is an activity diagram that details the *Testimonies analysis* <<Activity-structure>>.

Three swimlanes are used to identify the specific activities performed by each role; these swimlanes are consistent with the roles assigned to the *Testimonies analysis* <<activity-structure>> in the use-case diagram presented in Figure 7. In

Figure 10, we can notice that the *Testimonies analysis* <<activity-structure>> exposes four activity-structures (e.g., the *Analysis available testimonies* <<activity-structure>>) that can be further detailed using a top-down approach, some collaborative activities (e.g., *Replies to Questions asked* <<collaborative activity>>), some resources (e.g., the *Belief Graph* <<Resource>> to be assessed when it is updated by any real actor playing the <<role>> called *Investigator role 1 to 3* to 3).

Figure 10 also denotes how designers can describe collaborative activities (i.e., activities with a *c* flag); in the scenario, *Investigator role 1 to 3* cannot initiate any synchronous conversation but this role can read information and answers questions asked by *Investigator role 4* (at implementation stage, and will lead developers to specialize a chat service according to these requirements).

An *ObjectFlowstate* denoting a <<Resource>> can be described with a UML State-machine diagram. For example, Figure 11 represents the lifecycle of the *Belief Graph* model element elicited in Figure 10.

The underlying semantics is the following: each time an investigator adds a belief in his belief graph (e.g., a representation of the following belief: “the white car bumped into the back of the bicycle”), the state of the belief graph

Figure 10. An activity diagram to represent the details of the *Testimonies analysis* activity-structure

Figure 11. A state-machine diagram to represent the lifecycle of the Belief Graph <<resource>>

changes to “to be assessed” (since the *PoliceChief* role is played by a machine—that is, the class diagram in Figure 6, such a decision will entail particular design concern about the assessment process elicitation).

We noticed that educators encountered various difficulties when seeking to draw some CPM activity diagrams by themselves. It is true that these diagrams are not simple to create but they allow complex system/interaction processing to be represented efficiently. In order to get round this obstacle, we advised educators to produce a use-case diagram (in our example, a use case-diagram detailing the *Testimonies analysis* <<<activity-structure>>>) for identifying the activities of interest and their relationships; information technology designers used such sketches for discussion purposes with them; and together they produced the final 80% solution presented in Figure 10. Interestingly enough, once this deadlock was broken, educators were able to go further in the conceptual design process.

From this set of observations, we learned that when using CPM diagrams for modeling a learning/tutoring scenario, it is important to capture the requirements at a high level of abstraction. Whatever the diagram, the perspective must remain simple. Such an approach allows designers to emphasize important model elements while hiding low-level processing details. Indeed, such details may even obscure the model’s true purpose, which is:

- To identify key activities and dependencies
- To promote exchanges and communication in the ID team.

This is particularly true when drawing activity diagrams. In our experiments, some of these proved to be potential deadlocks that frustrated most educators during the design process. Dedicated cognitive tools (wizards, to-do-lists, etc.) could probably give them more confidence; but we consider that the correct answer will rely on efficient communication in the ID team. With this in mind, sketches (even when they represent intermediate design results) can now play a central role in enhancing such communication.

Lesson U2, Observation 2: *CPM contributes to producing both stratified and multiple perspectives for a given learning scenario. This combination is a key-factor to enable a designer team to collaboratively determine the constraints under which a Technology-Enhanced Learning (TEL) system is to be designed.*

UML is a widely accepted language to describe software systems. With the different perspectives of a TEL system that CPM offers, our profile adopts the same fundamentals (UML notation, UML semantics which we specialized with the CPM meta-model semantics) to also describe the educational context:

- At conceptual level, the language addresses the need to manage educational requirements effectively.
- At functional level, the language addresses the need to describe the required functionality of a TEL System in tune with such educational requirements.

Whatever the design level (conceptual vs. functional), it is very important therefore to communicate design decisions (and understanding) in an unambiguous form to all partners involved in the ID Team (including educators, information technology specialists and platform of learning developers).

In the previous subsections, we showed that CPM enables designers to produce multiple perspectives for a learning scenario. These perspectives favor coherent, unambiguous (within the limit of the UML semantics) but intelligible design decisions. The conducted case studies have also demonstrated that to reach such a goal, these multiple perspectives of a learning scenario should be correctly stratified. During the GEODOC case study, we noticed that, from the very beginning of the design process, some geographers were trying to map some educational goals with functionalities of the Geographical Information System viewer which they had been used to working with previously. Such design decisions were problematic because on the one side, educational goals had yet to be further detailed and on the other, such a detailed analysis failed because the designers were mixing conceptual and functional model elements.

The main gains of a correct stratification are modularity and design simplicity (i.e., Lesson U2-Observation 1 in the previous subsection). Modularity allows easier adaptability when changing requirements; it also allows clear separation of the domains of trust. By starting with the most fundamental educational factors (conceptual design) and designing them to be contextually appropriate, we were able in the course of the conducted case studies to build successive layers design and eventually reach functional design.

Figure 12 is an activity-diagram which exemplifies the frontier between conceptual and functional design. In this figure, some activities denote a <<CPL>> stereotype that represents a functionality offered by concrete software components. Such components may be those provided by most learning platforms (e.g., a

quiz component, a lecture component, a forum component, a whiteboard component, etc.) or they may be specialized components in relation with the domain to be taught (e.g., a Geographical Information System viewer).

In Figure 13, the <<CPL>> stereotypes denote different functionalities that specialize a forum component: Depending on his role, a concrete actor will register differently; the teacher role has rights to add a topic in the forum while the learner role can write entries for the topic that is currently covered.

Both figures were produced in SMASH PBLs to denote the Reciprocal teaching pattern (Palincsar and Brown 1986). The term “reciprocal” describes the nature of the interactions each person has in response to the other(s). Teacher and student take turns assuming the role of a dialogue leader (see Figure 13); sequencing of the concrete activities performed by both roles is formalized by the dedicated swimlanes in Figure 12. The ID team chose this pattern because the designers wanted the students to improve their reading comprehension of the available SMASH testimonies; the designers also wanted them to learn to monitor their own learning and thinking. Thus, in SMASH PBLs, learners’ peers are key actors in the reciprocal teaching pattern. These actors successively play the role of the teacher and the role of the student when trying to understand texts or interviews. Figure 12 details how they move from one role to another and what the responsibilities of each role within the collaboration are. For each text (interview), the teacher role has to select one text. The specification states that the teacher role is the one that formulates statements about his reading and understanding but that the student role is the one that can ask questions and which, at the very end of the discussion, will formulate the agreed statements that can be inferred from the reading.

Detailing how such functionalities should be implemented in a specialized forum is outside the scope of CPM. But the layered nature of CPM

Figure 12. An activity diagram for the reciprocal teaching pattern

Figure 13. UML state-machine diagram describing both steps of the reciprocal teaching pattern

contributes to the smooth (top-down or bottom-up) transition between the different domains of trust.

Both lessons presented in this section lead us to the following conclusions: even though CPM was specified as a language and not as a design method, experience gained from our case studies enables us to promote a design process in tune with the characteristics of the CPM language. UML is a language; so is CPM. Current object-oriented

methods focus on the specification of the static structure of software objects. A noticeable deficiency of these methods is that they do not provide any help on how requirements are refined, how class diagrams can be derived from scenarios, how to specify the active/dynamic parts of a system, or how such a specification may be transformed into an implementation.

During conceptual design, the analysis of the different case studies that we have conducted promotes the idea of bridging the gap between educational needs elicitation (including requirements elicitation, requirements refinement using a combination of use-case diagrams, of activity diagrams, of class diagrams and state-machine diagrams), and the more formal specification of class diagrams which are required to prepare the implementation of a TEL System (Nodenot, Marquesuzaà, Laforcade, & Sallaberry, 2004). The way we used CPM language is as follows. The specification process starts from the definition of use-cases. Each use-case diagram is refined either by other use-case diagrams or by one or more activity diagrams (representing teaching/learning scenarios). All model elements used in these diagrams are not unrelated parts; they are attributes, messages, etc. which are finally declared in the class diagrams. The behavior of each class is represented by a set of scenarios (activity diagrams/state machine diagrams) covering the events declared in the specification part of the class.

CONCLUSION AND PERSPECTIVES

CPM is a visual, layered, semi-formal, multiple perspectives language dedicated to the description of collaborative learning scenarios with special emphasis on problem-based learning (PBL). By means of the layering mechanism, designers may more easily tackle a complex situation using this graphical and conceptual feature: they start with a coarse-grained description to grasp the global situation and can then decompose each element to get a complete and detailed description (Lesson U2 Observation 1). Next, with the multiple perspectives mechanism, the designers may focus on the sequencing of activities, the behavior of a particular activity, role responsibilities, *etc.* A complex situation may be described through a set of simple and clear views (Lesson U1—Ob-

servation 2). Equally, the combination of these two mechanisms promotes collaboration within a team of designers (Lesson U2—Observation 2). Finally, as CPM is dedicated to a specific type of learning situations, it allows the designer using it to be more likely to be able to describe such situations more quickly than with more general educational languages like IMS-LD. According to model-driven approaches like OMG-MDA (OMG, 2003), these specialized (but limited) languages offer conceptual frameworks for preliminary analysis of learning situations before transforming the resulting models into more operational languages.

Lessons presented in this chapter also reveal some possible ways to improve CPM.

Improvements of CPM

Computer Support for Design Processes

Modeling learning situations is not an easy or usual task for practitioners. Among the several reasons that account for this, we might mention the two most obvious ones. First, practitioners seek to adapt their courses to learners *in situ*, as events occur/happen (opportunistic approach) and they tend to prefer to think in terms of content and coarse-grained activities. Second, in educational sciences, models are driven by learning events to detect and to react upon, rather than by a mere sequence of activities which are more typical within the computer world (i.e., workflow sub-domain). So practitioners are not used to getting involved in highly structured course modeling in their everyday routine. Because we are aware of this, we have already proposed guidelines related to CPM through ‘best-practices’ (Lesson U1-Observation 2) and a design process (Lesson U2-Observation 3) in order to help practitioners. Kent (2002) already pointed out the problem of ‘how to define a model’. He defines it as a

main hindrance for the emerging model driven engineering trend. While he generally highlights work about macro-processes ('the order in which models are produced and how they are coordinated'), Kent affirms the need for the MDE community to work on micro-processes, that is to say 'guidelines for producing a particular model'. We consider therefore that we need to improve *CPM micro-processes*. A related perspective must be to provide a computer support for our guidelines. First, such a support will make the application of guidelines easier (and accelerates it). Next, it limits the occurrence of errors caused by the misinterpretation of guidelines. Finally assisting the definition of a model allows designers to learn guidelines in a better way than by only reading the related document.

We have already worked on the computer support for a method dedicated to IMS-LD (Le Pallec, Moura, Marvie, Nebut, & Tarby, 2006). We intend to transpose this previous work to CPM.

Templates

Starting from scratch is another barrier to practitioners when defining models. The *Objecteering* repository provides a way of reusing existing and approved fragments of CPM models (i.e., Figure 12). UML templates address this issue much better. A UML template is a set of parameters to be applied to model elements before use. Such models have the advantage of clearly rendering explicit both the fixed part and the changing part of a model. Equally, defining a template is driven by reusability and modularity which is not the case when defining new model elements duplicated with copy/cut/paste. The application field of a template is consequently broader. However, using this mechanism, particularly when defining a template, is not an easy task, especially for a non-UML specialist. Even if *Objecteering* may provide a UML template mechanism, future work will likely involve embedding it into a more user-friendly interface.

Model Transformations

The different CPM perspectives are not entirely bound together. The attribute *Testimonies analysis* of *Investigator role 4* (i.e., Figure 10) is not automatically but manually 'deduced' from the link *performs* between *Investigator role 4* and *Testimonies analysis* (i.e., Figure 7). If the link *performs* is removed, the previous attribute will not be automatically removed. Not to impose constraints about the ubiquity of model elements can provide much freedom, and hence flexibility while defining models, especially for practitioners. But in addition to being a source of mistakes, it does not render explicit the repercussion of each action which the designer is performing. To address these two problems, we might consider, for example, developing dynamic transformations between all perspectives so that each action from a perspective should induce logic repercussion on other perspectives. These transformations would be proposed to designers through clickable operations.

Towards Other Conceptual Frameworks

UML and its profile mechanism offers a framework which may prove quickly efficient. First it provides several types of diagrams which enable many aspects to be described. Second, several design processes have emerged from the UML community over the last decade. They describe best-practices related to navigation between previous types of diagrams. Nevertheless, there are some weaknesses. First, defining new modeling concepts with a UML profile requires using (through inheritance) existing UML metaclasses like *Class* or *Actor*. UML profile designers do not necessarily need all inherited attributes or methods. They have to block access to these undesirable properties both in conceptual and graphical ways to respect the semantic of the language they are

designing (this can be achieved through OCL constraints or through *Jcode* (Objectteering, 2006) in case *Objectteering* is used). It is a complex and tedious process if we consider the definition of graphical languages for complex, condensed and non-software engineering meta-models (like IMS-LD). In addition, an efficient profile (that is to say, with conceptual and graphical filtered accesses) generally works only with the UML tool used to define it.

Lastly, for the time being, it is difficult to provide practitioners with a totally free UML-based model editor given that UML efficient tools are still expensive. Moreover using a UML profile means requiring the use of a whole software engineering oriented environment which may constitute a handicap for practitioners.

It is therefore important to explore alternatives like OMG-MOF (OMG, 2007) or Eclipse/EMF (EMF, 2007) environments. Based on a meta-modeling approach, they present some advantages. For example, defining a language starts with defining a meta-model (abstract syntax) which is not created from existing concepts but from scratch. So, there is no need to filter access to model elements because of undesirable inherited features. Another useful functionality of EMF is that creating a meta-model may be done simply by analyzing an XML schema or a DTD. Additionally, there are currently powerful graphical tools like TopCaseD (Farail et al., 2006) and the forthcoming GMF (GMF, 2007) which both allow defining an efficient graphical syntax for a language (concrete syntax). There are of course other facilities which are not as efficient in the UML community, like model transformation engines (GMT for Eclipse (GMT, 2007), YATL for MOF-based models (Patrascioiu, 2004)) and code generation engines like JET (JET, 2007).

But we believe it is still very important to see beyond technology and to maintain a global awareness of how organizational, social and technical issues are impinging on the usability of VIDL.

Chapter 1.13

History of Distance Learning Professional Associations

Irene Chen

University of Houston Downtown, USA

INTRODUCTION AND BACKGROUND

Most of the distance-learning professional associations were founded in the 1990s, at a time when most Internet backbone speeds were T1 or slower. Although scientists in universities, corporate, and military used the Internet for supercomputing capabilities, the predominant academic application was electronic mail. The public was generally unaware of the Internet's existence.

The explosive growth of information and telecommunications has combined to strengthen and diversify the options for school, skills development, technical and professional training, postsecondary credit courses, and special interests. New associations are established everyday to promote innovative educational strategies, as well as ways to leverage technology to provide new ways

of learning online. Each strategy suggested has some measure of support among the professional associations' participants, and represents a way to improve opportunities for distance education, and training:

1. Developing strategic alliances to support and encourage project-oriented coalitions amongst members as the need and opportunity arise.
2. Recommending standards of quality
3. Institution promotion under a common logo within the region and beyond
4. Identifying support markets that are currently unserved.
5. Sharing technological and human resources for development and delivery
6. Conducting applied research and development of distance-education technology and instructional design.

DOI: 10.4018/978-1-60960-503-2.ch113

7. Developing and maintaining a system to provide a central source of current and relevant information on courses and programs, the credit transfer system, and student assistance programs.

MAIN FOCUS: DISTANCE LEARNING PROFESSIONAL

North America

United States

In the U.S., the Director of the Office of Educational Technology in the Office of the Secretary for the U.S. Department of Education is responsible for coordinating programs and policies on virtual education and e-learning, the National Education Technology Plan, Technical Assistance Grants under Enhancing Education Through Technology, and the use of technology to further the mission of the Department and the No Child Left Behind Act (2006).

Founded in 1987, FARNET, the Federation of American Research Networks, was a primary information source for the government and industry during the preprivatization days of the Internet. FARNET's original mission was to coordinate regional and backbone high-speed networks, to promote the general advancement of science and education by assisting in the interchange of information and research using high-speed communication.

Later on, FARNET developed into a forum for state networks to share information. Beginning in the early 1990s, FARNET hosted a series of workshops discussing how the National Information Infrastructure (NII) and the Internet might impact the public sector, including healthcare, libraries, and K-12 education.

In 1995, FARNET opened a policy office in Washington, D.C. to monitor the regulatory environment and communicated developments back

to its membership via an e-mail newsletter called "FARNET'S Washington Update."

In 1996, FARNET received an NSF award to build a clearinghouse for tracking information infrastructure development on a state-by-state basis. The purpose of the States Inventory Project (located at <http://www.states.org/>) is to promote the exchange of information among state and local policymakers so that states may develop their own information infrastructures more efficiently. The State Inventory Project clearinghouse currently has over 4,000 entries in its database, divided into nearly 100 categories for each state, territory, and province.

One of the early associations, the Coalition for Networked Information (CNI, <http://www.cni.org/timeline.html>), was founded in 1990 by the library and information technology communities to enhance scholarship and intellectual productivity. At the end of its first year, CNI has 118 member institutions. In the early years, on their meeting agenda were contemporary issues such as economics of information, Rights for Electronic Access and Delivery of Information (READI) project, Elsevier TULIP Project (one of the earliest examples of instrumented large-scale experiments in electronic journal delivery), Wide Area Information Servers (WAIS), introduction of Gopher (an early tool to find and retrieve directories of information on the Internet), Electronic Theses and Dissertations, and the demonstration of NCSA's Mosaic, the first graphical Web browser.

In 1996, CNI cosponsored a conference, Networked Information in an International Context, with the UK Joint Information Systems Committee, the British Library, CAUSE and the First ACM International Conference on Research and Development in Digital Libraries. As the result of the conference, the Internet 2 Project was launched. CNI was represented on the Applications Council to launch the Internet 2 Project, and worked closely with this effort to help identify advanced networking applications. These associations together facilitated the starting plans of Internet 2,

which is an effort to establish higher education's leadership role in Internetworking.

EDUCOM is another early organization for the enhancement of information technology in higher education. The mission of EDUCOM is as follows: "EDUCOM is a nonprofit consortium of higher education institutions, which facilitates the introduction, use, and access to and management of information resources in teaching, learning, scholarship, and research. EDUCOM's work is done in cooperation and partnership with the broader education and library communities, professional societies, and information industries."

In the 1990s, EDUCOM focused on:

1. Increasing individual and institutional intellectual productivity through access to and use of information resources and technology.
2. Assuring the creation of an information infrastructure that will meet society's needs into the twenty-first century.

EDUCOM's Networking and Telecommunications Task Force (NTTF) monitored the education telecommunications-related changes of the federal government. NTTF was created in 1986 as a vehicle to provide leadership and focus for colleges and universities in identifying and communicating strategic networking and telecommunication policy issues. Its membership is composed primarily of chief information officers from leading universities.

In 1988, NTTF organized the first in what has become an annual conference in Washington, D.C. This conference brought together leaders from government, industry and the public sector to discuss the latest developments in telecommunications policy.

CAUSE is the Association for the Management of Information Technology in Higher Education (<http://www.cni.org/docs/infopols/CAUSE.html>). The mission of CAUSE is:

- To promote more effective planning, management, and evaluation of all information technologies in colleges and universities.
- To help individual member representatives develop as professionals in the field of higher education technology management.

In direct response to the changing nature of campus computing organization and management, CAUSE expanded its mission to reflect an expansion from an earlier focus on administrative computing to incorporate the planning and management of administrative computing, academic computing, telecommunications, and other information technologies in colleges and universities.

EDUCOM and CAUSE were consolidated in July 1998 with a mission to advance higher education by promoting the intelligent use of information technology. While CAUSE's FARNET primarily has concentrated on issues related to Internetworking, EDUCOM's NTTF has been actively involved in a broader range of telecommunications policy issues. Both FARNET and NTTF have played distinct and important roles in the initial development of the Internet in the academic and broader public sector communities. In early June 1998, FARNET merged with then- EDUCOM's NTTF to become Net@EDU, the networking arm of EDUCAUSE, to ensure that the organization maintained an effective policy presence in Washington. Their union within EDUCAUSE allows EDUCAUSE to be more effective as a policy and information resource for its members in the academic/research community.

The membership of EDUCAUSE is open to institutions of higher education, corporations serving the higher education information technology market, and other related associations and organizations. Its programs include professional development activities, print and electronic publications, strategic policy initiatives, research, awards for leadership and exemplary practices, and other online information services. As of spring, 2007,

the EDUCAUSE membership has grown to more than 2,100 colleges, universities, and educational organizations, including 200 corporations, with 16,500 active members. EDUCAUSE has major offices in Boulder, Colorado, and Washington, D.C. It hosts conferences, seminars, and institutes.

The EDUCAUSE regional conference on Information Technology in Higher Education includes the following:

- EDUCAUSE Mid-Atlantic Regional, Midwest Regional, Southeast Regional, Southwest Regional (formerly EduTex), Western Regional, and NERCOMP (An EDUCAUSE Affiliate).
- The CAUDIT -EDUCAUSE Institute is an international event offered every year in Australia/New Zealand.

In addition to CNI, EDUCOM, and EDUCAUSE, there are several other associations that promote distance education. United States Distance Learning Association (USDLA, <http://www.usdla.org>) promotes the development and application of distance learning for education and training. It is a non-profit national association formed in 1987 by Patrick Portway, Smith Holt, and Ralph Mills. The constituents it serves include K through 12 education, higher education, continuing education, corporate training, and military and government training. The Distance Education and Training Council (DETC, formerly the National Home Study Council, <http://www.detc.org/>), founded in 1926, is an association of accredited distance learning/correspondence schools that is dedicated to promoting the high quality in learning opportunities to learners of all ages, regardless of where they live.

American Distance Education Consortium (ADEC, <http://www.adec.edu/>) is a consortium of higher education institutions in the United States that provide distance-education programs via ICT, provides links to member universities, learning resources, and courseware tools.

There are numerous distance-learning professional associations on the regional level. To name a few, the Texas Distance Learning Association (TxDLA, <http://www.txdla.org/>) is a private, non-profit association for distance-learning professionals. TxDLA membership is open to all individuals, statewide, nationwide, and around the world, who are interested in promoting the implementation of effective distance learning. The Centre for Distance Learning Research located at Texas A&M University also sponsored an annual conference Distance Education Conference in Texas (DEC, <http://www.cdler.tamu.edu/>)

Canada

Canada has a long tradition in distance education, arising from the need to provide access to education across the vast expanses of the country.

The Commonwealth of Learning (COL, <http://www.col.org/>) is an intergovernmental organization hosted in Canada by the government of Canada with headquarters located in the Province of British Columbia. It was created by Commonwealth Heads of Government to encourage the development and sharing of open-learning/distance-education knowledge, resources and technologies. As of spring 2006, COL's partners include other Commonwealth agencies, members of the UN System (UNESCO, UNICEF, UNIFEM, UNDP, and the World Bank), national and regional distance education associations, and industry.

Computer Using Educators of British Columbia (CUEBC) <http://www.cuebchorizons.ca/>, and Canadian Association for Distance Education (CADE) <http://www.cade-acad.ca/>, are another two associations in Canada that promote innovative educational strategies, as well as ways to leverage technology to provide new ways of learning online, in the classroom, and in the workplace.

NODE Learning Technologies Network (Network for Ontario Distance Educators) or the NODE (<http://www.thenode.org>) was established in 1996 as the Network for Ontario Distance Educators.

The initial objectives were to promote cooperation among distance educators in universities and community colleges in the province of Ontario, Canada, and to provide leadership for their exploration of new learning technologies. Soon their efforts attracted a wider audience of international community of educators.

Other Canadian associations such as Alberta Distance Education and Training Association (ADETA) (<http://www.athabascau.ca/html/collab/adeta/>), and Canada's Campus Connection (<http://www.schoolnet.ca/campus/en/index.html>) are collaborations between the postsecondary institutions voluntary, non-profit association of individuals and corporate members who are interested in distance education and training.

Australia/New Zealand

The Australian National Conference on Open and Distance Education (ANCODE) held its first meeting in October, 1993. This conference was established to succeed the National Distance Education Conference set up by the then Department of Education, Employment, and Training (DEET). In 1996, the name of the conference was changed to the National Council on Open and Distance Education (NCODE) as part of a process of defining the mission of NCODE.

NCODE-Flexible Learning Australasia was created in 2000 as a result of the restructuring of the former NCODE. In December 2000, the members voted to extend membership to universities in the region and change the name of the organization to NCODE-Flexible Learning Australasia. NCODE - Flexible Learning Australasia became the Australasian Council on Open, Distance, and E-learning (ACODE, <http://www.acode.edu.au/>) in December 2002 with the ratification of a constitution and a new name. The mission of ACODE is "to enhance policy and practice in open, distance, flexible and e-learning in Australasian higher education."

Australian Association of Distance Education Schools (AADES, <http://www.aades.edu.au/>) was formed in 1993 and, as of spring 2006, has in excess of 1,200 members in all Australian states and New Zealand. It is the professional organization representing K-12 school level distance education in the region.

The Open and Distance Learning Association of Australia Inc. (ODLAA, <http://www.odlaa.org/>) is a professional association of members interested in the practice and administration of distance education and open learning. Its membership is open to all persons, organizations and groups interested in the practice and the administration of distance education.

The Distance and eLearning Association of New Zealand (DEANZ, <http://www.deanz.org.nz/>) is a national association committed to fostering growth, development, research, and good practice in distance education, open learning, and flexible delivery systems for education. Its membership is open to individuals or institutions with an interest in distance education and open learning.

Europe

Established in 1991, the European Distance and E-Learning Network (EDEN, <http://www.eden-online.org/eden.php>), is one of the oldest European associations for open, distance and e-learning. Its aim is to foster developments in this constantly evolving field of distance education. Its members include a wide range of institutions including the following countries: Austria, Belgium, Bulgaria, Cyprus, Czech Republic, Denmark, Estonia, Federal Republic of Yugoslavia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Norway, Poland, Portugal, Romania, Russia, Slovenia, Spain, Sweden, Switzerland, The Netherlands, Ukraine, United Kingdom. Institutions from other parts of the world such as U.S., Israel, South Africa, Canada, and Mexican have also joined.

EDEN supports several workshops, conferences, and journals and publications. Among them, the *European Journal of Open and Distance Learning (EURODL)* is an online journal on open and distance and e-learning.

The European Commission adopted several action plans to promote the development of online education by European universities.

Adopted in 2000, the “eLearning: Designing Tomorrow’s Education Action Plan” aims at promoting digital literacy in Europe. This 3-year plan envisions communication technologies like digital television and satellites playing a larger role in European higher education and training systems.

The “eEurope 2005 Action Plan” was endorsed by the Council of Ministers in the eEurope Resolution of January 2003 aiming to develop modern public services for business and education alike through widespread availability of broadband access at competitive prices and a secure information infrastructure.

One of the e-learning projects supported by the European Commission is EQUOL, which stands for “e-quality in e-learning.” This project establishes a virtual center of excellence that involves key researchers and e-learning practitioners from European institutions of higher education.

One of the latest initiative, “i2010” (European Information Society in 2010, http://europa.eu.int/information_society/eeurope/2005/index_en.htm), will provide an integrated approach to information society and audiovisual policies in the EU, covering regulation, research, and deployment and promoting cultural diversity.

In addition to the government initiatives, the European Association of Distance Teaching Universities (EADTU, <http://www.eadtu.nl/>) is the representative organization of both the European open- and distance-learning universities and of the national consortia of higher education institutions in distance education and e-learning. Based in the Netherlands, EADTU was established in January 1987 by the principals of Europe’s distance-teaching institutions to foster coopera-

tion between European organizations dedicated to higher education through distance-teaching methodology.

Established in 1998, European Federation for Open and Distance Learning (E.F.ODL <http://www5.vdab.be/vdab/test/efodl/top.htm>) is a pan-European network of open and distance learning that provides services to organizations involved in the development, distribution, and use of technology-based open and distance learning.

The European Open and Distance Learning Liaison Committee (ODL, <http://www.odl-liaison.org/>) is another influential non-government organizations in Europe. Established in 1998, the liaison committee agreed to meet on a regular basis and to create a common platform that would be an added value for the networks.

The founder members of the ODL Liaison Committee are:

- Association of European Correspondence Schools (AECS), since 1999 new name: European Association for Distance Learning (EADL).
- Coimbra Group
- EuroPACE 2000
- European Association of Distance Teaching Universities (EADTU)
- European Distance and E-Learning Network (EDEN)
- European Federation for Open and Distance Learning (EFODL)
- European Universities Continuing Education Network (EUCEN)
- International Council for Open and Distance Education - Europe (ICDE-Europe)
- Network of Academics and Professionals (NAP)

Other European associations of distance education are such as Research and Training Institute of East Aegean (<http://www.ineag.gr>) and The Open Learning Foundation (OLF, <http://www.olf.ac.uk/>) is a consortium of UK and European

universities and colleges dedicated to improving the effectiveness and flexibility of higher education. Site includes details of current projects and a catalogue of publications geared to specific online courses, graded by level, in order to provide a cost-effective way to develop flexible learning materials and staff development in their uses.

There are hundreds of distance-education professional associations on the national and regional level in Europe. For example, the Irish Learning Technology Association (ILTA, <http://www.ilta.net/>) has been in existence since spring, 2001, and has a membership throughout the island of Ireland. The British Association for Open Learning Limited (BAOL, <http://www.baol.co.uk>) is an association for open learning in the United Kingdom. Its goals are to build a community with global reach, committed to innovation, excellence, and best practice in learning.

Here is a brief list of other European distance education professional associations:

- British Educational Communication and Technology Agency (BECTA, <http://www.becta.org.uk/>)
- Open Distance Learning Quality Council (ODLQC, <http://dspace.dial.pipex.com/odlqc/>)
- Online EDUCA Berlin (<http://www.online-educa.com/>)

Latin America

In the series of Online EDUCA conferences, Online EDUCA Madrid (<http://www.online-educa-madrid.com/>) is organized in Spain with the aim to encompass Spain, Central and South America, and the rest of the Spanish speaking populations in the e-learning industry. The official conference language is Spanish. Since 2003, over 500 distance education administrators in higher education, business, and government from more than 30 countries come together at Online EDUCA Madrid, making it the key networking venue in

the rapidly expanding sector of e-learning in the Spanish-speaking world. EXPOCAMPUS is a parallel event that takes place alongside the Online EDUCA Madrid conference (<http://aedisi.org/>). This is another forum for e-learning experts of the main Spanish and Latin American universities, which adds further academic value to this international gathering of e-learning professionals in Latin America.

Consorcio - Red de Educacion a Distancia/ Inter-American Distance Education Consortium (CREAD, <http://www.cread.org/>) was founded in 1990 at the International Council for Distance Education World Conference in Caracas, Venezuela. CREAD is composed of a vast network of individuals and institutions throughout North, Central, and South America, conjoining resources and expertise to redefine educational partnerships in the 21st century.

Asociacion Iberoamericana de Educacion Superior a Distancia (AIESAD, <http://www.uned.es/aiesad/>) is another distance education professional association in Latin America.

Middle East

Among the various distance-education professional associations in the Middle East, the Middle East E-Learning Technologies (MELT) is also called the Middle East Learning Technologies Forum. It is a series of conferences and exhibitions coupled with a trade show in Dubai and the Middle East region for e-learning in the Middle East world. The mission of MELT is as follows:

- To provide e-learning buyers/users with objective, well-documented learning from international e-learning experiences in enterprise.
- To provide e-learning buyers/users with objective, well-documented learning from international e-learning experiences in enterprise.

- To provide business executives with a clear overview of e-learning, its potential, its benefits, critical success factors, components, and lesson's learned so far.
- To provide ME e-learning professionals with in-depth tracks on hot topics such as managing and measuring the benefits, instructional design, localization, and so forth.

Other major conferences in the area include the Middle East Forum on Learning Technology, the Global Training and Human Resource Development Forum, the Gulf Education and Training Exhibition, (GETEX), and the Middle East Forum on Academic Research and Reflection.

The Arab Open University (AOU, <http://www.arabou.org/>) is developing a Web-based curricula, and partnering with UNESCO to establish a telecom network between university branches in nine countries. It was established in 1996 under the umbrella of the AGFUND (Gulf Program for United Nations Development Organizations). It has been adopted as a private Arab institution of higher education of special status. The AOU launched its teaching programs in October 2002 in a number of Arab countries including, in the first stage, Kuwait (where the AOU Headquarters is seated), Lebanon, Jordan, Bahrain, Egypt, and Saudi Arabia. AOU has a goal of reinforcing solidarity and unity between Arabs through culture and education.

Africa

One of the earliest African distance organizations, South African Institute for Distance Education (SAIDE, <http://www.saide.org.za/>) was formed in 1992 to assist in the reconstruction of education and training in South Africa by promoting open learning principles and the use of quality distance education. SAIDE cooperates with educational institutions, as well as national and provincial

governments, to translate these approaches into practice.

In view of the fact that developing countries have not benefited from the growth of online resources on distance education, UNESCO has partnered with World Bank in developing a consolidated information database in sub-Saharan Africa called the Sub-Saharan African Open and Distance Learning Knowledge Base (<http://www.africaodl.org/>). The purpose of this knowledge base is to offer an integrated knowledge guide to distance education and open learning. The components of the knowledge base include selected readings, reports of good practice, and other information tools.

Confederation of Open Learning Institutes of South Africa (COLISA, <http://www.col.org/10th/best/colisa.html>) was founded by the University of South Africa, Vista University, and Technikon Southern Africa. It aims at communication between the constituent parties on both academic and administrative levels, organizing workshops, discussions and conferences, creating a forum for sharing of expertise, and establishing a Development Fund for the furtherance of the Joint activities.

Adult Education Network (AEN, <http://home.global.co.za/~proplib/>) promotes the activities of its members, which include clubs, associations, special interest groups, and service organizations in South Africa.

The main objective of the Acacia Initiative (the South African Academic and Research Network, http://web.idrc.ca/en/ev-5895-201-1-DO_TOPIC.html) is to provide a computer network that works to the standards of the Internet, for the use of every academic, researcher, and student in South Africa.

Asia and Pacific Islands

One of the earliest professional distance education organizations, Asian Association of Open

University (AAOU, <http://www.aaou.net/>) was founded in 1987 by a number of open universities in the Asian region as a non-profit organization of higher learning institutions with distance education programs. As of January 2005, there are 71 members in AAOU including 38 full members, 31 associate members, and 2 individual supporting members.

Funded by the Chinese government, the China Education and Research Network (CERNET, <http://www.edu.cn/HomePage/english/index.shtml>) is the first nationwide education and research computer network in China. CERNET plays a pioneer role in China's information initiative such as online enrollment and admission system for universities around the country.

Since its establishment on 27 February 1997, South-East Asian Ministers of Education Organisation Regional Open Learning Center (SEAMOLEC, <http://www.seamolec.or.id/>) has a mission: To assist SEAMEO Member Countries in identifying educational problems and finding alternative solutions for sustainable human resource development through the dissemination and effective use of open and distance learning. Its member countries include representatives from Brunei, Cambodia, Indonesia, Lao PDR, Malaysia, Myanmar, Philippines, Singapore, Thailand, and Vietnam.

The educational division of the UNESCO-Bangkok office fosters educational innovation and research in support of development by sponsoring the Asia-Pacific Programme of Educational Innovation for Development (APEID, <http://www.unescobkk.org/education/aceid/apeid.htm>).

APEID promotes regional cooperation by forming a network of institutions, called Associated Centres, across the region to facilitate educational innovations and, assist Member States build national capacities according to the self-perceived needs of the countries themselves. Associated Centres benefit from the exchanges of insights,

skills and expertise promoted. The APEID-related functions of the Associated Centres include:

- Sharing of innovative experiences with other centres in the network
- Organizing national, sub-national or regional APEID activities such as training workshops, seminars, and development of instructional materials
- Participating in the design, conduct, evaluation and follow-up of the inter-country/inter-project visits and studies
- Participating in the exchange of personnel with other centres
- Facilitating the dissemination and exchange of information on educational innovations related to development.
- Cooperating with other centres in projects of mutual interest and concern

As part of its support for international distance education, COL has sponsored research and planning into the design of telecommunications networks, specifically targeted to the needs and resources of smaller distance education organizations.

The Indira Gandhi Open University (IGNOU, <http://www.ignou.ac.in/>) was established in 1985 with a networking of Regional Centres and Study Centres, all over India. IGNOU has also set up a collaborative project with open universities in Pakistan, Bangladesh, and Sri Lanka. It has also crossed national boundaries, providing higher education as well as assisting other developing countries.

Pacific Islands region contains a large proportion of small states, concentrated in the South and Western Pacific, as well as many key distance-education institutions. The Pacific Islands Regional Association for Distance Education (PIRADE, <http://www.col.org/pirade/>) is sponsored by Commonwealth of Learning.

FUTURE TRENDS AND CONCLUSION

International Center for Distance Learning (ICDL, <http://www-icdl.open.ac.uk/>) of the Open University of UK has established a research center for teaching, consultancy, information, and publishing activities, based at the Institute of Educational Technology (IET). It hosts an extensive database containing more than 300 distance-learning providers worldwide, over 12,000 thousand books, journal articles, research reports, conference papers, dissertations, and other types of literature relating to the theory and practice of distance education; contains a link to free online distance education database.

International Council for Open and Distance Education (ICDE, <http://www.icde.org/>) is a long established international association affiliated with SEAMEO and recognized by UNESCO. Its goal is to provide leadership and facilitate cooperation, development, and communication at the global level in distance and virtual learning. It has global membership of educational institutions, national and regional associations, corporations, educational and agencies in the fields of open learning and lifelong learning

COL has supported the communications of associations for distance-education professionals, and has facilitated the formation of a pan-Commonwealth federation of these associations called Federation of Commonwealth Open and Distance Learning Associations (FOCODLA, <http://www.col.org/focodla/members.htm>). The following regional associations have joined FOCODLA:

- Distance Education Association of Southern Africa (DEASA)
- Distance Education Association of Tanzania (DEATA)
- Open Learning and Distance Education Association of Eastern Africa (OLDEA-EA)

- National Association of Distance Education Organisations of South Africa (NADEOSA)
- West African Distance Education Association (WADEA)
- Zambia Association for Distance Education (ZADE)
- Zimbabwe National Association of Distance and Open Learning (ZINADOL)

The International Association for the Study of Cooperation in Education (IASCE, <http://www.iasce.net/>) is an international non-profit educational association dedicated to the study and practice of cooperation in education, a field that includes the increasingly popular cooperative classroom methods by which students work together in learning teams to master academic content and collaborative skills.

KEY TERMS AND DEFINITIONS

Commonwealth of Learning (COL): The Commonwealth of Learning (COL, <http://www.col.org/>) is an intergovernmental organization hosted in Canada by the government of Canada with headquarters located in the Province of British Columbia. It was created by Commonwealth Heads of Government to encourage the development and sharing of open learning/distance education knowledge, resources, and technologies. As of spring 2006, COL's partners include other

Commonwealth agencies, members of the UN System (UNESCO, UNICEF, UNIFEM, UNDP, and the World Bank), national and regional distance-education associations, and industry.

EDUCAUSE: EDUCOM and CAUSE were consolidated in July 1998 with a mission to advance higher education by promoting the intelligent use of information technology. The membership of EDUCAUSE is open to institutions of higher education, corporations serving the higher education information technology market, and other related associations and organizations.

Its programs include professional development activities, print and electronic publications, strategic policy initiatives, research, awards for leadership and exemplary practices, and other online information services. As of spring, 2007, the EDUCAUSE membership has grown to more than 2,100 colleges, universities, and educational organizations, including 200 corporations, with 16,500 active members. EDUCAUSE has major offices in Boulder, Colorado, and Washington, D.C. It hosts conferences, seminars, and institutes.

Chapter 1.14

Using Games to Teach Design Patterns and Computer Graphics

ABSTRACT

This chapter discusses some possibilities of using computer games to effectively reach didactic goals in undergraduate teaching. Nowadays, undergraduate students belong to the Net generation and usually play different kinds of games on consoles, computers, and the Internet. Some elements such as creativity and abstraction could be included in computer science and information technology curriculums through the use of games as educational methodological resources, due the motivational

factor they inherently have. This learner-centered approach not only contributes to personalizing the knowledge-building process but also permits the consideration of learning styles to adapt different ludic environments and/or real-world situations according to topics of the course. To demonstrate the possibilities of this educational scenario, two case studies were conducted. One focuses on Design Patterns contents in a computer science course, and the other spotlights computer graphics topics in an information technology course. The results gained in these processes demonstrate the students' involvement in the proposed activities

DOI: 10.4018/978-1-60960-503-2.ch114

and the capacity to apply the lessons learned in diverse situations.

INTRODUCTION

The acquisition of skills related to creativity and abstraction, indispensable to any computer science and information technology curriculum, constitutes unquestionably a didactical challenge. From the educational point of view, the use of games in this process is a motivational element that could help to make the knowledge-building process more personalized. It is also possible to take into account students' learning styles, thus establishing an adaptive and flexible environment where any skill, subject, or even concept can be effectively learned (Prensky, 2007; Gee, 2003; Bransford, Brown, & Cocking, 2000).

Another aspect that must be considered is that actual undergraduate students belong to the so-called "Net generation" (Tapscott, 1998). According to Tapscott, "N-Geners" could be characterized by having autonomy sense, intellectual openness, technology inclusion (or the facility to use technological elements even though never having any previous contact with them), freedom of expression, curiosity, immediacy, and mainly trust. This scenario perfectly fits into a game universe-based andragogic proposal, because nowadays it is necessary to institute mechanisms that take advantage of technological culture over where they are steeped and transform it into learning resources. The same author also points out the need for an interactive learning posture where focus is learner centered and related to interaction with hypermedia-based systems in order to promote a lifelong learning from a customized—and mainly fun—point of view.

In this situation, professors could be, in a metaphorical way, considered analogous to game masters that guide and encourage players (the students) into a game (the educational process

itself) to play the game, face the challenges, and go through the next level (in other words, succeed in academic life). By exceeding curriculum demands, students could be able to enjoy a lifelong, meaningful learning experience (Ausubel, 1962).

In the role of gamer characters or game development, learners have the opportunity to compare, analyze, and experience situations similar to the real ones. When a student plays in this controlled environment or constructs them, it is possible to present fully inspiring situations where actions only occur in the virtual world, which contributes, among other factors, to reduce cognitive load.

Another consideration in this proposal is based on Shaffer's (2007) works, which focus real problem solving by role-playing a professional character that uses new digital technologies to assume his or her own learning process and institutes attitudinal changing by implementing epistemic games.

Nonetheless, teachers and students barely consider games as something detached from entertainment. The sole tentative of introducing "serious," non-entertaining games into a curriculum often causes the inverse effect, since these sorts of games tend to be tedious as they do not prime for the entertainment-related aspects that are responsible for retaining students' attention.

It must be remembered, although obvious, that the act of learning does not have to be a boring, unexciting situation that students are exposed for a significant part of their lives (Johnson, 2005). Instead, it must be a stimulating and—why not?—funny, entertaining activity to be performed by students. Thus, recovering the ludic side of learning is primordial to motivate students to learn the issues curricula tell them they have to.

Specifically in computer science and information technology areas, students often are already gamers; thus, they are completely aware of game strategies, terminology, and play. The introduction of game-related situations in their curricula has been a well-accepted operation, since games belong

to their cognitive comfort zone. Thus, given such familiarity with the pedagogical instrument—the game—even uncomfortable, hard-to-be-taught syllabi could make use of games in order to approximate curriculum subjects to students' social context (Sweedyk & Keller, 2005; Squire, 2002).

According to the elements previously presented, this chapter's main objective is to show how ludic aspects of electronic gaming could be used as motivation for advances studies in computer science and information technology undergraduate courses. This involves three aspects: the theoretical aspects of game playing as a contributing factor for constituting more autonomous, self-critical and inquirer students; how game-driven activities could be inserted in traditional curricula of such courses; and the demonstration of theory reviewed and discussed through analysis of two case studies about applying games in syllabi.

THE USE OF GAMES IN EDUCATIONAL PROPOSALS

An educational proposal based on games requires a different instructional design approach. In this special case, it is necessary to consider not only learning objectives, learning styles, contents, procedures, and other elements related to structure, such as methodology, evaluation, outcomes, and feedback (Mustaro, Silveira, Omar, & Stump, 2007; Reigluth, 1999). Games for education also demand the use of narratology—screen written and creativity components to develop a result that could be motivating, challenging, and enjoyable—being able to engage learners in a process where learn and play are combined into one.

This architecture can be established through the use of a learner-centered educational approach with adaptive systems that could take advantage of interactive media. The type of media or resource used in educational proposal influences learners' activity levels during the learning process (Dale,

Figure 1. Adapted Dale's Cone of Experience (Mustaro et al., 2007)

1969). According to this idea, it is possible to adapt Dale's scheme to the contemporary scenario (see Figure 1).

From the elements presented in the adaptation of Dale's Cone of Experience, games could be classified as activities with high levels of participation, which also amplifies information retention, making them more significant to students. This occurs because, through video games, learners can "interact with real rules while imagining a fictional world" (Juul, 2005, p. 1). Furthermore, game playing could be considered "an activity of improving skills in order to overcome...challenges, and playing a game is therefore fundamentally a learning experience" (Juul, 2005, p. 5).

According to Juul (2005) games present essentially two forms of providing challenges for players. The first is based on a combination/variation of a small set of rules (called *emergence*); the second is related to the level-based structure and sequence of events (denominated *progression*). Besides, the game universe developed for educational purposes also needs to consider knowledge and background abilities of students to present challenges that match the contextualization requirements, and they must also take into account Vygoysky's (1978) theory

about the Zone of Proximal Development (ZPD). This combination requires exploration of serious games' characteristics.

Bergeron (2006) pointed out that a serious game is mainly an interactive computer application that presents challenging goals, fun elements of engaging, and some score concepts, as well as provides knowledge, skill, or even attitudes that could be used in real-world situations. These concepts could be complemented with the following sentence: "To play a game is to improve... repertoire of skills, and the challenge of game design is to work with the skill set of the player through the game" (Juul, 2005, p. 5).

However, not only providing games to students could be effective, but it is also relevant to motivate them to develop their own games if possible, especially in computer science (CS) and information technology (IT) undergraduate courses. This approach can merge the Real Problem Solving approach proposed by Shaffer (2007) with Problem-Based Learning (PBL) developed by Barrows and Tamblyn (1980), thus exploring constructivist elements when considering previous knowledge and concepts of each student through the whole process of learning construction (Halverson et al., 2006).

In this situation, it is possible to retrieve concepts and knowledge, or even pieces of information to establish a relationship with new content. In a complementary way, it also allows one to experience solving problems that are similar or even equal to those that students usually find in their professional lives. According to Norman and Schmidt (2000), the use of PBL in curricula could improve knowledge retention, students' motivation, and self-learning capacity, and presents the capacity to transfer learned concepts to new scenarios. Because of that, the present research combines PBL with games to increase intrinsic motivation of students, thus instituting a significant learning scenario.

METHODOLOGY

Both case studies were taken in the context of undergraduate courses at a private university in Brazil, namely Mackenzie Presbyterian University. The first case study was carried out from 2005 to 2006 with three different groups of students from the fourth year of a CS undergraduate course, involving approximately 120 students. The second case study included nine different groups of IT undergraduate students during the same year, involving around 550 students.

The approach presented here is mainly based on Problem-Based Learning (Barrows & Tamblyn, 1980; Barr & Tagg, 1995; Wilkerson & Gijsselaers, 1996), which is an instructional theory that motivates students to work in a collaborative way to propose solutions to real-world problems. In both cases, students were faced with different sorts of game-related problems.

In the first case, the students had to have a software engineering vision about games, having to propose different solutions for the problem of modeling games in an object-oriented way, using extensively Responsibility Assignment Patterns (Larman, 2004) and Design Patterns (Gamma, Helm, Johnson, & Vlissides, 1995). According to the learner's evolution, the modeling evolved together.

Nowadays, a growing demand for some updates and changes in the curricula of software engineering-related courses is being noticed in CS and IT undergraduate courses, in order to include modern software development techniques. In this sense, inclusion of Design Patterns in such curricula is being considered as an urgent necessity. However, the Design Patterns' learning process demands students to have a high level of abstract reasoning, in addition to a certain degree of maturity on software engineering issues, which makes this task a non-trivial effort to be performed.

The main purpose behind Design Patterns (Gamma et al., 1995) is to provide to software

development community a set of problem-solution pairs so they are generic enough to serve as guidelines to solve recurrent problems in different application domains. Together with such a set, a common high-level vocabulary also arises, which makes integration easier among development teams, leading to a software development process with higher abstraction levels.

Using Design Patterns is an extremely good practice in the sense that it improves one's skills about object-oriented system design, and since it allows the evolution from a low-level reasoning, dealing with isolated classes and their object, to a more abstract way of thinking, where software is usually planned in a macro-structured way, and patterns can be applied in a plug-and-play manner.

In the second case, students were meant to face the problems related to computer graphics issues when creating a game scenario. Such modeling was supposed to evolve while students were presented new computer graphics techniques.

Modeling and rendering are major issues in a computer graphics course. However, IT undergraduate courses have some specific characteristics that often make the teaching of computer graphics topics a hard task, since many students consider the matter as uncoupled, isolated from the rest of curricula. Besides, computer graphics learning frequently requires from students a very good basis in Math, as well as dealing with a family of non-trivial algorithms for both modeling and rendering.

Games were used in this case study in order to improve students' sense of motivation, as long they were learning and applying sophisticated techniques to create a game scenario (Rucker, 2003). Simple board games were chosen, since they usually rely on a family of accomplishable challenges for undergraduate IT students, regarding their simple, but comprehensive modeling process of pieces and the board itself, as well as the fact that they open a wide range of possibilities for studying rendering techniques.

Case Study #1: Design Patterns and Software Metrics

This section will show some experiences from the years 2005 and 2006 in which games were used to teach patterns to CS students. These experiences will be divided in two phases: the first one, introductory, shows how games could be used in order to stimulate students in their first contact with basic software patterns, specifically Responsibility Assignment Patterns—some of them supported by object-oriented metrics—and Architectural Patterns. The second phase deals with the same students being taught GoF Design Patterns (Gamma et al., 1995), a more sophisticated subject of study. Games were also used in this second phase.

To explore this scenario, it is relevant to consider some elements. The increasing of processing power of computers, the spreading of mobile devices, and all the Internet phenomena are factors that contribute to the demand each time for more complex and sophisticated software. Since software is becoming increasingly complex, it is expected that its design follows the same path. Thus, professionals are required to act in a market with increasing demands for sophisticated designs (Cayley, 1999).

In this scenario, an average student of a regular CS course would not be completely able to ingress in such a software engineering market. With few exceptions, these students lack expertise in more realistic situations involving software development. The fact of not knowing Design Patterns could lead such students to propose simplistic, naïve solutions for problems that otherwise would require complex solutions. Such a gap in students' formations could be partially explained by the low level of abstraction that is commonly used in regular software engineering courses. In spite of it being very useful to teach basic principles about object orientation paradigm, such strategies

are shown to be inefficient when applied to larger, more complex systems.

A wide range of didactical aspects must be considered when dealing with such a category of subject, often considered too abstract and high level for undergraduate students, who must be motivated in some manner to build the knowledge related to these topics. Motivation, as stated by Gagné, Briggs, and Wager (1992), is a key factor to learning, and it can be achieved through a variety of strategies. For instance, a recent book about Design Patterns (Freeman, Freeman, Sierra, & Bates, 2004) tries to promote motivation through the usage of a metacognition-based approach, while an earlier publication (Duell, 1997) already tried to present Design Patterns' main concepts by associating them to non-software real-world examples. In the context of the experience, games are used as motivational factors, acting as triggers to the learning process.

The complexity of the subject is easily perceived, if confronted with—barely not naïve—approaches first-year students usually apply when modeling object-oriented systems. To depict this, a first case study was carried out in 2005 with a class of fourth-year students. Students were confronted with a simple but not trivial challenge: given a software already completed and how to analyze it, extract its main characteristics and, through a reverse engineering-based process, infer which would be a good object-oriented design for this software, particularly dealing with UML Class Diagrams. In order to improve students' motivation, a game was proposed as the subject software for this study (Berguin, Reilly, & Traynor, 2005; Björk & Holopainen, 2005; Nguyen & Wong, 2002). The targeted game is known as *Extreme Farm Simulator*,¹ a very simple game done in Adobe Flash®. It is a third-person shooting game, with a solely—and funny—goal: a farmer, controlled by the player, must shoot a flying saucer that tries to abduct his cows. Although simple, it is a multi-phased game, in which new levels add

new flying saucers, requiring simply players' quicker reactions.

Students' first attempts to propose a class diagram for this game, based on their previous knowledge about object orientation, resulted often in simplified models, whose cores dealt only with that which is known as resource tier in a five-layered architecture. Some of these attempts can be seen in Figures 2 and 3, which depict two different diagrams for the same subject. Since they are made by Brazilian students, all projects were originally written in Portuguese. For the sake of readability, all class diagrams in this chapter show translated versions of the originals.

Both cases show how students cope with the concept of classes in the Object Orientation paradigm: they are merely representations of visually perceived “real” objects that are present in the application domain. Even though this is a conceptually correct first concept, to reach higher levels of abstraction, students would have to be able to recognize classes that are not necessarily direct representations of “physical” elements. Thus, invariantly, at this time students are able to present diagrams that would better fit as data-tier elements in a multi-tiered approach.

Some interesting questions arose from a first analysis of these diagrams made in the classroom. For instance, which class would be responsible for controlling the game? Which would be responsible for creation of other objects (the student that authored Figure 3's diagram tried to solve it using a “self-creating” class-like level)? Since students, at that point, were not yet presented to GRASP Patterns (Larman, 2004), they were unable to apply patterns like Pure Fabrication, Controller, or Creator to solve these problems, which remained unsolved until the next step forward.

Starting from this point, students were invited to present and discuss their diagrams with colleagues. Such discussion took place at two different times: first in the classroom, where students were stimulated to have a critical approach to

Figure 2. Simple class diagram for the game (example #1)

colleagues' proposals, and afterwards through a virtual environment-based forum (Moodle² was used in this case). The discussion allowed students to be presented to a high-level Architectural Pattern, namely Three-Tiered Architecture, based on the MVC (Model-View-Controller) Pattern

Figure 3. Simple class diagram for the game (example #2)

(Adams, 1988). Students were invited to rethink their designs after having contact with this pattern. One of the results can be seen in Figure 4.

It must be noted that Figure 4 represents an overall improvement from those depicted in Figures 2 and 3: by having made contact with the concepts around tiered architectures, students now go beyond the simple representation of a data/

Figure 4. A more elaborated class diagram, applying the Three-Tiered Architectural Pattern

resource tier by thinking in specific classes for encapsulating business rules. However, interface issues are not yet well addressed in these phases.

More than just modeling, in this educational approach, students were also invited to criticize colleagues' works. Again, the fact of using popular games as subjects of modeling was decisive, as their domains are widely well known by everyone. Below is an intervention (translated from Portuguese) of a student about the design proposed by a colleague in the semester before. In this case, students were faced with various diagrams, from which they had to choose the best one according to their own criteria. Using a virtual environment, they were asked to expose the reasons of their choices.

I think the diagram of students X and Y is the one that better represents the game, since it has the best class definition, keeping clear the idea about how game is structured. On the other hand, Z's diagram is without methods and attributes, making vague the idea about how the game works.

In the Game class I could not understand why there are methods like shoot(), moveRight(), or moveLeft(), since they are already defined in the following classes: Flying Saucer, Cow, and Farmer.

Where are the methods related to cow's abduction??? And those one related to flying saucers'shoots?

It was good to have tried to divide in tiers, although I'm not sure if it is correct.

After having contact with some basic concepts regarding architectural patterns, the next set of patterns studied was Larman's (2004) GRASP (General Responsibility Assignment Software Patterns), which is a set of nine general-purpose patterns. Such patterns serve as guidelines for software development, as well as being the foundations for Gamma's Design Patterns.

In order to motivate the use of GRASP concepts, it was proposed that the students choose a game and build a class diagram to represent it, with posterior applying of two object-oriented metrics—LCOM and CBO—from the well-known set of metrics proposed by the classical work of Chidamber and Kemerer (1994). These metrics were chosen since they support the application of two GRASP patterns, respectively High Cohesion and Low Coupling (Larman, 2004).

One of the students choose *Tetris* (from Russian Тетрис), a well-known game whose pieces are composed of four square blocks, called *tetraminoes* (Figure 5), that fall down on the playing field.

The basic mechanics of the game are to manipulate these tetraminoes, by moving each one sideways and rotating it by 90-degree units, with the aim of creating a horizontal line of blocks without gaps. When such a line is created, it disappears and the blocks above (if any) fall. As the game progresses, the tetraminoes fall faster, and the game ends when the player “tops out”—that is, when the stack of tetraminoes reaches the top

Figure 5. Possible configurations for Tetri's tetraminoes

Figure 6. An intermediate Tetris configuration during a game session

of the playing field and no new tetrominoes are able to enter.

A non-end configuration of a *Tetris* session is depicted in Figure 6.

To contextualize object-oriented metrics, the following section revises LCOM and CBO metrics.

The Lack of Cohesion Metric (LCOM) is an object-oriented metric and states the dissimilarity of methods in a class by instance variable or attributes. Lack of cohesion or low cohesion increases complexity, thereby increasing the likelihood of errors during the development process. Classes with low cohesion could probably be subdivided into two or more subclasses with increased cohesion. A highly cohesive module should stand alone, and high cohesion indicates good class subdivision. High cohesion implies simplicity and high reusability, and indicates good class subdivision. LCOM measurement is not a trivial problem, since it requires classes' methods to be already well defined in an algorithmic way. Besides, there are currently different methods to perform it, leading to different interpretations of this metric. A comprehensive analysis of these different methods can be found in Lakshminarayana and Newman (1999).

The Coupling Between Object (CBO) is a count of the number of other classes to which a class is coupled. It is measured by counting the number of distinct non-inheritance-related class hierarchies on which a class depends. Excessive coupling is detrimental to modular design and prevents reuse. The more independent a class is, the easier it is to reuse it in another application. The larger the number of couples, the higher the sensitivity to changes in other parts of the design, and therefore maintenance is more difficult. Strong coupling complicates a system since a class is harder to understand, change, or correct by itself if it is interrelated with other classes. Complexity can be reduced by designing systems with the weakest possible coupling between classes. This improves modularity and promotes encapsulation. Computation of CBO is often done through the class diagram being represented as a directed graph, where edges represent dependencies among classes. An individual node's CBO is its outer degree. One result devised from the proposed experiment is depicted in Figure 7.

The proper application of GRASP could lead students to a satisfactory project for the games they have chosen. By means of PBL and Collaborative Learning, students themselves could build these solutions and, through criticism, supported by LCOM and CBO metrics, they were able to decide if they had made the correct choices during design phases.

This first attempt to bring a higher level of maturity to students concerning object-orientation issues owes a considerable part of its success to the fact of using well-known games as subjects of modeling. Such a decision allowed students to be motivated by dealing with a ludic, stimulating problem, which was also a chance for them to model a "complete" system, due to its simplicity.

After this first approach, students were able to deal with more sophisticated concepts, like Design Patterns. Recently, the use of patterns, as defined by Gamma et al. (1995) and Alur, Crupi,

Figure 7. A class diagram with applied Design Patterns and corresponding object-oriented metrics

and Malks (2003), among others, is increasing in the software industry. In some countries, the study of patterns, especially Design Patterns, is to be considered as standard in the core of undergraduate courses (Astrachan, Mitchener, Berry, & Cox, 1998; Wick, 2005). In other countries, such initiatives are in their early stages. In Brazil, for instance, the official Curricular Guidelines barely mention Design Patterns (Menezes et al., 2001).

To satisfactorily understand and apply Design Patterns, a set of previous skills is required of students. Many of them were developed in a

previous phase—for instance, the awareness of cohesion and coupling issues, and the separation of concerns, among others. Nonetheless, the results produced by students are not yet satisfactory if compared with professional expectancies of complex software. An example of this, shown in Figure 9, is presented by two students to model the classic Checkers game.

It can be noted that, in spite of being conceptually correct, this diagram primes for simplicity. It presents a proper three-tiered organization—business rules are dealt by CTR—Controller

Figure 8. Modeling Checkers with GRASP

classes (Larman, 2004), objects creators are well-defined, and so on—although its implementation, if carried through up-to-date frameworks or APIs, would present a considerable gap between conceptual design and implementation project.

Based on this, games were used again to move a step forward in direction to a more sophisticated set of patterns, namely GoF Design Patterns (Gamma et al., 1995). Using students' criticisms

and some punctual interventions of professors, students were able to absorb the main concepts involving such patterns. The text below shows one of these interventions, and Figure 9 shows the final version of the diagram from Figure 8 after some months studying GoF Design Patterns.

This new version for the diagram is better than previously presented in classroom. However, there are still some issues to be addressed:

Figure 9. Discovering the Command Pattern in a game of Checkers

- What's the need of having a class for black pieces and another one for reds?
- There is no relationship among Player, Action, and Piece?
- Coupling of CTR_Piece is over the diagram's average.

By means of the triad of *criticism, intervention, and auto-criticism*, students were able to discover by themselves, in the application domain of the game, some of the patterns taught. For instance, Figure 9 shows part of the diagram made by the same students that authored the previous diagram (Figure 8). Figure 9 shows how students were able to properly identify and apply the GoF Command Pattern (Gamma et al., 1995).

Case Study #2: Computer Graphics

Teaching computer graphics in the context of an IT undergraduate course has been the topic for discussion. Now we ask, how do we teach highly algorithmic content to students that are not really motivated to it? IT courses educational purposes, different from CS courses, are usually more driven to the application of technology than the behind-the-scenes content CS courses are used to having.

In the 1970s the issue was already being discussed, and a large range of APIs and frameworks appeared in order to make computer graphics learning easier in different contexts (Knowlton, 1972; Towle & DeFanti, 1978). More recent works proposed alternatives to the omnipresent OpenGL through the use of widespread languages that give support to 2D-3D basic modeling tools, such as Java (Mukundan, 1999) and Java plus Java3D API (Zhang & Liang, 2005; Tori, Bernardes, & Nakamura, 2006), or even languages that were not as widespread like Ada (Brown, 2004). Other tests focused on modeling software like Maya and Blender (van Gumster, 2003; Zhu & Owen, 2004). The present case study was carried out using Blender.

Groups from a fourth-year IT course had been submitted to one experiment: modeling and rendering of a board game. Initially, the groups had chosen which game they wanted to work on, and, using concepts of modeling and rendering, had produced a final project of a game in two phases.

In the first phase, the objective was to apply extensively concepts of polygonal modeling, NURBS, and generative curves, in such a way to show the difficulties and applications of each of these types of modeling.

Some concepts involving modeling are sometimes extremely abstract to students in general, specifically to IT undergraduate students, which are meant to face computer graphics issues not as full developers of algorithms and techniques, but instead as having a comprehensive knowledge about techniques and methods.

A relevant unit on this course is about modeling. On this topic, students were meant to be presented to a range of modeling techniques, which vary from direct polygonal mesh modeling to procedural techniques (Foley, van Dam, Feiner, & Huges, 1995; Watt, 1999). One of these techniques is CSG (Constructive Solid Geometry), which is based on combining pre-built solid primitives according to a set of Boolean operators. A solid is thus described by its scene graph, in which leaves are the primitives and internal nodes are the operators.

CSG is a very easy technique to learn. However, the more formal specification through scene graphs is not always an easy topic for IT students, since it requires basic knowledge about trees, besides basic algebra and set theory.

This topic was addressed over three semesters by proposing to students the modeling of some board games' pieces using CSG. According to the game chosen, some pieces were extremely easy to create—checkers, for instance. Ludo, dominoes, or some chess pieces, for instance, require a little more modeling effort, being a proper issue to be addressed with CSG techniques. To achieve this goal, a modeling tool was used.

Tools instead of direct programming with APIs like OpenGL have been used in an effective manner to improve student's learning of hard topics in computer graphics. The works of Abdullah, Suyoto, and Ahmad (1997) and Song, Ou, and Shiau (2000) show experiences that used tools to teach computer graphics concepts to undergraduate students.

More than just using tools, the experience in these classes was meant to stimulate students to use such tools. It is well known that complex modeling tools have inherently also complex, user-unfriendly interfaces, besides being, most of the time, machine-consuming, proprietary, and expensive. The solution found to some of these problems was using Blender,³ an open source, cross-platform suite of tools for 3D modeling and rendering.

Figure 10 shows some students' results applying CSG modeling techniques in some pieces of a domino game. Typically, these pieces are the result of applying an intersection among a box and a sphere (to generate a rounded-corner piece basis); holes are built by applying a difference between such basis and a hemisphere, which is built by again using the difference operator between a sphere and a cube; a box is used as separator. Linear transformations and the union operator are applied afterwards.

Some other topics that require a deeper knowledge of math are specially considered as difficult matters, with no practical application. For instance,

NURBS (Non-Uniform, Rational B-Splines, see Piegel & Tiller, 1997) is a non-trivial topic when teaching computer graphics, since it is a kind of curve that require students to have some knowledge about the concept of continuity (positional, tangencial, and curvature). Besides, they are expected to cope with a curve's weighted control points and its knot vector. More than this, NURBS surfaces require an extra degree of complexity.

NURBS curves are extremely useful in some modeling techniques, such as sweeping through revolution. Students were stimulated to model some chess pieces using such technique. Again, once the goal was well established, students were able to understand and apply some intricate concepts related to such curves in the chosen tool. Figure 11 shows a chess piece created using a mixed approach, combining sweeping and CSG.

Having some pieces modeled, students were assigned the task of modeling an entire board game, with all pieces. Such a game was supposed to be located over a surface, like a table. Some results obtained by students in this phase are shown in Figure 12.

The variety of proposals was sufficiently great, and the motivation with the use of a game as the subject was very well accepted.

Figure 10. Domino pieces modeled with CSG

Figure 11. Chess horse modeled with NURBS-based sweeping and CSG

Figure 12. Some of the best results in the modeling phase

After that, in the second phase, the challenge was to add realistic effect (illumination effects) to the models generated in the previous phase. Our current program of computer graphics includes two basic illumination models: Lambert and Phong. Although they represent the most basic models of illumination in computer graphics, they demand certain mathematical maturity to understand them.

The Phong Reflection Model is an illumination and shading model, which allows the assignment of shades to points on a 3D model. It represents a simplification of the more general rendering equation, whose computation is a hard computational task. Essentially, the Phong illumination model comprises three components—ambient, diffuse, and specular—as depicted in Figure 13.

The Lambert illumination model is a more simplified model and includes only the diffuse component. Both equations for these models are obtained by the formula in Figure 14.

In this equation, the terms (k_a, k_d, k_s, α) represent the material to be bound to the 3D model and quantify the amount of reflected light i_a, i_d, i_s (ambient, diffuse, specular). The required maturity to understand these models includes methods from vector calculus and analytic geometry, which, not always, are remembered when we are initiating the topic of illumination models. For example, in order to calculate the normal vector (N), an important step for both Lambert and Phong Models, we need to evaluate partial derivatives over polygonal surfaces (Foley et al., 1995; Watt, 1999).

Figure 13. The components of the Phong Illumination Model

Figure 14.

$$I_p = k_a i_a + \sum_{\text{lights}} (k_d (L \cdot N) i_d + k_s (R \cdot V)^\alpha i_s).$$

This direct approach often shifts the focus of the discipline for a purely mathematical scenario, which often decreases the motivation of students to learn more complex illumination models.

As the model of illumination of Phong is empirical, we also follow the same empirical strategy to teach the model to our students. As a strategy, initially, groups had been motivated to test several lighting conditions in order to gain mathematical and perceptual skills related to photo-realistic parameters. Using these skills, they had tried some models to get realistic qualities for wood and plastic, among other materials that could appear in the scenes of the games. The results obtained from these experiments are shown in Figure 15.

Using the common approach of the Phong model, the students extrapolated the results to include models of texturing, using the qualitative equation *material* = *lighting model* + *texture*. The textures were generated by procedural models involving complex models, such as Perlin's noise (Watt, 1999), for wood and marble.

The results were very interesting, mainly because the students had faced the mathematical barriers of the model and had been able to transform them into sufficiently convincing products of the point of view of realism.

IMPLICATIONS AND FUTURE TRENDS

These case studies demonstrate the effective use of instructional design elements to elaborate a proposal of applying games exclusive in undergraduate courses such as computer science and information technology. In these types of

courses, students use and explore computers and technological tools constantly. It is necessary to implement the methodology developed in other areas as social sciences, philosophy, biology, and so on to compare the results and analyze the specialties of these experiences.

Another element that can be pointed out is to research the possibilities of amplifying the collaborative approach combined with massive multiplayer games to investigate how students work and structure an autopoietic system to examine and solve problems in a game universe.

But not all of these proposals can be developed without a change in the posture of teachers, which includes increasing the value of ludic (playful) in education and verifying, by use of instructional design analysis, how different contents can be combined in a game universe to contextualize and offer a meaningful experience to students. This proposal requires an interdisciplinary approach and new curricula structures that also consider different learning styles and the use of group dynamics to provide an environment where ZPD can emerge.

CONCLUSION

This chapter showed two case studies carried out by the authors at a university in Brazil in which games were effectively used to teach two different subjects: Design Patterns for a computer science course and Computer Graphics for an information technology course. To implement this proposal, we used an instructional design approach that pointed out a learner-centered methodology and constant analysis of games contexts, contents, and

scenarios development during the course periods in a blended solution that amplifies the laboratory classroom when implementing a virtual environment to discuss students projects.

These elements enhanced the proposal because students were challenged to study, in a detailed way, Design Patterns and Computer Graphics content so to have the opportunity to create their games architectures and interact with other colleagues to find solutions to real projects, not in a hypothetical or theoretical manner.

The use of games as a motivation factor for the presented concepts showed importance not only for the ludic aspect, but for the wealth of exploration elements as well. In both cases, the exploration factor represents a relevant aspect for attainment of clear and cheap solutions for software, as well as three-dimensional realism in models.

KEY TERMS AND DEFINITIONS

Design Pattern: A proven solution for a recurring problem. Some authors provide a catalog with 23 Design Patterns (Gamma et al., 1995).

Instructional Design: Constitutes a systematic framework that involves educational theories, instructional strategies, and other elements to support learning experiences, and permits one to acquire competences based on educative goals.

Learning Styles: Involves individual preferences of perceiving and processing information in response to educational stimuli.

Ludic: The Latin word *ludus* (meaning “game”) originated the concept of ludic, which represents a human behavior characteristic that synthesizes social and educational principles, and establishes a vehicle of imaginary expression and action through knowledge and rules appropriations in a pleasant way. Curiously, *ludus* also refers to a “school” for roman gladiators: they used to be

taught to fight and use weapons—daggers, swords, tridents, and so on—in *ludi* (plural form of *ludus*), by “teachers” (in fact, gladiators’ trainers and often owners) called *lanistae* (plural form of *lanista*). The “game” gladiators were meant to “play” was also called *ludus*.

Modeling: In computer graphics, modeling is related to the process of representations of n-dimensional elements in a well-defined language or data structure. There are many techniques for modeling, many of them more suitable to some kinds of objects to be modeled.

Rendering: In computer graphics, rendering is the process of generating a still image from a scene, taking in account information about the geometries present in the scene, as well as viewpoint, lighting, shading, and texture information.

Software Metrics: Metrics are a set of parameters used to perform assessment of a product or process meant to be measured. Software metrics are commonly applied to the software engineering

process or the artifacts derived from them. The object-oriented metrics targeted in this chapter are part of a set of metrics proposed by Chidamber and Kemerer (1994), which are meant to give some quantitative values over a class diagram.

Zone of Proximal Development (ZPD): Determined by distance existing between real capacity to solve problems in an autonomous way and potential capacity to solve problems with the help of a partner (another person as teacher, colleague, or even a group).

Chapter 1.15

Using Video Games to Improve Literacy Levels of Males

Stephenie Hewett
The Citadel, USA

ABSTRACT

This chapter examines the differences in the educational needs of males, the origins of video games, and the issue of the decline in literacy achievement levels of male students worldwide. It promotes the idea that a new literacy which includes computer technology and visual literacy has changed the scope of literacy and that males have succeeded at developing the new literacy skills. The chapter is intended to inform educators of the literacy skills involved in video games, make connections with video game literacy and traditional literacy, and to encourage teachers to integrate video games into their curriculum.

INTRODUCTION

According to the 2005 National Assessment of Educational Progress (NAEP) females scored thirteen (13) points higher on average in reading than male students (National Center for Educational Statistics, 2005). Gurian (2001) also cites statistics indicating that boys:

- Earn seventy percent (70%) of D's and F's and fewer than half of the A's,
- Account for two-thirds of learning disability diagnoses,
- Represent ninety percent (90%) of discipline referrals,

Using Video Games to Improve Literacy Levels of Males

- Dominate such brain-related learning disorders as ADD/ADHD, with millions now medicated in schools,
- Make up eighty percent (80%) of the high school dropouts, and
- Make up fewer than forty percent (40%) of college students.

The current educational system around the world is failing to meet the educational needs of males. In the United States, Black males are three (3) times more likely than white students to be labeled as mentally disturbed (www.BET.com, 2005). Males are more often classified as being mentally retarded, having learning disabilities, and having attention deficit disorders.

Girls performed better than boys academically in the thirty-five (35) countries who participated in a three (3) year study of knowledge and skills of males and females. The Organization for Economic Co-operation and Development (OECD) studied males and females in industrialized countries including the United States, Canada, European countries, Australia, and Japan. The results show that reading and writing skills brought the male scores down the most. (Gurian & Stevens, 2004) The dismal educational achievement of males continues in the high school dropout rates and graduation rates of males.

The difference in graduation rates for males and females widen within minority groups. There is an eleven percent (11%) difference in graduation rates of African-American males and females, nine percent (9%) fewer Hispanic males graduate than Hispanic females, five percent (5%) fewer white males graduate as compared with white females, and three percent (3%) fewer Asian males graduate from high school than Asian females (Greene & Winters, 2006). During the past decade, the graduation rate for Black women improved while the rate for Black males slipped. Fifty-six percent (56%) of Black women graduate from high school compared with forty-three percent (43%) of Black

males (NAEP, 2005). The differences in high school graduation rates of males and females lead to differences in college attendance rates. Women earn an average of fifty-seven percent (57%) of all BA's and fifty-eight percent of master's degrees in the United States (Conlin, 2005). The United States Department of Education predicts that if the current trend continues that by 2020, there will be 156 women for every 100 men earning college degrees. The college attendance rates for African-American males are even lower with only thirty-seven percent (37%) of Black males being enrolled in college (NAEP, 2005). The college graduation rate of Black males is lower than any other group.

The research clearly shows that males are getting lost in the educational system. One of the problems could be that the current curriculum is designed for all students to learn the same things at the same time in the same ways. It does not examine the cultural expectations of or for the males and does not consider the differences in the males' brains, learning styles, or developmental levels. With the use of the current curriculum, the unrealistic expectations of teachers for males in the classroom, inappropriate teaching and presentation styles, and the restrictions on student movement in the classrooms, it becomes easy to understand why males appear to be angry, aggressive, and frustrated.

In order to relieve the frustrations of males and to reverse the current educational trends of males, it is important for educators to consider all types of instruction. All students should be taught utilizing the knowledge of cultural gender differences as well as gender differences in brains and interests. Cultural expectations and gender differences are difficult to quantitatively study but have been extensively researched by literary and developmental experts such as Leonie Rowan (2002), Elaine Millard (1997), and many others. Research on the brain has vastly expanded with new medical technologies available to scan and

learn more about the brain. Neurologists are finding that there are major differences in the characteristics of males' brains and females' brains. Evidence supporting brain differences in males and females is referenced by Michael Gurian and Kathy Stevens (2004) showing that:

- “boys brains have more cortical areas dedicated to spatial- mechanical functioning, males use, on average, half the brain space that females use for verbal-emotive functioning. The cortical trend toward special-mechanical functioning makes many boys want to move objects through space, like balls, model airplanes, or just their arms and legs. Most boys, although not all of them, will experience words and feels differently than girls do. (Blum, 1997; Moir & Jessel, 1989).
- boys have less serotonin than girls have, but they also have less oxytocin, the primary human bonding chemical. This makes it more likely that they will be physically impulsive and less likely that they neurally impulsiveness to sit still and empathetically chat with a friend (Moir & Jessel; 1989, Taylor, 2002).
- boys lateralize brain activity. Their brains not only operate with less blood flow than girls' brains, but they are also structured to compartmentalize learning. Thus, girls tend to multitask better than boys do, with fewer attention span problems and greater ability to make quick transitions between lessons (Havers, 1995).
- The male brain is set to renew, recharge, and reorient itself by entering what neurologists call a rest state. The boy in the back of the classroom whose eyes are drifting toward sleep has entered a neural rest state. It is predominantly boys who drift off without completing assignments, who stop taking notes and fall asleep during a lec-

ture, or who tap pencils or otherwise fidget in hopes of keeping themselves awake and learning. Females tend to recharge and reorient neural focus without rest states. Thus, a girl can be bored with a lesson, but she will nonetheless keep her eyes open, take notes, and perform relatively well. This is especially true when the teacher uses more words to teach a lesson instead of being spatial and diagrammatic. The more words a teacher uses, the more likely boys are to “zone out”, or go into rest state. The male brain is better suited for symbols, abstractions, diagrams, pictures, and objects moving through space than for the monotony of words (Gurian, 2001).”

The schools are failing to recognize and respond to the current educational gender specific needs of males. In today's world, computers and video games play a major role in a student's life. Whether the student is completing work on the computer or using it for video games, a major portion of a student's day is spent using a computer of some type. The education system has embraced the use of computers to complete assignments and conduct research for class projects. The disconnect between the educational system and technology occurs with the lack of a complete integration of the use of technology including video games for instructional purposes.

HISTORY OF USING VIDEO GAMES FOR INSTRUCTIONAL PURPOSES

In examining the history of educational games (video games), it is important to define the term educational video games. In this chapter, the definition of the term educational video games is written by Sara de Freitas (2006) in a report to the JISC e-Learning Programme in London. She defines educational games as “applications

using the characteristics of video and computer games to create engaging and immersive learning experiences for delivering specific learning goals, outcomes, and experiences” (de Freitas, 2006, 10). With this definition in mind, a review of the history of video games for educational purposes will be focused on the use of electronic games to enhance learning. *Spacewar* was the first computer game to be developed. In 1961, Steve Russell used a PDP-11 at the Massachusetts Institute of technology to develop the game that was collaborative and exhibited learning capabilities (Herz, 2001). The first games used to support learning and training were simulations. These games were war games and led to the fighting and shooting games of today (de Freitas, 2006). In the 1980’s, Brøderbund and the Learning Company are two of the first companies created who developed educational software. Reader Rabbit, developed in 1989 by the Learning Company, is one of the first software programs designed to teach children basic reading and spelling skills (http://en.wikipedia.org/wiki/Educational_software, 2007). The personal computer promoted the development of software that could be used to help students learn concepts, provide practice, and engage students in a fun activity. Peter Catalanotto first coined the word edutainment in the late 1990s as he traveled around the country edutaining school children about writing and illustrating. Edutainment is defined as “a form of entertainment designed to educate as well as to amuse” (<http://en.wikipedia.org/wiki/Edutainment>, 2007). Edutainment typically seeks to instruct or socialize its audience by embedding lessons in some familiar form of entertainment (<http://en.wikipedia.org/wiki/Edutainment>, 2007). Today, there are millions of video games that are considered as edutainment. Parents and children can use a search engine (google) using the key words “reading video games” and one hundred twenty-nine million (129,000,000) sites can be accessed.

CURRENT USE OF INSTRUCTIONAL TECHNOLOGY

Since the invention of the teaching machine in the 1920’s by Sidney Pressey, an educational psychology professor at Ohio State University, and the problem cylinder by M. E. LaZerte, Director of the School of Education at the University of Alberta, the use of technology in the classroom has been expanding and developing. In 1960, Programmed Logic for Automated Teaching Operations (PLATO) created the first computer assisted courses at the University of Illinois at Urbana-Champaign. From there, distance education classes were developed where students did not have to actually sit in classrooms to learn the concepts. Students could use the computer to assist them in mastering objectives and completing coursework at their convenience. In the 1970’s computers were first used in elementary classrooms in Canada. In 1976, the first virtual college was founded in the United States. In the 1980’s, PLATO introduced a cartridge to be used at home with the ATARI home computer escalating the use of home systems for instruction. The 1990’s saw an increase in the use of computers in schools with the establishment of computer labs in most schools. Teachers were able to individualize instruction with the software programs that were available. Educational software companies exploded with some school districts forming their own software libraries for teachers to check out programs for use in the computer labs. As computers became less expensive and more attainable for schools, computers began to appear in classrooms. Teachers began to develop PowerPoint presentations with the introduction of computer to television connections and LCD projectors. Learning games became less prevalent as teachers struggled to integrate technology into their daily lesson plans.

Sandford, Ulicsak, Facer, and Rudd (2006) conducted a MORI poll of teachers in the United Kingdom and found that thirty-one and five tenths

percent (31.5%) of teachers have used games designed for entertainment in their lessons and fifty-nine percent (59%) of the teachers reported a possibility of considering them in the future. The study also found that sixty-three percent (63%) of the teachers believed that students using games actually learned specific content knowledge.

In a Eutopia survey conducted by Sara Bernard, five hundred one teachers responded to the question, “Are computer and video games effective teaching tools?” (Bernard, [Http://www.edutopia.org/are-computer-and-video-games-effective-teaching-tools](http://www.edutopia.org/are-computer-and-video-games-effective-teaching-tools)). Seventy-eight percent (78%) of the responders voted yes that “computer games engage, motivate, and inspire students and educational researchers and game designers are collaborating to create their ideal niche in the classroom” (Bernard, [Http://www.edutopia.org/are-computer-and-video-games-effective-teaching-tools](http://www.edutopia.org/are-computer-and-video-games-effective-teaching-tools)). Many teachers agree with the theory of the benefits of video games without actually integrating them into their curricula. This is where there is a disconnect between the approval and actual application of video games into classroom instruction.

Video games are definitely part of students’ lives, especially the males. The interests of students need to be considered in creating an active, engaging learning environment. The integration of video games into instructional practices may help to connect males back to learning experiences.

VIDEO GAMES AND MALES

Males can find the action they seek from using video games. They enjoy fighters, shooters, action adventure games, and strategy games. More and more, males find the adventure and action they seek not from books but from video games. In an American study, one thousand four hundred ninety-one (1,491) children aged ten (10) to nineteen (19) comprised a representative sample of adolescents. It was found that thirty-six percent of

the sample population played video games. Eighty percent (80%) of the males and twenty percent (20%) of the females played video games for approximately one hour on weekdays and ninety (90) minutes on weekends. On the average, students who spent time playing video games spent thirty percent (30%) less time reading and thirty-four percent (34%) less time doing homework (Cummings; Vandewater, 2007). The study also found that for every hour males played video games during the week, they spent two (2) minutes less time reading. Educators and researchers need to understand what draws students, especially males, to sit for long periods of time and focus on video games. The studies have shown that there is a sharp difference in the percentage of males and females who play video games as well as differences in their video game preferences and amount of time spent playing video games. Male video game players tend to like person shooters and sports games. These games increase the chances that the player will be completely absorbed in playing the game. Game promoters believe that people play video games to escape from everyday life and to a world of adventure without risk. Adults who play video games report that video games are mentally stimulating and that hand-eye coordination is improved by playing (Dawson, 2007)

MALES AND READING

Reading assessments throughout the world are substantiating the fact that males are scoring lower than their female counterparts in reading. The National Center for Educational Statistics has been reporting reading and mathematics assessment results from 1971 to 2005 for the United States. Its report, the National Assessment of Educational Progress, documents that from 1971 to 2004 that males have consistently scored below females. Average scale score differences range from 12.7 (1971) to 5.3 in 2004 (<http://nces.ed.gov/nation-sreportcard/litnde/viewresults.asp>). In 2006, the

Canadian Human Resources and Social Development concluded from their assessments that “females have much superior reading achievement than males” (<http://www.hrsdc.gc.ca/en/cs/sp/hrsdclp/publications/2006-002833/page06.shtml>) In the Canadian study, sixty-one percent (61%) of the students in the high achievement reading category (75th percentile) were females leaving males with only thirty-nine percent (39%) scoring in the seventy-fifth (75th) percentile. Males also had seventy-three percent (73%) scoring in the low achieving category which is below the twenty-fifth (25th) percentile. Michael Sullivan, the director of the Weeks Public Library in Greenland cited research done by Lanning Taliaferro from the Journal News stating that “By the time boys are in the eleventh (11th) grade, they can be three (3) years behind girls in their reading levels” (Cicco, 2005)

In 2002, Smith and Wilhelm summarized their literacy and gender research in their book *Reading Don't Fix No Chevys: Literacy in the Lives of Young Men*. The conclusions include that:

- Males spend less time reading for pleasure than females.
- Males do not report reading as an enjoyable experience as often as females.
- Males are not as confident in their reading abilities as females.
- Males take longer to learn how to read than females.
- Males talk about what they are reading less often than females.
- Males like to physically respond to the reading by acting out responses or by making something.

Males do report that they enjoy stories and information that they can relate to through their own personal experiences (<http://www.liberating-boys.com/books.html>). Magazines, internet text, and even video games capture males' attention as being reading that they can relate to. Elizabeth

Haydon, an author of adolescent books, writes that “Themes that are appreciated by boys this age [preteen] are action, the more detailed the better, some sort of struggle, threat or fighting, particularly of the heroic sort – whether it is epic or in the schoolyard – suspense, puzzles, horror and humor, often of the crass kind.” (Brown, 2007)

VIDEO GAMES AND LEARNING AND LITERACY CONNECTIONS

Learning occurs when a person “gains knowledge or understanding of a skill by study, instruction, or experience” (Webster's New World Dictionary, 353). James Paul Gee, a University of Wisconsin-Madison curriculum and instruction professor, has studied the connection between video games, learning, and literacy. He found that learning principles and knowledge about human learning is incorporated into video games (Gee, 2003). Video games captivate players by giving them complex problems to solve in real world settings that get progressively more difficult with each level mastered. The players' problem solving skills are tested at each level with the game giving positive reinforcements for each accomplishment. That description of a video game could be the description of a learning centered environment producing successful students. “Playing video games evokes a potentially powerful, active learning environment that includes demonstration, rehearsal, and reinforcement” (Funk et al, 2006). Thinking and learning skills can be developed by playing some video games. Reading skills, logical thinking skills, observation skills, vocabulary development, problem solving skills, and strategy planning can all be improved through the use of some of the available video games. Most of the video games require reading. The problem occurs because the reading required in video games is not the traditional form of literacy thought to develop reading skills. Video games are creating new forms of literacy. In today's world, print

media and literacy of print media is not enough to be successful. Playing video games offers the opportunity to learn a different type of literacy. Computer games, the internet, instant messages, and phone texts have shaped the way people, especially males, interact with texts. Males use a sub-standard form of English to communicate with others quickly while playing games. The language used is to help them reach the goals of the game. The literacy of the games is action oriented. Paul Gee (2003) writes that visual literacy is an important part of communication that is often ignored in typical classrooms. The viewing and understanding of symbols, graphs, charts, and visuals is necessary to obtain an adequate level of literacy in today's world. "Visual literacy is just as important an element as that of reading the written word in gaining a more complete understanding of society and culture" (Madill and Sanford, 2006). Active learning can occur and generate a greater understanding by interacting visually with something rather than simply reading about it.

"Experiencing the world in new ways, forming new affiliations, and preparation for future learning" are the three (3) components of active learning identified by Gee (2003). Video games offer the student a visual image that invites the student to become completely involved in the experience. As the students interpret and become immersed in their imaginative play, the meaning of the experience is more tangible (Robertson, 2005). "They're learning to take up different pieces of information all at the same time. This is not just about entertainment. The skills that they are learning will transfer to the world of work" (Madill and Sanford, 2006). The skills obtained from playing video games may be more intricate than those required by simply reading a text.

Researchers (Schmidt, 2006) at the University of Victoria found that males exhibited high literacy levels in video game technology. The study concluded that the "unique richness" of the literacy of males in regards to video games

is not recognized as being meaningful or useful in today's educational system (Schmidt, 2006). Males enjoy reading the magazines and web sites that give directions, tips, and clues on how to progress further in the level of the games. Students actively seek information on the new game systems and video games that will be available in stores. Males interact with one another with a different heightened sense of excitement when discussing the video game, its characters, and action scenes. The interaction about and excitement regarding video games are the same behaviors that teachers seek in students required to read books and stories. The video game has led males to become a different type of reader requiring him to develop a literacy of the world of computers and online resources. Gee (2003) states that "video games are not replacing books, they are simply an art form that will interact with them, and change them and their role in society in various ways".

Teachers do not recognize that video games are a form of literacy or art. "It's very sophisticated, but a lot of adults aren't reading this kind of text, so we don't recognize it as high functioning because it doesn't look like traditional literacy", Leanna Madill said at the Canadian Society for the Study of Education in Toronto (2006). The video game players take for granted their knowledge of the video game terminology and computer literacy not recognizing the actual level of difficulty. Males are not becoming less literate; they are becoming more literate in a less traditional form of literacy. The new literacy is difficult for teachers to relate to and is one of the most pressing challenges for an educator in today's world.

CHALLENGES OF USING VIDEO GAMES TO IMPROVE LITERACY

One of the challenges facing educators is assessment of the new literacy. In order to measure improvement of literacy, there must be some form of assessment. Currently, the forms of avail-

able literacy assessment are the read the passage and answer questions type. This type of literacy assessment does not measure the new literacy that males have acquired. The use of games in instruction may promote different, more flexible types of assessments. It becomes the teacher's responsibility to become technologically literate to be able to develop and incorporate the new forms of assessment. Most teacher preparation programs have basic integration of technology classes in their programs but do not have the advanced level technology courses required for teachers to become adequately prepared to fully utilize and assess various forms of technology and technological literacy. Basically, we have PK-12th grade students entering classrooms with better developed technological skills than the teachers. The rush of new technology into the world has created a technological blockade in the educational system. Students have the abilities and skills to use technology and video games to learn, but teachers do not have the computer skills and video game knowledge to integrate video games into their learning curriculum.

Educators know that it is extremely important to motivate student learning through the use of the students' interests. Teachers also know that males are extremely interested in video games. To promote traditional literacy development, teachers must match students' interests with the right book. The same pedagogy holds true for using video games for instruction. Not all students like to play video games. Not all students like the same types of video games, and not all students are good at playing video games. Many students, including males, find video games to be frustrating. Providing a wide range of types of video games is important to match the interests and meet the needs of all male students.

Providing a wide variety of video games for instruction poses an additional problem. The expense of the hardware and software along with the lack of funding for such endeavors poses a threat to the development of a program that

utilizes video games to improve literacy. In the report, "Learning in Immersive Worlds: A Review of Game Based Learning", Sara de Freitas (2006) reported that "The main barrier to using games in school...is a lack of access to equipment and availability of up-to-date graphics/video cards-making it difficult for teachers to run games on their own PC's – a problem also faced in higher and further education". De Freitas (2006) listed the seven (7) major barriers to the integration of video games in learning practice including:

- "access to the correct hardware including PC's with high end graphics video cards;
- effective technical support or access to suitable technical support;
- familiarity with games-based software;
- community of practice within which to seek guidance and support;
- enough time to prepare effective games-based learning;
- learner groups who would like to learn using effective games-based approaches;
- cost of educational games software or licenses" (16)

Although barriers do exist for the integration of video games into the instructional process, there are ways to overcome the barriers.

POSSIBLE SOLUTIONS

Examining the barriers to the integration of video games into classroom curriculums can result in a more flexible instructional curriculum and assessment process. To ease the process of including video games to improve literacy of males in the regular school curriculum, the following initiatives need to be explored:

- Increase and improve video game training in teacher preparation programs;

- Create and adopt video game guidelines for teachers;
- Develop video game curriculum based on skills used in novels;
- Seek expanded funding for schools to purchase hardware and software;
- Analyze data to determine that video games do improve literacy in males.

Schools and colleges of education have begun to include instructional technology classes for all future teachers. These courses need to include methods of including video games into the curriculum as well as computer programming languages so that they will be able to develop video games that meet the curriculum requirements of individual classrooms. New master degree programs in instructional technology have appeared which may allow for more support in the schools for the teachers implementing game technology. Professional development classes in video game instruction for current teachers will also enhance the initiative. Having the teachers play the video games with the students will also serve as learning experiences for both the students and the teachers. The teachers can help instruct the concepts to be learned through playing the games; while the students teach the technology skills and literacy to be successful in the game.

For video games to be a successful tool in the classroom, teachers will need to have guidelines to follow and have video game learning outcomes aligned with the content standards. Typical guidelines for using video games to improve literacy of males include:

- Define and establish clear learning outcomes;
- Select the video game that supports the learning outcomes and that can be appropriately assessed;
- Sequence the learning activities so that the game fits and flows within the instruction,

practice, and assessment of the learning outcomes;

- Structure the game playing session with pre-play connections to the desired learning outcomes and post-play reflection on the actual concepts and skills learned;
- Assess the learning outcome of the video game including computer literacy skills;
- Evaluate the effectiveness of the game for reinforcing and teaching the desired skills and outcomes; and
- Make changes as needed based on the assessment data and feedback from students (de Freitas, 2006).

With the aforementioned guidelines serving as a framework and structure for teachers to follow, development of curricula integrating video games into literacy instruction will utilize best practices in teaching with video games.

In promoting literacy, best practices have typically revolved around the use of novels. Fiction and non-fiction books were used to teach classic literature skills. In today's educational arena, this approach is not working for all students, especially males (Conlin, 2003; Greene and Winters, 2006; Gurian, Henley, and Trueman, 2001). The skills that are usually taught with novels can be taught through the use of video games. These skills would be the easiest connection to video games. The specific skills/learning outcomes to be taught by the novel should be identified and sequenced. Then a video game which teaches the same skills should be identified/developed. The video game can then be placed in the correct sequence of instructional activities to insure that the proper outcomes occur. Assessments would determine the mastery of the outcomes/skills as well as the effectiveness of the game to teach and reinforce the desired outcomes and skills. Currently this type of literature curricula is not commercially available and would have to be created by the teachers. Curriculum development of this type is

time consuming and may require additional funding for teacher training and software development.

Funding for new initiatives in technology is essential to have the training, technical support, software support, and hardware to ensure success. Software designers need to consider the needs of teachers in developing new games. Teachers need to be proactive in demanding funding for development of curriculum that uses video games. Software designers and teachers need to come together to align literacy skills and standards with the current available video games to facilitate the development of the video game/literacy curriculum.

RECOMMENDATIONS FOR USING VIDEO GAMES TO IMPROVE LITERACY LEVELS OF MALES

To quicken the process of using video games to improve literacy levels in males, it is important to explore the current technology available. Millions of video games are available in stores all over the country. Although their educational qualities have not been their selling points, most video games can be used to teach certain literacy skills. For example, reading skills can be enhanced for males through video games by requiring the game player to read the directions for play first, then allowing the student to play the game, and finally having the student research the tips and hints to reach higher levels of play. Through this structure, teachers are requiring males to read. The more the males read, the better they get at it. Males do not resist reading about the video games that they love. Additional traditional literacy skills can be taught through video games including symbolism, genre, comprehension, literary merit, vocabulary development, logical thinking, critical thinking, and problem solving skills to list just a few. By using the current software available, traditional literacy connections can be made to the video games.

Male students can already list video games that match concepts being taught in history classes. Civilization builder games are historically based and allow the player to better understand geography of different areas and the effect of choices on the success or failure of the civilization. Video games create new paths and different outcomes that encourage the student to consider how the choices not made in real history could have changed historical events (Whelchel, 2007). By changing the choices made, students can actually create better civilizations and determine the causes of civilization failures through trial and error processes.

For learning with video games to be effective, connections need to be made between what is learned in the game and how it is applied to practice in other literary genres. This follows most theories and best practices of teaching and learning. Follow-up reflection of the learning outcomes by the game player and connections to the literary applications in different genres are essential (de Freitas, 2006). Wilhelm (1997) found that males have to responsively interact with the reading before critical analysis could take place. Games promote the responsive interaction required to think critically. Bonk and Dennen (2005) conducted empirical studies concerning skills supported by game-based learning approaches and found that “...another way to build conceptual knowledge is to engage in dialogue with peers or experts about the game during game play” (29). The hands-on learning experiences offered by video games promote the types of discussions between students that all teachers encourage. Male game players are more likely to excitedly explain their moves in a step-by-step sequence to another game player and analyze their moves and decisions altering the outcomes of the game.

In the new literacy studies conducted by Gee (2006), results supported the concept that reading and writing are not only mental achievements but are also social and cultural practices. Video games allow the players to simulate characters

and to share the characters' experiences and social relationships. Critical thinking skills are gained through interacting with the game, taking on new identities, solving problems through trial and error, and gaining expertise or literacy within the game (Craft, 2004). The analyzing skills gained through video game play are of the highest level of reading comprehension. If appropriately assessed, the literacy levels of the males would increase.

Through the vivid graphic images, character analysis, and challenges that video games present, students interact with the game acquiring mastery of skills that literacy teachers would recognize as essential for traditional literacy. Although students do not recognize the learning aspects of the game, they quickly become immersed in playing the game. In a presentation on "Teaching Generation X", Christopher Clark (2005) presented facts about learning including that video games and teachers have 30 seconds to "hook the player or the player is gone for good". He challenged educators to establish methods (including video games) to get students emotionally connected with the content as quickly as possible (Clark, 2005). Video games can "hook" males into obtaining high levels of literacy without even knowing that they are learning. Males may be able to show their literacy skills better through video games than through the traditional literacy assessments.

With males consistently scoring lower on literacy assessments than females, teachers need to know that:

- There is a real difference in literacy levels of males and females;
- Text selection and curriculum development should be based on the knowledge of males and their interests;
- Teacher assigned reading should be enhanced with self-selected reading;
- Males should be guided in making connections with texts through a wide variety of activities to support their reading comprehension and analysis skills (Bowen, 1997).

Knowing how males learn literacy skills best and what motivates them to read and learn is essential in closing the gap on literacy achievement.

As the keynote speaker at the University of Newcastle's 4th Biennial Working with Boys Building Fine Men's conference Dr. Martine F. Delfos, a Netherlands researcher said, "Boys learning can be enhanced by taking into their account evolutionary deeply embedded preference behavior. Teaching strategies should encompass boys' preference for competitive behavior; a cognitive style orientated more towards discovery and rote memory; and a need for strong peer connections. Boys have a tendency to action, and need action in class" (<http://www.newcastle.edu.au/news/2005/04/teachingboys.html>). In Michael Pollock's book entitled *Real Boys: Rescuing Our Sons from the Myths of Boyhood* (1998) states that boys have superior spatial abilities and see things in three dimension easily. He advocates using activities with intense movements and make believe violence. He contends that by allowing these types of activities, boys would learn how to harness the energy. Video games can create the active learning environment that males need through demonstration, demonstration, rehearsal, and reinforcement (Funk et al, 2006).

SUMMARY

The researchers (Craft; Cummings; Dawson, de Freitas; Funk et al) studying the use of video games in promoting learning agree that video games offer the hands-on types of experience that males need to efficiently learn. Males learn differently from females and require a more interactive, physical type of activity. Video games offer the vivid images, flashy display of text, action, and challenges that engage males in participating and learning. The current generation of male students enters classrooms with technology skills that far

exceed that of the teachers. Many teachers do not recognize the technology skills as literacy skills, although the literacy outcomes of a male playing a video game may be very similar to the outcomes expected in traditional literacy activities. Research on the use of video games in classrooms is expansive with more positive impacts noted than negative. Research on the use of video games to improve literacy skills of males is limited, however. James Gee is the leading researcher in the area of video games, learning, and literacy. He strongly promotes the use of video games to improve literacy skills. He explains that the literacy skills of the males currently in school are not lower than they have been in the past. They are just different. He contends that the literacy skills taught by the use of video games reflect the skills necessary to be successful in today's world. In the Review of Game Based Learning, de Freitas (2006) explains the possibilities that game based learning holds for the future educational system.

For game based learning to progress in the educational arena, more funding needs to be offered to schools to improve their levels of technological support and provide up-to-date equipment and software. Teacher preparation programs need to include more indepth computer classes including computer programming as well as instructional technology integration. Teachers need to be trained in the structure and guidelines for integrating video games into their curriculum. Teachers and video game developers need to work together to align content standards and games. Game developers need to consider the educational possibilities of creating games that go along with traditional reading materials. Video games can expand the understanding of the written texts, especially of males.

If the goal of learning is to "gain knowledge or understanding of a skill by study, instruction, or experience" (Webster's New World Dictionary, 353), video games may be the best learning tool for males. It offers the opportunities for males to

study their choices/moves, analyze the outcomes of those choices/moves, reflect on the changes to be made to improve their level of play, and experience a wide variety of situations that simulate real world issues and problems. The active nature of video games match the learning requirements of males and better engage them in the learning activity. Video games have an addictive nature to them resulting in video games being an excellent tool for creating lifelong learners. The entertaining aspect of the video game combined with the educational components create an potentially exciting and invigorating classroom learning tool which may improve the literacy levels of males. More research on the literacy level gains with the use of video games needs to be conducted to best determine how to meet the twenty-first century literacy needs of all students.

KEY TERMS AND DEFINITIONS

Brain Differences: The variations found in the male and female brains.

Computer Assisted Courses: Software programs designed to provide extra instruction and practice on educational concepts. For example: extra computer based drill on multiplication facts.

Cultural Gender Differences: Ways in which males and females are expected to act and are treated in different cultures.

Educational Video Games: Software programs designed to provide instruction, practice, and feedback of educational concepts.

Edutainment: Entertaining ways to teach educational concepts typically through games.

Instructional Technology: The use of any type of computer software programs or computer components such as LCD projector and SMART Boards to teach students educational concepts.

New Literacy: The increased requirements of literacy, not only requiring understanding of the written word, but understanding of computer images, languages, software, and hardware.

Reading Assessments: Diagnostic tests to determine levels of reading.

Traditional Literacy: The ability to read the written word to gain understanding and meaning.

Visual Literacy: The ability to look at charts, graphs, pictures, and other visual images to grasp an intended message.

This work was previously published in Handbook of Research on New Media Literacy at the K-12 Level: Issues and Challenges, edited by Leo Tan Wee Hin and R. Subramaniam, pp. 286-299, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Section II

Development and Design Methodologies

This section provides exhaustive coverage of conceptual architecture frameworks to endow with the reader a broad understanding of the promising technological developments within the field of instructional design. Research fundamentals imperative to the understanding of developmental processes within instructional design are offered. From broad surveys to specific discussions and case studies on electronic tools, the research found within this section spans the discipline while offering detailed, specific discussions. From basic designs to abstract development, these chapters serve to expand the reaches of development and design technologies within the instructional design community.

Chapter 2.1

Planning for Technology Integration

Henryk R. Marcinkiewicz
Aramco Services Company, USA

ABSTRACT

Three models structure the planning for technology integration into instruction. Institutional needs are assessed for three dimensions suggested in Gilbert's, "Model of Human Competence." The areas needing addressing are typically within instruction; therefore, the process steps of a generic instructional design model are used. Within designing for instruction, Bransford's, "variables affecting learning," are the focal points organizational planners need to consider in planning instruction. Instruction is framed as "faculty-as-learner centered instruction." The variables are also a significant aspect of the content of instruction for faculty because faculty will use them in planning their own instruction integrated with technology.

DOI: 10.4018/978-1-60960-503-2.ch201

INTRODUCTION

The work of integrating technology into instruction at an institution may be daunting, particularly in the absence of a plan. To support technology integration, a plan is described with the goal of competence in the area of teaching. The plan calls for assessing the co-requisite conditions of an institution and their influences on the goal. The underlying model is Thomas Gilbert's model of human competence (Chevalier, 2003; Gilbert, 1978). The institutional needs assessment is combined with the general process of an instructional design model. The latter is used because a typical institutional condition needing intervention is the need for instruction among personnel. In practice, the entire process is best organized as a series of questions. The discussion is outlined according to that logic. The process flow will be familiar to instructional technologists and organizational

planners and it will appeal to their sense of a systemic approach to problem solution.

In the first part of the plan, technology is identified, and needs are assessed. The next two steps are instructional planning based on three reasons. First, most work in technology integration has a training need—personnel need to understand institutional information, or how, why, and when to use the target technology. Second, instructional planning models may be fairly wide-ranging and are flexible enough to apply to organizational systems—they work well for that purpose. Third, it is useful to consider faculty as the benefactors of learner-centered instruction, it may be considered as, “faculty-as-learner centered instruction.”

There are several strategies for the integration process that are based on research in the adoption of instructional technology. They are meeting subjective norms, which is akin to peer pressure, and the management of institutional expectations. The dimension for deciding the use of either strategy is the relative novelty or newness of a technology to an institution.

In summary, the process is workable, practical, and effective; that is, if followed it does help one to achieve technology integration at an institution. This ought to offer a strong measure of reassurance to those professionals undertaking the task. The challenge, as often happens, is in the actual implementation.

THE PLAN

Which technology is needed?

This is a wide-ranging question with conceptual as well as practical answers. For the purposes of institutional planning, the latter are more important; there are several notions of what technology is and which technology is wanted. Begin by considering the materials, tools, and processes that are useful for instruction. The technology used in instruction typically refers to computers or the software applications for computers.

The kinds of technology most institutional planners deal with include communication systems such as e-mail or messaging, and software applications for administrative use including student auditing systems. They also include instructional technologies that encompass software and hardware to facilitate learning. These include online learning management systems, individual audio devices, and online virtual worlds.

The purpose of identifying technology is to focus your work and to select that with which you will work. The result of this process is an answer to the question of which technology you want faculty to use in instruction. You know what is needed in general. Specify what is needed and set that as a standard expectation.

Part A: Assess the Institution Conceptual Model

1. Define Competence

A standard expectation has been established that faculty will use the given technology. (The working example in this chapter will be that faculty will use a learning management system (LMS) in instruction.) Express the expectation into operational terms—faculty will be competent in integrating an LMS in instruction. There may be other expectations, but for whichever expectation is decided, the criterion for it is competence. Identifying the expectation thus allows for using Thomas Gilbert’s model of human competence to structure this phase of the overall process (Chevalier, 2003; Gilbert, 1978).

The model suggests three co-requisite dimensions addressed from two areas of the institution. The dimensions are information, instrumentation, and motivation. The two areas are the external and the internal. The external refers to the institution. Typically, it includes the administration and its members who support and provide the conditions for the success of an individual faculty member. Because it does not include faculty, it is external to

Table 1. Gilbert's model of human competence

<i>Environmental Supports (Institution)</i> <i>Repertory of Behavior (Faculty Member)</i>	Information	Instrumentation	Incentives
	Knowledge	Capacity	Motives

the individual faculty member. The internal refers to individual faculty members. The emphases for the dimensions vary as appropriate for each area and are depicted in the matrix shown in Table 1.

For the external area—Information:

Information refers to the expectations of the institution expressed as vision, mission, and goal statements and includes institutional philosophy. It is the body of information about the institution that must be communicated to employees generally and specifically. It is likely that some parts will differ by institutional organization. There may be different expectations for faculty than there are for residential life staff, for example. The role of the external area including all levels of administration and support is to communicate the expectations for competence towards the faculty. This means that the provost as well as a librarian or a student activities staff member know that faculty are expected to use an LMS in instruction.

For the internal area—Knowledge:

To achieve competence in using an LMS for instruction, a faculty member must be aware of the information from the institution. A faculty member must also know, understand, and especially, accept the expectations for competence. The three dimensions are co-requisite meaning that all of them must be successful in order to achieve the goal of competence for individuals. It is obvious how if a faculty member does not accept the expectation, meeting competence is thwarted.

For the external area—Instrumentation:

Instrumentation refers to the tools and resources necessary to complete the competent behavior. For LMS use it includes computers, connection to a network, LMS software, support software, etc. The responsibilities of the institution are to ensure that the necessary resources are available and functioning at the expected level of quality, the availability is communicated, and use of the resources is possible. The institution is also responsible for providing education and training to learn how to use the technological resources.

For the internal area—Capacity:

Instrumentation for a faculty member refers to the ability or capacity, the interest or inclination towards, the scheduling allowing, or the selection of personnel for using LMS technology. Levels of individual instrumentation vary and the degrees of variation determine the quantity and quality of instruction or other remediation. Faculty may understand how to use LMS technology but do not have a preference for it, or vice versa.

For the external area—Motivation—Incentive:

The provision of incentives properly states the contributing role that an institution has towards a faculty member in regards to motivation. It is the responsibility of the institution to provide incentives for achieving competence by integrating LMS technology into instruction. There are a variety of incentives including salary, awards or other recognition such as the recognition for the

use of technology in instruction towards tenure and promotion. Motivation does not occur if the intended recipient does not accept the incentive. It is the responsibility of the institution to provide the appropriate incentives for faculty.

For the internal area—Motivation—Motives:

Faculty need to communicate their expectations for incentives. It is not accurately stated as a responsibility of faculty but rather as a natural consequence that if the appropriate incentives are made available, faculty will be motivated to achieve competence. For the purposes of this process, Gilbert's model is a useful structure. It is not entirely all-encompassing as an example, for much of faculty competence in using an LMS may be prompted by internal incentives such as personal or professional satisfaction. A knowledgeable institution will be aware of that, understand it, and foster it among faculty by making the conditions necessary for internal incentives to occur.

2. Assess Whether all Conditions are Met for Competence

Consider the three dimensions of the model of human competence. Use the model of competence to structure the assessment of an institution to determine which parts of the institution are providing the conditions necessary for competence to occur. Recall that the premise is that the competence is being sought. Specifically, competence in the integration of technology in instruction is being sought. The working example is the integration of Learning Management Systems (LMS) in instruction.

Here is what to do: External Information

Assess the institution's information. Recall that the external area refers to those parts of the institution that contribute to the work conditions of the target employee, which is in this case an

individual faculty member. Following are samples of assessment questions germane to the target of competence.

Message Communicated

- What is the institution's vision?
- Does it refer to the integration of technology? To what level of specificity?
- What is the institution's philosophy?
- Does it refer to the integration of technology? To what level of specificity?
- What are the goals of the institution?
- Do they refer to the integration of technology? To what level of specificity?
- Assess the layers of administration for the above questions beginning with the entire institution to the next level which may be a college, school or department, etc.

Communication Process

- How is the message communicated? It could be in an annual presidential or other executive address. It could also be in the institutional catalogue or other prominent publication.
- To whom is the message communicated? Is it for the general public? Is there an expectation that the message be received? How is that expectation operationalized? Is there an executive order directing all managers to announce the messages? Is it expected to be received by virtue of the fact that it is part of the primary point of contact for the institution, such as a Web site may be?
- Is there an expectation that the messages be accepted as well as being received and understood? How is that expectation operationalized? Is there an order from the executive or other level of administration directing the

Planning for Technology Integration

faculty to acknowledge and accept the messages?

- In summary, it needs to be established
 - Whether relevant communications are being made
 - Whether relevant communications are being made via appropriate channels
 - Whether the institution expects faculty to receive, understand, and accept the messages.

Internal Information

Assess faculty members' responses to the institution's information about competent behavior in the integration of technology in instruction—the use of an LMS.

Following are samples of assessment questions:

- Do the faculty know that the institution at some level of administration has a target of competence in the use of an LMS?
- Do the faculty know that competence in the use of an LMS is expected?
- Do the faculty understand the institutional target? Do they know what an LMS is? Do they know which is being used by the institution? Do they know what the implementation plans for such a system are?
- Do the faculty understand the institution's intentions?
- Do the faculty understand the institution's expectations?
- Do the faculty accept the institution's intentions?
- Do the faculty accept the institution's expectations?
- Will the faculty act on the institution's intentions and expectations?
- In summary, it needs to be established
 - Whether relevant communications about the expectations of competence are being received

- Whether relevant communications are being understood, and
- Whether relevant communications are being accepted by faculty.

External Instrumentation: Resources

Assess the institution's resources. In the discussion above about the conceptual model, an assumption was made that it was the responsibility of the institution—the area external to the target of competent behavior, the faculty member—to provide the necessary resources in all its connotations. These include hardware, software, and spaces for the instrumentation to be used such as laboratories, classrooms, or offices. The connotations include reasonable availability to the instrumentation in its various locations. Reasonable accessibility needs to be provided, also. Importantly, either instruction in the use of the instrumentation needs to be provided or means for the instruction need to be provided. The institution may conduct faculty development programming or faculty may participate in such instruction externally.

Following are samples of assessment questions:

- Is the appropriate kind of hardware provided?
- Is the appropriate kind of software provided?
- Is there enough instrumentation or are there enough opportunities to use it?
- Is the instrumentation functional, current, reliable, and in good working order?
- To what degree of accommodation must faculty submit in order to use the instrumentation? Is it within proximity? Is the schedule for the use of it reasonable?
- Is instruction for the competent behavior, using an LMS, provided?
- Is the necessary instrumentation accessible? (Can it be readily accessed?)

- Is instruction relevant to the needs of the students, that is, the faculty?
 - Is instruction scheduled to meet the widely heterogeneous schedules of faculty?
 - In summary, it needs to be established
 - Whether there is appropriate instrumentation
 - Whether the instrumentation is available, there is enough of it
 - Whether the instrumentation is operational
 - Whether the instrumentation is accessible, the distance to it is reasonable and the schedule for access is reasonable
 - Whether there is appropriate training.
- Internal Instrumentation: Capacity

Assess faculty members' responses to the instrumentation. Following are samples of assessment questions:

- Do the faculty know which resources are needed?
- Do the faculty know when the resources are available?
- Do the faculty know where the resources are available?
- Do the faculty know how to get access to the resources, that is, locations, log in, passwords, etc.?
- Do the faculty schedules allow for accessing the resources?
- Do the faculty know how to use the resources?
- Do the faculty know how to access instruction for the use of the resources?
- Do the faculty learn from the instruction?
- In summary, it needs to be established
 - Whether the faculty know what resources are needed
 - Whether the faculty know how the resources are available

- Whether the faculty know how to access the resources
- Whether the faculty can accommodate the expected use of the resources per their schedule
- Whether the faculty know that training is available
- Whether the faculty make use of available training
- Whether the faculty learn from the training.

External Motivation: Incentives

Assess the institution's use of incentives for faculty to reward competence in the use of an LMS. Recall that the institution's contribution to motivation is in the provision of incentives. Following are samples of assessment questions:

- Are there incentives for the use of an LMS?
- Which incentives are there for the use of an LMS?
- Do the incentives match the needs and expectations of faculty?
- Are the incentives material, such as salary or other compensation?
- Are the incentives symbolic, such as awards?
- Do the incentives acknowledge the professionalism of the faculty?
- Does competence in LMS use contribute to faculty promotion and tenure?
- Are conditions made available that promote faculty members' internal motivation for the pursuit of competence?
- In summary, it needs to be established
 - Whether incentives are available to faculty for LMS use
 - Whether the incentives are appropriate.

Internal Motivation

Assess the faculty members' responses to incentives rewarding competence in the use of an LMS. Recall that it is characteristic of human nature that an appropriate incentive be given in order for a person to accept it.

Following are samples of assessment questions:

- Are the incentives appropriate, that is, do they motivate the faculty to pursue competence in using the LMS?
- Is internal motivation encouraged?

In summary, it needs to be established

- Whether faculty respond to the incentives.

3. Repair the Areas of Deficiency

Communication Deficiency

The model suggests the most important dimensions that contribute to competence. Once they have been defined and identified in an organization, the next step is to determine the status of whether the dimensions are meeting the expectations for competence. If, for instance, the institution has formulated a statement about the use of an LMS but demonstrates limited communication of it as evidenced by the absence of principal communication media for the campus such as its Web site, internal e-mail or print publication, communication through the chain of command, etc. and if a survey of employees, particularly the faculty, reveals that there is a little awareness of the institutional view, then there is a deficit of some sort. From this deficit it can be inferred that there may not be enough communication, or that the media are ineffective, or that the intended audience, the faculty, does not respond to the media. It is impossible to expect that there would be action taken or understanding of a communication if attention is not paid to it. The action of identifying deficits in expectations and then correcting them is the essential process for enabling the conditions necessary for competence in the use of an LMS.

Instrumentation Deficiency

The institutional assessment may reveal that there is an LMS license, but few of the faculty have been exposed to it or have been instructed in its use. Deficiencies in this case are the lack of familiarity with and knowledge and skill in the use of the LMS for instruction. The need to be addressed would be the understanding and the skill sets of the faculty.

Motivation Deficiency

The institutional assessment may reveal that there are not any incentives provided to encourage and maintain the use of the LMS. The faculty members who have integrated it into instruction are largely early adopters who respond to their own personal incentives who would attempt to use the LMS regardless of an institutional common plan.

The examples of deficits are generalized and there will be nuanced versions of them in the organizational assessment. Predictable deficiencies are in the areas of faculty capacity and knowledge and in institutional incentives in respect of the integration of technology. Because these two areas of deficiency are the most likely to occur, strategies for addressing them are suggested.

Part B: Professional Development—Provide Instruction

When your organizational assessment reveals that the area of deficiency is capacity, it may be that training for professional development is appropriate. Consider the technology that you are targeting, LMS in a matrix of two dimensions: degree of importance and level of skill among faculty.

See Figure 1. The quadrant of interest is the intersection of high importance and low skills. This may be evidence for the need for instruction. If there were high importance and high related skills, then it is unlikely that instruction would satisfy the deficit determined by the organizational assessment.

Figure 1. A need for training indicated

The deficiency between the importance of the skills needed and the actual skills available illustrates a situation predicted by Rossett's (1987) initiators of training needs assessments—the use of an LMS may be a “new system or technology” for those faculty with low skills in the integration of the highly important use of LMS. When there is a need for instruction, follow an instructional design model even though the learners are faculty members. In this case, you can develop “faculty-as-learner centered instruction.”

An Instructional Design Model

Consider preparation for teaching faculty as planning for instruction—follow an instructional design model to guide your instructional planning. ADDIE is a model with most of the elements which are found in other instructional design models as well as in research and planning models. The acronym stands for Assessment, Design, Develop, Implement, and Evaluate (Molenda, 2003; Schrock, 1991)

Assessment

How do you know instruction is needed?

The organizational assessment that was done within the parameters of the model of human competence resulted in the identification of de-

ficiencies such as the need for instruction among faculty. The assessment should also have revealed the level of instruction needed.

Design Instruction

What do the faculty need to learn? What are your expected outcomes for the instruction?

Understand your students and their needs and plan to meet them. Plan “faculty-as-learner centered” instruction: What do you need to know about your faculty-students?

To guide your design process focus on the factors affecting learning suggested by Bransford (1979). These factors will be used twice in your planning; once for planning the instruction of your students. The second time will be as the content of the instruction your faculty-students will learn. The factors are the learners’ characteristics; the media of instruction, the method of instruction, and assessment of learning.

Learner Characteristics

Who are faculty?

What are their needs?

How do they respond to technology?

Some characteristics of academic faculty include the love of and the pursuit of learning and recognition for one’s intellect. Find other traits

that would be relevant to your instruction of them. Faculty response to the use of technology may not be the same as the general public because faculty members are increasingly confronted with technology in their work. As a result, they would have more opportunities and direct experience to form opinions about technology.

Media

Which media are appropriate?

Because one of the subjects being taught would be the use of an LMS, the system itself ought to be used directly in instruction. Faculty as highly intelligent, adult learners ought to respond well to the medium of instruction being the same as the subject of instruction. There is a double lesson in this instruction in that if the media are used well to demonstrate how technology can facilitate media, then the point needs to be made that that is the eventual goal.

Method

What will the learners need to do during instruction?

In the basis for Bransford's original work, the term used was orienting task. This refers to the activity that the learner performed in order to learn the point of the instruction. This could be a method. Would the presentation and practice of information be orchestrated for the learners' discovery or would it be provided by the instructor or other source of information? For this group of adult learners, experience has shown that non-embarrassing actual or "hands on" practice in very small groups is appreciated.

Assessment

How will you and the students know they are learning?

Are your faculty-students learning what you and they expected? Is your instruction successful? A much used and useful assessment of your instruction is the Small Group Instructional Diagnosis (Clark & Redmond, 1982).

There are three questions:

1. What did you like about the instruction?
 2. What should have been excluded from the instruction?
 3. What should have been included in the instruction?
- Content
What will they learn?

The subject of the instruction for the faculty is the knowledge and skills necessary for using the LMS. In order to achieve integration of the LMS, the faculty-students also need to learn about the factors affecting learning to help plan their instruction. Just as the planner for technology integration follows an instructional design model and the factors affecting learning, faculty need to know about the factors affecting learning for their students. They need to know the characteristics of their students, the ones that will cause them to modify or target their instruction such as students' reading ability. There may be needs to keep in mind such as the familiarity with the native language of instruction.

The faculty-students need to know which media work well with the subjects they are teaching and with the needs of their students. They need to know which methods work well with their students and with the media they use. They also need to know which assessments are informative and instructive.

Part C: Motivation: Select a Strategy

It is necessary to create the conditions for which technology can be integrated. To select your strategy, determine the relative novelty for technol-

ogy use at the institution. The assessment of the institution using the competence model ought to reveal the relative novelty of the technology being integrated. Is the use of an LMS something new and unfamiliar or is it common knowledge and there is much experience in the use of it? There are two principal organizational strategies to employ based on the relative novelty. At an institution where the use of technology is novel, motivate with the goal that there is much awareness, much interest, much familiarity: use subjective norms, create dependencies, and create infrastructure. Where technology use is typical and not novel, manage use per institutional needs. Identify expectations, plan staffing and curricula accordingly. At such institutions, technology is integrated and the strategic goal is to maintain the integration through management of it.

Technology Integration as Novel

For an institution where technology is new, the goals are widespread awareness building and motivation. The strategies are to use subjective norms, create dependencies, and create infrastructure.

Subjective Norms

A series of studies (Marcinkiewicz, 1996, 1995/1995, 1995, 1993/1994) revealed that the most predictive personological variable of teachers' use of instructional computing was subjective norms. Subjective norms refers to the perception that teachers use technology because they believe that significant constituents expect them to use technology. They use technology because they believe that students, administrators, learned societies, and their colleagues expect them to. It is similar to "peer pressure" in that the incentive is meeting the perceived expectations of others. Subjective norms are operationalized by communicating the expectations to faculty. The research has shown that faculty will use technology if they

believe that the constituent groups expect it of them. It supports the need for excellent communication. They need to know that students expect LMS in instruction. Students can be surveyed to know their minds on the matter. Faculty need to know that administration expects them to use LMS. This coincides with the prediction of the model of human competence discussed above. Faculty need to know that their colleagues and learned societies expect them to use LMS. These groups are the support system of faculty; they are the peers and colleagues with whom faculty identify.

Create Dependencies and Infrastructure

One knows that one is responding to a dependency for technology when a task cannot be accomplished without it, or the completion of a task would be done differently than typically expected. An example of this is the cessation of departmental memos on paper; memos will only be posted online via e-mail or perhaps via an LMS. New course offerings will be availed if they are conducted as hybrids with some percentage of them requiring online LMS instruction; otherwise, the courses are not run. Many occurrences exist in professional and personal life including the upgrading of technical services, price changes for needed services, etc. The creation of dependencies is not a goal, but rather a strategy that provides the incentive of completion of a necessary task. The tasks to be performed ought to be a part of the infrastructure of an institution. An example of the complete use of an LMS as a part of the infrastructure of an institution is an LMS for an online degree. In this instance, completion of the degree is made possible or required by the use of an LMS because it is a fundamental part of the infrastructure of the institution offering the degree. Make the use of the technology necessary for the performance of activities that are parts of the infrastructure.

Technology Integration as Mature

An institution that can post employment announcements for faculty requiring knowledge and experience in the use of LMS demonstrates maturity in the integration of technology for instruction. Under such conditions, an institution has defined technology and its expectations for its use; faculty, staff, students, and administration accept and expect the use of the technology. There is sufficient instrumentation available and accessible and there are continuous opportunities for professional development. There are also incentives for the successful use of the technology and faculty are motivated by the incentives. This level of technology integration is the ideal goal state for institutions. In this state the strategy for the integration is management of expectations. This is accomplished by hiring appropriately and providing professional development opportunities. Furthermore, there is continual planning for technology integration.

SUMMARY

The purpose of this set of processes is to guide organizational planners for the integration of technology into instruction. A model for human competence is used to specify the deficient areas, those not supporting competence in the integration of technology. Typically, the deficiencies are the lack of knowledge or skills. An organizational strategy for the introduction of new technology is to begin to create dependencies on it for the completion of necessary tasks. Another strategy is to communicate the expectation that the faculty are expected to use technology by their peers, students, learned societies, and administration. For organizations where technology integration is mature or not novel, integration can be managed by the administration as by institutionalizing job descriptions that require integration.

KEY TERMS AND DEFINITIONS

Dependency: The need for using technology in order to complete one's work.

Integration: The condition in which technology is used in instruction so that without it instruction would not be possible as intended.

Learning Management System (LMS): A set of online processes focused on instruction that function together.

Subjective Norms: The personal belief that others have expectations that one should behave in a certain way. The belief influences one to behave that way.

Technology: The materials, processes, or tools used to solve problems.

This work was previously published in Handbook of Research on Technology Project Management, Planning, and Operations, edited by Terry T. Kidd, pp. 385-396, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 2.2

Bringing Reality into the Classroom

Antonio Santos
Universidad de las Americas Puebla, Mexico

ABSTRACT

Researchers and practitioners have been advocating that the nature of learning is contextually situated, and that this should be reflected in the development of learning experiences designed to acquire knowledge. However, learning experiences are still being developed as mere one-dimensional processes aimed to move, from the teacher into the student, pure autonomous pieces of content that are stripped from all their contextual and cultural information. The purpose of this manuscript is to propose a methodology to allow instructional designers and teachers to encompass the complexities of reality so that they can bring it pedagogically into their classrooms to build meaningful authentic learning experiences. This methodology permits students to first engage

in problem solving activities and then present their solutions using a computer application as a cognitive tool. The chapter discusses literature related with the development of situated learning environments, proposes a methodology for facilitating context-dependent knowledge building, and describes a case where the methodology was used and evaluated.

INTRODUCTION

For more than a decade, researchers and practitioners have been advocating that the nature of learning is contextually situated, and that this should be reflected in the development of learning experiences designed to acquire knowledge. However, in spite of all the evidence gathered so far about the importance of understanding the process of human learning as intrinsically linked to context

DOI: 10.4018/978-1-60960-503-2.ch202

and culture (Brown, Collins, & Duguid, 1989) and indistinct from acting (Maturana & Varela, 1998), learning experiences are still being developed as mere one-dimensional processes aimed to move, from the teacher into the student, pure autonomous pieces of content that are stripped from all their contextual and cultural information.

According to the constructivist perspective, this linear, cause-and-effect understanding of the learning process is used because knowledge, the product of learning, is wrongly conceptualized as an object that can be transferred from some form of repository to a human mind. Thus, knowledge is confounded with information and content. Moreover, information and content are also incorrectly understood as being independent of the contexts and cultures in which they were developed and used. Consequently, human knowing and learning are equated with the basic acts of being exposed to, and storing, independent entities of information and content.

The consequence of educating students this way is that they end up with rather big amounts of inert decontextualized knowledge, which they do not know what to do with, besides using it to move forward in the school system that has given them this kind of knowledge. During their school years, basic education learners memorize content as if they did not have to do anything with it besides answering a test. They, more or less, accept as an act of faith their teachers' promise about the

possible future transfer of that knowledge to their "real life." Nevertheless, in higher education, students that are finishing their degrees always worry about not having cleared the relationship between what they learned and the practical nature of their upcoming jobs. In general, it can be said that students do not relate what they learn to the contexts and cultures where they are supposed to use that knowledge because it is context-independent and lacks the components that are necessary to link it to real life situations (See Figure 1); they only relate what they are learning to the very school's traditional didactic culture (Brown et al., 1989). In a few words, students receive, memorize, repeat, move to the next grade, and forget.

Some causes that could explain why educational institutions remain in the didactic teaching and learning paradigm are:

1. Accepting the constructivist notion that knowledge, learning, and content do not exist in a vacuum and that they are always context related entails profound changes to the school as a whole because, in essence, this posture represents a new paradigm. In consequence, it "...requires more of a paradigm shift in educational practice than most institutions are ready to accommodate." (Jonassen & Carr, 2000, p. 166). It is not just a matter of using a new group of teaching strategies, it means innovating in several of the schools'

Figure 1. Knowledge is built as context-independent

basic educational processes such as curriculum design, teachers training, learning assessment, relationships with parents, and most importantly, classroom environment. The basic teaching and learning process has to change profoundly because, as Miettinen (1999) states, to incorporate content context into the classroom the didactic model of teaching needs to be broken.

2. Even when some schools are opened to this new view of learning, they do not take action because they still do not know how to manage the different educational processes that emerge under this new paradigm. That is, under the traditional paradigm, administrators clearly understand the orderly cause and effect model of pre-stating objectives, identifying instructional strategies to teach them, and assessing if, what was stated in the objectives, was or not achieved. A linear model like this facilitates the control and supervision of what is going on inside the classroom and allows to account for its results. We could say that, at the organizational level, there is not a situated learning model for administering an educational institution.
3. There are few instructional design models for creating learning activities under this different paradigm, and the ones that have been developed have not been sufficiently tried and researched to be proven practical.

The purpose of this manuscript is to further explore and add to the solution of the third identified cause. That is, based on several years of applying constructivist theory on my teaching and research projects, I will propose a methodology to allow instructional designers and teachers to encompass the complexities of reality so that they can bring it pedagogically into their classrooms to build meaningful authentic learning experiences. The aim is to describe how to contextualize content so that students can actively build and negotiate meanings and link them to environments where

they can potentially apply those meanings. In other words, I will try to describe a methodology to, on the one hand, “bring reality into the classroom,” and, on the other, facilitate for students the process of transferring the newly constructed knowledge back to “reality.”

On this subject, some important questions that have been addressed by researchers are:

1. How can we analyze and comprehend the complex real-life situations, where human knowledge is created, together with their contexts of activities and cultures? (See Leontev’s studies, for example Leontev, 1978; Engeström, Miettinen, & Punamäki, 1999; Brown & Duguid, 2000; and the special section of volume 45, number 2, 2005 of the *Educational Technology Magazine*, which was dedicated to cultural studies in instructional design).
2. How can we bring those complex real-life situations into the classroom so that our students can live meaningful authentic learning experiences? (See the literature around the design of learning environments, for example: Cognition & Technology Group at Vanderbilt, 1993; Campbell & Monson, 1994; Jonassen, 1999; Jonassen & Rohrer-Murphy, 1999; Wilson, 1996).
3. How can this type of knowledge construction be evaluated, that is, how can we assess how knowledge is being actually constructed inside the students’ heads? About this particular aspect, although most of the authors cited in the previous questions also address evaluation issues, assessing this type of learning becomes complicated because it requires a qualitative orientation. In this line, as part of the proposed methodology, this article will discuss an innovative way to assess student’s learning.

The first two questions have been well addressed by Leontev’s activity theory and Jonas-

sen's model for constructive learning environments design. However, to further explore how we can bring complex real-life situations into the classroom and to address the evaluation issue, this article will suggest a methodology, which can be used by teachers and/or instructional designers when they are developing a problem-based learning environment. This methodology permits students to first engage in problem solving activities and then present their solutions using a computer application as a cognitive tool. The software used during this study was developed by the local software company *Jacarandas Software* (www.jacarandas.com), which specializes in educational software. The software is commercially registered as *HiperVideo Studio®*, and it basically allows students to display a produced video and stops it at selected points where they believe that more information should be given to further explain their ideas (see Figure 2). The idea is that by indexing the context depicted in a video, students bring out their mental representations of the learned content.

The rest of this article is organized in three sections. The first discusses literature related to the constructivism paradigm and its implications for the development of situated learning environments. The second section takes into account the ideas of section one and proposes a methodology for facilitating context-dependent knowledge building. Finally, the third section will present a case where the methodology was used and evaluated.

BACKGROUND

Situated Cognition

The idea that knowledge, learning, and content are contextually situated can be traced to several theoretical endeavors, for example Bednar, Cunningham, Duffy, and Perry, 1992; Brown et al., 1989, 2000; Greeno, 1998; Lave and Wenger, 1991; and Wenger, 1998. In their seminal situated cognition model, Brown et al. (1989) stated that knowledge that is being built in the present moment is in part a product of the interdependency of the actual activity, the information and tools used, and their context and cultural underpinnings. Thus, students not only learn about concepts and the use of tools, but also about the context and cultures where those concepts and tools were developed and used. Furthermore, the authors state that "All knowledge is, we believe, like language. Its constituent parts index the world..." (Brown et al., 1989, p. 22). That is, the constituent parts of the knowledge that is built during a learning experience are linked to both the context where it is learned and to the context where the information that is being learned was developed by other human beings.

Therefore, a learning experience designed to facilitate the construction of context-dependent knowledge by students must also include contextual elements from the context where the information was originally produced. This way, students

Figure 2. A film analogy to what students can do with the *HiperVideo Studio®* software

establish explicit links or indexes between their constructed knowledge and the content's context; which, in turn, facilitates transferring back knowledge to the students' everyday problematic situations (see Figure 3).

These ideas are important for the purpose of this article because based on the notion that our built knowledge, like language, indexes, or points to certain elements of our life situations, the proposed methodology will ask students to index a video produced by them depicting a certain situation by sticking pins, metaphorically speaking, with their ideas attached to them. These ideas can be presented in several formats (i.e., as text, as images, or as audio using other software applications like a PowerPoint slide presentation, an Excel graph, or a Web page (see Figure 2)). These indexes are context-dependent because they are directly related to a certain time and place as shown in the video. Students decide at which point to stick a pin and how to further explain their ideas, that is, they can show an image, a graph, or a piece of text. In this way, they are explaining to the world their inner understanding of certain content.

USING ACTIVITY THEORY AS A FRAMEWORK

As discussed so far, situated learning theories propose that knowledge is context-dependent and that learning experiences must be multi-dimensional

to include context information. This perspective understands teaching and learning systemically; that is, not as a systematic linear cause-and-effect process. Thus, if one wants to include contextual information in a learning environment, it is better to have a holistic conception of the learning process to encompass all relationships and interconnections (Carr, 1996) that naturally happen in a complex human learning activity. Once a teacher has selected a subset of information as content (not all information is content, but all content is information), he or she needs to develop a contextual type of learning and to deeply understand the context where that information was produced. Generally speaking, information is produced by a group of people acting as a community with a common interest and purpose. These groups can interact informally, like a stamp collecting club or very formally like a group of professionals interacting together to build the bodies of knowledge that define a certain discipline.

Consequently, to include contextual information related to the group of persons that developed the content to be learned as part of the whole learning experience, a teacher needs to analyze that group's complex real-life situations and settings. Above all, the teacher must analyze their systems of activities because that is where their knowledge is created. To this end, although useful methods for cultural and contextual analysis are still a concern for research (Quek & Shah, 2004), several investigators are proposing, in tune with the socio-constructivist epistemology, to use activity

Figure 3. Knowledge is context-dependent

theory as an appropriate socio-cultural framework for analyzing human community systems (Engeström et al., 1999; Jonassen, 1999; Jonassen et al., 1999; Johri, 2005; Quek et al., 2004; Wilson, 2005). The strength of activity theory lies in the fact that it offers a systemic perspective to analyze complex human systems of activities.

Activity theory was developed by Russian psychologists Leontev, Luria, and Vygotsky. It is based on the principles of dialectical and historical materialism, which Vygotsky used to analyze the historical development of social activity and how it shapes and is shaped by changes in human consciousness (Vygotsky, 1982). Jonassen et al. (1999) state that activity theory “is a powerful socio-cultural and socio-historical lens through which we can analyze most forms of human activity.” (p. 62).

Traditionally, linear cause-and-effect propositions are established to understand actions, for example, if teachers teach then students learn. Alternatively, activity theory proposes triangular relationships, a model that is more powerful to encompass all the relational complexities of a human system. This structural model of an activity system portrays the dynamic relationship between a subject, the object of his activity and the mediating tools employed during the activity, such as symbol systems, methods, and instruments (see Figure 4). It is in this Vygotskian idea of mediation that the context information is included because different cultures choose different tools

to perform their specific actions, which, in turn, “shape the way people act and think.” (Jonassen et al., 1999).

To encompass community actions and to see the process more as a collective activity system, Engeström et al. (1999, 2002) depicts these triangular relationships graphically as shown in Figure 5. The dynamics in this basic model states that through the recursive activity of a subject, or a team of subjects, who belong to a community whose activities are mediated through rules of relationship and division of labor, the object is transformed and projected into a broader final outcome. In addition, the subjects’ activities are organized hierarchically, according to Leontev (1978), in actions and operations.

Thus, in order for teachers to apply activity theory to understand the activities that characterize the everyday actions of a particular group of professionals, they can apply several data collection methods like observations, interviews, questionnaires, analysis of documents, etc. For example, to understand the context of social researchers, a teacher can observe the everyday actions of those professionals and interview them. Some of the tasks are identifying the professional goals that this group of professionals is traditionally pursuing, clarifying the inner motives that drive these individuals to perform as members of that profession, and identifying the types of products that this group of professionals obtains as the result of doing their activities.

Figure 4. Activity system

Figure 5. Collective activity system

Jonassen et al. (1999) present and discuss six steps to use activity theory as a flexible framework for analyzing a certain system of human activities. The data can then be used to design the components that a constructive learning environment should have. The first step explains the purpose, motives, and goals of the activity system; the second clarifies the components of the activity system; that is, the subject, object, community, rules, and division of labor; the third step analyzes the structure of all the activities that are done by subjects; the fourth analyzes all the tools and mediators used by the activity system; the fifth analyzes the context within which activities take place; and the sixth links the outcomes of the previous steps to clarify the activity system dynamics.

THE CONCEPT OF COGNITIVE TOOL

The concept of tool is substantial in socio-constructivist notions. To further understand it, it is important to bring into consideration Vygotsky's theory of mediated activity, an essential part of activity theory, which argues that "all purposeful human activity is accomplished through the use of physical and/or psychological tools...by the subject in order to achieve the object" (Quek et al., 2004). In this sense, tools are not just conceptualized as mere physical extensions of the subject to increase his or her physical strength like a hammer or a screwdriver; they are understood as cognitive tools that mediate the subjects' activities by supporting, guiding, and extending their thinking processes (Derry, 1990, discussed by Jonassen et al., 2000). Jonassen (1996) calls this type of tools *mindtools* (i.e., knowledge construction tools that students learn *with*, not *from* or *about*). He defines them as "computer-based tools and learning environments that have been adapted or developed to function as intellectual partners with the learner in order to engage and facilitate critical thinking and higher-order learning" (p. 9). Also, Jonassen et al. (2000) refer to

mindtools as computer software applications that "...enable learners to think in ways that they otherwise would not and could not" (p. 167) and that "...scaffold different kinds of thinking and knowledge representation" (p. 167).

This concept of cognitive tool is relevant to the methodology proposed in this article because students, going through the problem-solving process inside the learning environment developed by the teacher, are asked to produce a program using the HiperVideo Studio software to argue in support of their selected problem solution by explaining and justifying their selection.

The HiperVideo Studio software is considered a cognitive tool because it enables learners to capture in video a piece of a real life situation and relate it to their inner process of meaning construction. Learners engage in higher-order thinking by deciding in which parts of the video to put indexes to further explain how they understand the learning environment content. When they present their produced programs to the rest of the class, they engage in metacognitive thinking by identifying their own knowledge production process.

The set of indexes placed in the video by the students are context-dependent because they are related to the context shown in the video. The set constitutes in itself a network or a map that shows what is in the student's head and explains how he or she sees the world in relation to his or her (the knower's) understanding of the content.

THE PROPOSED METHODOLOGY

Based on the ideas discussed in the previous section, in this one, the instructional methodology for bringing reality into the classroom is presented and discussed in more detail. For the purposes of this article, a methodology is conceptualized as an organized body of pedagogical strategies. According to the socio-constructivist base of this methodology, the pedagogical strategies discussed in this section are not only related to the teaching

aspects of the process, but they also incorporate collaborative actions, including thinking done by instructional designers, teachers, and students.

The pedagogical strategies are categorized (see Figure 6) into three different kinds of strategies: (1) Learning environment development strategies, where the instructional designer and/or teacher develops problem-based learning environments that replicate a system of activities done by a particular group of professionals; (2) Problem solving engagement strategies, where the teacher and the students collaborate in the knowledge construction process and engage in complex problem-based learning; and (3) Knowledge representation strategies, where learners engage in further reflection by constructing a product to represent what they are learning and show it to the rest of the learning teams. This product is also used by the teacher to assess how students understand the learning environment content.

THREE PEDAGOGICAL STRATEGIES

1. **Learning environment development strategies:** These strategies develop a learning environment based on the system of activities

that characterize the everyday actions of a particular group of professionals.

As stated earlier, information and content are intrinsically related to the contexts and cultures in which they were developed and used. For the regular school classroom, this means that most of the content domains to be learned are actually linked to the different activities of a group of professionals. For instance, Cobb, Perlwitz, and Underwood-Gregg (1998, p. 73) state that “students who engage in mathematical practices involving conventions, models, and symbolisms must necessarily be constructing the taken-as-shared concepts of the mathematics community.” That is, in the learning of mathematics, students not only learn the subject matter but also live a process of acculturation on what it means to be a mathematician or any other profession, which makes a wide use of the mathematical language such as physicist or engineer. Also, if we consider that most of what experts do in their professional contexts is solving problems and not answering exams, as Jonassen (2004) states in the introduction of one of his books on problem solving, then a mathematics learning environment must include conventions, models, and symbolisms used by mathematicians, physicists or engineers, and allow students to engage in solving the traditional problems that these professionals face every day.

Accordingly, to initiate the methodology proposed in this section and use activity theory, the instructional designer and/or the teacher (it is very common in schools that the instructional designer and the teacher are the same person) must develop a constructivist learning environment based on the system of activities that characterize the everyday actions of a particular group of professionals. For example, a learning environment can be based on the traditional activities of the community of historians that gather information about a certain event and inductively analyze it to identify the

Figure 6. Pedagogical strategies

possible causes that originated it. Another learning environment could be built around the set of activities that a social researcher performs to phenomenologically understand a certain social context, such as the complex human dynamics of a school classroom. Another example would be a learning environment based on the everyday actions that an electronic engineer does when working at a steel producing company, like designing a device to control temperature.

Once the activity system of a particular group of professionals has been identified using activity theory (See Table 1 as an example), the methodology recommended in this section suggests that the

teacher develops a learning environment based on the data gathered from that group. The type of learning environment suggested here has two characteristics: (1) according to the traditional definition of a learning environment, students should live meaningful, authentic learning activities making use of tools and resources to develop the skills to solve problems (Wilson, 1996); and (2) in order to facilitate the process of acculturation, the environment should also simulate the type of problem solving activities that a community of professionals face everyday. Both characteristics are suggested because knowledge construction is both understood as “a person’s meanings con-

Table 1. Components of the community of social researchers’ activity system

Community:	Educational researchers working in social sciences (scholars, academics, social workers) Purpose of their activity: Develop research projects towards the building of theory frameworks to better understand the social phenomena
Subjects:	Educational researchers working under the qualitative paradigm Purpose of their activity: apply qualitative research methodology to understand, from the participants’ perspective, relationships among different people, meanings, events and contexts related to education
Tools:	Theoretical models and concepts, research methodologies, terminology, communication systems, computers, software, video, and audio equipment, etc.
Rules:	Research is done according to the norms accepted by the international community of researchers. Research must be done with scientific rigor. Research is done based on postulates of a research paradigm. Qualitative research is based on the postulates of the phenomenological posture. Research questions should match the used methodology. Research is done based in a theoretical frame of reference. Always cite ideas taken from other researchers.
Division of labor:	Directors of the whole research project General advisors Designers of research instruments like interview and observant guides. Producers of research materials Field workers
Object:	Research projects
Outcome:	New educational theory The research project implemented, presented in a report, conference, and publication
Actions:	Read cutting edge literature in their field of education Identify problems and solutions in education and argument to convince others Select research methodologies Design and implement research studies to better understand the educational phenomena and to create theory Writing academic papers to disseminate findings in scientific journals and conferences Teach younger researchers
Operations:	Filling out research proposals for funding Design research instruments Do field work, gather data Analyze data to find patterns Write research reports

structed by interaction with one's environment" and as "enculturation or adoption of a group's ways of seeing and acting" (Wilson, 1996, p. 4).

Perkins (1992) proposes that a learning environment should have five facets: Information banks, symbol pads, construction kits, phenomenaria, and task managers. Information banks are warehouses of information resources from which both teacher and students select the learning environment's content. These can be textbooks, electronic encyclopedias, the Internet, etc. Symbol pads are tools that students use to register and manipulate symbols and language; examples include notebooks (paper and electronic), video cameras, software to create concept maps, drawing, and graphing software, etc. Construction kits allow students to build artifacts from prefabricated parts, a classic example is Legos; however, a more sophisticated example is the MIT Media Lab's technology called The Tower (<http://gig.media.mit.edu/projects/tower/>), which is an inexpensive modular development system for designing and prototyping electronic devices. Other examples of construction kits include different types of software that allow students to create computational programs to control de-

vices using a computer. Phenomenaria is an area that a learning environment should have where students can go to explore and test their hypotheses. Examples include laboratory equipment, complex computational simulators, microworlds, etc. Finally, task managers are components of a learning environment that set the tasks that should be accomplished by the students, and provide feedback and guidance. The obvious example of a task manager is the teacher, and also textbooks and different computational programs.

As can be seen from the literature discussed so far, the development of a constructivist learning environment is a rather complex process; however, the methodology described here represents an effort to simplify it, probably by sacrificing some of its pedagogical strengths. The intention is to make things easier for teachers who do not have profound instructional design knowledge (Figure 7 and 8).

2. Problem solving engagement strategies:

According to these kinds of strategies, students solve problems presented in the learning environment. Once the teacher gathered information regarding a group of profes-

Figure 7. The HiperVideo Studio® software editor

Figure 8. The HiperVideo Studio® software Presenter

- sionals and used it to develop a learning environment, he or she lets the students freely interact inside the learning environment so that they can build their own meanings about the environment subject matter.
3. **Knowledge representation strategies:** Students here develop a program with Hyper Video Studio software to crystallize their knowledge construction. As part of the activities suggested by the learning environment, learners are asked to collaboratively or individually produce a program using the Hyper Video Studio software. To do it students:
- Shoot a video that they decide is related with the solution they selected to the learning environment's central problem. Students decide what to shoot and what not to; through this action, they are already showing part of their inner understanding of the content.
 - The video is incorporated into the software so that it can be indexed. To do it the students use the editor part of the software (see Figure 7).
 - Students then insert pins at certain points in the video to stop it while they are showing it so they can present more information about particular ideas at those points. This is done by using the tools available on the right side of the screen (see Figure 7).
 - Finally, each team of students presents their products to the rest of the class. To do this, learners use the presenter part of the software (see Figure 8). As can be seen, the left part of the screen shows the video running. Then the video stops at certain points, during which the right side presents the extra information that students developed to further explain their ideas.
- This part of the suggested methodology has two objectives: (1) to evaluate how students built their inner conceptual map (to this end a rubric can be used to assess students' products, which can then be compared to evaluate how different teams of learners understood the subject matter); and (2) to allow students to engage in metacognitive thinking processes (i.e., when they make a

presentation for the rest of the class and justify their solution by arguing (providing evidences and explanations) in support of their ideas, they are also overtly reflecting about their learning process, which increases their learning).

All the time that students are building their programs with the use of the HiperVideo software, they are engaged in both cognitive and metacognitive thinking. In fact, when indexing they are going through a deep process of reflective analysis, and when they present their programs and explain them loudly to the rest of the group, they engage in another level of reflection. Thus, although this experience allows them to concretize what they learned interacting in the learning environment, it should be considered as an integral part of the whole learning environment. In fact, this is a clear example where learning and evaluation are merged into the same practice, according to the constructivist concept of evaluation.

TWO CASES DESCRIPTION

The methodology described in this article is still a prototype. Research projects to further examine it are on their way. Here, two cases will be presented mostly to clarify more the methodology to the reader. The results discussed in this section represent part of the groundwork needed to develop more complex research projects.

Case 1

The methodology was applied in a group of 12 students that were participating in an undergraduate course about qualitative research methodology; the course belongs to an education program offered by a private university in the area of Puebla, Mexico. Participants were all women with a rather high degree of technology literacy.

Learning Environment Development

According to the three discussed pedagogical strategies and to the course objectives, the components of the system of activity were identified in the first place. These components included typical actions and operations of the community of researchers working in social sciences (see Table 1).

With the data gathered about the system of activities of the researchers' community, a learning environment was developed around one of their professional activities: doing fieldwork using participant observation. The environment central problem and its context were created around an imaginary school. Its main learning goal was that students comprehended the philosophical underpinnings of the qualitative data gathering method called participant observation.

The learning environment was built using as its context problem an imaginary high school called *Escuela Benito Juárez*. Students could relate to the school downloading a couple of text files from the course's Web page, which thoroughly described the school and the problem that students were supposed to solve; the problem stated that the school's mathematical scores were among the lowest in the nation, according to a national standardized test.

Problem Solving Engagement and Knowledge Representation

The learning experience consisted of three weekly face-to-face periods of two and a half hours each and of the tasks that students did as homework. The first class began with an explanation of the learning goal. Then the school was described and the problem was explained. Students were divided in three teams. They were told that they should imagine that they were doing educational practices in the school. The teacher told them that one day, when they were at the school, the school's principal informed them about the problem related

to the low mathematical scores and how he did not know what to do about it. They were also told that they had advised the principal about using qualitative methodology to better understand what was going on inside the classrooms and that the principal had answered that he did not really believe in the qualitative paradigm, but that he was willing to attend a presentation where they could explain it to him.

The objective for this first class period was that students identified from the start of the learning process that they were being asked to solve the problem and produce a program using the HiperVideo to present their solutions. It was also explained to them that to complete both tasks, they could read about participant observation in the materials selected for them by the teacher.

Subsequently, a general and basic explanation of the HiperVideo Studio software was given to the students and each working team installed the software in their laptops so that they could practice and ask questions about how to use it. The first two and a half hour period was dedicated to explaining the problems and letting students become familiar with the software.

During all this process, a research assistant was present taking notes in a field diary for further qualitative analysis, describing how each team collaboratively learned to use the software. Students were given a two-week period to finish the task and were told that they should make a presentation for the rest of the class and the teacher acting as the principal.

Students were also told that they should send an e-mail after each class period with a diary explaining how they were learning. These diaries were also analyzed as part of the evaluation strategy. To evaluate the student's presentations, the teacher and the research assistant took notes of the whole process. Originally, it was intended to use a rubric, but it was not ready by the time of the study.

Results

Judging from the learners' diaries and from the type of advice that they asked for during the first week, it was clear that the time was dedicated to solve the technical difficulties that they encountered learning to use the software, for example, how to shoot and edit the video in digital format and how to insert it into the HiperVideo environment. During this first week, it was not explicit if the teams were also reading about participant observation. For the second week, students had solved most of the technicalities about the use of the software; however, it was clear that the videos they were producing were not clearly related with the subject matter. To correct this situation, the teacher explained to the group how to do a video storyboard on paper. This helped students to pre-visualize their videos and to realize the need to make them more content related. Also, the teacher strongly emphasized the need to read the observant participation materials. All the teams answered that they were already reading them.

In the third week, the teams finally presented their programs. The teacher and the assistant registered the process in the field diary. Later, using the constant comparison method of data analysis, some interesting results were found.

Most teams produced videos depicting real classroom activities and one team made an enactment of an actual classroom showing a teacher with his students. As expected, students showed classroom contexts with the video, but when they inserted an index to stop the video, most of the times they explained why they did it using text in the right part of the software screen. Even when they used audio files at the pinpoints, they were their own recorded voices. The team that performed the classroom enactment used most of its indexes in the video to show text balloons explaining the characters' thoughts.

It can be concluded that students participating in this small study accepted to use the video

images for analogical communication, but used the indexes to explain their ideas using digital communication. This is an interesting result because although they could explain their ideas analogically using images or even another video, most of the times they preferred to explain their ideas digitally. This, according to Watzlawick, Bavelas, and Jackson's (1967) model of human communication, could be explained because, in general, we use analogical communication (non-verbal) to explain relationships and digital (verbal) for the message's content.

A similar result was found in the few cases where students used analogical communication to explain their indexes. That is, in one case, one of the teams decided to use a small video showing a child doing homework at an index, but it was not self-explanatory; they had to explain orally in great detail what the video meant. In another case, a team showed another video at an index showing one of them explaining orally something regarding observant participation. In conclusion, students relied too much in their oral explanations and less in what was actually shown.

Regarding their comprehension level of the content (i.e., observant participation), it can be said that they were able to understand its main purpose as a qualitative method. For example, one team said that by shooting a video in a classroom, they were actually doing participant observation. Another expressed that participant observation allows us to be closer to a certain context. When one of the teams was asked by a classmate after their presentation why they shot that particular video to explain observant participation, they answered that they did it to explain how students and their teacher in that classroom were behaving.

However, it was not possible to identify any type of pattern in the set of indexes used by each team (i.e., the places where teams actually inserted their indexes did not give any relevant information regarding the students' understanding of the subject matter). This result was probably due to

the fact that this was the first time that the students were using the HiperVideo software; it can be hypothesized that after several experiences, they will become experts in knowing where and why to index a video at a certain point. Also, better evaluation instruments are needed to relate the indexes network to the subject matter.

Case 2

The methodology was again applied to a different group of the same university as Case 1 to further understand how it can increase the quality of learning of students of different educational levels. The group consisted of 2 men and 10 women enrolled in an educational technology graduate course. In this case, all of the participants had a bigger level of technology literacy, as compared with the group in Case 1, and had much more experience in developing educational projects because all of them had teaching experience.

In this second case, to obtain more feedback from the participating students, right after they finished the HiperVideo projects, each team filled out a questionnaire where they were asked to explain in detail how they had developed the project. The main purpose of the questionnaire was to analyze the process that each team followed to produce the main video and to decide when and what type of information they would insert in each pin.

Learning Environment Development

For this Case 2, Table 2 shows the components of the system of activities of the community of instructional designers working at educational institutions.

Based on the instructional designers' activity system, a learning environment was developed for the graduate course on educational technology and loaded to the Web page of the course. Within the environment, students acting as in-

Table 2. Components of the community of instructional designers' activity system

Community:	Instructional designers working at educational institutions Purpose of their activity: Develop and apply instructional theories for instructional planning
Subjects:	Instructional designers working as media experts in the public school system Purpose of their activity: Apply instructional theories for instructional planning to develop information and communication technology-supported learning environments
Tools:	Theoretical models and concepts, research methodologies, project development methodologies, terminology, communication systems, computers, software, video, and audio equipment, etc.
Rules:	Instructional design is done according to the norms accepted by the community of instructional designers. Instructional design is done applying accepted instructional design models. Instructional design is done based on expert knowledge and creativity. Media experts select information and communication technologies (ICT) considering: Learning objectives, characteristics of the learners and the context The main purpose of a learning environment is not to use ICT, but to increase learning. Always pilot test the produced products
Division of labor:	Instructional designers Content experts Media producers Technicians. Designers of evaluation instruments.
Object:	Instructional plans.
Outcome:	Instructional theory Instructional design models Learning environments
Actions:	Read cutting edge literature in their field of education Identify learning needs and problems Manage the process to develop an information and communication technology-supported learning environment Disseminate results in the institution and in the public school system Writing academic papers to disseminate findings in scientific journals and conferences
Operations:	Receive and discuss learning needs and problems Apply needs assessment models Select an instructional design model for planning instruction Develop instruction Evaluate results: Interview teachers and students, do participant observation, apply questionnaires, etc. Design evaluation instruments Tell every body in the design team what to do.

structional designers and media experts working in a public school were asked to solve a problem presented to them by the school's administrator. He explained that the school had just received federal funding to increase the quality of learning using computers in its classrooms. Students received reading materials explaining the educational concepts related to using media in schools because the main objective of the learning environment was that students learned to use media as cognitive tools.

Problem Solving Engagement and Knowledge Representation

For Case 2, the learning experience was developed during a two and a half week period. During this time, students and teacher interacted face-to-face for a total of 15 hours. Moreover, students, learning in teams, worked on the project for at least another 25 hours on their own.

Again, as in Case 1, students were told that they should solve the learning problem presented to them and that they should base their solutions in the reading materials. They were also told

that they should use the HiperVideo software to explain their solutions to the school's administrator. Next, the teacher explained the basics of the HiperVideo software and from then on, he acted as a facilitator asking and answering questions, supervising, and giving feedback when needed.

To assess the student's learning process and presentations, the same methods were used as in Case 1. However, in this second case, a questionnaire was added; it was designed and applied to obtain more feedback from the students regarding their learning experience. We wanted to better understand the students' thinking processes when they were developing their presentations in HiperVideo. The questionnaire asked students to (1) explain in great detail how and why they took all the decisions related with the production of the video; (2) explain why they decided to stop the video at a certain point and insert a pin; and (3) explain, also in great detail, what type of information they decided to insert in each pin and why they chose to use video, text, graphics, audio, etc. to display it.

Results

As happened in Case 1, three of the four teams dedicated their first week to understanding how to use the HiperVideo software and the video equipment. However, one team realized that using the software and equipment was rather easy and started right away to solve the instructional technology problem that was posed to them. In general, the whole group showed higher technology literacy than the undergraduate students. This fact allowed them to dedicate much more time to solve the instructional design problem and thus were more able to reach the educational objective that we were looking for.

According to the data gathered in the questionnaire regarding the production of the video that was going to be the core of their HiperVideo presentations, it can be said that all of the teams went to their familiar contexts to do their shooting.

All students are or were working at educational institutions, thus they either videotaped classrooms in the institution where they are students or at the institutions where they work. Their intention was to shoot real examples of the use of media inside a classroom and then use them at their presentations so that the audience could compare the traditional uses of media as opposed to using them as cognitive tools. It is interesting to realize that because they could not find real examples of actual teachers using media as cognitive tools they decided to enact their own, however, they decided to act as teachers using media as cognitive tools in a real classroom with authentic students. One of the teams decided to produce a piece of animation, something that was unexpected and unwanted by the researchers. However, it was considered that this team also appealed to their familiar context because the characters in the animation represented real people known by all. These results support the methodology proposed in this manuscript because students, by shooting the video in real contexts, linked the content to people's activity systems interacting in those contexts; in this case, actual classrooms including their teaching and learning situations.

Inductively analyzing the explanations that the students gave in the questionnaire regarding why they decided to place a pin at a certain place in the video, we can say that students first produced the main video and then decided where and with what purpose to stop the video. In general, students reported that they did it to further explain, enrich, reinforce, complement, or to make a more careful study of what was being shown in the images of the video. For example, one team was showing a video of a classroom where a group of students was using a certain type of technology, they stopped it and presented in the right part of the interface an Internet link to a page that explains in detail that particular technology.

As expected, and similarly to what was found in Case 1, in many occasions students used text to present information, some students reported that

they decided to use text because: (1) they wanted to explain key concepts that were analogically presented in the video portion of the interface. As already discussed in Case 1, this further supports the Watzlawick et al.'s (1967) model of human communication, which states that we use analogical communication (non-verbal) to explain relationships and digital (verbal) for the message's content. In this line, one team said that "we used text because written information allows students to read it as many times as they need to understand it; also, because when we want to understand a concept it is more significative to read it than to hear it."; (2) they wanted to ask the audience to perform a certain task; and (3) they wanted to elicit reflection processes in the audience by presenting questions to them. This is a rather interesting result, which can be explained by the fact that the students were also teachers used to apply instructional strategies to explain content.

Audio was also used in the insertion pins; however, it was almost always used redundantly just to repeat what was written in text. Nevertheless, in a couple of instances, one team presented a photograph with an audio clip explaining what it meant; and another presented a video with background music. Students reported that they used audio because: (1) they felt that it is more attractive for students to hear the information and read it; and (2) they wanted to underscore some key aspect of the video by linking a piece of music to what they are seeing in the video.

Analyzing these results, we can conclude that, in this second case, the whole learning experience allowed them to build context-dependent knowledge, even though the content they read was in general context-independent.

Also, the diaries sent by students to the teacher after the learning experience showed that all the students were very highly motivated during the whole task. In the diaries, they wrote very positive comments regarding the learning experience, for example: "It was very hard, but I enjoyed it very much" or "I am so tired, but, at the same time,

very satisfied." Also, this high motivation was shown by the fact that they stayed rather long hours working collaboratively, even meeting during weekends to work in their projects.

CONCLUSION

Most of the critiques made to the constructivist pedagogy state that it has not been able to modify deeply the teaching and learning processes; in spite of the fact that it has been recognized as a new paradigm in Education. It has been said that different educational changes move back and forth, while researchers and academia widely discuss them in journals around the world without making any important impact in the classroom. With this in mind, the main purpose of this article was to suggest a way to ground one of the most relevant ideas of the socio-constructivist paradigm, that is, that human learning is contextually situated. To this end, a methodology was proposed consisting in several pedagogical strategies including the use of software as a cognitive tool. The methodology proposed in this article can be considered design theory because it can be used as a guide to help students develop their higher order learning abilities (Reigeluth, 1999). Accordingly, it can become the subject for a larger, formative research project as suggested by Reigeluth and Frick (1999).

ABSTRACT

The purpose of this chapter is to discuss how instruction, technology, and models converge to create online model-facilitated learning environments. These instructional environments are designed in such a manner that the interaction with the model on the computer network is essential to the learning experience. The idea is to use these models to maximize the pedagogical power that helps students construct conceptual mental representations that lead to a greater degree of retention and overall recall of information. How students will act and learn in a particular environment depends on how the instructional designer creates the environment that maximizes their learning

potential, considering the interrelationships between the learning experience, the technology, cognition, and other related issues of the learner.

CHAPTER OBJECTIVES

The reader will be able to:

- Discuss models
- Describe online model-facilitated learning
- Find evidence that supports decisions to design online model-facilitated learning experiences
- Define complex systems and their association with online model-facilitated learning
- Understand the role of collaboration in the design of online model-facilitated learning

DOI: 10.4018/978-1-60960-503-2.ch203

- Consider specific issues and challenges in designing online model-facilitated learning experiences

INTRODUCTION

You are, once again, preparing your lesson plans for a fall semester online science class. For the past two years, your students have expressed problems learning certain scientific principles, and their opinions have been substantiated in their overall test scores. You are trying to decide how to revise your instruction to teach some of the more complex scientific concepts. To your credit, you are aware of the challenge and are willing to consider alternative instructional methods. You become curious about *model-facilitated learning* after reading Hestenes (1987, 2006) describe a decade of successes using modeling in physics, chemistry, and physical science classrooms. In addition, today's powerful computers allow you to go beyond traditional methods of instruction by breaking down the limitations and constraints of conventional methods of teaching and assessment. They give you the capability to use electronic applications and processes to deliver the content, and situate learners in a domain of information and a set of circumstances that maximize the cognitive potential of learners. By creating these online learning environments, you can give the students the opportunity to use computer-based models and simulations to explore, and better comprehend and communicate complex ideas (Maier & Größler, 2000). In an extensive review of the literature to examine computer-mediated communication in educational applications, Luppici (2006) reported that learners in online courses did just as well as face-to-face courses, therefore, it seemed a favorable alternative.

Online model-facilitated learning has its roots in the learning sciences, an interdisciplinary field of study that focuses on building innovative learning environments that incorporate multimedia

and computer-based technology. Therefore, we define online model-facilitated learning as an instructional experience whereby the instructional materials and resources are managed and run on a computer system. The system is connected by a network of devices that are used and manipulated by the students to support and enhance their participation in the learning experience. Students are placed in experiences that allow them to learn with and from other students in a system that uses a model. The model is the artifact structurally designed and created to represent or to demonstrate a theoretical construct of a system or some chosen phenomenon. The instruction is designed in such a manner that the interaction with the model on the computer network is essential to the learning experience. The instructors and students may or may not be geographically separated.

The intent of this chapter is to discuss how instruction, technology, and models converge to create online model-facilitated learning environments, and discuss the pedagogical structures within which they operate. More specific objectives for the chapter are:

- a. Define models and their function in online model-facilitated learning
- b. Develop a theoretical platform and related principles as these apply to online model-facilitated learning
- c. Apply pedagogical principles to teaching and assessment in online model-facilitated learning

MODELS

Models are instructional tools that teachers can use to enhance the human cognitive power (Kozma, 1987) and enhance higher order thinking as they “function as intellectual partners with the learner” (Jonassen, 1996, p. 9). They are used to provide a learning situation that is more contextually bound than most conventional instructional approaches

because they situate the students in an experience that gives them the chance to experience and “play with” selected aspects in the domain of knowledge. As a *representation*, a model is the tangible depiction or portrayal of some original object or phenomenon. For example, a globe is a representative model of Earth that the learners can interact with to find different locations around the world; the interaction between the learners and their interaction with the model are most important. As a *demonstration*, a model becomes the means to demonstrate or show the learner how to do something without having to actually build a model. For example, a scale model of the solar system demonstrates the size of the planets in relation to each other. Regardless if it is a representation or a demonstration, a model is primarily a tangible communication device for conversing with self and others immediately and through time (Pea, 1994).

How Are Models Used In Instruction?

Instructors can employ models in different ways. They can create a model that the student can use or they can instruct the students to build their own model. Bliss (1994) refers to this as explorative modeling and expressive modeling respectively.

Using Models

Students can be instructed to use instructor-created dynamic models (computer simulations and games) or static models (illustrations and concept maps) to learn about a domain of content. These models are usually designed and created by instructors for learners to use within a specific sphere of interrelated knowledge. Löhner, van Joolingen, Savelsbergh, and van Hout-Wolters (2005) say, “Learners explore a given model representing someone else’s ideas by trying it out and perhaps modifying it” (p. 442).

The primary learning objective of using models is to acquire domain content at the application

level. For example, intuiting the effects of supply on demand or grasping the possible affects of global warming on hurricane strength are case in point.

Building Models

Students can be instructed to build models in order to construct their own new understanding of a domain content area or of the dynamics of a system. Students learning about the human cardiovascular system can build a concept map (e.g., a static model) of the content and then use their concept map to write an expository essay of the content. Or they can build a dynamic model of the same system using *Stella*^{®1} (a software modeling program for creating *dynamic systems*) and examine the structure and function of the heart. With both strategies, students build their own understanding of the content. If decision making is your instructional aim, there are software packages that students can use to build a model of a system that needs to be managed (e.g., SIMPROCESS[®] is a product that can be used to build models that support decision making²).

Model building typically seeks to answer questions of inquiry (Kolb, 1984). The knowledge gained allows the student to understand causal relationships and make predictions. The overarching learning objective is aimed at the students’ ability to gather information; to communicate knowledge; to transfer the knowledge; and to apply complex cognitive skills to other novel real-life encounters (van Merriënboer, Clark, & de Croock, 2002). Thus building models directs attention to higher-order, transferable cognitive skills and develops a domain-specific base of content knowledge.

Tasks Accomplished with Models

We propose that the tasks learners are asked to accomplish with models in online settings fall under one of two categories: *peremptory* and *dialectic*.

Peremptory Online Task

A peremptory online task invites either acceptance or rejection, it is “a-dialectic” and it brings along an underlying worldview. Working alone on a computer-based simulation or game is a peremptory task. A learner who has become proficient in *Simcity* has acquired important concepts and principles regarding city planning that reflect the theory that undergirds this simulation, including a positive bias (but perhaps misplaced trust) towards public transportation. Said differently, the learner ‘wins’ when their intuitive planning actions and interactions with the simulation most agree with the hidden theory and the learner *appropriates the theory usually without reflection* (rather like brain washing). This assumption is derived from the research on implicit learning.

Reber (1967) refers to implicit learning as a process by which knowledge is acquired independently of conscious and deliberate attempts to do so. What is implicitly (unconsciously) learned about the domain through simulations and games can probably be evaluated only within the simulation or game. This is an important issue that is overlooked. Further, learners will internalize the “grammar” of the technology tool that they are using; for example, thinking in terms of stocks and flows when using *Stella*, or in terms of variable control when programming. At a minimum, given enough model-facilitated exposure, students will begin to think about everything as a system, and this represents a substantial mental shift that may not be measured by traditional tests.

Dialectic Online Task

In contrast to the peremptory online task, a dialectic online task invites argument or participation. The learner must ‘fill-in-the-blanks.’ If the instructor posts a detailed concept map of a topic and requires students to study it for a test, this approach is highly peremptory. However, if the students are given the same concept map and are

told to work individually to find the errors and correct it, then it becomes less peremptory. If the students complete this same concept map task in a collaborative group with appropriate ground rules, then this becomes a dialectic experience.

In summary, the model is a contextual representation whose primary function is to provide the basis of an experience where the students can experience and investigate the fundamental attributes and properties of what is to be learned. If the instructional intent in online model-facilitated learning is to promote a conceptual change, according to Windschitl (1996), allowing students to interact with the dynamics of a modeling system can create unique ways to help students conceptualize the information. Common to both uses of models is simulating a situation, specifically designed to situate learners in experiences that serve to stimulate their process of inquiry and understanding (Kolb, 1984).

A THEORETICAL PERSPECTIVE

Learning, as we know it, is an active cognitive process whereby knowledge is built on existing knowledge as the learner seeks to understand the information and experience as it is presented (Duffy & Cunningham, 1996; Winn & Snyder, 1996). In online model-facilitated learning environments, regardless whether the learner builds or uses the model, he/she takes the information from the model and adopts mental representations of the system to help organize the information in a *personally* coherent and meaningful way. The degree of learning rests in how well the learner can connect the existing facts, concepts and principles with the new information that is given or discovered in the modeling experience.

How this information is stored in memory and how it is linked in this complex, abstract and interconnected network of memory structures is the schema (Bruning, Schraw, & Ronning, 1999; Driscoll, 2000; Rumelhart, 1980; Schunk,

2000; Winn & Snyder, 1996). If you think of the brain as a neural file cabinet, these schemas are neural memory files that hold information about specific concepts. Over time, we make associations between and among them, and this intricate network of neural files become highly elaborate, interconnected, and cross-referenced. Online model-facilitated learning environments provide a powerful way for learners to develop these conceptual arrangements and manage the interrelationships and integration of these complex systems. In online model-facilitated learning, Papert (1993) argues that constructing and manipulating “quasi-concrete” representations of knowledge on computers leads to more robust internal knowledge structures.

Online model-facilitated learning is a generative learning approach that uses strategies to encourage learners to actively create and consider the relationships among various elements of information, between lesson information, and personal knowledge, and find personal meaning (Jonassen, 1988; Jonassen & Wang, 1993; Wittrock, 1992). Following the theory of generative learning, it is the process of generating relationships between and among the information and integrating that with memory, whereby “meaningful understanding and comprehension are predicted outcomes” (Grabowski, 1996, p. 898). Generative strategies, such as asking the learner to formulate new questions, form direct inferences, and demonstrate and represent how the concepts connect, typically require learners to consider *multiple information elements at the same time*, thus encouraging the development of the organizational and structural relationships between the information elements (Grabowski, 1996; Ritchie & Volkl, 2000). The focus is to generate new conceptual understandings, not just transform what is already known (Grabowski, 1996).

The view that students actively participate to construct their own knowledge through direct participation in the modeling experience (whether using or building the model) is from the philo-

sophical point of view called constructivism—a doctrine of beliefs that knowledge is constructed by the learner through experiences and direct participation with the environment (Duffy & Cunningham, 1996). Based on what we know of online model-facilitated learning environments, Cobb’s (1994) interpretation of the complementary nature of the two perspectives of constructivism and socioculturalism apply. According to Cobb (1994), the cognitive constructivist perspective explains the unique configuration of knowledge constructed by the learner and the quality of the individual interpretation of the experience in constructing that knowledge, while the sociocultural constructivist perspective emphasizes the construction of knowledge when individuals engage in discussion and activity about shared problems and experiences in a community of learning. Accordingly, *social interaction is necessary for the construction of knowledge*, and meaning will differ among the learners because meaningfulness is an individual interpretation based on past experiences. These interactions are uniquely understood by the learner through personal reflection and dialogue with others as they gain a shared understanding of the complexity of the concept being explored (Gasparini, 2004).

In the online model-facilitated learning environment, the student is situated in the learning experience in a manner that directly confronts the intellectual, practical, personal and social aspects the model brings to the experience. According to Collins’s (1988) definition of situated learning, knowledge, and skills are learned in contexts that reflect the way they will be used in real life (p. 2), and he goes on to cite benefits of situated learning that we feel are applicable to the design of online model-facilitated learning instruction:

- Students are placed in the conditions for applying knowledge
- Students are situated in conditions to apply information and problem solve

- Students learn the implications of knowledge as they work through the problem
- Students are supported in structuring knowledge in ways appropriate to later use by gaining and working with that knowledge in context

Brown, Collins and Duguid (1989) suggest that embedding information in the situation provides essential parts for its structure and meaning. The knowledge gained in the learning experience becomes coded in such a way that it is connected to that situation; therefore, context and authenticity become important considerations. In online model-facilitated instruction, the idea is to create models that simulate authentic practice.

We have continued to talk about the role of the experience in online model-facilitated instruction. We believe it is the hallmark and the distinguishing characteristic in your design. How you create the online modeling experience and then situate the learner in that experience will greatly influence the success of achieving the learning outcomes. Carl Rogers (1969) paved the way for student-centered, experiential education, and any instructional method that gives the student the opportunity to actively participate in the encounter with a goal of acquiring knowledge is considered experiential learning. The students directly experience the subject matter, either by using or building models.

PEDAGOGICAL CONSIDERATIONS AND ISSUES IN THE ONLINE MODEL-FACILITATED LEARNING EXPERIENCE

Among the pressing issues for instructors in designing online model-facilitated learning experiences lie in understanding of the complex systems taught with models, and appreciating the role of collaboration. Placing a student in the experience, knowing how information is cogni-

tively processed, and understanding the role of the social and collaborative aspects of learning about complex systems are important considerations in building a theoretical framework to support the pedagogical decision to use online models. These aspects are mutually connected and interrelated.

Complex Systems

Wilensky and Resnick (1999) describe complex systems as having multiple levels of simultaneous hierarchical interactions; the system under study may in fact be a sub-system of a larger system. An example of this would be the human body. When you consider the body as a functioning “whole” the interrelated, interdependent, and simultaneous interactions among the sub-systems, for example, oxygen transport system, the renal system, the cardiovascular system, the nervous system, and so forth, are essential for life. These complex systems are becoming increasingly important to understand in the 21st century as the relationships among the systems becomes more integrated (Lesh, 2006). But, learning about these systems is difficult because of the amount and complexity of subject matter within and across domains and disciplines (Hmelo-Silver & Azevedo, 2006).

These systems tend to be defined by the dynamic interactions and interrelationships among and between the multiple constituent parts and frequently cannot be explained by a set of linear, functional rules (Lesh, 2006). As stated by van Merriënboer et al. (2002), “In complex learning, the whole is clearly more than the sum of its parts because it also includes the ability to coordinate and integrate those parts” (p. 40). Therefore, approaching it from a traditional, behaviorist learning point of view will not suffice. The theories in behaviorism focus on forming associations between a stimulus and a response, and they do not account for the complicated and involved nature of systemic thinking in these complex online model-facilitated learning environments.

The memorization of facts limits knowledge to the constituent parts rather than fully comprehending how these parts fit together into one cohesive whole (Feltovich, Coulson, & Spiro, 2001). The instructor must break down the prevailing “silo” mentality so that the students can more easily find meaningful associations and see the patterns of relationships, and the control and influences among the parts. These relationships are not necessarily linear and the pattern of differentiation makes them complex. Specifically, Milrad, Spector, and Davidson (2002) suggest learners usually experience difficulty in the following:

- Comprehending nonlinear relationships
- Understanding and viewing the problem within the context of the system
- Considering the full range of connections, influences, and controls within a system
- Transferring what is learned in one context to find the solution to a problem in another

Kukla (1992) claimed that using models designed to represent various situations and complex systems will help develop cognitive systems that enable the learner to process information, solve problems by reasoning, infer consequences, form hypotheses about the world that’s external to the “microworld,” and make predictions about the future with reasonable accuracy.

The Association with Complex Systems

When learners are plunged into a system, they become more aware of the system’s dynamics in terms of the processes, relationships, and consequences of decisions. To illustrate this, we turn to work done by Colella (2000), who designed a microworld using miniature computers called *thinking tags* to explore viral transmission. Each learner in this “participatory simulation” wore a *thinking tag*³. To begin the session, only one *thinking tag* contained the virus. As the experience

unfolded the virus jumped from tag to tag infecting the other learners. Colella created this model of the dynamic system of viral transmission so the students could experience the transmission of a virus, understand the problem, develop hypotheses, explore the underlying rules (cause and effect) of the system, and learn the consequences if the rules were broken. Colella could have taught the students about viral transmission without giving them the chance to experience it; however, the power of using a model to explore this helped the students discover the knowledge of how a virus is transmitted, understand the social relationships in this community of learners, and feel the accompanying emotion when infected with the disease. According to Hmelo-Silver and Azevedo (2006), learning about these systems confronts our cognitive, meta-cognitive, and social resources.

Regardless if the students are instructed to use a model or build a model, the microworld becomes the place for the group to learn. The instructor creates these microworlds and models to simulate the real world so the topic of instruction can be taught in the safety of an instructional environment yet learned in a real-world context. Context and authenticity are important considerations in the design and creation of models because the model represents domain-specific situations and systems constrained within “microworlds” that are meant to activate the cognitive system in ways that traditional teaching by lectures often cannot accomplish (Colella, 2000; Kukla, 1992). According to Colella (2000, p. 474-475), “the flexibility of microworld environments opens up the range of possible experiences that can be created.” Thus a critical design issue in online model-facilitated instruction is determining the “level” of the microworld and the “size” of the model.

Role of Collaboration

Collaborative online projects are some of the most exciting ways to motivate students. Getting students involved with posting projects on the web,

emailing other students or experts, discussing issues on a threaded discussion, or chatting online is a great way to motivate students. Stahl (2004, p. 64) defines collaborative learning in terms of building “the gradual construction and accumulation of increasingly refined and complex cognitive and linguistic artifacts.” The students commit to a shared goal and work together in a mutual and joint effort to construct meaning, share learning tasks to build a knowledge base, clarify issues, explore a topic, and solve a problem (Hron & Friedrich, 2003; Nevgi, Virtanen & Niemi, 2006). In online model-facilitated learning environments, students gathered together in virtual groups not only learn from their own individual experiences as they solve a problem, but they learn from each other. The nature of the task, the context of the experience, the learner characteristics, and the group relations all affect the collaboration (Dillenbourg & Self, 1995).

Clark and Mayer (2003) make a distinction between two alternative collaborations: product-oriented and process-oriented. The product-oriented collaboration results in some tangible output. These types of assignments need sufficient instructional guidance and resources that guide the experience, yet allow enough openness for the student to explore, be creative and feel challenged. The process-oriented collaboration focuses on learning that is gained from structured group exchange rather than the production of a tangible finished product. The learning is stimulated by how the instructor designs interactions around the model. In either case, structuring the online model-facilitated learning environment to promote collaboration and maximize the power of the interactions is important and is critical for a successful outcome as suggested by Clark and Mayer (2003). During collaboration, all members *should* contribute equally to the model and begin to develop a sense of co-ownership of the model. In cooperative association, each member individually completes a discrete portion of the task in

detail, and then brings that portion or piece back to the group. A properly designed collaborative task engenders dialectic interactions as the group works together reaching consensus or compromise on every part of the project. Although the online model-facilitated learning itself may vary among different authors (Kanuka, Rourke, & Laflamme, 2006; Roberts, Andersen, Deal, Grant & Shaffer, 1983; van Merriënboer, 1997; van Merriënboer et al., 2002; Wolstenholme, 1990), the process generally moves through the following phases as described below:

1. **Problem orientation:** The problem is presented and the learner is oriented to the modeling task, which includes goal setting and engagement. These problems or scenarios are not only authentic and relevant but also have the correct level of complexity for the learners.
2. **Conceptualization:** The learner puts the problem into some context. Important components and causal relationships are recognized.
3. **Formulation:** The learner develops hypotheses and a method of collecting the data he/she needs to move forward with the problem.
4. **Rules and Principles:** The learner explores the cause and effect relationships.
5. **Testing:** The learner verifies in that their evolving mental model does not contradict data from the real-world system.
6. **Application:** The learner transfers the knowledge and applies the cognitive skills to authentic situations to solve problems (Perkins & Unger, 1999).

Collaboration in online learning, by its very nature, requires attention to the social interactions and communication strategies because this is very different than face-to-face collaborative learning experiences many students are familiar with.

PEDAGOGICAL CONSIDERATIONS

Instruction must be designed to teach students how to apply skills in a coordinated and integrated fashion (van Merriënboer et al., 2002). The instructor-created experience must be thoughtfully designed because it is paramount for learning. Rogers (1969) has provided us with essential guidelines to create an environment for learning. Although these guidelines were developed for face-to-face instruction, we believe they are so fundamental to learning that they are noteworthy considerations in creating online model-facilitated learning environments:

1. Setting the initial mood or climate of the group or class experience
2. Elicit and clarify the purpose of the individuals in the class as well as the more general purposes of the group
3. Make easily available the widest possible range of resources for learning
4. Take the initiative in sharing feelings with the group in ways which do not demand nor impose but represent a personal sharing

Just as important is the course design. Goldman, Williams, Sherwood, Hasselbring and the Cognition and Technology Group at Vanderbilt (1999) have provided us with these four principles for course design:

1. Organize it around the solution of meaningful problems
2. Provide scaffolds for achieving meaningful learning
3. Provide opportunities for practice with feedback, revision, and reflection
4. Promote collaboration, sharing of expertise and independent learning

Milrad (2002) concludes that the design of these environments should include multiple perspectives of the problem, support for learning and

cognitive development, opportunity to develop meaningful collaborative interactions among the learners, and concrete feedback to facilitate the learners' understanding. However, there are specific issues and challenges in designing these collaborative learning environments due to the unique characteristics of online instruction and online learning groups, most specifically in the areas of social context, the nature of the communication, cognitive load, and the emotional state of the learner (Hron & Friedrich, 2003). Suitable instructional supports must be considered in each area.

The social context of online model-facilitated learning experiences cannot be ignored because it differs from face-to-face experiences. There are no facial expressions, body gestures, voice inflections, or head nods to help the instructor or the students make judgments on interest, response, or participation. In addition, the "whose next" question can become an issue in deciding when and who takes the next turn to participate. How the instructor communicates the idea and how he/she draws all the participants into the model will determine the collaboration among the participants. The instructor must take the lead to establish clear ground rules and set the convention of etiquette for the communication at the onset of the experience so the students know what to expect and how to manage their role. It is the challenge of the instructors to ensure that the student interactions and discussions are engaging, productive, and meaningful in developing knowledge and understanding (Littleton & Whitelock, 2005). In a study conducted by Navarro and Shoemaker (2000), students enrolled in an online economics course were generally satisfied with the online student-to-instructor interactions, however, students were generally unsatisfied with their student-to-student interactions. Instructors, by providing appropriate supporting materials and resources, activities that support the learning, and feedback will enhance the quality of interaction between students and instructors.

Communication in online collaboration is an important consideration in terms of the technology and the quality of the message. Tolmie and Boyes (2000) have found that asynchronous communication not just facilitates discussions between students but “any disagreements which occur will promote growth and understanding (p. 121). The technology greatly expands the potential of the instruction, but it does not come without problems. Navarro and Shoemaker (2000) found that technical problems are pervasive in online learning environments. The system can go down, the students may have problems accessing some instructional materials, the software may not be compatible, the video and audio system might malfunction; indeed, a whole host of problems could occur. Technical support to students and instructors must be available, and instructors must match the course design to the technology that is available to the students. How the information is delivered to the students is very important because messages are more enduring and permanent in online collaboration (Hron & Friedrich, 2003). They can be accessed or sent at any time, and the sheer volume and the task of following them can seem unmanageable. Instructors must be concerned with the effect in how the message is interpreted, the value of the messages produced, and the manner in which the messages motivate the learners. In addition, it is the instructor’s responsibility to ensure that the students are not learning the “wrong” concepts that are transmitted in the messages. This is particularly important when the students are working and learning from each other. The instructor should intervene to bring the students back on track if this occurs.

Cognitive load can overwhelm the student (Hron & Friedrich, 2003). The complicated computer network, the complex subject matter, the sheer volume of information, and the different pattern of communication all contribute to this. It is important for the instructor to provide help for students to cope with the complexity. Technological support systems should be included

in the design of the instruction so that problems can be dealt with in a reasonable manner and without disruption to the learning. In designing online model-facilitated learning environments when multimedia is used, instructors must create experiences that maximize the opportunities for the learner to mentally organize the information in meaningful and coherent cognitive structures for meaningful learning to occur, while at the same time paying attention to the cognitive load associated with multimedia learning (Mayer & Moreno, 2003). This becomes particularly important when the model uses and presents visual and verbal representations of information. Mayer and Moreno (2003) highlight the potential for cognitive overload in multimedia learning environments due to the substantial cognitive processing that is necessary for meaningful learning to occur. They report that in their research on multimedia learning, they are “repeatedly faced with the challenge of cognitive load” (p. 43). In response, they explored nine ways to reduce cognitive load in processing information aimed at redistributing the demands of cognitive processing (Mayer & Moreno, 2003): off-load processing demands on the visual and verbal channels, segmenting, pre-training, eliminate extraneous information, provide signaling cues, minimize incidental cognitive load, eliminate redundancy, synchronize the presentation of material, build in ways for it to be individualized to the learner’s characteristics. In addition, other strategies to help manage this cognitive load might include breaking a larger problem into sub-problems, the inclusion of the heuristic aids, or the integration of metacognitive self-assessment tools (Malopinsky, Kirkley, Stein, & Duffy, 2000). Instructional supports in online model-facilitated learning experiences would include a plan to monitor the messages, coach the students, build in scaffolding strategies, and provide reflection and feedback mechanisms.

The emotional state of the learner cannot be ignored in online model-facilitated learning experiences. Interest and motivation are im-

portant learner attributes to the success of these experiences whether you use or build models. This is a concern, because low participation in discussions in online learning environments has been reported across the board (Tolmie & Boyle, 2000). Instructors must find ways to stimulate and motivate the learners to participate. They should include mechanisms to involve all students and not let a few dominate the discussions. Techniques used by experienced instructors include personal electronic workbooks as well as records of their contributions to the group projects; participating in instructor supported computer conferences; and having the students use critical reflection on both the content and the process. In a discussion on issues related to designing inquiry on the Web, Lim (2004) suggests using questions, student planning, careful sequencing of activities, and reflection to engage the students.

ASSESSMENT CONSIDERATIONS

Online model-facilitated instruction is aimed at teaching complex, higher-order thinking skills; therefore, online model-facilitated learning is defeated if the focus of the assessment is on declarative knowledge only, and using the traditional methods, such as paper and pencil tests. These methods are unlikely to measure the full range of knowledge, skills, and attitudes accumulated by the learner.

When developing an assessment plan in an online model-facilitated learning environment, the question is, “what should be assessed—the process (contribution and interaction), the product (the model), or both?” The assessment of process and product are equally important; yet, assume different types of assessment strategies and methods. In online model-facilitated instruction, the model represents the group’s understanding of a large amount of information from multiple disciplines due to the complexity of the modeling experience, and so assessing the model (the product) makes

sense. The evaluators(s) must assess the breadth and depth of information represented in the model as well as the students’ thinking and reasoning strategies. A process assessment would be used to measure the students’ contribution to the group structure, and participation in the discussion and information gathering.

Educational assessment plans should include two functional categories: formative or summative. *Formative assessment* supports the progression of learning by providing immediate, contextualized feedback and encourages self-reflection. Formative assessments should focus less on how closely student responses match a pre-determined model and more on the competency of the performance as a whole (Pellegrino, Chudowsky, & Glaser, 2001). In online model-facilitated learning, students work collaboratively to construct their own knowledge within the structure of the course objectives. Instructors must be diligent to guide the students “back on track” through either coaching or scaffolding or other pedagogical techniques if the students stray too far from the learning objectives. *Summative assessment* is done at the conclusion of a course or some larger instructional period to determine individual student success or to what extent the program/project/course has met its learning objectives. Because of the complex nature of online model-facilitated learning, we suggest that summative assessment must be designed to measure higher order thinking skills to learn how they reason through situations, how they transfer knowledge, how they make decisions, and how they critically think through problems. Reeves (2000) suggests three alternative assessment methods to use in an online environment:

- Cognitive assessment is the assessment of a wide range of abilities, including attention, memory, problem-solving, language skills and intellectual functioning. It is the process of determining a student’s cognitive strengths and weaknesses through observed behavior

- Performance assessment requires that a student carry out an extended, complex process or produce a product, such as a model
- Portfolio assessment can be either formative or summative. An example of a formative assessment portfolio is a “growth and learning portfolio,” which contains the student’s work that demonstrates their program toward a goal. A summative assessment portfolio is a “best works portfolio” which is representative of the student’s work that provides evidence that they have a specific learning target (Nitko, 2004).

Assessment must not be an afterthought to be effective, but strategically integrated into the instructional design plan from the very beginning, so it has the ability to assess the transfer and integration the conceptually-complex ideas, which are best measured through complex, authentic assessment methods (Erickson, 2001; Nitko, 2001).

CONCLUSION

This chapter provides a framework for online model-facilitated learning environments that offers pedagogical considerations not seen in traditional instruction. These models embedded in carefully constructed “microworlds” are artifacts within a specific sphere or domain of information that instructors create for learners to interact with and experience. The idea is to use these models to maximize the pedagogical power that helps students construct conceptual mental representations that lead to a greater degree of retention and overall recall of information.

Based on what we learned in this chapter, learning and most importantly, the comprehension of complex systems, are enhanced in online model-facilitated learning instructional environments because students can interact with the content and each other to apply it to real-world scenarios. The

overarching goal is to teach students a body of knowledge that may draw from the integration of many disciplines, and get this stored in long-term memory so it can be recalled and transferred to solve problems in different situations.

Perhaps the greatest value of online model-facilitated learning environments is in developing a student’s “thinking skills.” Reasoning and making judgments is a multi-layered, complex process of constructing evidence that is based on a social interaction with others and gathering evidence to support the claim. Learners must have the ability to organize large amounts of information through complex cognitive processes and mental associations to critically analyze many facets of a problem, reach an informed conclusion, develop a plan to solve the problem, and systematically justify their response by making a reflective judgment of their decision (Bruning et al., 1999; Winn & Snyder, 1996).

How students act and learn in a particular environment depends on how the instructional designer creates the environment that maximizes their learning potential, considering the interrelationships between the learning experience, the use of the technology, the cognitive conditions and other related issues of the learner. Pedagogical decisions depend on the interrelationships between the instructional goal, the instructor, the theory, and all the resources. The importance of considering these factors in the design of an online model-facilitated learning environment cannot be overstated. Surging ahead without this understanding will result in a situation that does not maximize the learning potential in online model-facilitated experiences.

FUTURE TRENDS AND RESEARCH

This area of online model-facilitated learning environments is relatively new and educators are at the fringe of gathering empirically valid and reliable data to support the pedagogical decisions.

As suggested by Hmelo-Silver and Pfeffer (2004) in talking about the complexity of the systems we are trying to teach, we are still at an early stage of understanding how this all fits together. For this reason, much more needs to be learned. The decision to choose model-facilitated instruction should not be solely driven by the available advances in technology, but by the principles grounded in empirical research findings. The major elements of model-facilitated instruction, learning and assessment, and the inherent relationships among them, provide important areas for investigation.

A pressing issue in online model-facilitated instruction lies in the complexity of the system being taught, and how the instructor integrates the breadth and depth of a vast amount of knowledge related to that system. These modeling systems cross disciplines and cross themes within a unit of study as they relate complex concepts and generalizations, yet are all linked to the common topic of interest (Erickson, 2001). Therefore, designing these learning environments takes a highly coordinated approach, sometimes involving experts from several disciplines because the instructional designer must be concerned with the integration of content (what essential topics to cover and which experts need to be involved in those decisions) and the integration of process (strategies to maximize learning and promote thinking). What we want from the design of on-line model-facilitated instruction is to integrate all the concepts associated with these complex systems in careful associations to the students to “integrate their thinking at a conceptual level (Erickson, 2001, p. 64), and commit this to long-term memory.

Complex dynamic systems surround us and it is critical that students are provided with the tools to understand these systems. We as instructional designers and educators have the tools and the knowledge to provide students with the learning environments to develop these skills. However, Stahl (2004, p. 9) argues that in spite of the wide

recognition of artifacts as “an embodiment of shared understanding,” only a few education scientists have focused on how new users learn to use them. To fully implement online model-facilitated instruction, we must learn how to use models to expand the capacity and capability to help students process the information, and construct conceptual models that lead to greater retention, and recall and application of knowledge to new and complex situations. Mayer, Dow, and Mayer (2003) focused on the pedagogic features of agent-based microworlds to begin to address how to promote deep learning in the next generation of highly interactive computer-based environments. How best we can facilitate learning in these complex environments and how our cognition changes to do this is an area to be explored.

Chapter 2.4

Developing Learning Communities: Improving Interactivity of an Online Class

Pawan Jain

Fort Hays State University, Hays, USA

Smita Jain

University of Wyoming, Hays, USA

ABSTRACT

This study concerns the design and development of online instruction and specifically targets interaction and communication between online learners. Facilitating appropriate and meaningful interactions in designing instruction is a major goal for anyone developing an online class. The guiding question of the study was: how do the instructional design elements and discipline area impact the quantity of learner-learner interactions? The data for this study came from the online courses offered at one of the major Rocky Mountain University. The research subjects and courses were taken from the College of Education, College of Business, College of Arts and Sciences and College of Health Sciences. Forty graduate online classes, 10

from each college, were analyzed. The findings of this study suggest that the interactivity in an online class depends on group size, grade weight for discussion, use of web 2.0 technologies and multimedia and the discipline it belongs to.

INTRODUCTION

For hundreds of thousands of years, people lived in hunting and gathering economy until humans made the transition to an agricultural economy. The agricultural society continued until about 200 years ago, when the Western world ushered in the Industrial Revolution. A few decades ago, the industrial economy began to give way to the present day information-based society (Dagget, 1998). The advent of the computer and the Internet were instrumental in changing society to a global,

DOI: 10.4018/978-1-60960-503-2.ch204

knowledge-based economy or to what is known today as the information age (Crossman, 1997). This shift in society has had an insurmountable impact on institutions of higher education. Today higher education is reaching beyond the walls of the traditional classroom by providing alternative methods of educational delivery through the use of the Internet and the World Wide Web. This type of distance education delivery is referred to as online learning.

Facilitating appropriate and meaningful interactions in designing instruction is a major goal for anyone developing a course, especially an online course. Although not supported by a specific research study, Kearsley (1998) claims that the “single most important element of successful online education is interaction among participants.” He further states that it is “the instructor’s role as a facilitator to ensure that a high-level of interaction occurs in an online course” (p. 3).

The concept of interaction has received considerable attention in the literature related to distance Internet-based learning (Hill, Wiley, Nelson & Han, 2004). Daniel and Marquis’s (1988) challenged the educators to “get the mixture right” between independence (student-content interaction) and interaction (mainly student-teacher interaction). In the 21st century we are still challenged to get the mixture right (Anderson, 2003). Appropriate mixtures will result in increased learning and exciting new educational opportunities; inappropriate mixes will be expensive, exclusive and exigent. Our responsibility as experienced educators remain- to insure that the modes of interaction that we practice and prescribe maximize the attainment of all legitimate educational objectives and support and increase motivation for deep and meaningful learning (Anderson, 2003).

In this study the researcher assumes that the opinion of Kearsley (1998), “single most important element of successful online education is interaction among learners” (p. 3) holds and wants to understand the role the various instructional design elements and differences in discipline plays in

impacting the overall interaction among learners. Hence, the guiding question of the study is: do the instructional design elements and the discipline area impact the overall interaction among learners as defined by the number of learner-learner interactions?

BACKGROUND

As access to the Internet and World Wide Web has continued to grow, Web-based learning has continued to expand. With approximately half of the households in the United States (or 150 million people connected to the Internet), an estimated 2 million students are taking post-secondary courses that are fully delivered online (Galt Global Review, 2001). Millions of other students at all educational levels (primary, secondary, post-secondary, continuing education) participate online in hybrid, mixed mode, and Web-enhanced face-to-face courses (Picciano, 2002).

Interaction has been recognized as one of the most important components of learning experiences both in conventional education and distance education (Vygotsky, 1978; Holmberg, 1983; Moore, 1993). Gunawardena and Zittle (1997) revealed that social presence contributed more than 60% of learner satisfaction with computer conferencing courses. A common element for learning in a typical classroom environment is the social and communicative interactions between student and teacher, and student and student (Stubbs, 1976). The ability to ask a question, to share an opinion with a fellow student, or to disagree with the point of view in a reading assignment are all fundamental learning activities (Picciano, 2002). In online education, it is particularly important to provide an environment in which meaningful interaction can occur (Collins & Berge, 1996).

There is a scarcity of research on the importance of interaction in education especially in online education. There have been a few studies and opinion papers on the relationship of interaction

to learning (Picciano, 2002). Many observers and researchers have supported the concept interactions among learners are important elements in the design of a Web-based course (Fulford & Zhang, 1993; Kearsley, 1995; Klesius, Homan & Thompson, 1997; Kumari, 2001; Picciano, 1998; 2001; Sherry, 1996; Smith, 1996; Zirkin & Sumler, 1995). Both students and faculty typically report increased satisfaction in online courses depending on the quantity of interactions (Dziuban & Moskal, 2001; Gunawardena & Zittle, 1997; Hartman & Truman-Davis, 2001; Kanuka & Anderson, 1998; Shea, Fredericksen, Pickett, Pelz, & Swan, 2001).

Previous research has indicated a strong, positive relationship exists between student perceptions of their interaction in the course and their perceptions of the quality and quantity of their learning (Dziuban & Moskal, 2001; Shea et al., 2001). Interactions among learners and positive contributions to students' learning are directly related (Laurillard, 1993; Moore, 1993; Ramsden, 1992). Michael Beaudoin (2001) examined the relationship between student interaction and learning. In the study, he divided an online class into three groups (high interaction, moderate interaction, and low interaction). He finds that the high interaction students achieved the highest performance. Adelskold *et al.* (1999) suggested collaborative interaction among learners could have greater effects on learning in a problem solving situation than other types of interaction.

Rust (2006) in her study, found that there is a significantly positive relationship between the number of postings per person and the student retention rate. She also concluded that a significantly positive relationship exists between the students' perceptions of the interaction and their final grade. Picciano (2002) showed, using correlation analysis, that perceived interaction and the actual interaction were significantly positively correlated.

Taiwei (2006) used structural equation modeling to show that learner-learner interaction plays an important role in student motivation. Students

who were engaged in learner-learner interaction were more motivated than those who were not engaged in learner-learner interaction. Karayan and Crowe (1997) used surveys to examine students' perceptions of electronic discussion groups. Their research was designed to discover whether or not student behaviors changed as a result of participation in an electronic discussion group. They believed that the convenience of interaction, the provision for different kinds of learners, and the opportunity to "think through writing" would be evidenced in changes in student behaviors (p. 70).

According to Berge (1997), online class size is an area that is scarcely researched that may have significant affect on students learning and interaction. A research study by Jiang & Ting (2000) found that grades for discussion and requirements for discussion were significantly and positively correlated to students' perceived learning. Bouton and Garth (1983) stated that learning is a group process: the learner actively constructs knowledge by formulating ideas into words, and these ideas/concepts are built upon through reaction and responses of others (Harasim, 1990, p. 43). A unique feature of online education is its capability to support this interactive group process. As Internet-based education programs expand, educators are being challenged to go beyond delivering information to remote learners to building community among them (Bruffee, 1993; Dede, 1990, 1996; Harasim, Hiltz, Teles & Turoff, 1995; Kaye, 1995; Renniger & Shumar, 2000). Several researchers have found that the social aspects of the online learning environment are very important (Meyer, 2000).

MAIN FOCUS OF THE CHAPTER

John Dewey (1916) noted that "Every expansive era in the history of mankind has coincided with operation of factors which have tended to eliminate distance between peoples and classes previously hemmed off from one another" (Dewey, 1916,

p.100). Distance educators also follow this tradition of using the technologically “expansive” of eras to remove the distances from distance education.

The field of distance education has a very long history, however significant to this study, is the brief history of online learning and the need to expand the research base that exists specific to online pedagogy. The majority of research has focused on the continuous debate of comparing online course with traditional courses (Strachota, 2003). The majority of such research has arrived at the conclusion that both the environment of the face-to-face course as well as online course are considered to be equally as effective (Johnson, Aragon, Shalik & Palma-Rivas, 2000; Phipps & Merisotis, 1999; Saba, 2000).

Of concern to the practice of online learning is the scarcity of research studying the impact of effective design of instruction on appropriate and meaningful interactions. There is no single “best way” to improvise these interactions. “Each institution, discipline, region, and user group will develop unique cultural practices and expectations related to their need for and use of interaction. Too much of our practice in distance education is not evidence based and our actions and instructional designs are often grounded on untested assumptions about the value of the modes of interaction (or lack thereof). Thus, research that focuses on interaction in all its forms is critically important” (Anderson, 2003). The guiding question of the study is: do the instructional design elements and the discipline area impact the overall interaction among learners as defined by the number of learner-learner interactions?

SAMPLE

The data for this study came from the graduate online courses offered at the University of Wyoming during the fall of 2007. Ten classes each, from the College of Education, College of Business, and

College of Arts and Sciences and 9 classes from the College of Health Sciences, were analyzed. Hence, the analysis was conducted on a total of 39 online classes.

PROCEDURE

Data were collected on the actual number of student postings to the formal instructional discussion board. The site that provided the archived data for the study is recognized as being one that offered a large number of online courses each semester. The research courses were taken from the College of Education, College of Business, College of Arts and Sciences and College of Health Sciences. The postings to be counted included all comments or questions made to the formal instructional discussion board by the learner addressing other learner(s). These learner-learner postings were then sub-classified as Planning, Contributing, Reflecting, Social Interaction and Parroting, based on the rules developed by the researcher (Table 1). Actual number of student postings made to the formal instructional discussion board by the learner addressing other learner(s) was counted for three different weeks during the semester- week 3; week 8 & week 14, for each of the 39 online classes included in the study. So, the total number of the observation for this study was 117. To control for the variability in class size, this count of the number of learner postings per week was normalized by dividing by the class size and was the dependent variable for this study. By analyzing the Course syllabus and structure, data on exact grade weight assigned to the discussion, use of chat sessions, class size and group size statistics were recorded.

Rules for Sub-Categorizing the Learner-Learner Interaction

On the basis components of collaborative behavior described by Johnson & Johnson (1996), Curtis

Table 1. Rules for Sub-categorizing the Learner-Learner Interaction

ActivityLearner- Learner Interactions	DescriptionGroup skills: a generic code applied to expressions that encourage group activity and cohesiveness	ExampleI know that [names] have given you good advice, but I think it's worth knowing that you need patience.
	Organizing work: Planning group work; setting shared tasks and deadlines.	I just want to set a time-line for myself. Is everyone OK with that?
	Initiating activities: Setting up activities such as chat sessions to discuss the progress and organization of group work.	I would like to chat on the blackboard. What about this Friday at 7.30pm SA time?
	Monitoring group effort: Comments about the group's processes and achievements.	I believe the overall contribution and collaboration of working as a group requires an increase within itself as part of our learning.
	Help seeking: Seeking assistance from others.	Does anyone know how to read the chart on pg. 12 of the text..?
	Feedback seeking: Seeking feedback to a position advanced.	What do you think about answering the question that...has put forward?
	Help giving: Responding to questions and requests from others.	To read the chart, look at the Appendix A of the text..
	Feedback giving: Providing feedback on proposals from others.	I agree with you and I believe... Good point...
	Exchanging resources and information to assist other group members.	"With the implementation of an internet service ... there has been a major shift in the communication function in business."
	Sharing knowledge: Sharing existing knowledge and information with others.	I think we also need to give thought to the following. 1. The issues of quality/efficiency in teaching and learning...
	Challenging others: Challenging the contributions of other members and seeking to engage in debate.	I agree but I wondered about the applicability of the argument: "The individuals or other units in a system ..." (Rogers, p. 295). The example used in the book to support is a valid argument but I am unconvinced
	Explaining or elaborating: Supporting one's own position (possibly following a challenge).	Chery, you have a good point about generalizations but I think the cell phone is a little harder to see why the less fortunate may need it more than the wealthy. I think it has a lot to do with the marketing of the product.....
Learner – CMS interaction	Help seeking: Seeking assistance from others about the use of technology.	Does anyone know how to edit/add/append data on the student pages?
	Feedback seeking: Seeking feedback to a position advanced.	What do you think about tutorial on how toin an online class?
	Help giving: Responding to questions and requests from others about the use of technology.	To access the chat room, click on virtual chat in the blackboard; chat screen will come up; click on enter...
	Feedback giving: Providing feedback on proposals from others about the use of technology.	I like your idea of a generic booklet and everyone contributing aspects of interesting internet services...
	Reflecting on medium: Comments about the effectiveness of the medium in supporting group activities.	The email for the discussion group seems to work OK for me. You know it has gone through because you actually receive your email back almost straight away if it has worked.
Social Interaction	Social interaction: Conversation about social matters those are unrelated to the group task. This activity helps to 'break the ice'.	Regarding chat - my weekend is pretty hectic – I have my family flying in from Greece ... so the Greek festivities will be in full swing.
Parroting	Repeat or mimic (another's words, etc) unthinkingly, one line agreement/disagreement statements	I agree with you Me too...

Adapted from Curtis & Lawson (2001)

& Lawson (2001) developed a list to describe the various activities in an online course and based on that list, the researcher developed the following set of rules to categorize student postings into four sub-categories- Learner-Learner interactions, Learner- Course management system (CMS) interactions, Social Interactions and Parroting

ANALYSIS

Data were organized in SPSS 15.0 statistical software for analysis. Descriptive statistics were utilized to summarize, organize and simplify the data (Gravetter, & Wallnau, 1996). Means and standard deviations of the sample were determined to tell us about the distribution of the variables included.

To control for the variability in class size, the dependent variables (overall interactions per week) was normalized by dividing by the size of the class. Bivariate Correlation analysis was used to find the relationship between the dependent variable and the interval and ordinal independent variables- group size and grade weight for discussion and a t-test was employed to understand the differences due to the use of chat sessions. One-way Analysis of Variance was used to find the relationship between the dependent variable and the nominal independent variable, discipline. Follow-up tests were conducted to analyze the pairwise differences among the means and Scheffe's post hoc comparison test was employed for this purpose

Multiple regression analyses were used to identify the individual contribution of each of the independent variable included in the study. A change in R^2 test was employed to test if the independent variable made a unique contribution in predicting the dependent variable. Equation of the following form was estimated:

$$Y_i = \alpha + \beta_1 X_{1i} + \beta_2 X_{2i} + \beta_3 X_{3i} + \beta_4 X_{4i} + \epsilon_i \quad (1)$$

where,

Y_i : Number of Learner-learner interactions per week normalized by class size.

X_1 : Use of chat session

X_2 : Group size

X_3 : Grade weight for discussion

X_4 : Discipline

α : Intercept

β_j : Regression coefficients

ϵ_i : Residual

Overall Interaction and Learning

This study is based on the assumption that the more the interaction, the greater is the learning. To test this assumption the researcher used average grade for classes included in the study as a proxy for learning. This is not the best measure of learning, but it does serve as a beginning point and a concrete measure of learning application. The result of the bivariate correlational analysis showed that the average grade was significantly positively correlated with the overall interactions per student per week, $\rho = 0.32$, $p < 0.01$ (Figure 1). One of the reasons for a smaller correlation coefficient might be that the grade is not the only or the best indicator of learning. The student's final grade is the undiscussed average (Biggs, 1999).

The above analysis tested the assumptions of this study. Hence, more interaction results in better learning, which also supports the opinions and researches by various authors in the literature (Dziuban & Moskal, 2001; Gunawardena & Zittle, 1997; Hartman & Truman-Davis, 2001; Kanuka & Anderson, 1998; Shea, Fredericksen, Pickett, Pelz, & Swan, 2001).

Figure 1. Scatter plot showing the relationship between the average grade and overall interaction

RESULTS

Correlational Analysis

Table 2 presents the Pearson's product moment correlation coefficients between the 4 variables included in the study. The result of the correlational analysis showed that 2 out of 3 independent variables (Grade weight and Group size) were significantly correlated with the independent variable, interactions per student per week.

The reader should be cautious while interpreting the magnitude of the correlation coefficient as most of the variables had skewed distributions due to the presence of outliers, which would reduce the magnitude of correlation coefficient (Lomax, 2007, p. 188). So, most of the coefficients shown in Table 2 are under-estimate of actual size of the correlation.

Regression Analysis

After testing the underlying assumptions, the researcher conducted the multiple regression analysis. The linear combination of independent variables was significantly related to overall interactions among learners, $F(4, 112) = 6.83$, $p < 0.01$. The coefficient of determination (R^2) was 0.27, indicating that approximately 27% of the variance of the overall interactions in the sample can be accounted for by the linear combination of the independent variables included in the study. The results of the regression analysis showed that discipline and group size were significant predictors of the dependent variable at 5% level of significance, while the use of chat session and grade weight were not significant in predicting the overall interactions per student per week.

To further support the above results and to find the individual contribution of each predictor variable, the researcher used multivariate regres-

Table 2. Correlation matrix showing the bivariate relationships among the variables included in the study

		1	2	3	4
1	Intper Student	1.00			
2	Grade Weight	0.19*	1.00		
3	Group Size	-0.35*	0.06	1.00	
4	Chat session	0.10	0.23	0.04	1.00

* Significant at 0.05 level

sion analysis to conduct a change in R square test. The result of this analysis is presented in Table 3.

Overall Interaction and Group Size

The size of groups is an important element of the success of the online learning process (Learning Team Handbook, 2003). A unique feature of online education is its capability to support the interactive group process (Gusky, 1997). This study found a significantly negative relationship between the overall interaction and group size (tables 1 & 2). Hence, the overall interaction among students was higher when the group size was small which supports the fact that smaller virtual learning groups build synergistic learning efforts among students in online courses (Scarnati, 2001).

Overall Interaction and Grade Weight For Discussion

Online courses included in this study incorporate a threaded discussion element in their courses with a varying grade weight assigned to it. This study

found a weak positively significant correlation between the overall interaction and the grade weight (table 1). But a more powerful regression analysis failed to find any significant unique contribution made by this variable in explaining the variation in the dependent variable (Table 3). Hence, the grade weight assigned to the discussions was not a significant predictor of the overall interactions among students. This result contradicts the views of Jiang & Ting (2000) who found a significant positive correlation among discussion grade weight and students' perceived learning.

Overall Interaction and Differences In Disciplines

In this study the researcher selected sample courses from 4 different disciplines. Ten courses each from Colleges of Business, Arts & Sciences and Education and 9 courses from College of Health Sciences were included. The results showed that the Health Sciences courses had a higher overall interaction per student per week then the other disciplines but the differences in interaction between

Table 3. Summary of regression analysis for understanding the individual unique contributions of the independent variables in predicting the overall interactions per student per week (N = 117)

Excluded variable	Change in SE	Change in R ²	F-statistic	Df (n,d)	p-value	VIF
Discipline	0.18	0.10	4.96	(3,110)	0.003	1.84
Group Size	0.10	0.05	6.77	(1,110)	0.011	1.28
Grade Weight	0.01	0.01	1.64	(1,110)	0.20	1.31
Chat Session	0.01	0.01	0.56	(1,110)	0.457	1.12

Table 4. Summary statistics for overall interaction per student per week for the different disciplines

College	Mean	SD
A & S	3.42	2.03
Business	2.81	1.35
Education	5.71	2.77
Health Science	7.36	6.16

Education courses and Health sciences courses was not significant (Table 4). The researcher did not find any literature that researched this variable in the past.

Overall Interaction and Use of Chat Sessions

This study failed to find any significant relationship between use of chat sessions and overall interactions (tables 1 & 2), which is in direct contrast to the views of Rohfeld & Hiemstra (1995), who concluded that chat sessions are important to build a friendly and social environment which fosters learning.

CONCLUSION

This study began by asking “do the instructional design elements and the discipline area impact the overall interaction among learners as defined by the number of learner-learner interactions?” The following conclusions can be drawn on the basis of analysis done:

- Design Elements:
 - There is a statistically significant negative relationship between group size and overall interaction. The smaller is the group size, the higher is the overall interaction.
 - There is no statistically significant relationship between the grade weight for threaded discussions and the overall interaction.
 - There is no statistically significant relationship between use of chat sessions and overall interaction, i.e. the interactivity in an online class does not depend on the use of chat sessions.

Figure 2. Distribution of the overall interaction per student per week for the four disciplines

- Discipline:
 4. The differences in discipline made a unique contribution in predicting the overall interactions, i.e. the interactivity in an online class depends on the discipline it belongs to.

The results of this study can prove to be very important in designing effective and interactive online courses. To improve the interaction in an online class, students must be divided into smaller groups. The results of regression analysis showed that differences in discipline made a unique contribution in predicting the overall interactions and was the most important predictor of overall interaction. This result suggests that the interactivity in an online class depends on the discipline it belongs to and hence, future research must focus on impact of instructional design elements on overall interactions within a discipline.

FUTURE RESEARCH

1. Similar studies can be conducted using a more representative sample of online courses particularly from different institutions.
2. The researcher limited this study to interactions in online classroom but it can be extended to a face to face class as well.
3. This study was limited to graduate level classes but future research can be extended to undergraduate classes as well.
4. A longitudinal study should be conducted to understand the impact of technological advancement over time on overall interaction in an online class.
5. The researcher considered four different predictor variables but a future study may include more variables that can influence the interactivity of an online class.

6. A future study may be conducted on similar lines using non-parametric estimation techniques.

KEY TERMS AND DEFINITIONS

Distance Education: In this dissertation refers to “online delivery of education to remote locations, using either or both synchronous and asynchronous delivery of course content” (Distance Education at Postsecondary Education instructions: 1997-1998). In this research project, Distance Education does not include correspondence or broad-cast based education.

Face-to-Face Learning: Refers to teaching and learning that occurs when both teachers and students are confined within a single room.

Instructional Design Elements: Refer to the components of a course that facilitate learning. For the purpose of this study 3 different instructional design elements will be considered: Group size, grade weight assigned to threaded discussions, and use of chat sessions.

Learner-Instructor Interaction: Refers to the human interaction consisting of communication

between the learner and the instructor (Moore & Kearsley, 1996).

Learner-Learner Interaction: Refers to the human interaction consisting of two-way communication between one learner and other learners (Moore & Kearsley, 1996).

Traditional Courses: Refers to the courses essentially taught in a face-to-face classroom environment but may use some web-based technology to support the course content.

Chapter 2.5

Developing Prescriptive Taxonomies for Distance Learning Instructional Design

Vincent Elliott Lasnik
Independent Information Architect, USA

INTRODUCTION

There are simple answers to all complex problems... and they are uniformly wrong. -- H.L. Mencken

One of the central problems and corresponding challenges facing the multidisciplinary fields of distance learning and instructional design has been in the construction of theory-grounded, research-based taxonomies for prescribing what particular strategies and approaches should be employed when, how, and in what combination to be most effective and efficient for teaching specific knowledge domains and performance outcomes. While numerous scholars and practitioners across a wide range of associated instructional design fields have

created a rich variety of effective, efficient, and very current prescriptions for obtaining specific learning outcomes in specific situations (Anderson & Elloumi, 2004; Marzano, 2000; Merrill, 2002a; Nelson & Stolterman, 2003; Reigeluth, 1999a; Shedroff, 1999; Wiley, 2002), to date, no single theory-grounded and research-verified unifying taxonomic scheme has successfully emerged to address all existing and potential educational problems across the phenomena of human learning and performance.

BACKGROUND

Descriptive taxonomies developed in educational theory and practice have provided rich organizational schema for classifying the structure of conditions for learning describing the approaches,

DOI: 10.4018/978-1-60960-503-2.ch205

types, events, methods, and goals of instruction (Gagne, 1977). While affective and psychomotor capabilities have gained increasing importance (Krathwohl, Bloom & Masia, 1964, Martin & Briggs, 1986), classic instructional design theory has tended to focus on the cognitive domain, as exemplified by the widely adopted hierarchical taxonomies of Bloom (1956) and Gagne, Briggs, and Wager (1992). There have been serious efforts to revise and update *Bloom's Taxonomy* with the applied focus towards more specific and pragmatic "best practice" teaching strategies in instruction (Anderson, Krathwohl, Airasian, Cruikshank, Mayer, Pintrich, et al., 2000). However, few correspondingly robust prescriptive taxonomies have emerged to encompass the optimal design solutions for distance education and online e-learning professions. This article examines the critical issues involved with understanding the nature and function of prescriptive educational taxonomies for improving the efficiency and effectiveness of rigorous instructional design solutions adaptable and applicable to the burgeoning field of online learning, user-centered design, and technologically distributed distance learning environments.

MAIN FOCUS: INSTRUCTIONAL TAXONOMIES - WHAT THEY ARE AND WHY THEY MATTER

In his hallmark narrative work on the complexities of successfully building a learning environment, media pioneer Edgar Dale identified important considerations for the development of any prescriptive taxonomy for instruction, as well as this encyclopedia broadly conceived:

Indeed product and process must not be separated, any more than we would separate form and content...A major issue in all learning deals with the processes by which learning experiences become structured, organized, mapped, patterned,

clustered, and systemized. We group experiences, using some kind of framework, paradigm...schema, summary, matrix, model, unit, brief, diagram, category, concept, hierarchy, grid, or outline. We use hierarchies, superordination and subordination...All these terms indicate a linking, a relating of experience on the basis of their differences and likenesses. Process and product, form and content become fused, structured. (pp. 82-83)

Human learning and the collateral formation, representation, acquisition, generation, and creation of knowledge in the mind of the learner are unquestionably immensely ill-structured and complex human problems (Reigeluth, 1999b). Philosophers and scholars have explored, for ages, questions of ontology and epistemology, and numerous competing schools of thought (i.e., instructional design paradigms) have developed across a wide array of knowledge domains (Richey, 1986; Visscher-Voerman & Gustafson, 2004). The enactive, intentional, unifying higher-order problem-solving endeavor is *design* itself, and numerous universal principles, exemplars, and epitomes of design have emerged (Lidwell, Holden, & Butler, 2003). "Designing is, therefore, more than ordering and arranging, more than constructing. It is composing. It is using the codes and pattern languages of a domain to create wholes with not only parts and relationships but also ordering-underlying principles (Rowland, 2004, p. 40)." Critical in this human design process for instruction are systems thinking, creativity and evaluative judgment, metacognitive awareness, and the seemingly paradoxical nurturance for an eclectic, broad-minded tolerance for ambiguity while simultaneously possessing a pragmatically strong drive towards tangible closure (i.e., deliverables) in the design activity (Lasnik, 2003b). To illustrate the relative complexity of this phenomenon, an easy-to-grasp architectural analogy is provided in Table 1.

Table 1. Simple analogical model of e-learning environments

BUILDING ARCHITECTURE	E-LEARNING ARCHITECTURE
Buildings, structures, bridges	Courses, scope & sequence (curricula)
Macrodesign form, leitmotif, treatment	Instructional design approaches/models
Purpose & function of building	Information design
Properties of materials	Media design
Patterns of interior/exterior space	Interactivity design
Structure lifecycle (repair, modification)	Iterative courseware design (improvement)
Settlements, zones, cities	Lesson activities, modules, units
Power, water, air, transportation	Courseware management infrastructure

First Principles of Prescriptive Theory: The Taxonomic Function

The critical problem of taxonomic formulation is to provide a cogent, comprehensive, conceptual model of phenomena that is (a) dynamic (capable of change), and robust (representing all relevant attributes) without being reductionist, and (b) parsimonious (graspable, usable) without being an oversimplification. Two broadly adopted exemplars are the classification schemes of Carl Linnaeus (i.e., his 1735 System Naturae that evolved into modern biology's kingdom, phylum, class, order, family, genus, and species schema) and Dmitrii Mendeleev (i.e., his 1889 Periodic Law of the Chemical Elements that evolved into today's Periodic Table). Mendeleev's perspicacious insights into the nature of atomic structure arguably rank him with Albert Einstein as the paradigm-shifting geniuses of modern science. Moreover, the Periodic Table has provided a unified scaffolding between the detailed description of matter and the effective prediction about how that matter will behave. In other words, a single, well-organized, seemingly simple diagram in fact illustrates a highly sophisticated metageography literally encompassing the known universe and simultaneously explaining how all matter within that universe will interact (Atkins, 1995). This is the fundamental character of prescriptive theory: the power to explain and to predict. It is arguable

whether a verifiable unified theory of learning and instruction can be found, is even desirable, and ultimately whether learning, instruction, and the active construction of knowledge are even truly capable of a single, complete prescriptive taxonomic classification. It is the premise of this article that such a comprehensive architecture will one day emerge.

Learning Taxonomies: Envisioning the Problem Space

Ideally, descriptive instructional schema can support the diagnostic function, and prescriptive schema can support the remedial, corrective function in the teaching/learning enterprise. The underlying rationale for hybrid descriptive-prescriptive taxonomies for instruction is (a) to demonstrate that content and method are inextricably linked and are synergetic (i.e., mutually reinforcing entities that create a combined, holistic design alloy greater than either in isolation), and (b) to provide a powerfully eclectic, flexible foundation of a more effective and efficient design solution for particular e-learning requirements.

Well-constructed taxonomic models should clearly and unambiguously represent all of the important concepts and principles (change relationships) in a knowledge domain, in this case connecting instructional activities (inputs) to learning performance (outputs). An effective

taxonomy can present a metatheory of the instructional design problem space complete with a detailed map of the possible routes between the origin and the destination. Moreover, Bertin (1981) emphasized that:

In considering hypotheses and methods, it is necessary to envisage the whole problem. The matrix analysis of a problem is a process which enables us to see the whole...and to "foresee" the possible choices and their repercussions. (p.17)

Therefore, the use of a taxonomic table or diagram can serve as a representational schema displaying both a heuristic method and an ostensible design strategy. Such a model could enhance the e-learning repertoire of distance teachers and contribute to their ability (a) to systematically define the educational problem (i.e., the content to be taught, the specific needs of the students, and the intended performance outcomes), and (b) to produce an appropriate instructional design solution. Unfortunately, much of what constitutes secondary and college-level instruction continues to be predominantly receptive learning approaches that separate content from method and disembodiment information into predigested, decontextualized, abstract chunks that are easy to deliver but provide little scaffolding for meaningful learning (Bransford, Brown, & Cocking, 2000; Lasnik, 1988, 2003a; Mayer, 1989, 1999; Perkins & Unger 1999; Shuell, 1986).

Levels of Complexity in Taxonomic Design

Complexity levels are key to the development of any robust taxonomy, but levels of cognitive, affective, or sensory-motor complexity may or may not directly translate to levels of difficulty and achievement in the learning experience. In course design architectures, simple taxonomies are often created to describe categories and subcategories of topics covered in the course (Posner & Rudnitsky, 2001).

Each of the taxa may also be comprised of various levels of subcomponents: for example, rules are logical control structures containing prepositions, concepts are logical schema containing critical attributes and variable attributes, principles are predictive change relationships containing static and dynamic concepts, laws combine into theories, and theories become explanatory systems. Viewed as layers of an onion, the organizational structure focuses on progressively smaller, less abstract units from higher-order macrolevel down to lower-order microscopic dimensions. More substantive taxonomic layers describe superordinate and subordinate rules, superordinate and subordinate concepts, superordinate and subordinate principles, superordinate and subordinate laws, and coherent, integrated, unifying theories that subsume the descriptive *taxa* of rules, concepts, principles, and laws. These perspectives are congruent with the salient dimensions of modularity, granularity, and combinatorial flexibility that have emerged in the evolving definitions of learning objects (Merrill, 2002b; Wiley, 2002).

The Emergence of the Postmodern Knowledge-Based Curriculum

Existing education and training curricula that reinforce the artificial division between information's purpose, structure, and the student's firsthand experiences within that information are vestiges of an earlier learning paradigm that is no longer relevant or effective in the postmodern e-learning environment. In fact, this is one of the principal flaws in Benjamin Bloom's (1956) widely adopted cognitive taxonomy: the Industrial Age percept of knowledge as the mere acquisition, storage, and retrieval of passive information is placed at the foundation level of the entire scheme! Ideally, perceiving knowledge itself as an integrated, learner-centered design process can ameliorate this disconnect and may serve to narrow the mind's gap between inert information and applicable, useful, and most critically *transferable* knowledge

(diSessa, 1977). The bridge between static information and dynamic, transferable knowledge is more soundly built on authentic competency and performance ability across a range of analytical, practical, and creative domains (Howard, McGee, Shin, & Shia, 2001; Perkins & Unger, 2001).

Dale's (1972) insightful systems view of how people learn also conveys the underlying rationale for designing instruction around practical, functional conceptual schema:

In mastering any subject, in learning to learn, we must map the field, note its basic principles, its key ideas and vocabulary, and its conceptual structure. For example, no sensible person studies the automobile by first trying to master the names of all its parts. Instead, he thinks in terms of systems—ignition, fuel, transmission, braking, and so on. In each of these classes are meaningfully related concepts...The crux of learning is to develop a conceptual scheme. (p. 52)

Perkins (1992) has further elaborated on the prescriptive practices that can contribute to a more effective and efficient instructional design across the curriculum from pedagogy to androgogy. Previously, Perkins (1986) had deftly proposed the intriguing, powerful metaphor of *knowledge as design* in constructing first principles of empirical (i.e., discovery-driven) teaching and learning. This is a reflective, recursive, parsimonious, and practical taxonomy with both descriptive (of product and process) and prescriptive (the inquiry-based learning activities) dimensions based upon four fundamental questions about the nature of a particular design: (a) what is its purpose?; (b) what is its structure?; (c) what are model cases of it?; and (d) what are arguments that explain and evaluate it? By carefully addressing each of these post-Socratic interrogatories, both descriptive and predictive components of concepts, principles, objects, and systems can be understood in the broader educational context and conversely, ef-

fectively (i.e., successfully and robustly), and efficiently (i.e., optimizing time, cost, and human resources) taught.

Experiential Learning Models: From the Student's Perspective

Edgar Dale's widely known Cone of Experience (Dale, 1954) is an exemplar of a simplified but parsimonious hybrid taxonomy that synthesizes both descriptive and prescriptive domains. Conceptually modeling a progressive spiral curriculum of media and learning types, Dale's Cone (author's interpretive update with significant modifications as shown in Figure 1) juxtaposed specific educational technologies with cognitive change, effectively providing a descriptive hierarchy where the level of increasing engagement with the active learner predicts deeper learning and acquisition of transfer. From the perspective of granularity with learning objects, Dale's learner-centered system uses large, aggregate technologies/levels across a spectrum from more inert, static, abstract, expository-declarative materials (e.g., texts, lectures, audio and video recordings) to more dynamic, concrete, discovery-experiential activities (e.g., field trips, discussions, and participatory, collaborative learning projects).

An Experiential Learning Taxonomy

While variations on this theme have emerged across the literature (Anders, 1999; Reigeluth, 1983, 1999b; Richey, 1986; Shedroff, 1999; Stolovich & Keeps, 2002; Wiley, 2002), the essential principles easily map into a cohesive topography (See Table 2) like a broad continent with two opposing coasts unified by the general observation that all learning is experiential and occurs across a wide multileveled continuum proceeding *from—to*.

Figure 1. A 21st century update of Dale's Cone of Experience Taxonomy (Lasnik, 2006)

Applying Prescriptive Taxonomies to Instruction

Prescriptive taxonomies attempt to address how specific learning types and capabilities can be enabled and achieved by which corresponding experiences. In recently examining the affordances and medial qualities of interactive game-based learning, Prensky (2000) posited a basic set of learning types (i.e., intended outcomes) and corresponding learning experiences (i.e., facilitating interventions). Extrapolating these observations

with other perspectives about how people learn (Allessi & Trollip, 1985; Bransford et al., 2000; Mayer, 1983; Merrill & Tennyson, 1977; Perkins, 1986; Screven, 1999) leads logically to a pragmatic prescriptive matrix constructed in Table 3:

Integrating Cognitive and Affective Domains

Conventional didactic classroom instruction in secondary and postsecondary institutions has been predominantly focused on the delivery of

Table 2. Selected summary of experiential learning dimensions

More passive learning to more active learning	More expository/delivery to more discovery/inquiry
More abstract concepts to more concrete activities	Less learner control to more learner control
From parts/components to wholes/systems	Teachers on top to teachers on tap
Deductive rules to inductive processes	Sage on the stage to guide on the side
Isolated part-tasks to situational whole-tasks	Less interactivity to greater interactivity
Rule-learning practice to problem-oriented	Surface learning to deeper learning
Independent facts to inter-dependent contexts	Extrinsic rewards to intrinsic value
Convergent thinking to divergent thinking	Lower order thinking to higher order thinking
Well-defined problems to ill-defined problems	Telling/showing/listening to doing/making/acting
More algorithmic solutions to more heuristic design	Less creativity to greater creativity
Less learning transfer to greater learning transfer	Receptive learning to applied learning
More quantitative data analysis to more qualitative observation & evaluation	Knowledge of results to constructive/remedial feedback

Table 3. Descriptive learning types & prescriptive experiences matrix

LEARNING TYPES (Learn this)	LEARNER EXPERIENCES (By doing this)
Facts, information, declarative knowledge	Drill, repetition, memorization, viewing data
Skills, performance capabilities/competencies	Practice part/whole tasks, receive coaching & training, continual hands-on practice
Concepts, rules, associations, classifications	Identify attributes, view multiple examples & non-examples, compare & contrast
Principles, change relationships, correlations, critical paths, inheritances & comparison & contrast across time dimensions & functions	Critical thinking, analyze & synthesize data patterns across x/y dimensions; create concept maps, fault-trees and troubleshooting protocols
Procedures, processes, cause-effect reasoning	Deconstruct problem or process into component parts, sub-systems, beginning & goal states; analyze independent & dependent variables, inputs & outputs; map IF-THEN logical control structures; identify functionality & model cases; “work the problem” & “follow the data”
Systems, theorems, explanatory schema	Reflective inquiry & observation; conduct experiments, formulate & test hypotheses, understand tradeoffs & interdependencies; search for patterns, create conceptual models
Creativity, innovation, novel & original ideas, resourcefulness, collaborative decision-making, resolving complex, ill-structured problems	Divergent thinking, team role-playing, problem-solving, simulation games, group design tasks, “break set”, brainstorm, generate alternatives, challenge assumptions, take calculated risks

“content” as abstract information and, at best, employs critical thinking, reflective thinking, collaborative learning, and creative problem solving as ancillary scaffolding activities to ostensibly engage learners to acquire this predominantly declarative knowledge. Convergent thinking assessments generally designed for administrative convenience are then often employed to evaluate how well this specific content has been absorbed. This instrumentalist paradigm tends to dilute the essential role of thinking, reflection, and both creative and technical communication (e.g., writing, composition, art) emphasized in exemplary constructivist course design, and has the additional onus of reinforcing a surface approach towards all instruction and learning (Nickerson, Perkins, & Smith, 1985; Perkins, 1992; Perkins & Unger 1999).

Stolovich (1978) and Stolovich and Keeps (2002) have engineered a variety of interesting and helpful ways of addressing prescriptive approaches in education and training. A sample of their integrated “learner-centered, performance-based” strategies for instructional media is outlined in Table 4.

Identifying Critical Attributes of Taxonomic Philosophy

For any instructional taxonomy, it is essential to identify the core epistemological assumptions underlying the categorization scheme. The cognitive-constructivist pedagogical approaches all appear to recognize the following broad observations: (a) Real-world knowledge develops from active, authentic (i.e., realistic, actual), and engaging experiences within personally meaningful contexts; (b) this knowledge is cross-disciplinary, multisensory, multidimensional, and problem-oriented; and (c) the principle inner experience of learning is discovery-driven, meaning-seeking, sense-making, goal-based and intrinsically self-motivating towards the actualization of achievement and competency (Lasnik, 1999).

Rather than emphasizing abstract, iconic, conventional, static, and redundant expository descriptions of various empirical phenomena on an idiosyncratic case-by-case basis, the teaching of concepts and principles are better founded on a deeper level of human cognitive processing. All robust learning is viewed as operational and

Table 4. Modified Learning Element & Instructional Method Taxonomy (Significantly enhanced while broadly adapted from Stolovich 1978, and Stolovich and Keeps 2002)

LEARNING ELEMENT	INSTRUCTIONAL METHOD
Environmental	The learner activity provides non-abstract, real-world contexts in which the skills are to be applied. Employ actual case studies, local events, conditions, and current problems to engage learners, augment direct relevance, and connect learning to application.
Enhancement	In teaching a procedural task, the supporting media should clearly and unambiguously show each of the steps during the demonstration of the skilled performance from start through goal. Learners should be provided opportunities to replicate tasks and practice skills to enhance their performance mastery/competence.
Examples	In teaching a concept or principle, the media provide a divergent set of examples and non-examples across a range of complexity, difficulty, and thinking skill (lower to higher) dimensions. Opportunity to compare & contrast independent and dependent attribute variables will support identification & generalization.
Instructions	The training provides directions given in the procedure or process that ensure the learner will follow them, including part tasks & whole tasks. Instructions and remedial help should be aligned and embedded (context-sensitive) to task performances.
Summary	The training provides summaries of the principles and procedures taught in the lesson and module. Summarize and organize rules, concepts, unifying theory, and best practices to be used as job aids (performance mnemonics) and cognitive strategy scaffolds.
Enrichment	The media facilitate logical opportunities to go beyond the specific instructional objectives of the module without interfering with its essential focus. Provide supplemental “value added” media resources and additional opportunities for applying new knowledge through advanced projects, creativity, & collaboration.

experiential in nature: that is, by doing tasks, hands-on activities, experiments, comparisons of examples and non-examples, individual and group interactive role-playing simulations and tasks-manipulating attributes, and rule parameters, variables, and constants. These firsthand, inquiry-driven, inductive reasoning, heuristic-based approaches are particularly vital for compelling distance-learning educational experiences requiring reproducible outcomes in improved thinking skills, longer retention and integration of content, and a better transfer to on-the-job task performance (Dede, 2002; Lasnik, 1988; Schank, Berman, & Macpherson, 1999).

Deep vs. Surface Approaches Toward Learning

Insufficient serious attention to the problematic effects of the dichotomy between deep learning and surface learning continues to plague educational policy and practice worldwide. A student with a surface approach towards learning maintains an instrumentalist view towards coursework char-

acterized by an impersonal disengagement and extrinsic motivation toward learning tasks, little interest in integrating new knowledge with prior knowledge, concern about the duration of learning tasks, and the reliance on memorization to learn new material. Conversely, a student with a deep approach towards learning develops a personalized engagement and intrinsic enjoyment in learning tasks, interest in integrating new knowledge with prior knowledge, and the search for hypotheses, explanations, and meaningfulness in new material (Biggs & Rihn, 1984). This observation is critically important to the future design and development of effective e-learning courseware because instruction emphasizing heavily expository delivery of information, content that students can acquire perhaps more efficiently on their own via books, Web sites, libraries, in the field on their own), reduces the power of the online communication environment to a mere convergent thinking funnel. Meaningful deep learning can be facilitated by appropriate levels of thoughtfully designed interaction between students and teachers, students and content, and student peer-to-peer communica-

tion. Moreover, “the challenge for teachers and course developers working in an online learning context is to construct a learning environment that is simultaneously learning centered, content centered, community centered, and assessment centered” (Anderson, 2004; p. 50).

A Learner-Centered Media Taxonomy

Bruce and Levin (1997) proposed a four-part user-centered instructional media taxonomy based broadly on the well-known learner-centric Progressive pedagogical philosophy of John Dewey. Like Dewey, their organizational schema places the conventionally central roles of both technology and traditional “content domain” disciplines into the background, and elevates the individual’s intrinsic interests and social learning needs into the focal plane of the educational experience. In particular, they emphasize the constructivist notion of technology as media: reconceptualizing learning activities as well as hardware and software infrastructure as enabling, mediational,

motivational, growth-fostering components of the learning intervention and learner’s transformation (Keller, 1983). Their inclusive model of media acts as an instructional catalyst, a dynamic scaffolding between passive and active realms much like the muscles of the forearm provide the medial function of motion between the (active) brain and the (passive) bones of the ulna and radius. These metacognitive media models are defined by their respective functions for inquiry, communication, construction, and expression, and apply prescriptive activities and experiences for their attainment. An expanded synopsis of their taxonomy is shown in Table 5:

Teaching Learners Heuristic Reasoning

Heuristic principles and strategies are ostensibly at the heart of all meaningful instructional design treatments. The word origin is *heuriskein*, the Greek term for “to discover, find.” It is the source of Archimedes proverbial “Eureka!” (i.e., I have

Table 5. Media Taxonomy for Inquiry, Communication, Construction, & Expression (modified from Bruce & Levin, 1997)

MEDIA LEARNING FUNCTION	PRESCRIPTIVE LEARNER EXPERIENCES
INQUIRY	1. Theory-building; media for thinking: visualization, simulation, procedural & parametric modeling, knowledge representation schemes 2. Data-mining: online libraries, hypertext tools, accessing digital media assets, databases of audio, video, text, voice, music, graphics 3. Data-collection: active audio/video recording, remote real-time scientific data acquisition tools, tablet PCs 4. Data-analysis: environments for inquiry, hypothesis testing, statistical search for patterns, make tables, graphs, diagrams, matrixes to model problems, inter-relationships
COMMUNICATION	1. Design & produce communication artifacts: outlining ideas, arguments, writing clear & compelling documents, creating presentation materials, persuasive use of text & visuals 2. Collaborative synchronous & asynchronous media: threaded discussions, computer conferencing, email, blogs, wikis, podcasts, listservs, online journaling, multiuser domains 3. Teaching & training multimedia: instructional simulations, telementoring, tutoring, coaching
CONSTRUCTION	Student goals: build and make things; similar to <i>Communication</i> function but learner experiences are designed to produce tangible, transportable multiple media artifacts for use in portfolios, Web sites, software applications, tools and affordances to affect, influence, and impact physical, intellectual, and cultural worlds
EXPRESSION	The uniquely personal creative design function: original, self-expressive writing, scripting, music composing, 2-D & 3-D drawing, painting, animation, video, digital photography, Web design, interactive multimedia microworlds, and so forth.

found it!) exclamation. Heuristic techniques and devices, far more than mere “rules of thumb” in the problem-solving vernacular, profoundly assist discovery and guide further investigation. Insightful, deftly employed heuristic pedagogies can designate “the educational method in which the student is allowed or encouraged to learn independently through his own investigation.” (Morris, 1976, p. 620). In other words, heuristic design principles are at the epicenter of every deep learning-centered environment. For example, a cognitive-constructivist prescription for an e-learning course might redesign, reformulate, and restructure content from the learner’s perspective, or more precisely, based upon how people actually learn (Bransford et al, 2000). There would be no arbitrary arrangement of course structure or metacurriculum, but one carefully organized around logical, intuitive, organic patterns and models of knowledge acquisition within the particular subject or discipline. Heuristic courseware focuses the affordances of the online environment on the learner as user, the learner as client, and ultimately on the experiential transactions between the dyads of learner-teacher, learner-learner, and learner-content. An exemplary prescriptive instructional-design scheme superbly adaptable to distance-learning courseware can be applied from the five “First Principles for Effective Instruction” (Merrill, 2002) as summarized and elaborated in the following five paragraphs:

1. *The courseware should be presented in the context of real-world problems.* This is one of the premises of problem-oriented learning. It is also helpful to clarify the importance of integrating concepts within realistic contexts and demonstrable learning outcomes. Learner activities should utilize a range of problem difficulty and complexity that gradually reduces the need for scaffolding as competency increases across problem types. The activities might involve a progression of problems rather than a single problem, and should engage students at the problem or whole task level and not just the operation or action levels.
2. *The courseware should attempt to activate relevant prior knowledge or experience.* This is the precursor to a learner’s acquisition of transfer skills, and recognizes the need to scaffold learning activities between the gap of prior knowledge and new knowledge. Also, appropriate online help and coaching should also be provided, but the need for assistance should gradually be diminished as the new skills/knowledge are successfully acquired. The courseware activities should direct learners to recall, relate, describe, or apply knowledge from relevant past experience as a foundation for their new knowledge. For example, embed the use of analogical and inductive reasoning from prior examples/cases as scaffolds for improved transfer to the newly encountered situations or problems. These analogies should help learners recall or form appropriate structures for organizing the new knowledge, thereby augmenting new schema formation and concept acquisition.
3. *The courseware should show examples of (demonstrate the new skill) what is to be learned* rather than merely tell information about what is to be learned. For active learners, showing is better than telling and doing is better than showing (principle 4 following), and knowledge goal-state exemplars need to be as explicit and as concrete as feasible (i.e., clearly show learners the task they will be able to do or the problem they will be able to solve as a result of completing a module or course), applying an appropriate use of media to reinforce, supplement, complement, augment, enhance, clarify, and scaffold learning. The kind of showing is important (i.e., examples and non-examples

for concepts; demonstrations for procedures; visualizations for processes; and modeling for behavior).

4. *Learners should have an opportunity to practice and apply their newly acquired knowledge or skill*, consistent with the learning objectives. This learner demonstration of transfer competency should be routinely occurring throughout the instructional intervention and not only at the end of instruction (summative finals). It is a core instructional design practice to facilitate congruence and alignment between learner practice activities and measured performance criteria used to evaluate learning attainment. Also, the courseware should ideally require learners to solve a varied sequence and range of difficulty of problems while receiving corrective (i.e., remedial) feedback on their performance. Moreover, the kind of practice (i.e., doing) is very important in prescribing what specific activities are most beneficial for various learning objectives: (a) **Information-about** practice requires learners to recall or recognize information; (b) **Parts-of** practice requires the learners to locate, name, or describe each component part; (c) **Kinds-of** practice requires learners to identify new examples of each kind; (d) **How-to** practice requires learners to perform the skill or procedure; (e) **What-happens** practice requires learners to predict a consequence of a process given conditions, or to troubleshoot faulted conditions given an unexpected consequence.
5. *The courseware should provide techniques that encourage learners to integrate (transfer) the new knowledge or skill into their everyday life*. This extends the prescriptive curriculum from problem-oriented to project-based activities that foster a deep approach towards learning, as described in this article. Also, while systematic, indi-

vidual student practice of skills is suggested in principle 4, this principle requires learners to reflect on, discuss, defend, and demonstrate their new knowledge in some public or semipublic capacity (e.g., online forums, threaded discussions, wikis, blogs, etc.). Finally, the e-learning experience should also provide an opportunity for learners to create, invent, or explore new and personal ways to use their new knowledge or skill (See parallel with Communication, Construction, & Expression functions of Bruce & Levin, 1997).

While it is true that the practice of instructional design involves more than consideration for these “first principles,” per se, a judicious application of these guidelines to the iterative information-interactivity-media design process of learner-targeted products like immersive real-time educational simulations, and both synchronous and asynchronous distributed courseware would ostensibly accommodate the needs of as many learners as possible and in effect, meet or exceed many of the collateral concerns about the economic, engineering, cultural, and environmental impact of the prescriptive design solution. Moreover, while these principles are not exhaustive in scope or detail, they provide a helpful starting point for a pragmatic heuristic evaluation of any online learning product’s learner experience portfolio.

Future Trends and Conclusion

Experiential instruction designed for deep-learning heuristic skills, critical and reflective thinking, creative problem-solving, and project-based, problem-oriented activities combines a superior educational paradigm with far richer and compelling utilization of new media accessible through the computer platform and Web infrastructure (Firdyiwek, 1999; Fraser, 2001; Harvey & Lee, 2001). The emergence of theory-grounded and

research-validated prescriptive taxonomies for e-learning instructional design will offer an invaluable contribution to the successful achievement of this new, comprehensive paradigm in learning. Anderson (2004) has cautiously observed, however, that:

There is no single, right medium of online learning, nor a formulaic specification that dictates the kind of interaction most conducive to learning in all domains with all learners. Rather, teachers must learn to develop their skills so that they can respond to student and curriculum needs by developing a set of online learning activities that are adaptable to diverse student needs. (Anderson, 2004, p. 54)

While much of “the message” is subsumed by “the medium,” it is an equally valid proposition that much of the content is, in actuality, the method. This is particularly relevant to incidental learning, collateral learning, creative and practical performance skills, heuristic and procedural knowledge, and problem-solving transfer capabilities, long after the immediate content of the current lesson has been forgotten. To this end, pioneering innovation in the field of distance learning will require a design synthesis towards the deliverable goal of fully integrated courseware built within a research and theory-grounded, learner-centered, problem-oriented focal architecture based on the active acquisition of real, transferable skills and metastrategies, and authentically assessed performance competencies. To the degree that the development and implementation of sound prescriptive taxonomies for learning can contribute toward this goal, the distance-learning enterprise shall lead the educational reform of the 21st century.

Perhaps the most intriguing paradox of the continuous search for a “unified field theory” of instruction is the fallacious premise that it can actually be achieved. Despite emerging efforts to create ubiquitous standards of learning achievement across the curriculum, we are no closer to

achieving this lofty albeit suspect goal. In a new and fascinating exploration of the foundations and fundamentals of design competence, Nelson and Stolterman (2003) caution that perhaps the most common mistake in systems design “is to assume that there are universally ideal systems. That one size fits all, so to speak. In reality, this is never the case (p. 112).”

It might be just as self-delusional to seek an absolute standard that conclusively and perfectly integrates all of the descriptive phenomena and prescriptive practice within a holistic design solution paradigm for instruction. It has been a nearly intractable challenge to establish unequivocal technical standards across ANY industry, as current competing specifications for DVD, HDTV, widescreen format aspect ratios, Web-streaming formats, SCORM compliance and transportability, interoperability, reusability, and granularity controversies associated with learning object models continue to rage on. While over time many competing technology systems find some reasonable accommodation to coexist on some level within the same universe (e.g., AC and DC, AM and FM, Apple and Microsoft), idiosyncratic conceptual paradigms like learning theories, educational philosophies, and instructional design models have ultimately “agreed to disagree” in addressing the same, similar, or related issues and problems from different perspectives. And this is not only intelligent and mature but probably wise, for as the redoubtable learning psychologist and teacher Jerome Bruner posited in his collection of seminal essays *In Search of Mind* (1983):

I think the best that we can do is get on with it, but with a Wittgensteinian skepticism. Learning about each use or facet...will itself be revealing. We will delude ourselves if we think it will come out singular and comprehensive. And we make the pursuit less revealing and doubtless less enjoyable if we insist that any one approach...in the one to which all others should be reduced. (p. 176)

The compelling task of creating comprehensive explanatory models of complex phenomena that are parsimonious and robust without being overly reductionist, and concise and cogent without being over-simplifications, continues to be formidable. This emerging future will need to integrate the many complex factors involved in the human—information—learning triad, including the learner's dynamic cognitive and affective states, the nature of the knowledge domain being taught, and the implicit assumptions of the learning environment. A reexamination of the fundamental issues in designing epitomes of prescriptive taxonomies for instruction might positively contribute to this collaborative endeavor.

As described in this article and throughout this encyclopedia, numerous scholars have labored in the creation and development of comprehensive, subsuming descriptive and prescriptive principles and practices for improving instruction and learning environments. It is also evident that today's students are now fully independent clients, customers, and peripatetic shoppers for their learning. There is an increasingly imperative need for systematically designing active learner experiences requiring cross-disciplinary higher-order thinking skills (analysis, synthesis, evaluation), procedural knowledge, reflective inquiry, model-building, theory-linking, decision-making, creative expression, complex (i.e., ill-defined and with no single universal solution) problem-forming and collaborative problem-solving, and improved communications skills. As the dynamic and burgeoning fields of online learning and distance education continue to play increasingly vital if not central roles in the evolution of education generally and globally, future research and development of hybrid descriptive-prescriptive instructional design taxonomies will augment our ability to transform the pragmatic nature and quality of distance education in the new millennium.

KEY TERMS AND DEFINITIONS

Descriptive Taxonomy: In educational theory and practice, an organizational scheme for classifying the structure of conditions for learning describing the approaches, types, events, methods, and goals of instruction. While affective and psychomotor capabilities are also of importance, classic instructional design theory has focused on the cognitive domain and has been exemplified by the widely adopted hierarchical taxonomies of Bloom (1956) and Gagne, Briggs, and Wager (1992).

Granularity: Granularity is a hierarchical concept associated with the relative degree of complexity of a component part to its aggregate, subsuming structure. Fine silt is more granular than sand, which is more granular than rock, and so forth. In taxonomic development, the smaller the relative size to the taxons (units) of classification, the higher the degree of granularity. In instructional design, the concept of granularity is multifaceted, and can refer to the size of learning units or scope (e.g., degree or certificate curricula, courses, lessons, modules, activities); learning element prioritization or sequencing (e.g., logical order of lessons, concept formation and skill acquisition to optimize scaffolding in new knowledge construction); content domains archi-

tecture (e.g., superordinate concepts, subordinate concepts, rules, principles); teaching strategy (e.g., individual vs. group learning, passive learner/expository vs. active learner/discovery, inductive vs. deductive, tutorial vs. simulation, abstract vs. problem-oriented, synchronous online chat vs. asynchronous threaded discussions, etc.); media design and utilization (e.g., relative size and complexity of single components or combined components, type of media element including text, graphics/visuals, audio, animation, degree of user control, etc.); and learner assessment (e.g., conventional declarative-convergent testing using multiple-choice, matching, and short-answer questions vs. holistic, constructivist-divergent portfolios with demonstration work-product artifacts from individual and group projects, internships, and service learning).

Hybrid Learning Taxonomy: A comprehensive organizational scheme in applied learning and instructional design theory and practice that integrates both descriptive and prescriptive taxonomic domains. While a number of conceptually useful hybrid learning taxonomies have been proposed, there is, to date, no single, inclusive, unifying hybrid taxonomy that effectively synthesizes all of the design elements of instruction to sufficient practical levels of granularity and application.

Instructional Design: An applied, cross-disciplinary professional (postgraduate) design discipline that integrates human learning theory and instructional practice to develop, produce, implement, and evaluate effective educational experiences and learning environments to improve human performance outcomes, knowledge construction, and the acquisition of robust transfer competencies.

Prescriptive Taxonomy: In educational theory and practice, an organizational scheme for specifying the optimal and appropriate approaches, types, events, methods, media, strategies, techniques, activities, tasks, projects, scope and sequence of instruction to achieve corresponding specific learning objectives and desired performance out-

comes. While numerous scholars and practitioners across a wide range of associated instructional design fields have created a rich variety of effective and efficient prescriptions for obtaining specific learning outcomes in specific situations, to date no single theory-grounded and research-verified unifying taxonomic scheme has successfully emerged to address all existing and potential educational problems across the phenomena of human learning.

Taxonomy: From the Greek *taxis* (for arrangement, order) and *nomos* (law): Every serious taxonomy is an organizational scheme that includes a system representing structure, order, and relationship. Some form of hierarchical structure is generally defined, but this may be multidimensional and nonlinear in form. The purpose, domain, attributes and granularity of schema vary, but all taxonomies attempt to provide a robust (i.e., logical, coherent, cohesive, internally consistent) architecture. Prominent examples include the widely adopted schema of Carl Linnaeus (biology) and Dmitrii Mendeleev (The Periodic Table of Elements). Most taxonomies contain their own nomenclature for describing the taxons (singular) and taxa (plural) that correspond to formal units in the classification scheme, such as kingdom, phylum, class, order, family, genus, species (adapted from Linnaeus). Taxonomies may evolve over time. Neither systems of Linnaeus or Mendeleev are exactly in the original form when they were first presented, but they are fundamentally and substantially the same in all relevant aspects and overall structure, changing only as our knowledge of science changed over time to add additional granularity to the taxons and taxa of their brilliantly original and enduring descriptive taxonomies.

User-Centered Design: User-centered (a cognitive/perceptual term) and usage-centered (a behavioral/functional term) are postmodern design descriptors often arbitrarily or ambiguously defined and interchangeably used and misused. In the context of 21st century instructional product

design theory and practice, user-centered design focuses on constructing a user experience and environment with physical and virtual affordances that are manipulable, controllable, customizable, and adaptable from the essential perspective of the *conceptual model of the learner*. This means both (a) the learner's metamodel of their own learning processes and the learning activities and environment, and (b) the designer's model of the learner and the corresponding educational activity and experience, with the former driving and superseding the latter in the design solution. Thus, the conceptual model of the learner becomes the superordinate principle guiding the design process

and learning outcomes (i.e., the highest level of the prescriptive taxonomy). Usage-centered design focuses primarily on the functional goal-based behavior of learners and structuring activities, procedures, processes, and corresponding affordances to optimize the effectiveness of the learner to efficiently accomplish those intrinsic goals. In both of these approaches, however, the conventionally deterministic structure of the content and the underlying information architecture of the knowledge domain are secondary considerations, while the learner's conceptual model and intrinsic goal-driven behavior provide the guiding blueprint for the instructional design solution.

Chapter 2.6

Drawing Circles in the Sand: Integrating Content into Serious Games

Matt Seeney
TPLD Ltd., UK

Helen Routledge
Freelance Instructional Designer, UK

ABSTRACT

One of the most important differentiators between Commercial Games and Serious Games is content; delivered in a way that is successfully integrated with engaging game play and achieves the desired learning outcomes by delivering skills and knowledge effectively to the end-user. This ability to integrate content effectively is the key to producing “killer” Serious Games that deliver demonstrable learning outcomes, business benefits and overall value. However, achieving this nirvana is not a trivial task. Utilising lessons learned and case studies, this chapter provides an overview of why this process can be so challenging, including the differing experiences from the perspective of

three stakeholders (game designer, instructional designer/learning psychologist and subject matter expert), how to manage preconceptions and balance their priorities. The case studies will also show how different methodologies, techniques and technology have been applied to help solve this fundamental challenge of delivering a successful serious game. Advice is provided on how to facilitate this process, capture the correct requirements and create a design that meets and exceeds the expectations of all the stakeholders involved, including the client/customer and the end user.

INTRODUCTION

Much interactive material and training has, in the past, consisted of ‘click to turn the page’

DOI: 10.4018/978-1-60960-503-2.ch206

applications, where the technology was merely used as a delivery tool for the content. Recently we are seeing more focus on other more interactive applications for the technology, moving from a delivery platform to products with actual educational significance. The technology can be used to engage learners and provide experiential opportunities which learners may not have had before. As Kurt Squire explains... “For educators designing games, this shifts the question from one of delivering content to one of designing experience” (Squire, 2006, p20). Serious games are considered to be the new interpretation of what e-learning can offer, but with the benefits of engaging story lines, player rewards and goals, and true interaction.

Serious games also offer instruction beyond traditional means of skill and drill, multiple choice questionnaires and text with fancy graphics; however, the skill sets required to develop them are often out of reach of many instructional designers and subject matter experts. Therefore a partnership is required, forged by the passion of creating something exciting: a learning program that people actually want to complete and come back to again and again in order to practice and improve.

Unfortunately it is not as easy as finding a games designer, subject matter expert and an instructional designer and locking them in a room together, expecting a game design within the week. Communicating with someone that speaks a different language can be very difficult and shouting or speaking slowly is not the answer! The serious games industry is no different. Game designers and instructional designers often speak very different languages and have very different requirements.

Now drawing circles in the sand is a slight exaggeration, but communication between each of the parties involved in serious games design is one of the major challenges faced by the industry going forward; however, it is one that can be solved. Using real examples in the form of case

studies, this chapter aims to translate practical experience into lessons learned for the industry when designing and developing serious games with diverse subject content.

So why is it so hard? There is also a misconception by many new to the industry that serious games will be successful because they use games technology (Gee, 2005). Simply by forcing content into games technology will not produce an effective learning environment. Commercial off the shelf (COTS) games may act as the motivational wrapper, but there is a lot more to achieving real, tangible learning outcomes than that.

Many claims have been made in the past two decades that link real life behaviours to the influence of video games, and often in a negative light. A popular culture reference to the impact video games can have, came from the movie ‘Snakes on a Plane’ which depicted a character able to pilot and land a plane safely due to his skills learned from Microsoft’s Flight Simulator game. This is the ideal, but rather unrealistic goal of serious games.

It could be asked, why a training course could not just be taken to create a simulation or a game that uses all the learning outcomes? The answer is that most learning is seen in black and white and is extremely linear. This is the course, this is the content, and this is what you will learn. Most training material is created focusing on the ‘What’ and not the ‘How’ and this is one of the contributing factors to high drop-out and low retention rates of traditional training and e-learning. In most cases, learning outcomes are only achieved through facilitation and one to one interaction with a skilled teacher or trainer; however, this is often an inefficient, costly and lengthy process, particularly for large numbers of learners. Serious games are more flexible in the way you can interact with them. You can choose whether to follow the story line or explore the environment, sometimes you are able to choose which missions you tackle and you can experiment with how you choose to play. The learner takes a far more ac-

tive role with a game than in other, more passive forms of learning. Quinn (2005) concludes this nicely: ‘We are not, cannot be, about designing content. A fundamental perspective I want you to take away is that we are designing experiences. If nothing else, start thinking not about creating content but about designing learner environments and architecting experiences.’

Serious games must also work in the domain of learning theory. ‘The use of instructional theories has been shown to enhance learning, increase motivation and student achievement’ (Gunter, Kenny, Vick, 2006). Gunter, Kenny and Vick aimed to create a unique design rubric specifically conceived for serious games by analysing instructional methodologies and comparing them against current game design ‘best practices’. They conclude instructional strategies must be applied concurrently to the content development in game design, and therefore students would quickly adapt to the process of learning and actually enjoy the conditions under which they learned the concepts. Piaget (1970), and Vygotsky (1978), both leading names in learning psychology, shared the commonality of an interest in the active role a learner must play in the learning process, and Vygotsky (1978) placed an emphasis on the interpersonal aspects of learning, including collaborative group work, where he demonstrated students achieved higher intellectual levels when working in a group, compared to working on their own.

Gagne (1977) highlighted nine “events of instruction” that contributed and facilitated an individual’s learning, each of which can easily be applied within a serious games environment.

They were:

- Gain attention; where the learner’s attention is initially grasped by an exciting story line or animation, for example.
- Set out clear learning outcomes; give the learner a set of instructions or goals that they are aiming to achieve.

- Stimulate recall of prior learning; where the individual has to use prior knowledge to aid them in the current situation.
- Present the content.
- Provide guidance to help the individual; this could take the form of step-by-step instructions, for example.
- Elicit performance; this is achieved through practice and completing tasks.
- Provide feedback; this allows the individual to understand areas that need improvement, and also gives them positive, motivating feedback on areas where the individual excel, or are improving.
- Assess performance; which typically occurs through a post-test evaluation, or debriefing session.
- Enhance retention and transfer; allowing the learner to generalise the information they have learnt and apply it to other situations.

Keller (1987) developed the ARCS model of motivational design as an alternative to Gagne’s events of instruction. Keller proposed four steps, instead of nine, that could be put in place to promote and maintain learning; attention, relevance, confidence and satisfaction. For Keller attention involved both perceptual and inquiry arousal, where inquiry arousal relates to providing questions and problems for the individual, as well as varying the content presented. Relevance referred to achieving goals and matching motives (where the learning style of the user and the users interests are matched as closely as possible), whereas confidence was associated with the learners’ perceived self-control and opportunities for success. Satisfaction looked more at the extrinsic rewards (external rewards) and intrinsic reinforcements (internal reinforcements) an individual could gain from the task. Attention, relevance and confidence all have a dependence on the content.

UNDERSTANDING CONTENT

To understand how to integrate content, one needs to understand what the content is. Gee (2004) refers to this as ‘a central paradox of all deep learning’. Gee analyses the two sides of the coin by arguing that it will not work to throw the learner into the deep-end due to a lack of knowledge to leverage the environment effectively and that the domain of knowledge needs to be built up over time and is a complex process that will be beyond a novice. This paradox is a concern to both instructors and advocates of immersion. The key as Gee explains is to use “post-progressive” pedagogies that combine immersion with well-designed instruction; and one area that is exceeding in this mix is the use of Video Games and Simulations.

Just in Time content delivery is easily exploitable within games. Shaffer, Squire, Halverson, & Gee (2005) have created an emerging model of games and propose that they excel by providing learners with situated experiences of activities, whereby they develop new ways of thinking, knowing, and being in ‘Worlds’.

It is understood that content is central to a serious game, but what exactly counts as content? Aldrich (2004) describes 3 categories of content: Linear, Cyclical and Open-ended content. Each category requires a different approach.

Linear content, that of movies, books or television is most familiar to us. It is a recipe that works for entertainment. Most training is also linear: lectures, PowerPoint presentations and most e-learning. Linear content allows most online courses to easily be stored in a Learning Management System (LMS). LMS’s are very often used in large organisations; however they vary immensely from one another. The LMS is the interface between the learning content and the learner, and is the place where the learner’s records of achievement are kept. Serious games have no standard methodology for LMS integration and therefore it is a choice to be made by both the developer and customer or client on how important

this issue is. What is certain however is that in order for more flexible, non-linear user-centred content to become the norm, LMS structures must be reconsidered to be relevant in the Web 2.0 world (Derryberry, 2007).

Cyclical content is the same action performed repeatedly, whilst the action or method is perfected. Aldrich defines cyclical content as the ‘DNA of video games’ (p26). For example, a user spends hours perfecting micro movements in order to shave a few seconds off the time left by taking a corner more smoothly.

Open-ended content refers to content where there is no right or wrong answer, and two experiences are rarely the same. Second Life or The Sims are good examples of open-ended content in games.

Each content category is valid in its own right, and can be used independently; however Aldrich argues that for any educational game all 3 should be combined, liberally. The authors would argue that there is a 4th category of content that is well used in games and simulations, which is non-linear, branching content that sits somewhere in the middle between traditional linear content and completely open-ended content. At the end of the day these categories sit on a continuum, rather than as discrete classifications.

Malone (1981) defines two alternative categories of content in games: Intrinsic and Extrinsic. The example mentioned above where the movie character was able to land a plane from playing a simulation in his spare time, is an example of intrinsic content, which is integral to the structure of the game. Achieving success in the game is equal to learning to fly the plane. Extrinsic content, Malone’s second classification, is less tightly linked to the game play, where there is a structure which has flexible content, such as quiz shows and question/answer-based role-playing and adventure games. Again, these categories are not an either/or but a continuum of possible options that compliment different content styles.

Training and e-learning generally use Linear Extrinsic content, whereas games can use a mixture of all the categories defined above. The challenge is combining each category effectively with the existing subject matter to produce an effective serious game. Early choices made in the development cycle will impact the effectiveness of the content and the effectiveness of the game as a learning tool. If the wrong game genre is chosen for the wrong content, it is likely that a poor learning tool will be produced.

SYNERGISTIC ALIGNMENT OF GAME AND CONTENT

We know what content is and we know that certain types of game suit particular content types. So what are the rules? Prensky (2001) argues that there is no one way for developing applications and that serious games must be created on a case by case basis. In his description of game-based learning, he calls out principles of instructional design, domain or subject knowledge and game design. However, as mentioned previously the likelihood of success from locking these skill sets in a room together, no matter how long for is minimal. This is a view that is expressed by many serious games experts. One thing is true, however, in that the content must be intertwined with the subject matter within the game and usually with some kind of emotive context. Separated game play from content is merely the carrot on the stick; the reward completely independent of any learning and is not what the authors would consider a serious game.

The balance of content with affective components within serious games is a delicate one and in order for the application to be effective, the right balance must be achieved. Appelman & Goldsworthy (1999) argue that to create the most effective learning environment, the designer must balance the content density against the level of understanding of the content by the user, and

continuously adapt this balance throughout the game experience. For example, as the learner's familiarity with the content increases, the presentation can become more abstract and the level of fun or 'affective experiences' required can be reduced. This inverse relationship highlights the reason why simply integrating content into games technology will not work: too much instruction will 'suck the fun' out of the game, but too much fun, particularly in an abstract or context-less game environment, can make the learning harder to contextualize without extensive reflection or a skilled facilitator.

METHODOLOGIES IN PRACTICE

In their study to create a new instructional design paradigm, Kürşat and Kaplan (2006) concluded that instructional design requires teamwork consisting of very diverse skills including, field knowledge, proficiency in technology, strategic, holistic and especially creative thinking abilities, project management skills, leadership qualifications, communication skills, responsibility, honesty, empathy, professionalism. High-level programming knowledge and advanced coding skills were also required, although these are highly specialised skills that are often sought from experienced computer scientists and game developers. They also concluded that the quality and qualifications of the team members affect the quality of the instructional system produced.

They emphasised flexibility and a holistic approach to instructional design, where a modular approach would be ideal. At the centre of their ideal instructional design methodology is prototyping and evaluation. They defined their own model for instructional design for game based learning entitled the FIDGE Model which stands for "Fuzzified Instructional Design Development of Game-like Environments" for learning. Within FIDGE there is a dominant focus around context, both in regards to the situation in which

the instruction takes place, and the socio-cultural needs of the organisation.

Most serious games companies, such as TPLD, have no, or very limited, credible direct subject knowledge in many domains. Although when moving into a new area we try to immerse ourselves in the subject matter and content, we do not try to learn everything or become experts in a condensed timeframe for a particular project or product development; rather, we look to engage with appropriate and credible subject matter experts, who become integral to the project.

Here are the key participants typically involved in a successful Serious Game design process at TPLD:

- **Game designers:** Responsible for recommending the most appropriate game genre and game rules/mechanics for achieving the desired learning outcomes, creating any storylines and defining any characters required, as well as designing levels and helping to define the artistic style (although this is often done in collaboration with an experienced artist).
- **Instructional designers/learning psychologists:** Responsible for validating whether the learning outcomes will be achieved by the proposed game design during all stages of development, typically including a number of evaluation studies with target end users (ideally throughout the entire development cycle, through the use of iterative development methodologies, such as Agile), often working in collaboration with the game designer on the pedagogical aspects of the design, as well as ensuring that good learning practices are being adhered to. TPLD utilise a number of serious games essentials to ensure sound pedagogical design. (Routledge and Seeney, 2003)
- **Subject matter experts:** Responsible for defining the desired learning outcomes and

the necessary subject content required to deliver these outcomes, often in the form of processes, decision trees, standard templates/exhibits as well as more traditional text-based content or character dialogue, depending on the game genre and content delivery mechanism

We also work hard to ensure that throughout the process the whole development team assigned to a project is involved to some level with the design, whether in conceptual brainstorming or reviewing a final idea. This ensures that as the application is developed, the team are aware of what they are creating and why, which helps give them a sense of ownership. It also makes it easier for them to know intrinsically what to build, as not everything can always be defined or effectively communicated up front.

In software terms we have moved to AGILE development over the last year and this too encourages involving the whole team with continual reviews and refactoring through iteration. Taking this one step further, with much of our more recent work we try to create opportunities for our developers to see the game actually being used by the target audience, as without this it is often difficult for them to step away from the ‘gamer’ perspective and move to that of, for example, a 45 year old executive or a 14 year old high school student.

CASE STUDIES

Using a number of case studies and examples, the authors now aim to share their first-hand knowledge and experience to better inform those working on serious games, either at present or in the future. These case studies range from games where the content and the game play are completely seamless, to more context-based simulations where the content and game are less tightly integrated. (Figure 1)

Figure 1. Case study classification

eQA

eQA, which stands for Electronic Quality Assurance, was created as a bespoke project for a molecular diagnostics company in the UK. The client came to TPLD with a fairly well-defined design and script, and we were given the task of embedding this content within an immersive 3D environment, primarily in the form of dialogue interaction between a player avatar and multiple non-player characters (NPCs).

After an initial review of the design, we encouraged the client to consider adding some further elements to the game to provide more engagement for the target users, who were primarily University students. These included a laboratory management aspect, where users must purchase and install lab equipment, after which required diagnostic tests can be performed and some kind of feedback is given to indicate whether the dialogue, tests and other decisions within the scenario are going down the correct or incorrect path. The proposed feedback mechanism consisted of a sick patient in an adjoining room, who was visible through a large window. The patient would gradually become worse or get better depending on the

player's choices. In reality this situation would never occur, and the patient would most likely be quarantined in an isolated hospital ward many miles away from the laboratory; however, this instant feedback mechanism provided some much-needed emotional engagement for the player, who (we hoped) would become genuinely concerned about the well-being of the patient.

The scenario consisted of 4 NPCs for the player to interact with, not always present at any point in time. The script we were given for these characters was initially very dry and technical and didn't enable the player to form any emotional or memorable attachment to the characters. Therefore, another proposed change was to give each character extreme personalities, occasionally going as far as major personality disorders. For example, a megalomaniac boss intent on taking over the world and a paranoid lab technician, who was convinced that everyone was out to get him! This led to some humorous dialogue exchanges that we felt enhanced the game significantly and provided the engagement that was previously lacking.

Unfortunately these dialogue changes were a step too far for the client and many of them were

removed late in the project; however, some of the character quirks remained and this did enhance the learning experience. Overall we think it would be fair to say that this game does not represent our most successful attempt to integrate content into the game play in a seamless way. However, because the game was primarily dialogue-based, with scripted NPC movement and basic interaction with objects, it was relatively simple to create a game editor to allow some of these aspects to be easily customised, and even author entirely new scenarios using the existing game's art assets.

GY\$T

GY\$T, which stands for Get Your Sales Together!, is another example of a primarily dialogue driven game targeted at sales training and development; particularly in a Business-to-Business context. This game was a joint product development with an American-based creative learning company and a leading subject matter expert (SME) in the field of sales training.

Although the subject matter expert had authored a best-selling book and the creative learning company had run many sales training workshops, there was actually very little content present at the start of the design process. Therefore, we held a series of workshops to step through a typical sales engagement process and to identify the desired learning outcomes from the game, as well as listing a number of common "traps" that sales people fall into, which often lead to an unsuccessful conclusion or lost opportunity. This led to a well-defined process consisting of a number of steps to close a sale, including "doing your homework", "getting in" and "closing the deal" as well as mapping out a decision making process within the target customer's organisational structure.

From a content perspective, this naturally led us to the conclusion that a branching scenario, which consisted of a combination of research and dialogue interaction with the target customer, was the best way to go. Early in the project we

decided that because of the importance of getting the language right (including the appropriate level of "Americanisation"), as well as being able to successfully embed many of the messages from the SME's book, the majority of the content would be authored by the SME directly, using specific tools and templates for the project.

Due to the globally dispersed nature of the team, this led to a clearly defined separation between the game play development and the content creation, with minimal levels of understanding about each other's respective disciplines, despite a number of face to face meetings to try to get things back on track when they started going awry. An experienced game developer was brought in by the content authors to help mitigate this issue, but due to differing ideas and priorities, this solution caused as many problems as it solved from a content perspective (although this individual made a significant contribution to the technical design of the game).

The game was created as a template or shell for the subject matter content and some excellent graphical authoring tools were created for the SME to define scenarios and dialogue with NPC's. A demo scenario with dialogue content designed specifically to show off all aspects of the game's functionality was also created, which included a number of powerful concepts that moved it well beyond the typical multi-guess dialogue systems found in most e-learning simulations and dialogue-based games. A number of guides and tutorials were also created for the SME to learn how to use the tools to create the content they desired.

Unfortunately, the content that was created during the lifetime of the project was generally poor and made very little use of the powerful features provided by the game framework. Although the dialogue was professional and reasonably engaging, many opportunities were missed due to the SME's lack of experience with basic game design principles, such as having an appropriate difficulty curve and introducing new features and complexity slowly over time. A good example was in the

up-front research phase that required the user to do background research on the target customer in the game. This was supposed to consist of some basic information to get the user started in the objective of understanding the customer's needs in order to create an initial communication that included a value proposition to get the company's attention. What actually happened was that over 40 documents needed to be reviewed by the player before they could extract this basic information and move forward in the scenario. Engaging and captivating the audience, within the first 5 minutes, this certainly was not! Unfortunately the end result became yet another not entirely successful attempt to seamlessly integrate gameplay and content.

Our experience with this project and others has led us to seriously question and doubt the approach of getting a subject matter expert with no knowledge of game design principles and best practice to directly author game content without any consultation and collaboration with a suitable intermediary, such as an experienced designer of serious games. However, over the last couple of years we have seen an increasing trend towards this model for content development, particularly with the advent of web 2.0 and its user-generated content model. From our perspective, the only place we believe this approach may work is with younger, game-savvy SMEs (or even school pupils and University students) who can effectively balance the game play and content. With tools requiring little of no technical expertise, we believe that powerful and engaging learning experiences can be created. Designing a serious game also requires a developer to become completely immersed in the relevant subject matter, even when an SME is involved, which in itself is a very effective learning process (many of TPLD's developers are now experts in molecular diagnostics for example!). This is the reason why this type of high-level authoring and customisation tool remains core to TPLD's company strategy in relation to content development.

After two examples where the content has not been particularly well integrated with the game play we will now go through another four examples where this integration is almost entirely seamless, with the content being delivered directly through the game play as opposed to via dialogue or direct simulation.

Contamination!

This project originated from the same molecular diagnostics company who commissioned the eQA project. Due to their previous experience working with us on the eQA project, they had been approached by a government organisation to create an immersive 3D simulation for teaching quality control processes in laboratories in conjunction with a tutorial book. Traditionally this has been a difficult area to teach, due to the high cost of getting access to laboratory equipment and the consumables required to perform and practice particular tests. Therefore, a 3D simulation that accurately modeled the process and outcomes of these tests was a logical solution.

The initial content consisted of a fairly detailed walkthrough of the desired scenario and a decision tree to show the different points in the process where things could go wrong. Like any simulation, one of the initial questions was whether the game would encourage or force the player to correct a mistake or wait until later in the scenario to see the actual impact of the mistake. We strongly encouraged the latter approach, along with some supporting information to show the player what they had done wrong in order to help them improve next time.

Our initial reaction to the content was that it provided a very useful starting point for the game design, but like the previous eQA project, it was fairly dull, dry and technical, which was not appropriate for the intended student audience. Therefore, we suggested adding an engaging back-story to provide some emotional context to

the player. Given the nature of the content and desired learning outcomes we suggested setting the game in a fictional town where there has been an outbreak of a disease and the player needs to identify the source of contamination by going through the actual process of testing the samples. This concept was met with approval and during a face to face meeting with the subject matter experts we were even able to suggest a further embellishment to the story by making the disease turn everyone in the fictional town into zombies and using this as a direct feedback mechanism in the game! Depending on whether the user is following the correct process (i.e. if mistakes are being made), the zombies will start to attack the lab and more people within the town will be killed. We also decided to give the player regular updates about the current situation via a series of news reports that break up the simulation-based gameplay. Finally, we were able to integrate a couple of engaging mini-games to provide an effective metaphor for some of the diagnostic tests (these would normally be automated and conducted by a machine). The primary reason that these changes were accepted without question was because the subject matter expert was actually a gamer and one of her favourite games happened to be House of the Dead! Another reason was because the SME had seen some of the engagement issues with the eQA project and did not want to fall into the same trap.

Overall, despite some quite dry and very technical content, due to the additional elements that were added to the story and game play this was a very effective example of how to integrate subject matter content with game play to create a powerful learning tool. We have taken many of the lessons learned from this project forward into more recent developments, such as:

- Try to ensure the SME is familiar with games and encourage them to play games and genres that may be relevant to the current project or product development.

- When working in partnership with an SME for more than one project, always be sure to take on board any lessons learned from previous projects to ensure a more successful outcome next time.
- It is often a good strategy to split the serious game design phase up into a high level design to articulate the overall concept, game play and walkthrough of the game to non-technical subject matter experts and other key project stakeholders.

Once this has been agreed and signed off then move into a detailed design phase.

Concept demonstrators will often be needed throughout the entire design process to help communicate concepts and ideas that will not be familiar to non-gamers.

Is important to define any assessment criteria or metrics within the design, as well as tying any game mechanics and content directly back to the desired learning outcomes, using game genres and an appropriate graphical style for the target audience.

KiddyKare

KiddyKare was created just before the eQA project and, unlike any of the previous examples; this was developed on a speculative basis rather than for a particular client. The concept was to provide an effective marketing tool for suppliers of child safety devices for the home, such as Mothercare. The gameplay consists of a typical house on two levels, with a baby walking and crawling around, being drawn towards areas of danger. The user has an RTS-style view on to the world and can scroll around without any constraints, trying to buy and deploy child safety devices before the baby can injure itself.

Examples include an iron that could fall, an electrical socket the baby could poke its fingers into, a fire that could burn the baby, a set of stairs the baby could fall down and a dog that could get

a bit over-zealous while playing with the baby. Given that the baby was not always in view, the user had a baby monitor that would sound an alarm when the baby was getting close to a hazard, which would prompt rapid deployment of the correct safety device before the baby got hurt. However, due to the humorous nature of some of the injury animations, players often preferred to see the effects of not deploying the safety devices around the home!

Although the game never became a commercial success, we felt it was a perfect example of how to successfully integrate content and gameplay, and took many of the concepts and lessons learned forward into subsequent products and projects.

Winning

The Winning Game was commissioned by the Scottish Institute of Sport Foundation and is based on a concept and theory devised by a leading Israeli-based subject matter expert in Winning and what it takes to become a Winner, called Yehuda Shinar of Winning Enterprises. The concept and an original computer-based simulator, which encapsulated the Winning theory, had been successfully piloted in a number of market sectors by Winning Enterprises, but TPLD was given the task of evaluating its effectiveness in Scottish Education (primarily at high school level). Our initial findings concluded that the concept was extremely valuable and provided significant benefits to school pupils for their general studies, sport and music. However, the user interface needed substantial development in order to create a deployable commercial product.

The Winning Game teaches the user to think correctly under pressure and utilises continual debriefing to improve in all aspects of the game and maximize personal potential. Unusually, the theory and content are very tightly integrated with the gameplay. The Winning principles are codified as a series of rules that are defined as “combinations” within the game engine. These

combinations are constantly monitored to assess whether certain actions are triggered while the game is in a particular state. If a combination is fired, the player is given direct and instant feedback on their actions by an intelligent coach, with results summarised at the end of each game in the form of a detailed assessment report, including graphs to show metrics and improvement over time. Combined with a personal learning plan framework and an opportunity to debrief continually, with the assistance of the coach and a comprehensive replay mode, the game includes all the tools required to become one of the most successful serious games so far.

At the time of writing, we are still finalising the development of the game, so we cannot state definitively that it is a successful integration of content and gameplay; however, all indications from pilot activities so far indicate that this is the case. Perth High School, Scotland, has worked with the game’s designers to help modify its design and assist in determining how the game can be applied within a high school environment. The initial part of the pilot has evaluated the game’s impact on developing a culture of self-improvement and success within the school, both on a personal and an academic performance level. Feedback from the pupil’s has been very positive, with comments such as “The in-game coach does help; it teaches you to be calm, take time and always give encouragement” and “This is the first game I have ever played that has actually taught me anything useful”. (Boyle and Seeney, 2008)

Eduteams/Infinteam

Infinteam, and its education-oriented cousin, Eduteams, are very good examples of how to effectively integrate content with gameplay. These award-winning products developed by TPLD as boxed products rather than commissioned projects, are targeted at developing team building, communication and leadership skills through a range of collaborative problem solving modules. The

modules provide a safe environment to practice working as part of a team to solve a variety of problems commonly faced in outward bounds-style physical training activities, such as getting across a river using limited resources and effective communication within the team.

These soft skills are becoming increasingly important in today's society, particularly as more organisations move towards having globally dispersed virtual teams. One could argue that the modules within *Infiniteams* and *Eduteams* are literally just collaborative multiplayer games with no visible learning value or subject matter content; however, this would be missing the point entirely. Simply watching a group of young high school pupils or a senior executive management team playing the games, it is easy to see that real learning is actually taking place. Anyone who has experienced the game would also agree that the way a group of individuals approaches the problems and challenges they face, provides a strong correlation with the thought processes involved and actions in the real world.

However, in order to bring this learning to the team's attention, it is often necessary to have a skilled human facilitator on hand to provide support and conduct debriefing exercises with the individuals as each of the modules are completed. Failed attempts, communication breakdowns and underlying problems with the team dynamics can be brought to the forefront of everyone's mind, with the consequences clear to see; along with the evidence of real improvement during subsequent attempts, once the team has talked about and resolved many of these issues, through reflection and debriefing, with the help of the facilitator.

In order for anyone to facilitate a session with *Eduteams* and *Infiniteams* effectively, they need to be given training on how to use the software, how it can fit in with a blended learning approach (particularly if they have existing team-based course material) and how to accurately monitor team and individual behaviour and performance

within the game to help stimulate discussion during the subsequent debrief.

This training and the player's learning is further enhanced through the use of social networking and web 2.0 technologies such as blogging, forums and wikis to share experiences and note down personal thoughts and opinions. The use of this technology helps establish communities of best practice by allowing others to learn from how the game has been applied in different ways. This type of surround and community-based support is becoming increasingly important for successful serious games, because it is unrealistic to assume they will operate in isolation in the vast majority of cases.

Both *Winning* and *Eduteams/Infiniteams* have heavily utilised user-centric design approaches throughout the design and development cycle. Early prototypes were tested with large numbers of target end users (these included both teachers/facilitators and pupils/adult learners). This process has continued through subsequent product updates, to ensure that functionality is only added or changed when repeated requests have come directly from end users. We believe that utilising a user-centric design methodology is essential for any successful serious game development. This approach also fits very well with the AGILE development methodology.

CONCLUSION

"What you want to do is create a game that's built on a set of consistently applied rules that players can then exploit however they want. Communicate those rules to the player in subtle ways. Feedback the results of player choices so they can make intelligent decisions moving forward based on earlier experience. Rather than crafting single-solution puzzles, create rules that describe how objects interact with one another and turn players loose – you want to simulate a world rather than emulate specific experiences".

Warren Spector, creator of Thief, as quoted from Aldrich (2004, p. 97).

The rules used within each game should also apply to the content used. The most important rule to communicate is to ensure the medium chosen is appropriate for the content that the developer and/or client wish to get across. Also, ensure that the content is linked to learning goals, which, in turn, are linked to experiences within the game. Remember to gradually build up with content density in the game, as too much too soon can be damaging to the learner and will continue the self-fulfilling prophecy of dull serious games.

The quality of the content is incredibly important. To writers, they say, write what you know. The same is true for game designers...and if you do not know it, find someone who does. Starting with existing content will make the whole process less painful and more efficient.

As can be seen from the discussion and examples mentioned above, content needs to move from text based presentation to be truly interwoven with the game play; the choices and actions the player makes within the game. Only when this is achieved, will true stealth learning be achieved.

Achieving a balance between learning theories such as those of Gagne (1977) and Keller (1987) and engaging experiences as created by games designers will aid developers to be on the right path to creating an effective serious game.

Chapter 2.7

A Model for Knowledge and Innovation in Online Education

Jennifer Ann Linder-VanBerschot
University of New Mexico, USA

Deborah K. LaPointe
University of New Mexico Health Sciences Center, USA

ABSTRACT

The objective of this chapter is to introduce a model that outlines the evolution of knowledge and sustainable innovation of community through the use of social software and knowledge management in an online environment. Social software presents easy-to-use, participatory technologies, thus bringing increased interaction with others and a diversity of perspectives into the classroom. Knowledge management provides the opportunity to capture and store information so that content and learning can be personalized according to learner preferences. This model describes a circuit of knowledge that includes instructional systems design, individualization of learning, interaction

and critical reflection. It also represents a new framework within which communities develop and become more sustainable.

Introduction

In this chapter, we suggest that the field of online education adopts effective practices from knowledge management, and the best social software tools to create a knowledge community. As social software tools become more available for formal online learning environments, current conceptualizations of online communities must be modified. Where are these social technologies leading us and what are the impacts?

This model proposes a more dynamic online classroom where learners use cutting-edge social software tools to capture and disseminate collec-

DOI: 10.4018/978-1-60960-503-2.ch207

tive knowledge from the participants in the course, as well as the virtual and local community. This model facilitates the evolution of knowledge within the classroom, and encourages a sustainable knowledge community, wherein innovation

may be enhanced. Our vision of this dynamic partnership of knowledge management, online education, and social software is described in the following scenario (Table 1).

Table 1.

<i>Futures of Technology and Knowledge in an Online Classroom</i>
Fiona, Tim, and Vita are enrolled in Organizational Learning and Instructional Technologies (OLIT) 565, a graduate course designed to function as an interactive online course using multimedia content, information literacy tools, tests, assignments, and small group projects. The course requires intensive study of the content available in numerous formats for many devices, including desktop computers, iPods, and smart phones. The content can be read online or offline. Interactions with classmates, instructor, mentors, and experts are a critical component of the course and occur through discussion forums, chats, and Web conferencing in the learning management system (LMS), as well as wikis, blogs, and virtual content outside the LMS. Through a pre-assessment the students completed when registering for the course, the LMS captured their profiles, past performance, and interests. With this information, the LMS organizes several approaches to present course content according to learner preferences. An interactive concept map presents multiple ways of exploring and integrating the content with prior knowledge and outlines the suggested path for each learner. Clicking on the nodes in the concept map brings up the content, supplemental materials, assessments, and group discussions. The concept map also lists the times and places that experts who produced the examples will be available for discussion. The learners explore the content, applying their own structure to it. Additionally, the social networking software inside the LMS connects the three learners based on their shared interests. During the orientation, the instructor provides an introduction to the synchronous and asynchronous communication technologies, LMS and social software. The instructor, mentors, and learners negotiate ground rules, expectations, roles and responsibilities when using asynchronous and synchronous communication and social software technologies. The ground rules and expectations support active participation in achieving the development of a future sustainable community. The students come to realize that careful attention to one's online presence, reputation, and contributions to discussions is crucial, as they influence trust, cognitive presence and social interaction for learning purposes. On her way home from a movie, Fiona posts an audio message and a journal article she scanned using her mobile phone. She tags the document with metadata enabling future searching and sharing for reuse and repurposing. The wiki notifies Tim's iPhone and Vita's e-mail account. Tim responds to the message, agreeing with her ideas but providing minimal additional information. The LMS and Fiona both note Tim's brief response and prompt him to think more critically and elaborate on his message. Essential components of the online environment are evaluation and reflection. For this reason, users provide feedback on the user-created content, the contributions to the discussions, wikis, blogs, and podcasting, and the system. Learners are encouraged to rate each posting using rating systems similar to e-Bay or Slashdot. The ratings are used to continuously improve the posted content and to identify gaps in the material. With the abundant amount of choice in the ways information and knowledge are created and shared, Fiona looks for the tagging, certification of fact-checkers and group rating systems before making a content selection. Course designers specify multiple routes through a collection of learning objects. Just-in-time information is organized into small units and presented to learners precisely when they need it. The LMS identifies Fiona's preferences for learning, as well as recognizes that she needs to develop other ways of learning in case she encounters online courses without such individualized features. The LMS monitors and logs the student's individual learning processes and creates a collaborative memory to offer aid when needed. The instructor and group mentor review the logs before communicating with the individuals and group, and responding to the group's requests for guidance. The enrolled learners are not the only participants in the course. In previous courses in the OLIT program, instructors have encouraged emergent leadership from the group—meaning that learners with great interest in the content and technologies take a leadership role in the course. Some of these learners were so stimulated by the content and interaction that they have organized a community in which members meander in and out of courses, as they see fit. Additionally, the social software outside the course LMS is hosted, and the content created, reviewed, and shared by community members. Previous course enrollees and program graduates bring their work experiences to the community. The lessons they have learned through interacting in the world, reflecting on the experiences, and making sense of them through collaboration with others in the community become powerful stories that create part of the community's resources and memory. This community of learners and experts may choose to participate in the online OLIT courses; however, they may also decide to focus on spreading the collective knowledge co-constructed in the community to local schools and organizations. This knowledge community expands and contracts throughout its existence, but the common feature is that a passionate group of contributors collaborate to solve problems within the community and share their learning and expertise with others outside of the community. The interaction within and between the course and the community creates a space for reflection where learners, leaders and instructors constantly consider necessary changes that need to be made so that the course continues to evolve, as does the learning. Belonging to such an innovative community that provides valuable learning opportunities gives identity to the members and further motivates their participation. This evolutionary process facilitates the innovation and sustainability of the learning community.

Although the case scenario may seem like a list of items for online instructors to buy, the reality is that these tools are currently available for learners and instructors alike to manipulate to create meaningful and long-lasting online interaction. Granted, adaptation is a constant challenge, but it is our hope that through describing this model, more practitioners will realize the potential for incorporating social software tools and knowledge management in online learning. This model breaks the previous boundaries presented by virtual communities and suggests possibilities for increased collaboration and participation.

Definition and History of Key Terms

Knowledge Management

Knowledge Management (KM) was a concept initially established by Peter Drucker in the 1970s. However, it was not until the 1990s with Nonaka and Takeuchi's introduction of a knowledge organization, that it became a more integrated concept in business practices. At that point, publications and university courses expanded peoples' understanding of the benefits of KM (Wiig, 1997). Within the past few years, a larger number of educational institutions have begun implementing KM systems to enhance the community knowledge and encourage innovation (Hirschbuhl, Zachariah, & Bishop, 2002; Kidwell, VanderLinde, & Johnson, 2000; Na Ubon & Kimble, 2002).

Traditional KM initiatives are often divided into three processes: (a) design, (b) development and (c) technology (Conway & Sligar, 2002). Not all KM plans follow a rigid process flow; some are flexible enough to incorporate, "how people learn, how they implement what they learn, and how they share their knowledge" (Bassi, 1997, p. 426). By connecting the KM system to the users, the advantages become more apparent. The terminal goal of a KM plan is to create a sustainable system that enhances the growth of the organization's knowledge (Salisbury, 2003)

with the ultimate purpose being to enhance organizational creativity and innovation.

Online Education

Distance education supports the learning process when learners and instructor are physically separated and hence rely upon technology to interact (Moore and Kearsley, 2005). Distance education has made great advances since its inception in the 1800s, with the most recent innovation being online education (OE), defined as distance education delivered through the Internet. Current trends in OE include the incorporation of social software, which is a central feature in this chapter.

One of the major benefits of OE is that instructors are forced to be as technologically savvy as the students that they are teaching. Another advantage is that learners have access to the professor and to a community of peers all hours of the day so that they can debate, problem-solve and discuss the concepts associated with their course. OE has been especially helpful in connecting remote students to each other to form an online learning community. Most important to the progress of education, the online platform encourages learner-centered activities, where the instructor guides learners to co-create knowledge, and share that knowledge with other members of the learning community.

Social Software

Social software (SS) is not a single type of software, but instead a combination of two or more modes of computer-mediated communication, resulting in the formation of a community. A social network built from SS allows members to create and participate in a self-made community. With the rise of Web 2.0, SS applications seem to be introduced at such a rate that not even the most technologically savvy can keep up. Yet these communication and interaction tools influence how virtual communities form, and how they sustain themselves even after the online course has ended.

The affordances of SS include ubiquity, searchable content and referral to people with common interests. These benefits then support multi-scale social spaces and conversation discovery.

Some of the latest applications include 30 Boxes, a social calendar; Lazybase, a site where individuals are given the tools to create and share a database; Zoho Show, a tool that helps create and publish presentations; and voo2do, a task management tool (Brown, 2007). In fact, this paper was developed using *PBwiki*, a secure, open-source wiki that allowed us to co-create this chapter at a time and place that was convenient for each of us. When one person edited the chapter, the other person received an email update, so she could see the progress being made. When we needed to communicate synchronously, we used *Yahoo! messenger*.

Although SS tools have not been typically applied to educational settings, we side with Dalsgaard (2006) in that we believe SS tools can and should be used to support learning. These tools encourage the creation and contribution of user-created content and facilitation of learning instead of management of learning—a paradigm shift that calls for a new model for OE.

This model acts as a plea for the target audience including researchers, teaching practitioners, and educational technologists to embrace a paradigm shift that applies social systems in OE. SS can increase the diversity of perspectives in the content, virtual presence of a community and establish and enhance peer-to-peer social networks, as suggested by the case illustration. The incorporation of this emerging trend in this proposed model will facilitate the dynamic evolution of knowledge beyond the classroom and contribute to the innovative and sustainable community outside of the formal learning environment.

Existing Literature

The first collaboration of OE and KM was envisioned by Albert and Thomas (2000) who taught

at the Business School at Britain's Open University. They focused on the tools and technologies used to teach an online course on KM. Similarly, Townley, Geng and Zhang (2002) collaborated between New Mexico State and Beijing University to teach a class on KM. They explained that global education was becoming a rapidly growing field that addresses the need for the development of international relationships. Both collaborations were primarily interested in the course management tools used, not on learning or community development.

Fry (2001) explained how many organizations turn to OE as a strategy for transition and corporate development. The Ernst and Young Center for Business Knowledge, for example, has applied components of OE to assist in the organization's strategic development by using asynchronous discussion groups and online communities of practice, as well as personalization and profiling techniques. Different from the studies mentioned above, Fry (2001) uses OE to enhance current KM practices.

Universities are working to close the gap between the change in technology and the learning needs in an online environment. Hirschbuhl, Zacariah and Bishop (2002) suggest that this gap can be minimized by using KM tools to deliver OE. By fitting the instruction to the individual learning needs of the student, KM can provide increased success for all learners, regardless of their ability or familiarity with technology. Hirschbuhl, Zacariah and Bishop (2002) encourage students and instructors to shift their mental model of teaching methodologies and collaborative strategies in order to develop successful online courses that can be customized to meet individual learner needs. KM is the suggested remedy to smooth and prepare all participants in the paradigm shift from traditional face-to-face classrooms to OE. Almost opposite from the study above, in this case, KM tools are supporting OE.

Saxena (2007) proposes that the integration of KM tools within OE will provide online dis-

tance education administrators and instructors with data that could result in improved decision making, reduced course development time, improved academic and administrative services, and reduced costs. He believes the integration of the two will reveal patterns and relationships that provide the knowledge necessary for improving OE. Lytras, Naeve and Pouloudi (2005) also believe in the promise of KM in contributing to the evolution of online learning, and believe that, "The convergence of e-learning and knowledge management will be evident in worldwide initiatives that will foster a constructive, open, dynamic, interconnected, distributed, adaptive, user-friendly, socially concerned, and accessible wealth of knowledge" (p. 68). Only one article was located that connected the fields of OE, KM and SS. Pettenati, Cigognini, Mangione, and Guerin (2007) built a model in which SS was used to track personal knowledge in an online learning environment. However, they do not consider the potential for knowledge development and innovation in a dynamic community environment.

Gaps in the Literature

KM and OE share several common elements, including community, collaboration, trust, knowledge sharing and SS tools (Na Ubon & Kimble, 2002; Saxena, 2007). Despite the availability of tools and technologies and increase in familiarity with these tools, universities seem reluctant to integrate OE and KM. This is demonstrated by the minimal capturing and sharing of knowledge assets in the university environment. An additional gap in the KM literature is the lack of information related to the affective domain which is frequently described as underlying cognition. Emotions and attitudes are critically important in order to interpret experiences positively and to learn effectively, as well as support and trust others.

Although there is literature on the combination of KM and OE, there is not a true collaboration

where they are working together towards an improved system as envisioned in the case scenario. Since SS tools are such a recent introduction to the field, there is even less literature on their role in this relationship. Saxena (2007) recommended that KM be used to gather data on students so that universities can then use that data to better understand distance learners and their learning environments. He concludes his article by encouraging researchers to more deeply explore the opportunities for KM in an online setting. This chapter provides a model and an outline for a system where KM, OE and SS combine to create a more dynamic formal online learning environment, as described in the case illustration.

Description of Model

The model shown below represents a cyclical process with five major components: (a) critical reflection with leadership, (b) instructional design, (c) individualization, (d) collaboration and interaction among course participants, and (e) an innovative and sustainable community. This community development of graduates and interested others is ongoing, and feeds experiences and resources back into the model.

The interplay among the components that contribute to the evolution of knowledge occurs throughout the online course. There is not a particular order in which it happens—the boundaries are blurred. For example, instructional design may be the first step for the instructor, followed by implementation in which individualization of the learning experience is considered. Critical reflection may be a structured process at the end. And it may not be until the course ends that learners diverge from the cycle and engage in the community development process. On the other hand, the community development may be a carry-over from a former online course or provide authentic learning opportunities during the course, thus allowing the interaction to be a central component of

Figure 1. Evolution of knowledge and community development model

the online course, with learners who already know each other well. We will describe each component of the model in the section below.

Instructional Design

We will explain the innovative relationship among KM, OE, and SS beginning with instructional design. Instructional design provides the template for determining learner needs, collecting appropriate content and designing interaction to enhance the growth and development of future professionals. A significant amount of the work of instructional designers and instructors is not accomplished through declarative and procedural knowledge alone. Working with instructors and students involves affective aspects, such as responding to emotional or evaluative responses. We remind designers that affective and social content must be a part of the implementation process.

Content

The goal of a majority of KM systems is to capture the most essential knowledge assets for the users (Conway & Sligar, 2002). This may include course projects, archived dialogue or recorded

voice conversations. Content will not magically appear in the learning environment—learners and instructors must collaborate to select, contribute, and rate the knowledge that is pertinent to the learning environment. Often times in KM systems, a Subject Matter Expert (SME) is selected to maintain cohesion in the community and distinguish the most essential content to be shared with the group. In the corporate setting, the SME is typically the most knowledgeable member of the community, yet in an online course, it might be more effective to have a rotating SME so that a variety of perspectives can be a part of the knowledge capturing process. An outside member of the community, such as an expert in the field or a former class member, may also act as the SME, providing relevant content that is applicable to the course objectives. All members of the learning community must work with the SME to continually reflect upon and refine the content that is captured and stored. New information should be frequently reviewed and assessed, and older information should be regularly revisited to determine if it is still valuable to the learning community.

In order for these captured knowledge assets to be accessed frequently, the content must be prepared in standardized formats that can be

later customized in ways that are meaningful for individual users and support carrying the content forward. As LMS programs become more sophisticated, they allow online courses to offer more individualized content that is adaptable to needs of each learner, as indicated through describing the process of tagging in the case illustration above. Until that becomes common practice, passionate content creators and fanatical reviewers are needed to maintain a dynamic system so that learners look forward to accessing and applying content to different contexts (Conrad & LaPointe, 2007).

Technology and Tools

It does limited good to have extensive knowledge sharing without the technological means to enhance the information. Fortunately, advancements in technology afford users from around the world the ability to participate in the knowledge sharing process in real-time (Kilby, 2001; Lan, Xian, & Fu, 2000; Na Ubon & Kimble, 2002). All technology and tools chosen to support the learning process must facilitate the multiple phases of learning, including exploration, reflection, collaboration, testing out new ideas, knowledge construction and feedback. These technologies do not necessarily need to be complex. Instead, the critical characteristic is that the technologies allow easier communication in the online course to facilitate in the process of interaction.

RSS feeds notify learners whenever a new entry, podcast, email message or wiki posting has been added. Instead of checking in frequently with the constantly updated LMS, an RSS feed allows learners to create and distribute a list of Web links to quickly review at a time and location that is convenient for them. This provides organization for the online participants to know what they have already accessed in contrast to what they still need to review. Online participants depend on ease of use to get started and build confidence in using the tools. Thereafter, accessible support is essen-

tial. The technology helps learners organize and find their way through the LMS, as well as make sense of the content presented in many formats and through multiple perspectives.

The type of technology used should depend on the participants. If learners do not understand the functionality of the interface where content is displayed, then the significance of the content may be lost. Content should also be available in the platform preferred by learners, such as computer, cell phone, mp3 player, instant messenger, wiki posting, etc. Na Ubon and Kimble (2002) encourage the use of advanced technologies because they have the potential to increase the sense of trust, identity and commitment of the community. Pre-established standards help guarantee a useful and progressive product. Despite the recommendation to use cutting-edge software and tools, we suggest that the instructor establish a balance between user-friendly and innovative technologies.

Individualization

Although content, technology and tools are essential components of the instructional design process, as illustrated in the model, they are not the only factors to consider. Throughout the design and development process, instructors and course designers must think of the learners for whom they are developing the course because KM and OE are more complex than technology and multimedia tools (Liebowitz, 2001; Na Ubon & Kimble, 2002). The focus cannot simply be on the use of technology, but also on the human issues behind the success or failure of the technology (Davenport, 2005).

All participants enter a course with different levels of familiarity and confidence in terms of technology and content. Whereas some learners are willing to immediately engage in online communication and capturing knowledge, others are more hesitant to participate in this type of online interaction. Other still may apply signaling to pres-

ent themselves as different people to the online class. It does not come as a surprise that a small percentage of individuals usually create a majority of online content (Kamel Boulos & Wheeler 2007). Instructional designers and instructors must determine how to develop an individualized system that encourages equal participation from all learners. Fisher and Baird (2005) encourage the use of peer mentoring to build students' levels of confidence in using online tools. Similarly, Gunawardena, Linder-VanBerschot, LaPointe, Barrett, Mummert, Cardiff, et al. (2007) reported that e-mentoring facilitated in cross-cultural learning transformation. Community members may volunteer to be mentors for students, establishing their confidence in the learning platform at a pace that is appropriate for each individual. Once students become more familiar with tools and determine how to best apply them for their personal needs, a stronger sense of community begins to emerge. Due to these benefits, instructors are increasingly utilizing community programs like Living Treasures to bring community members and community culture into the classroom to localize course content.

Additionally, there must be space for users to provide feedback on the system (Wiig, 1997) so that the effectiveness can continuously be improved. When communication between knowledge creators and SMEs is limited, the knowledge often becomes outdated and users stop accessing the system after losing interest (Ravitz & Hoadley, 2005). LMSs such as WebCT Vista have a rating option on discussion messages, so learners can rate messages that they find useful, as described in the scenario. When a particular message has a high rating, learners are more likely to visit it because they want to be accessing the most pertinent information in the course, as described in the case illustration. This rating system allows all users to become SMEs in capturing data that is most important to the collective whole.

Interaction

Interaction is a central component to OE. Moore (1989) outlines three types of interaction: learner-content, learner-instructor and learner-learner. A fourth type of interaction is especially important in OE—learner-interface (Hillman, Willis & Gunawardena, 1994). Similarly, interaction is a foundational component of KM and is facilitated by SS tools. It has even been found that groups of individuals who regularly share knowledge tend to perform better than those who do not (Davenport, 2005). Through interaction, individuals learn to analyze, question, interpret, and make sense of phenomena. Members of the community facilitate their thinking and innovation through the questions, problems, issues, solutions, resources, and tools that members bring to the community.

Collaboration is not always a natural process for learners in an online environment. In fact, Anand (2007) expresses concern that online services coupled with KM software may reduce the need for human interaction. Therefore, instructors must minimize transactional distance and establish a strong sense of social presence so that learners *want* to interact with each other. SS tools can be used to develop and enhance interaction and social presence in the course. Online learners often have different personal goals, and, thus, there is not one tool that will fit the interaction needs of all learners. An additional concern to consider in an international online course is Internet accessibility of all learners (Beldarrain, 2006). McLoughlin and Oliver (2000) provide several suggestions for online instructional designers, one of which is to include communication tools that encourage social interaction so that all learners have the opportunity to co-construct knowledge.

Conrad and LaPointe (2007) remind us that just because these tools are included, it is not guaranteed that they will necessarily facilitate enhanced interaction, or even be used. Their research revealed that collaboration depends on

the design, nature, purpose and structure of the SS tool. In their course wiki learners were willing to post content, but did not want to edit other classmates' content. Instead, the learners wanted additional opportunities to discuss the content on the wiki. This adds to our growing awareness that merely capturing and sharing information does not necessarily lead to deeper understanding. New information can only lead to shared knowledge when it is integrated with prior data and tested through dialogue with other learners. In the end, it is the learners who will decide whether or not they will accept and apply the tools to their thinking and learning processes through interaction within the course.

Critical Reflection

In order to make sense of an experience, learners must interpret it. This interpretation then guides learning actions. Mezirow (1990) suggests that this process of reflection "enables us to correct distortions in our beliefs and errors in problem solving" (p. 1). It is a necessary strategy for all online users, as it directs future professional practice and improved performance through the discovery of personal meaning. *Critical* reflection takes the learning process a step further to include "challenging our established and habitual patterns of expectation" (Mezirow, 1990, p. 12). This process provides a potential transformative learning or teaching experience.

Although reflection is embedded in every step of the process, we believe it is important enough to explicitly detail through the description of strategic alignment and leadership. Instructors and instructional designers must reflect on every step of process. For example, instructors must reassess the applicability of the content in the online class. As course objectives change, the content must also be adapted to support learners' needs. Additionally, the instructional designer must reflect on the applicability of the tools chosen to meet course objectives. Both the instructor and

instructional designer should review the sense of individualization of content that then encourages collaboration both within and outside of the online course. Finally, we recommend that the instructor and instructional designers ensure critical reflection holds a central position within the learning activities so that learners can also participate in the process.

Strategic Alignment

The goals and objectives of the online course must drive the selection of SS and KM tools. What works for a problems-based biology course cannot be plugged into a lecture-based math course and expect comparable results. Similarly, cultural differences hinder the effectiveness of the drag and drop method. For example, an instructional technology course taught at a university in southwestern United States must be culturally adapted before implementing it at a Chinese university. This has become more apparent as open content and open educational resources are shared between academic institutions, as described in Caswell, Henson, Jensen and Wiley's (2008) recent article on universal education.

All SS tools and KM processes must be connected to the institutional culture and overall course goals so that users feel like it is a valuable use of their time. In fact, Liebowitz (2001) mentioned that one of the three reasons for a failed KM strategy is that it was not connected to the central goals of the institution. If that is the case, users will not see the functionality of the initiative and will most likely not engage. The model proposed in this chapter provides a broad structure within which instructors can adapt to fit their course objectives.

Alignment of the proposed initiative with the organizational strategic plan should be closely related to leadership characteristics, internal organizational structure and external characteristics of the institution (Rogers, 1995). The degree of centralization of power and control in an organiza-

tion, the formalization of rules and policies, and the degree to which new ideas can flow among organizational units all impact organizational innovativeness and its implementation. Additionally, strategic alignment supports the future sustainability of the initiative.

Leadership

As mentioned above, leadership has the ability to minimize or maximize the impact of this innovative model. Leadership's purposes, expectations, and goals for the model will vary, depending upon the lens through which it views the system. In a formal educational setting, most people define the leader as the instructor or instructional designer who may perceive the model as a way to encourage learners to become involved in a community to create, share, and use content to solve problems and instigate change. Yet, if the leader is unwilling to recognize, encourage and share the collective knowledge, s/he is putting the entire online course community at risk of losing vital information.

Openness to a variety of perspectives enables new understandings and encourages innovation. Sustainable improvement depends on successful and sustainable leadership (Hargreaves & Fink, 2006). This may mean that the leadership is equally distributed across the course—members of the online course take turns in holding the leadership role. This not only provides different perspectives, but also encourages emergent leadership within and beyond the course.

Community Development

When learners take responsibility for their learning goals and take on a leadership role in their online class, they develop confidence not only in their knowledge of the content and technology, but also in their ability to lead others. They further value the interdependence and the responsibility of all members of the community to teach and to learn.

Knowledge management uses the term Community of Practice (CoP) to describe a place where people unite for a common purpose so that they can work together to achieve a particular goal (Conway & Sligar, 2002; Wenger, McDermott & Snyder, 2002). A CoP may emerge from the community development process. However, we feel that a knowledge community does not have to be as structured as a CoP in order to be successful. Learners may come in and out of the community, as they feel necessary. Some learners may share their knowledge from the online course with the community, while others may distribute information from the community with the online course. The community development moves beyond the classroom to peer networks before, during and after the online course. It is this flexible interplay of expertise that creates an environment of knowledge sharing and innovation.

People choose to belong to social organizations where value is gained through the exchange of information and life experiences from highly credible sources. The value received reinforces the connections between course members and the community. The partnership of community with online course participants allows flexible groupings of students and practitioners to work on projects. Students have increased opportunities for authentic experiences and research that they can bring back to the online classroom.

Innovation

Organizations cite innovation as one of the primary benefits of implementing KM practices into organizational practices (Conway & Sligar, 2002; Davenport, 2005). It is an educational institution's responsibility to determine how to encourage innovation at all levels (Kidwell, VanderLinde & Johnson, 2000; Rogers, 1995). Brown (1998) suggests that "innovation is everywhere; the problem is how to learn from it" (p. 156). Through having the capability to search and navigate a diverse,

extensive knowledge base, learners may build new connections, and in turn, enhance the likelihood of developing further innovative products (Merlyn & Välikangas, 1998). Innovation contributes to a greater institutional knowledge base, providing information of value that the community members want to continually access and contribute to; thereby, creating a sense of community rather than a collection of content.

Even the best innovations will get lost in the shuffle if leadership does not know how to communicate them with other members of the community (Brown, 1998; Rogers, 1995). Leaders cannot pass a memo and expect the innovation to be diffused in to everyday practice. Brown (1998) suggests that users need to have the opportunity to experience it in a way that “evokes power and possibility” (p. 168). Sustainability of the innovation is more likely to occur if learners participate and give input throughout the generation and diffusion process (Rogers, 1995).

Sustainability

Organizations that use KM and SS to enhance OE must plan for a dynamic system. Barron (2000) mentions that online content can be considered outdated in less than eight months. Additionally, learner experiences are consistently transforming and are always open to reinterpretation. For these reasons, the dynamism of economic and social change requires a flexible system that is created to adapt to future changes. Thus, the role of KM is to keep the knowledge base “alive and vibrant” (Wiig, 1997, p. 2) with knowledge gained through everyday practice in the community as well as with current research in order to secure the online course’s buy-in and later sustainability of the learning community.

The learning and performance supported by this model are based on the recognition and philosophy that learning is a way of being. It is an ongoing set of attitudes and actions by a community of learners who try to keep abreast the myriad of events that are

occurring in their field. The leader must embrace the vibrant nature of the online community and work to sustain it. All participants can participate and contribute to knowledge building. Trust and confidence must also be nurtured to support the sustainability. Again, it is recommended to apply shared leadership so that the leader does not burn out and cause the captured knowledge to be outdated and minimally applied.

Future Trends

With the rapid expansion of the fields of OE, KM and especially SS, leaders in the field must step back and review broad trends in the field, as well as reflect what those trends mean for the field. Social software presents easy-to-use, participatory technologies, thus bringing increased interaction with others and a diversity of perspectives into the classroom. Knowledge management provides the opportunity to capture and store information so that content and learning can be personalized according to learner preferences. Online education offers instructional design and facilitation of presence and learning. The relationship of KM, OE, and SS supports participation that encourages innovation. This will bring opportunities and challenges.

Security of content and provision of a safe learning experience while inviting the community into the online course will require a solution. Copyright and digital rights management will impact the viability of the model and our case illustration. Websites such as Creative Commons has found a way to provide a space for users to share content with one another with the goal of creating something greater than what one person could develop working independently. Content and interaction, as described in the current model, will blend with virtual world technology. Extensive future evaluative and research opportunities exist to determine the pragmatic value of the model and to build a body of knowledge related to the convergence of technologies and communities to support

continued innovation of the organization through the dynamic development of faculty, students, and interested others. Additionally, international interpretations of this model are welcomed.

Conclusion

This model describes the evolution of knowledge and sustainable innovation of community through the use of SS and KM in an online environment. Two major limitations to this model exist. First, it was developed using western pedagogy. However, an international literature base was used to build the model. The second major limitation is the lack of a discussion of the model's security concerns—given the extensiveness of this topic, it could not be covered in this chapter.

The model describes a new method of learning—one in which the tools from KM and SS facilitate the learning cycle of an online course. Feeding into this model is innovation that comes from our relationships with the community outside the classroom. We are long past the time of believing that instructors are the only people who can create and maintain the course. Emergent leadership is needed to sustain the evolution of knowledge, thus leading to increased innovation. As online education, knowledge management and social software become better known, research must be done to combine these fields in order to effectively integrate more formal and informal learning communities.

ACKNOWLEDGMENT

The authors would like to thank Nate Schneider for his contribution in developing the graphics for the model.

KEY TERMS AND DEFINITIONS

Community: A purposeful group of people centered around a knowledge concept who collaborate through the use of knowledge management and social software tools to support a sustainable and innovative online course and to share learning experiences with person(s) outside of the group.

Individualization: A process in which differentiated instruction based on learners' needs and interests allows the learner to personalize the knowledge in a meaningful way.

Instructional Design: The systematic application of instructional content, technology and tools used to design an individualized, interactive and reflective online learning environment.

Interaction: An exchange of knowledge and ideas between learners, instructor, content and learning interface(s) that encourages sustainable community development and innovation.

Knowledge Management: The process of capturing, storing and distributing information across learning environments to improve the application of knowledge to a variety of social contexts, thus increasing its availability to others to increase innovation in the evolution of community development and learning.

Online Education: A dynamic learning format taught by means of the Internet in which learners

and instructor interact through the use of several of technologies for the purpose of intentional learning.

Reflection: A process in which online participants (learners and instructors) and community members (former learners and experts in the field) observe and interpret the learning experience so that they can consistently adapt and improve the high quality instructional systems design.

Social Software: A combination of two or more online tools encouraging learning, interaction and community development between two or more people.

Chapter 2.8

A Large-Scale Model for Working with Subject Matter Experts

Judith A. Russo-Converso
CSC, USA

Ronald D. Offutt
Northrup-Grumman Information Technology, USA

INTRODUCTION

The evolution of complex and distributed commerce requires the implementation of training design and development models that capture and mold the expertise of subject matter experts (SMEs). A SME is defined as “that individual who exhibits the highest level of expertise in performing a specialized job, task, or skill within the organization”. SMEs possess in-depth knowledge of the subject you are attempting to document (http://www.isixsigma.com/dictionary/Subject_Matter_Expert_-_SME-396.htm). This chapter describes a unique issue, and potential risk, along with a solution to work with a large number of geographically dispersed SMEs (separated from one another due to their respective locations), whose efforts are standardized and synchronized.

This solution is based on a collaboration model implemented and led by an integration team whose role and responsibility is to allow the SMEs to achieve consensus, efficiency, and standard of quality in both products and processes.

The model is exemplified using a current large-scale military eight-year initiative to design training support packages to prepare soldiers to use advanced technologies and employment concepts in a blended delivery format of live, virtual, and constructive. The Live-Virtual-Constructive environment combines any of these three approaches to create a common battlefield, on which live units can be represented along with virtual and constructive. These units can interact with one another and conduct a coordinated fight as though they were physically together on the same ground (United States Army Combined Arms Center, <http://usacac.army.mil/CAC/functions/constructive.asp>). This initiative will be used throughout

DOI: 10.4018/978-1-60960-503-2.ch208

the chapter as our illustrative example as we describe the rising challenges and opportunities.

Therefore, this chapter will provide a detailed examination of the existing education and training development fundamentals that provided the framework to meet the requirements of this training design and development challenge. The first step in the process was to identify potential problems, issues, and/or potential risks of this training initiative. Two obvious issues were identified: 1) working with three different companies, each with their own internal structure and philosophy on training and development thus, resulting in a need for standardization; and 2) having a large number of individuals geographically dispersed, responsible for contributing to or creating the initiative's policies, processes, and products resulting in a need to find a means to work collaboratively from a distance.

Adding to the complexity of the initiative was acknowledging the nature of the training design and development team; the fact that it consists of forty (40) SMEs, analysts in the initiative, representing three leading defense contractor companies, known as the One Team Partners (OTP). To resolve the issue of standardization, a three-member integration team (IT) was assigned to facilitate the design and implementation of policies, procedures, and processes to accomplish the expected project goals and objectives of their primary customers by synchronizing, integrating and standardizing the SMEs' work.

The end-product (instructional/training product) was designed to support the instructional and training efforts for soldiers deployed, awaiting deployment, or conducting combat operations. The authors of this chapter are two members of the three-member IT, serving as the lead instructional designer and lead content SME. During the first three years of an eight-year initiative, this joint effort, using the collaboration model, has completed or is nearly completed with the initial planning and analysis phases (i.e., mission,

job, and task analyses) in preparation for the next phase, the design and development of training support packages.

Typically when managing an educational or training initiative, instructional designers (IDers) depend on the SME for their expertise in curriculum content. The IDers' involvement is critical during the analysis and design phases of a systematic instructional design approach.

However, in our illustrative example, the content SMEs were the lead component and instrumental in actively participating in the planning phase (the design and development of the policies, procedures, and processes) and were primarily responsible for writing the analyses results/findings. The content of the results were then reviewed by OTP IDers for writing convention format (e.g., use of acronyms, punctuation, spacing and numbering) and instructional design format (e.g., sequencing of steps, alignment of performance steps and sub-steps with performance measures). To meet this ID review requirement, each OTP has a SME IDer whose responsibility was to guide analysts (OTP SMEs) and to comply with the standards and guidelines related to instructional format and writing conventions. In addition, there were vertical and horizontal reviews conducted by other content SMEs (e.g., internal and external to the OTP) for accuracy and completeness in terms of breadth and depth of content, in context.

The intent of the IT in designing this methodology was to actively involve the SMEs from the onset, not only to capture their expertise, but also to gain and sustain their buy-in and commitment throughout the different phases of the initiative, and to do so primarily from a distance. Therefore, to resolve the second issue of the OTPs collaborating from a distance, the lead IT developed a process using technology (e.g., Web-based application and tools, relational database) to lessen the impact of being geographically dispersed.

BACKGROUND

The goal of this large-scale collaboration model is to integrate the contributions submitted by multiple subcontractors (known in our illustrative example as the OTPs). To meet this goal, the prime contractor appointed a lead IT with the responsibility to the customer, prime contractor, and the OTPs to synchronize (move along at same rate) and standardize (end-product has the same structure and language) processes and products.

Systems designers envision the entity to be designed as a whole; as one that is designed from the synthesis of the interaction of its parts. Systems design requires both coordination and integration. We need to design all parts interactively, therefore simultaneously. This requires coordination. The requirement of designing for interdependency across all systems levels invites integration. In an age of continuous and intensified change, the understanding of the role of systems design in creating our future and the development of competence in systems design are of the highest priority (Banathy, 2000).

Since the overarching component of such an initiative was the integration of work produced by the multiple OTPs, the lead IT adopted a systemic approach to achieve process and product standardization. To understand instructional development, it is helpful to view from within the context in which it functions. An educational or training environment is, in effect, *a system of systems*. By definition, a system (the whole) is a structure that is dependent on the product of the interrelationships of the parts rather than the attributes of any individual part (Ackoff, 1995). Therefore, it is imperative to view an instructional development initiative within a systems approach context based on general systems theory.

General systems theory (Gharajedaghi, 1999; Rothwell & Kazanas, 1992) is based on the belief that for significant and long-term change or opportunity to become institutionalized, it is imperative to recognize and manage the organization as a

system. A system, composed of the performance of interrelated subsystems, forms a unified whole which is more than the sum of its individual parts. The application of general systems theory develops performance and instructional strategies in a systematic manner and includes the following: identifying specific requirements, designing an optimum solution, developing an intervention, and comparing results to plans (Branson & Gilbert, 1997).

Keeping the system healthy and functioning at a level in which its goals are being met by means of actively contributing inputs, outputs, and continuous feedback is referred to as maintaining an open-system. A system in which all subsystems share a common goal must be receptive to inputs and outputs in making its goal a reality (Converso, 2001, p. 16). In order to create and sustain an open-system, the IT from the onset actively engaged the partners by formally requesting input and feedback as the initiative policies, procedures, and processes were being designed and developed.

Instructional development systems or models are then transformed through systematic design functions within the system (e.g., planning, analysis, design, development, and delivery/implementation). Similarly, open-systems continuously receive feedback from stakeholders/partners indicating how well these functions have been carried out. To survive, an open-system must gain advantages (e.g., return-on-investment) from its transactions with the environment (Rothwell & Kazanas, 1992, p. 10) (see Figure 1).

In our illustrative example, the instructional development structure has multiple tiers of partners functioning in change roles. The change roles are based on role assignments for change projects as defined by Conner (1992). "Working relationships can be highly complex and convoluted, with people playing more than one role and frequently shifting roles once a change is under way" (Conner, 1992; p. 105). The role assignments are defined as (Conner, 1992; pp. 106-107):

Figure 1. Components of an open-system organization (adapted from Rothwell & Kazanas, 1992)

- *Sponsor*: an individual or group who has the power to sanction or legitimize change. A sponsor decides which changes will happen, communicates the new priorities to the organization, and provides the proper reinforcement to assure success. Sponsorship takes far more than ideas and rhetoric; it requires the ability and willingness to apply and to enable the meaningful rewards and pressure that produce and enable desired results to be made on time and within budget.
 - *Initial Sponsor*: an individual or group who has the power to break from the status quo and sanction a significant change (e.g., primary customer - military or government agency). An initial sponsor is usually higher in the hierarchy than those who must perform the duties of sustaining sponsors. The initiating sponsor must be able to enlist the support of sustaining sponsors down in the organization, or the change is certain to fail.
 - *Sustaining Sponsor*: one who supports and follows through with the sponsor commitment and allocation of resources for his/her area of influence. A sustaining sponsor has enough proximity to local targets, those individuals or groups who must actually change, to maintain focus and motivation on the change goals (e.g., prime contractor). Sustaining sponsors minimize logistic, economic, and political gaps that exist between layers of the organization and produce the appropriate structure of rewards and punishments that promote achievement.
 - *Advocate*: an individual or group who wants to achieve a change but lacks the power to sanction it. However, advocates are influential and valued for their advice and recommendations given to the sponsor and others (e.g., dependent on the situation this role can be filled by the OTP project managers, the lead IT, or the SMEs themselves).
 - *Change Agent*: an individual or group who is responsible for implementing the change (e.g., IT, project managers). Agent success depends on the ability to diagnose potential problems, develop a plan to deal with these issues, and execute the change effectively.
 - *Change Target*: an individual or group who must change (SMEs - analysts, designers, developers). To increase the likelihood of success, they must be educated to understand the changes they are expected to accommodate, and they must be involved appropriately in the implementation process.
- In our illustrative example, the *initial sponsor* is the military or government agency (a.k.a., primary customer) who has the ultimate/final authority and

responsibility to accept/reject the end-product. The *sustaining sponsor* is the government contractor (a.k.a., prime contractor) who has the authority and responsibility to accept/reject end-product). The *change agents* are the OTP project managers (a.k.a., subcontractors) and the lead IT that has managerial roles and responsibilities to comply with standards and guidelines when submitting the end-product for approval/acceptance. The *change targets* are the content SMEs, OTP instructional designers, and training developers who follow the policies, procedures, and processes for creating the end-product (see Figure 2).

As noted by Conner (1992, p. 105), as with any change initiative, this large-scale model had individuals with roles and responsibilities that are multi-disciplined (having more than one area of expertise) and multi-functional (having to perform more than one role). For example, a project manager may have the following roles/responsibilities: 1) as a change agent leads/supervises the work of his respective team within the OTP organization/

structure, 2) as an advocate for individual analysts within his respective team, and 3) as a change agent who performs as approver of product that moves along the tiers of internal review/approval for submission to the external review team (i.e., the lead IT).

To oversee the instructional development (ID) initiative described herein, the lead IT adopted a systematic model for working with SMEs. ID models provide communication tools for determining appropriate outcomes, collecting data, analyzing data, generating learning strategies, selecting or constructing media, conducting assessment, and implementing and revising results (Gustafson & Branch, 2002, p. 2). The core elements/phases of any ID model are *analyze*, *design*, *develop*, *implement*, and *evaluate* (ADDIE)—each element informs the other as development takes place and revisions continue throughout the process via ongoing planning at the onset of each phase and formative evaluations conducted during each phase. The ADDIE ID Model is well documented

Figure 2. Chain of responsibility and authority within in a change management role-based organization

and widely used in military, business/industry, and academic training/education programs. However, the lead IT modified the ADDIE ID Model that appeared in Gustafson and Branch (2002, p. 3) to incorporate the upfront strategic planning phase and technology components.

For example, the ID Model adopted by the lead IT includes the following modifications and operational definitions: 1) upfront strategic planning (SP) – the phase where ADDIE is employed for the initiative or project as a whole, consisting of interrelated parts and 2) technology components that are comprised of tools and applications (T) to manage (e.g., relational database/repository, report generator, search engine); to produce (e.g., standardized tools to create documents); and to communicate (e.g., availability and accessibility of online collaborative meeting/classroom environment) aspects of development process/product, thus the new acronym SP/T-ADDIE (see Figure 3).

A critical task of the lead IT was to establish business rules (i.e., guidelines for developing consensus-building). Kaufman, Herman, and Watters (1996) present an educational strategic planning framework with a focus on the primary client and beneficiary of what gets planned and

delivered. This framework or model embraces a systems approach and illustrates the interrelationships among three major clusters 1) scoping, 2) planning, and 3) implementation and continuous improvement.

The *scoping* cluster begins the guiding star or ideal vision, defined as the kind of world we would want for tomorrow's performer, and then selects what the educational system commits to deliver. This delivery selection identifies the needs and mission objectives (e.g., what is and what should be and how to close the gap between the two).

The *planning* cluster includes the strategic plan devised by examining the strengths, weaknesses, opportunities, and threats of the implementation and identifying the long and short-term milestones (e.g., measure of incremental successes).

The *implementation and continuous improvement* cluster includes tactical and operational planning (e.g., how to get from here to there), securing resources, diffusing the initiative, and conducting formative evaluations for continuous improvement of the initiative policies, processes, and procedures. For the purpose of continuous improvement, criteria must be developed to measure the effectiveness and efficiency of the

Figure 3. Core elements of instructional development: SP/T-ADDIE Model

initiative. This was accomplished via the technical and management plans adopted by the OTPs, IT, and primary contractor.

Kaufman's strategic planning and decision-making model (1998) focuses on making societal contributions in addition to meeting its own requirements for contribution and survival, thus the three levels of focus 1) micro (e.g., individual), 2) macro (e.g., organizational), and 3) mega (e.g., societal). In our illustrative example, the true outcome or mega contribution to society is the development of a well trained soldier that has the skill, knowledge, and abilities to protect

home and abroad, resulting in the saving of lives and property (see Figure 4).

As stated previously, an important element to working with SMEs is the ability to develop and manage collaboration and decision-making. Therefore, the lead IT developed two main components: *Real time* (collaborative online learning/consensus-building environment) and *relational database/repository* (capabilities to manage document development; review with multi-tiered feedback; store documents in various states of development; search document whole

Figure 4. Strategic Planning Model Source. © 2008 Roger K. Kaufman, PhD. Used with permission.

or parts; and generate reports and automated notifications).

LARGE-SCALE COLLABORATION MODEL FOR SUBJECT MATTER EXPERTS

As with any implementation effort, there are inevitably issues, controversies, and/or problems. The following paragraphs discuss specific issues or problems and the resolutions to manage, minimize, or eliminate them.

Use of Technology Tools and Applications Issue

In order to provide a seamless environment to its end-users, the initiative required modifications of an existing relational database to meet the requirements of the implementation effort. Once the technology was in place, there was the matter of developing workable templates to capture the required data to produce the end-product.

This was accomplished via collaboration with the system technicians and analysts (i.e., those who would capture the data from multiple sources and entering data into the system). Then the issue of offline word processing for exchanging specific comments and edits on draft documents (e.g., track change features using MS Word or features within the relational database) became an issue to those unfamiliar with the features and techniques to work through the reviewing procedures.

Resolution of the issue was accomplished by the IT, OTP instructional designers, task leads, and analysts via formal training and direct one-one-one help/guidance. This training was delivered in a blended format, which constituted a combination of face-to-face live sessions and virtual online sessions, based on time and location constraints.

Real-time Online Collaborative Environment Issue

To meet the challenge of working at a distance, the lead IT selected to work within a real-time online collaborative environment. This mode of communication, fairly new to many of the partners, resulted in a training solution designed by the instructional designers representing the OTPs and IT. The real-time online collaboration minimized the requirement for travel, while greatly reducing associated costs (e.g., food and lodging, telephone charges, time away from office/work settings). However, the greatest value was in the ability to work at a moment's notice in an environment that closely resembled a live face-to-face setting. The key was having the facilitation skills and expertise to coordinate and conduct such meetings/training sessions. The lead IT was fortunate to have key personnel with these knowledge and skill sets and years of experience working within collaborative online environments, both in education and training contexts. The greatest controversy was a security issue when using such an environment when contracted by a military or government agency. There are license agreements and access issues; however, in our illustrative example the military had access to a proprietary online environment that had many of the same features as available commercial systems.

Nature of the Subject Matter Experts Issue

The areas of SME expertise are often focused on specific function (e.g., knowledge and skill set, experience) and oftentimes overlap and were interrelated with other SME expertise. To better understand the complex and multi-dimensional aspects of working with multiple SMEs, it is useful to first explore the very nature of SMEs from an expert-performance perspective. The relationship between nature and nurture has been a long-standing debate (Tenenbaum, 1999) since

it determines the quality of instruction and the amount of learning needed to acquire skills and establish a knowledge base. However, most would agree that nurture plays a significant role in the development of expertise and that in order to reach any significant level of expertise in a given domain, the performer must have the desire to excel and at least some domain-specific knowledge and skills that are acquired through practice and feedback.

It is particularly interesting to consider the role that SMEs are given within a project team. Typically, ID projects are structured such that the SMEs contribute to solutions, processes, and product design by providing their content knowledge to trained IDers. In our illustrative example, the SMEs were the driving force behind the effort and were therefore in key roles such as analysts, managers, and supervisors, going above and beyond their domain specific expertise. That is, the SMEs were serving as a project or team lead and had to make decisions and act from a perspective other than that of their domain knowledge. When you have such a vast number of SMEs with varying areas of specialization working together, lines of communication are of the utmost importance from the onset of the project for efficiency and effectiveness.

To deal with this issue of working with SMEs it was imperative to adopt a systemic approach where the interrelationships are known, understood, and embraced as strengths for problem solving and decision-making and not viewed as obstacles or challenges to the ID process. For example, in the initiative there were seven task leads (TLs), representing the OTPs. Their role was to follow the lead of the project manager and to oversee the work of the analyst. They served at times as a change agent, a change target, and advocate, depending on the situation or context of the problem or issue. The lead IT had to establish business rules that would guide the process for reaching consensus (e.g., accepting a common definition of approved terms and illustrative examples). Their

collaboration and recommendation was then reviewed by the OTP project managers and the IT. The goal was to get beyond an arbitrary decision or policy and adopt, based on active participation/decision-making process and procedure. It was the experience of the lead IT that this approach not only strengthens acceptance/adoption, but better ensured sustained buy-in and commitment because of the active involvement of the partners in the decision-making process. The key was to develop a continuous and open feedback loop, once again embracing a systemic and systematic approach to planning and decision-making.

Standardization and Compliance Issue

To carry out a large-scale initiative it was important to understand the power of standardization for outcomes/products and the compliance with standards and guidelines for processes and products. Compliance was resolved by creating an internal and external review process of product drafts and final versions. The business rules that governed the internal review process was determined by each of the OTPs, knowing that the external review would be dependent on certain criteria being met at the internal level. As it was the responsibility of the lead IT to approve the end-product that was then forwarded to the prime contractor, it was imperative that the end-product appear as if it were written by one partner, not three separate partners (OTP SMEs) – standardization enabled that to be accomplished.

Another important issue that emerged during implementation was the value of having a pressure-release - a means or process in which senior level managers had the ability to influence process and product via business rule set. An analogy would be a court of appeals. This capability provided the analyst an avenue to gain support/advocacy from senior management.

Collaborative Issues

Jensen (2002, cited in Warner, Letsky, & Cowen, 2003) addressed collaborative challenges, issues that can hinder or prohibit successful implementation if not address in a timely and organized/planned manner. Jensen went on to cite the following major factors influencing military collaborative teams:

- Increasing problem complexity– team effort needed
- Integrated Technology/Communications technology widening accessibility of contributors
- Problems addressed at international level – coalitions required
- Defense Transformation to agile and coalition operations
- Information overload condition

The lead IT revised this list of collaborative challenges based on its experience as noted below.

- Increasing problem and task complexity – team effort needed (e.g., resource reallocation: moving SMEs other roles/responsibility beyond the scope the original work order)
- Integrated Technology/Communications – technology widening accessibility of contributors and archiving and collection of end-products
- Problems addressed at a multiple tier level (e.g., IDers, TLs, IT, PMs) – where coalitions are required. For example, the PMs agreed to conduct a specific task analysis outside the scope of the contracted work, formed a coalition to how they would attack the problem and then presented a proposed solution to the prime contractor for approval/acceptance.

- Information overload condition. As with any adult learner, the learning curve is steep when experiencing new knowledge and skills. The lead IT developed training for the OTPs based on the theoretical framework of Ausubel’s meaningful reception learning and schema theory (Ausubel, et al., 1978), where a learner transfers previous learning to new information. For example, the lead IT designed the delivery of new information via illustrative examples so that the learner could relate to the information based on their prior experience, or learning. In addition, situated cognition theory, or situated learning, served as a theoretical framework. Situation learning is defined as occurring when declarative knowledge (“knowing that”) and procedural knowledge (“knowing how”) are integrated within a single framework (Driscoll, 2005, p. 154). Through constant feedback and training within the context of the situation and the community of learners that the partners formed, the information load was manageable and productive.
- Content SMEs must be balanced with instructional design analyst SMEs. It was understood that the content, or technical, SME was not expected to have the knowledge and skill set to write instruction; however, we found the greatest value when they worked in tandem with the instructional SMEs – to integrate or combine the expertise of both to make the whole.

FUTURE TRENDS

The use of online collaborative learning/training environments is gaining greater popularity in academic and business/industry settings. Military and government agencies are seeing the value and benefit, in terms of cost and effectiveness in training programs, as well. Hofmann (2004) states,

“like every innovation, learning technologies are a mixed blessing. They allow us to present content in many different formats and deliver that content to widely dispersed audiences at a relatively low cost” (p.1). In the illustrative example, the lead IT took the online learning environment and used it for that purpose, as well as to serve as a meeting and consensus building forum for its OTPs. As more individuals learn the features of the online collaborative environment (its tools and applications) and best practices for using those features, these types of environments will become a rich resource for many groups and organizations.

CONCLUSION

How do stakeholders or partners deliver successful large-scale ID initiatives? Everett Rogers in his book, *Diffusions of Innovations* (1995), defined diffusion as “the process by which an innovation is communicated through certain channels over time among the members of a social system” (p. 10). This concept is the backbone of implementation.

Rogers further defines an innovation as “an idea, practice, or object that is perceived as new by an individual” (p.11). The concept of lead integrator and learning communities of geographically dispersed SMEs was proposed as an innovated form of ID. Systems thinkers may suggest an elaboration to Rogers’ definition of innovation “what is perceived new by an individual” to include “a group, organization, and system as a whole (Converso, 2001).”

Inevitable to the implementation of this type of model is the diffusion of innovation. Critical to successful implementation is the understanding that problem/tasks are: increasingly more complex; technology is ever-changing; SMEs have a greater diversity in their experience, knowledge, and skill sets; and learning communities are geographically dispersed and hindered if limited to one/common or shared location (same place, same

time) – unless done virtually (any place, any time or in a blended delivery format). A most significant opportunity for those implementing large-scale ID initiatives is to use a collaborative model, such as the one described herein, thus breaking through the barriers of geographical locating and capturing of a combined level of expertise only made possible by employing a variety of SMEs collaborating via virtual environments.

KEY TERMS AND DEFINITIONS

Blended Delivery: A combination of instructional delivery options (e.g., instructional including face-to-face sessions with virtual online sessions).

Collaboration Model: A conceptual management and communication tool designed to work with a large number of geographically dispersed subject matter experts.

Collaborative Online Learning/Consensus-Building Environment: A web-based environment that allows participants to come together via their desktop computers at the same time, from any location in some kind of social interaction to work together to solve problems, reach consensus, or brainstorm/generate ideas. Success is much dependent on the skill level of the online facilitator(s) to meet required goals and objectives of the organization and/or of the group gathered online.

Geographically Dispersed Population: A group of learners or workers who are separated from one another and/or resources, including an instructor, due to their respective locations (e.g., individuals living in different parts of a region, nation, continent, or globe).

Instructional Development Model (SP/T-ADDIE Model): Communication tool for determining appropriate outcomes, collecting data, analyzing data, generating learning strategies,

A Large-Scale Model for Working with Subject Matter Experts

selecting or constructing media, conducting assessment, and implementing and revising results.

Integration Team: Group of individuals whose role and responsibility is to standardize, synchronize, and incorporate the efforts of participating subject matter experts (SMEs). The integration team's efforts allow the SMEs to achieve consensus, efficiency, and standard of quality in product and process.

Standardization of Processes and Products: Means provided to the subject matter experts allowing them to work within an organization consistently and with regularity and sameness; desired outcome is to create processes and produce

products that appear to the customer or end-user as seamlessly created and produced.

Subject Matter Expert (SME): Defined as that individual who exhibits the highest level of expertise in performing a specialized job, task, or skill within the organization. SMEs possess in-depth knowledge of the subject you are attempting to document (http://www.isixsigma.com/dictionary/Subject_Matter_Expert_-_SME-396.htm).

Systems Approach: A methodology used to create and sustain a system (e.g., educational, instructional), composed of the performance of interrelated subsystems, to form a unified whole which is more than the sum of its individual parts.

ABSTRACT

The authors are Instructional Designers developing online courses in higher education. These courses are facilitated by Subject Matter Experts and delivered through a Learning Management System. They propose that instructional alignment with pedagogic beliefs is the best instructional foundation for original course designs in this instructional context, and examine three factors

unique to this context. They propose new instructional design models and a new instructional system of design to address the instructional challenges specific to their learning system context.

INTRODUCTION

As Instructional Designers (IDs) in higher education, one of our main responsibilities involves working with Subject Matter Experts (SMEs) to design online courses for delivery in a Learning

DOI: 10.4018/978-1-60960-503-2.ch209

Management System (LMS). We have identified three main factors specific to this instructional context. The first is the ongoing nature of the relationship between SMEs and IDs as they collaborate on the design and delivery of online courses. The second is the constraint that these never-delivered courses must be designed without the benefit of learner-generated data to inform the process. The third is the foundational role which the course facilitator's pedagogical beliefs play throughout the course design process.

In this chapter we propose a taxonomy for an ID-designed Online Course and define the terms used in our discussion. We then discuss the three factors associated with our instructional context. We propose a model for achieving learner-driven course designs through a phased approach. We examine two elements which shape our learning system context: the pedagogical effects of LMS adoption and success factors related to Online Learning Environments (OLEs). We explore the role of context in ID. Finally, we present a framework for an Instructional System of Design

(ISD) we are developing to produce original course designs for our learning system context.

TAXONOMY AND TERMS

In order to communicate more effectively about our instructional context, we have developed the term "SME-F (Subject Matter Expert-facilitated) online courses" to refer to online courses taught by the same individual responsible for providing a course's content. We will refer to this person as the "SME/F" (Subject Matter Expert/Facilitator). We propose the following taxonomy in order to situate our terms within the larger context of online courses designed by IDs (see Figure 1).

We believe that there are critical distinctions between the instructional context for the type of course we have described and the instructional context for other types of online courses. For example, in an I-F online course the Instructor is facilitating a course with content provided by a SME, and she or he may or may not be an expert in the content. Also, the Instructor is not likely to

Figure 1. Taxonomy of online course designed by instructional designers

Course Type	Design Resources				Course Facilitator			
	ID	SME	SME/F	I	L-F	PA-F	I-F	SME/F
L-F	X	X			X			
PA-F	X	X				X		
I-F	X	X		X			X	
SME-F	X		X					X

L-F = Learner-facilitated

PA-F = Pedagogical Agent-facilitated

I-F = Instructor-facilitated

SME-F = Subject Matter Expert-facilitated

ID = Instructional Designer

SME = Subject Matter Expert

SME/F = Subject Matter Expert/Facilitator

I = Instructor

have played a significant role in the course design process, so one would not expect to find course design choices aligned with his or her pedagogical strengths.

For the purposes of this chapter we will use the term “course design” to represent the entire process of Instructional Design as represented by the phases described in the ADDIE model: analysis, design, development, implementation and evaluation (see, for example, Dick & Carey, 1996). We will use the terms Learning Management System (LMS) and Course Management System (CMS) interchangeably. We will use the term “learning system context” as defined by Tessmer and Richey (1997): “those situational elements that affect both the acquisition and application of newly acquired knowledge, skills, or attitudes” (p. 87). We will use the term “pedagogical beliefs” to refer to “teacher’s educational beliefs about teaching and learning” (Ertmer, 2005, p. 28).

THREE CONTEXTUAL FACTORS

We are part of a team of IDs providing ID (Instructional Design) services at a research-based university. Designing original online courses facilitated by SMEs is a major component of our responsibilities. In the course of our practice, we have identified three factors that we believe are unique to this instructional context.

Ongoing Relationship

Each ID on our team is assigned to work with specific university departments on an ongoing basis. Our IDs and SME/Fs work together throughout the entire pre- and post-semester cycle of course design. This arrangement creates an opportunity to make course design decisions driven by the pedagogical beliefs of the individual providing the course content and facilitating the delivery of the course.

Designing without Learner-Generated Data

By definition, never-delivered courses must be designed without the benefit of learner-generated data. According to Geber & Scott (2007), for designers operating “from the theoretical orientation of learning as interdependent with context and experience, it is not possible to know learners’ perspectives in advance of course development” (p. 464-465). The ID and SME/F are forced look to second-hand sources of information to construct assumptions about potential learners: data gathered from learners in similar traditional or online courses, research-based findings about online learners, learner characteristics implied by the LMS, etc. In their examination of ID practices using established instructional design methods, Sims and Stork (2007) state that IDs “...will often predict or assume certain characteristics of the learners” (3) and incorporate these assumptions into a course design.

For original course designs, we propose that IDs need to limit the assumptions made about the potential learners to one source: the SME/F. We posit that the SME/F’s assumptions about how the course’s future learners will achieve course objectives are inherently linked to their pedagogical beliefs and practices. We stipulate that documenting and incorporating these assumptions into a new course design will create an instructional foundation that maintains alignment with the SME/F’s pedagogy, and consequently his or her pedagogical practices throughout the course.

SME/F Pedagogical Beliefs

Working with the same individual throughout the design and delivery process presents a unique opportunity for instructional continuity. Our experience has led us to conclude that the pedagogical beliefs held by the SME/F are the best instructional foundation for original designs of courses

delivered online through a LMS. This conclusion is supported by Ertmer's (2005) examination of the research conducted on teacher beliefs: "... beliefs are far more influential than knowledge in determining how individuals organize and define tasks and problems" (p. 28). She also draws a direct connection between pedagogical beliefs and technology skills:

Given that these [technology] skills are unlikely to be used unless they fit with teachers' existing pedagogical beliefs, it is imperative that educators increase their understanding of and ability to address teacher beliefs, as part of their efforts to increase teachers' technology skills and uses (Ertmer, 2005, p. 37).

Zhao & Cziko (2001) also emphasize the importance of teacher beliefs when creating their Perceptual Control Theory (PCT) framework for understanding teacher adoption of technology. PCT defines three necessary conditions:

1. The teacher must believe that technology can more effectively meet a higher-level goal than what has been used.
2. The teacher must believe that using technology will not cause disturbances to other higher-level goals that he or she thinks are more important than the one being maintained.
3. The teacher must believe that he or she has or will have sufficient ability and resources to use technology. (Zhao & Cziko, 2001, p. 6)

Ertmer (2005) demonstrates how pedagogical beliefs have a global effect on a teacher's perceptions about new instructional tools and practices when she states "Even new information (about technology, alternative teaching methods, etc.), if attended to at all, will be filtered through these existing belief systems" (p. 30). Our in-

structional process recognizes and embraces this filter by systematically exploring, documenting, and integrating the SME/F's pedagogical beliefs into the course design. We share the hope that a greater understanding of the relationship between pedagogical beliefs and technology use:

...may enable us to facilitate a better alignment between research, practice, and beliefs and to provide more effective ways of supporting and documenting teacher change. Ultimately, the goal is to facilitate uses of technology that lead to increased student learning (Ertmer, 2005, p. 27-28).

We propose that creating and maintaining instructional alignment with the core beliefs of the individual responsible for the course's content and for the facilitation of the course will lead to the most significant learner outcomes. We suggest that it is the responsibility of the ID to gather and interpret course data, and then present evidence of course outcomes which are aligned or misaligned with the SME/F's pedagogical beliefs. If the evidence induces a shift in the SME/F's pedagogical beliefs, the ID should recommend changes to the course design that will increase instructional alignment, and then implement the changes that are approved.

DATA-DRIVEN DESIGN EVOLUTION

An ongoing relationship between an ID and a SME/F may lead to an evolution of the course design. Ideally this evolution would be the result of evidence derived from course data that led to changes in the SME/F's pedagogical beliefs. We have created the term "data-driven design evolution" to describe this process. We propose a three-stage model in which the course design shifts from "SME/F-driven" towards "learner-driven" (see Figure 2).

Figure 2. Data-driven Design Evolution in SME-F online courses

© 2008 USU/GJJJG

In Stage I, there is an insufficient quality of course data to justify changes to the course design decisions/revisions based on learner feedback. This occurs in courses which have yet to be delivered, but it may also be the result of an insufficient quantity of course data. The ID creates a course design based on instructional alignment between the SME/F's pedagogical beliefs and assumptions about learners.

In Stage II, the quality of the course data is high enough to identify learner characteristics that can replace the SME/F's assumptions. The ID provides the SME/F with evidence based on course data that demonstrates instructional alignment or misalignment. When the evidence produces a shift in the SME/F's pedagogical beliefs, the ID recommends changes to the course design that will increase instructional alignment, and implements the approved changes.

In Stage III, the increase in the quality of the course data has led to a fundamental shift in the SME/F's pedagogical beliefs. He or she has become willing to learner feedback drive design

changes to the course. The ID assists the SME/F in interpreting the learner feedback from the latest cohort of learners by using the entire set of course data to control for anomalies. The ID recommends changes and implements the approved changes.

TWO CONTEXTUAL ELEMENTS

Researchers have explored the role of context in ID for more than a decade. In 1994 Edmunds, Branch & Mukherjee stated:

Concepts, theories and models have an ecology, a context within which they function. Importing a theory or model from a significantly different context, without attention to contextual differences, violates this ecology, and subsequently results in inefficient solutions to instructional problems (p. 66-67).

Tessmer & Richey (1997) described the context of a learning system as "those situational elements that affect both the acquisition and application of newly acquired knowledge, skills, or attitudes

(p.87).” They identify the social, physical, and political elements which combine to create “a multilevel body of factors in which learning and performance are embedded (p. 87).” We have identified two contextual elements that interact with the previously-discussed instructional context to create our learning system context: the pedagogical effects of LMS adoption and the success factors associated with Online Learning Environments (OLEs).

Pedagogical Effects of LMS Adoption

The majority of the technological resources we use to deliver our courses are embedded in an LMS. In a comprehensive study of faculty and instructional staff in a multi-campus university system, Morgan (2003) found that more than a third of respondents stated “to solve a pedagogical problem or challenge” as their reason for CMS adoption (p. 3). Despite pedagogical problems or challenges being the number one reason stated for CMS adoption, Morgan (2003) found that “when probing below the surface, however, it seems that most of these needs have less to do with pedagogy, per se, and more to do with class management” (p. 2). Morgan (2003) reconciles this apparent contradiction:

Faculty using course management systems find that they achieve a number of pedagogical gains. This is something of a paradox given that faculty look to a CMS to provide them with organizational tools. But in the process of using these tools, many faculty members begin to rethink and restructure their courses and ultimately their teaching. The end result is a sort of “accidental pedagogy”. Faculty teaching is improved through the use of a CMS, but this is a side effect of the use of the software rather than a direct result of its use (p. 4-5).

We have also seen shifts in pedagogical beliefs among the faculty and instructors we work with that they attribute to their use of a LMS. Because our process is designed to establish “baseline” pedagogical beliefs, we will be in a position to document the changes to these beliefs. By following a research-based model of success factors in online learning, we can recommend changes to the course design that utilize these pedagogical shifts to generate increased learner outcomes.

Success Factors in OLEs

In order to identify success factors in OLEs, Bekele (2008) reviewed 82 studies from educational technology journals. Based on his review, he developed a model that identifies seven success measures: learning outcomes, student satisfaction, higher learning, faculty satisfaction, sustainability, scalability, and rate of return. The model illustrates that “...success in the OLEs was a function of a complicated interplay of human, technologic, course, pedagogic, and leadership factors” (p. 237). We have adopted this model to guide our ongoing development of an ISD specific to our learning system context.

THE AERO ISD

The AERO ISD is being developed to create course designs for our learning system context. By focusing on a specific learning system context, we believe our process will be practical, detailed, dynamic and flexible. We also believe that by maintaining a strict vision of solving the instructional challenges presented in our environment (as opposed to taking on global instructional challenges), we are creating a process that will evolve to be not only systematic, but systemic, where “the outcomes of each component directly or indirectly impact every other component of the instructional design to some degree (Edmunds,

Branch & Mukherjee, 1994, p. 56).” The AERO ISD utilizes two new context-specific ID models, incorporates the ADDIE design phases (see, for example, Dick & Carey, 1996), encompasses the instructional phases identified in Merrill’s First Principles of Instruction (Merrill 2002, 2006), and is being guided by Bekele’s model of success and success factors in Internet-supported learning environments (Bekele, 2008).

Assumptions

There are a number of assumptions that we have made as IDs in developing the AERO ISD. We assume that our process will be applied to courses for which: a) a needs analysis has been conducted, b) a need for the course has been established, and c) there is an institutional commitment to develop the course. We also assume that the SME/F has the necessary expertise in the subject area, and that they have, and/or can obtain, the necessary course content. We assume that IDs will be designing online courses to be delivered through a Learning Management System (LMS) or Course Management System (CMS). We assume that the extra effort expended in learning and utilizing our systematic process will be justified by increases in:

- Course usability for SME/Fs and learners
- Instructional alignment with the SME/F’s pedagogical beliefs
- Data-driven design choices
- Learner outcomes

The OAR Model

The OAR model (Figure 3) is a visual tool which represents the components of SME-F online courses in higher education, and their relationship to each other. The OAR model was developed to meet four criteria: a) maintain a strict focus on our particular learning system context, b) create a simple graphic-based aid which facilitates

communication among design stakeholders, c) remain inclusive by avoiding the use of jargon, and d) represent the basic order of operations in our ID process. The OAR model has proven effective in meeting these criteria by organizing the components of SME-F online courses in higher education into three domains: Resources, Objectives and Activities.

The OAR model defines resources as the physical, electronic and intellectual assets with which a course can be created. These resources are determined by an analysis of the learners, SME/F, ID, learning and performing environments, available instructional technology, and other relevant contextual factors associated with a course. IDs and SME/Fs use the results of this analysis to identify real-world problems and tasks to inform the design of objectives.

The objectives domain contains the learning and performance goals that are designed to guide the course. Objectives determine which resources will be delivered to influence learner behavior under specified conditions to meet defined criteria. Opportunities for learners to accomplish the objectives are created through activities that are as closely aligned with real-world problems and tasks as the available resources will allow.

Activities are the actual events that learners engage in to acquire and develop new knowledge and skills. At a minimum, these events involve an agent (most often the learner, but at times the facilitator) following an objective to engage with a resource. Activities are primarily delivered by a LMS and are facilitated and assessed by the SME/F.

Merrill’s First Principles of Instruction

The AERO ISD is being designed to generate activity types which correlate strongly to a well-known instructional theory: Merrill’s First Principles of Instruction (2002, 2006). In an effort to establish the most fundamental principles of instruction,

Figure 3. The OAR model

Merrill reviewed and synthesized several instructional theories and research reports. Merrill writes that learning is promoted when:

- Instruction takes place in the context of real-world problems or tasks that are progressively difficult
- Learners activate relative cognitive structures by recalling or demonstrating prior knowledge or experience
- Learners observe a demonstration of new knowledge
- Learners apply new knowledge, receiving feedback and coaching that is gradually withdrawn
- Learners integrate their new knowledge by reflecting on, discussing, defending, presenting new knowledge and creating personal ways to use it

Figure 4 illustrates these phases and their relationships to each other. The task/problem plays a central role by defining the learning context. The instruction begins with activation, moves clock-

wise to demonstration, followed by application, and ends with integration.

Figure 5 illustrates how Merrill's First Principles of Instruction relate to the three domains of the OAR model. The task/problem is a resource. Objectives determine how this and other resources will be delivered to create two types of activities: acquisition and application. Acquisition activities are the opportunities provided for learners to gain new knowledge and skills and encompass Merrill's activation and demonstration phases. Application activities are the opportunities provided for learners to use and develop the new knowledge and skills they have acquired, and correlate to Merrill's application and integration phases.

The OAR communication model is adapted to create an ISD-specific model by the addition of an evaluation component. The AERO model (Figure 6) represents the theoretical foundation of a new ISD for creating and revising SME-facilitated online courses developed by IDs in the higher education environment. The AERO ISD incorporates the ADDIE phases of instructional

Figure 4. Merrill's first principles of instruction

Figure 5. Merrill's first principles in the OAR domains

Figure 6. The AERO model

design and Merrill's First Principles of Instruction to create a systematic, research-based process targeted at this context.

An AERO ISD “cycle” represents the steps of the process when applied to one of three design levels: course, interunit or unit. The “course” design level refers to acquisition and application activities that may incorporate elements from all of the available objectives and resources, including introductory papers/discussions, assessments of prerequisite knowledge and skills, and comprehensive activities such as final exams, portfolios, capstone projects, etc. The “interunit” design level encompasses activities based on the objectives and resources from more than one unit such as midterm exams, projects, and learner presentations. The “unit” design level is the smallest grouping of related objectives, resources and activities, and in our experience is labeled by SME/Fs with a term denoting a “chunk” of instruction (ie, “Module 1”), or with a temporal unit (ie, “Week 1”).

An AERO ISD cycle (Figure 7) begins with an analysis of the resources available at the selected

design level. The results of this analysis are used to design acquisition and application objectives. These objectives are used to select resources and develop the vehicles for delivery to learners. The cycle is implemented when the learner engages in activities which are facilitated by the SME/F. The results of the activities are evaluated and the results of the evaluation are used to make necessary revisions or additions to the relevant objectives, resources, and/or activities.

FUTURE TRENDS

In our practice as IDs, we have experienced positive outcomes and feedback from our use of the OAR communication model. We are in the process of continuing to gather data from course stakeholders to design formal evaluations of this model. The results of these evaluations will allow us to determine the validity of its theoretical foundations and make research-based revisions.

The development of a systematic process based on the AERO ISD is in its preliminary stages, and

Figure 7. The AERO ISD cycle

continues to be challenged and revised based on the feedback we receive from our clients. We encourage other IDs operating in higher education to utilize any of its components that they might find helpful in developing a process for their own practices.

CONCLUSION

Three factors unique to new online higher education courses facilitated by Subject Matter Experts and designed by Instructional Designers create an instructional and learning systems contexts with unique challenges. We created the two context-specific ID models (OAR and AERO) and are continuing to develop the AERO ISD to address these challenges. Original designs in this context are most effective when aligned with the SME/F's pedagogical beliefs. As learner-generated data is gathered, our process documents shifts in the

SME/F's pedagogical beliefs and encourages a data-driven evolution from SME/F-driven designs to learner-driven designs.

Chapter 2.10

Functional Relevance and Online Instructional Design

Glenn E. Snelbecker
Temple University, USA

Susan M. Miller
Kent State University, USA

Robert Z. Zheng
University of Utah, USA

ABSTRACT

Online instruction will more likely be effective if it fits with, and is perceived by, students as being functionally relevant for their education, work, or other personal contexts. Existing practice may emphasize an ad hoc approach to online design by being pragmatic and somewhat unsystematic. It is proposed that using a functional relevance perspective, as described in this chapter, is more likely to have designers and online learners attain a greater advantage in using the capacity of the Internet to support teaching and learning. This chapter introduces the concept of functional relevance and identifies some of the underlying theories. Discussions are made on how the concept of functional relevance can be used as

a conceptual framework to identify and to drive decision-making processes that occur during the design and development of instruction.

CHAPTER OBJECTIVES

The reader will be able to:

1. Understand the meaning of—and conceptual foundation for—functional relevance
2. Apply functional relevance as a conceptual framework to clarify and drive decision-making processes during the design and development of online instruction
3. Recognize how general guidelines from this chapter may be applied to the design of online instruction

DOI: 10.4018/978-1-60960-503-2.ch210

4. Understand how a functional relevance perspective can aid designers to:
 - Decide whether particular theories or research findings might improve some aspects of their instruction
 - Identify those situations where social presence might constitute an area that merits careful study and possible important modifications in the online instruction, and
 - Consider which learner attributes may be most relevant for the instruction being designed and to discern how those particular attributes may warrant additional instructions of modification of the online instruction

INTRODUCTION

The proliferation of Internet use in general and online learning in particular has dramatically changed the landscape in K-16 education (DuCharme-Hansen & Dupin-Bryant, 2005; Salpeter, 2003). Fernback (2003) pointed out that Web-based instructional delivery has allowed educators to experiment with flexible, innovative, and progressive learning techniques that “permit students to contribute the learning process in new and active way” (p. 28). Although the idea of delivering instruction online has been heralded by teachers, administrators, parents, and students, doing so effectively takes more than a mere shift in modalities (DuCharme-Hansen & Dupin-Bryant, 2005). Recently, there has been a concerted effort among educators to create a successful online learning environment through *design* (Lim, Plucker, & Nowak, 2001). For example, DuCharme-Hansen and Dupin-Bryant’s model of distance education planning and Jones, Harmon and Lowther’s (2002) framework for online instructional implementation reflect the efforts in that direction.

Several important issues in online instructional design involve pedagogy and theoretical orientation. These issues include deciding whether: (a) an existing or a new pedagogical or instructional approach would be appropriate for learning; (b) someone’s research findings are likely to “fit” with teaching and learning; and (c) using a new pedagogical approach or new research findings might cause a change in the design of teaching. Some instructors respond to these issues by using an ad hoc approach to online design. This is to say that often they take a pragmatic but unsystematic approach, which usually, in the end, fails to take advantage of the capacity of the Internet for teaching and learning. An alternative position is taken by some who propose that online practice should be grounded in theory through a systematic application of evidence-based strategies (Wilson, 1999). With this position, what is important is the congruence between practice and theory, rather than selection of a correct theory (Bednar, Cunningham, Duffy, & Perry, 1992; Wilson, 1999). An example of congruence is the inclusion of scaffolding strategies in constructivist-based instruction, or the use of prescriptive strategies associated with cognitive theory that aid encoding and retrieval of information (Wilson, 1999).

All this reflection still leaves the designer uninformed on how to proceed. Wilson (1999) suggested a problem or practitioner-centered approach in which theory plays a supporting but non-limiting role. Jonassen (1999) suggested that a designer possess the skills to include multiple perspectives, such as the inclusion of objectivist and constructivist views. Miller and Miller (2000) suggested five variables that need to be considered by a designer of online instruction: (a) theoretical orientation of the instructor and of the students; (b) learning goals, either explicit or implicit; (c) nature of the content, such as well or ill-structured subject matter; (d) learner characteristics including cognitive and motivational characteristics; and (e) technological capabilities including available

infrastructure to support various types of online communication exchanges.

Snelbecker (1984, 1989, 1993) proposed that a designer should keep in mind the concept of *functional relevance* requirements regarding both the subject matter and delivery of that material to the learner. This idea suggests a perspective that addresses and integrates theoretical, technical, and practical context concerns. Functional relevance is congruent with the design considerations mentioned in the previous paragraph. In fact, functional relevance can be used as a conceptual framework to identify and to drive decision-making processes that occur during the design and development of instruction.

This chapter discusses (a) the concept of functional relevance from a design perspective, particularly how it can be applied to online instruction design and other Web-based learning, and (b) the relationship between functional relevance and design issues involved with pedagogical theory, social presence, and learner characteristics. The chapter focuses on these topics:

- Meaning of, and conceptual foundation for, functional relevance as a perspective that can yield fruitful implications for the success of online instruction
- Problems, learner needs, and online issues that are met by the inclusion of functional relevance
- Exploration of functional relevance as it relates to three aspects of online design: theoretical orientation, social presence, and learner characteristics.

CONCEPTS, PROBLEMS, AND SOLUTIONS

Functional Relevance

The concept of functional relevance can be depicted as the extent to which technology applica-

tions, including online learning environments, are actually supportive of learner activities and are perceived as such by learners as being relevant for how they function in a particular context (Snelbecker, 1989, 1991, 1993). The assumption is that it is only the degree to which technology is seen as potentially helpful that it will actually foster and support educational achievement and its use.

The importance of functional relevance for technology applications became apparent during the first author's (GES) work with various technology projects starting in the 1970s (e.g., Aiken & Snelbecker, 1991; Ball & Snelbecker 1982a, 1982b, 1983; Ball, Snelbecker, & Schechte, 1985; Roszkowski, Devlin, Snelbecker, Aiken, & Jacobsohn, 1988; Snelbecker, 1986; Snelbecker, Bhote-Edjulee, Aiken & Wilson, 1992; Snelbecker, Bhote, Wilson, & Aiken, 1995). Participants in these technology training projects initially consisted of nurses and physicians, but later mainly involved K-12 teachers. Many were computer novices who expressed some level of anxiety about using computers. Researchers involved in those projects also observed that teachers' *anxiety* was a barrier or restriction in their effective use of computers and related technology resources.

The solution of choice that emerged from those projects and related research was to focus on how computers can be relevant and useful for what teachers need to do in their work with students. Stated another way, once teachers were shown how computers could help them to function more effectively as teachers, indications of so-called computer anxiety and fear were no longer a major concern. Functional relevance involved providing concrete examples demonstrating how the participants could help their students gain technology mediated content. One method was the use of sample scripts—used first by teachers and then modified for their students. Teachers who previously had only limited computer and Internet experiences were hesitant about using computers. However, once they recognized how they could get useful ideas and activities for their students,

they were much more willing to take cognitive risks and explore technology resources and the Internet by themselves. Quite commonly with the different groups it was found that, even early in the training sessions, teachers and other trainees began to have more confidence, rejecting offers of help even though they initially had regularly sought help.

The initial experiences of these teachers reflect the experiences of many end-users. When computers and other technology resources became more readily available, available instructions and manuals almost exclusively focused on how computers functioned. In contrast, end-users need instructions and examples clearly describing how they could benefit from using computers in their respective learning or work contexts. Unfortunately, the trend to focus on how technology works rather than on its functional relevance continues today. All too often, many user manuals emphasize key-strokes (i.e., push X key followed by Y key) rather than guidelines about how the hardware or software can enhance how people function relevant to their respective learning or work contexts. One key idea derived from functional relevance is that fear of computers is less likely to occur when users recognize clearly how the computer resources can support and enhance their functioning.

During the previously mentioned school-related technology projects, the first author (GES) used his background and experiences as a clinical psychologist and as an educational psychologist to create and develop the concept of functional relevance. A number of theorists' ideas were helpful in developing facets and use of this concept. Carl Rogers (1969) is widely known for his concept of personally relevant learning, that is, students may be apathetic about teachers' comments but will become engaged in learning when students perceive learning to be personally relevant for themselves. This idea stimulated Snelbecker to explore ways that teaching-learning activities might have greater impact if and when students perceive those activities can be relevant for how

they function in personal, work, or other contexts. Concurrently, Heider's pioneering work regarding common sense psychology and interpersonal relationships (Fredenborg, 1995; Harvey, 1989; Heider, 1958; Snelbecker, 1988) provided insights and research methods to discern how people develop beliefs as to what can be functionally relevant for them.

Other theorists' ideas were helpful in developing procedures for selecting and improving interventions related to functional relevance. Many people are familiar with Selye's (1956, 1980) concept of distress, which is stress from highly undesirable or even potentially painful experiences. But, comparatively, few seem aware of Selye's concept of eustress, which is stress in conjunction with highly desirable but challenging experiences, such as getting a job or promotion, getting married, or having other challenging responsibilities. This raised questions about how to cope with challenging experiences during online and other learning activities.

Certain researchers' ideas were helpful in addressing cognitive operations that are regularly used by experts and that could be valuable for novices to learn. Herbert A. Simon and Alan Newell's key work on administrators' and other professionals' approaches to problem solving showed that, quite often, those experts were not aware of the many steps or sequences of actions they use in formulating or solving problems (Simon, 1981; Simon & Newell, 1971). Lev Landa (Landa, 1987; Landa & Kopstein, 1974, 1976; Main, 1987) created procedures (a) to uncover actual procedures used by experts—including logical steps that experts have described and also other cognitive operations that they could not describe, and (b) for teaching novices, effectively and efficiently, how to emulate experts in complex real world problem solving contexts. Those procedures and other ideas from Landa, Newell, and Simon proved to be helpful in designing functional relevance guidelines for teachers and students. Other aspects of functional relevance were influenced by the work

of educational technology leaders and various psychology learning theorists, including the views of scholars about the creation, modification, and use of theories and research findings (Azar, 1999; Oswald, 2002; Snelbecker, 1974, 1985). Thus, functional relevance draws from and is based on a synthesis of observations and ideas from formal theories and research findings, as well as common sense psychology and other so-called real world learning, ideas, and perspectives.

When Design Lacks Functional Relevance

Our premise is that potentially helpful technology applications will foster or support meaningful educational achievement successfully only in the degree to which they are clearly relevant for how students and teachers function. This requires having such helpful resources perceived, respectively, by students and teachers, as being functionally relevant for them in their particular context. Functional relevance overcomes frustration and anxiety, two human emotions that frequently accompany use of technology. We now need to recognize briefly some inherent, potentially problematic, attributes of technology before addressing ways to maximize learning benefits from technology.

It is a mistake to assume that the frustrations encountered by users in the aforementioned technology projects are a thing of the past. There are unending streams of examples about the frustrations people endure when trying to use technology resources. A June 16, 2004 *PC Magazine* article, entitled *Help Us Define PC Ease of Use*, depicted a PC as behaving like a stubborn child, including being obstinate and hard to figure out, much too often taking even simple tasks consume too much time. Also criticized were too frequent occurrences of poor design, inherent incompatibilities, and having things not working the way they should. Advertisements and articles in major IT industry publications (e.g., the June 28, 2004 issue of *ComputerWorld*) contain requests such as, “Can’t

there be a machine that adapts to my business, not the other way around?” More recently some IT industry publications have been proposing that an “IT attitude” (or, “IT” emphasis) should be discarded in favor of focusing on ways in which IT resources can enhance business, professional, or personal productivity. Each of these comments reflects a condition in which technology is *not* functioning in a manner that is recognized by users as being relevant for them. All too often, it seems intended end-users tend to judge that technology resources or ideas offered are so markedly different from their perspective that any benefit from such ideas would be too costly in time, frustration, or effort that they are judged as being simply *not* worth the effort needed to learn and use them.

Unfortunately, one source of frustration stems partly from inherent attributes of modern-day technologies, which constitutes strengths as well as frustration-laden weaknesses. These inherent aspects of technology resources include, but may not be limited to, the following: (a) complex software that can deal with complicated processes, and (b) general purpose software that can be modified for a variety of purposes. These attributes make it difficult for developers to know how and when software may malfunction. For example, once we know that a board can support 210 pounds we also know that the board can support objects weighing less than 210 pounds. Unfortunately, the same *may not* be true for many technology resources. Even if we know that software can handle complicated tasks, we cannot safely say that this software can separately handle all simpler tasks. That gap could exist even when those same simple tasks are being addressed successfully in the process of handling more complicated tasks. An example would be to create a universal design compatible website. It is believed that by adding technical features such as ALT tags for web graphics and enclosed captions for streaming videos, we are able to create a website that would address the needs for all people. Such an assumption may not be warranted. Even though the website is designed

based on the principles of universal design, it still lacks the capability to address the specific needs for all people who use the website.

A second source of frustration is the apparent tendency of designers to forget or ignore the fact that the main goal of online instruction is to facilitate learning that will be beneficial for learners. Instead, too often, designers apparently see a project from their own perspective, perhaps focusing on the technological “bells and whistles” and not through the eyes of the users who want to achieve or complete successfully a particular task. Some designers seem to think that their real goal is to convince others that only the best technology and technical details have been incorporated in their online instruction. It is very easy for online designers to get excited about some new gadget, device, or technology with many new features. Designers and developers of online instruction must be extremely cautious and sensitive about the selection and deployment of appropriate online instruction resources and become aware of the design related issues in online learning. Studies have shown that educators and designers tend to focus more on the technical aspects than the relevant functions in online learning (Baer, 2000; Carr, 2000; Tu & McIsaac, 2002). For example, many online instructional designers are fascinated by the nonlinear, associative nature of the Web and assume that learning will occur when such features are built into instructional Websites. However, physical connection between concepts in online courses does not necessarily guarantee the types of cognitive connections that occur during learning. According to Perkins (1990), “... ‘Connections’ is an effort to try to confront the need for conceptual understanding of subject matter on one hand and the need for general thinking skills on the other” (p. 53). Oftentimes, designers are overly concerned with the physical aspects of a connection, that is, how many links are needed and where to insert them, and so forth, leaving little room for examining the cognitive connections that are needed to support learning.

Some technology designers, developers, and vendors seem to misunderstand why technology resources are not readily usable. That reaction is evident each time designers assert that the solution to end-user problems is to make the software simpler (less capable) or watered down (i.e., providing less information rather than providing the valuable information more clearly). Instead, the designers should be trying to find out how their technology resources, whether intended for experts or novices, can be relevant to the ways that their target group functions. This means that the added value of the online learning for the user’s productivity or other aspects of work is effectively and explicitly provided. Adding value or getting a return on one’s investment (ROI)—time as well as monetary, personal, or business investment—is routinely expected by end-users, (but not necessarily recognized by designers) much of the time in business and professional contexts. Recognizing the perspectives of targeted end-users—during needs assessment and identification of purposes for the instruction and throughout the development process and follow-up evaluations—rather than depending so much on how designers perceive things is very important. Involvement of potential end-users can benefit the ultimate end—and also can help improve the productivity and positive impact of applications designers and developers in online learning.

What is needed is to have designers of online learning focus more on the learning benefits that can be derived from online learning, rather than only or mainly on the subject matter and technical aspects of the technology resources. Of course, all three of these plus practical and other matters must be considered. Online resources should be designed so that they provide students with learning experiences of relevance to the ways that they function in their educational program, personal lives, and/or work.

In the next sections we will offer some examples of how a functional relevance perspective can be useful in addressing online learning instruction

issues and problems. We'll offer some suggestions from a functional relevance standpoint regarding three online learning matters: theoretical orientation, social presence, and learner characteristics.

Functional Relevance and Design

Functional relevance is proposed here as an approach that can help improve and enhance the quality of online instruction. Although functional relevance can *not* be expected to solve all online instructional design problems, it can help the designer make decisions about students' likely reactions to online instruction and thus possibly avoid some problems. Here are some general guidelines to consider:

1. Before starting any design or development activities, get as much information as is feasible about the nature and attributes of learning that is desired and likely to be successful.
2. In addition to discerning what instructors, subject matter experts, and administrators consider to be important attributes and learning outcomes of the online instruction, also get the views and expectations of people who are presumed to be potential students. Where feasible, also be attentive to ideas from students who completed previous relevant instruction.
3. Online instruction quite commonly involves potential students who are not in the same geographical area. However, to the fullest extent that is feasible, seek information from those potential students. Identify similarities as well as differences among those students and note patterns that may have design implications. Use technology resources to communicate with geographically remote potential students.
4. Do *not* wait until you have set the final design of the instruction before getting potential students' views. Instead, as much as

possible, have representatives of potential students somehow involved in providing relevant ideas prior to, during, and after the actual design and development of the online instruction. Be especially attentive to their views and expectations, concerns they may have, and any special accommodations or other issues that might impact on their access to and active participation in the online instruction.

5. As you should do regarding your reactions to ideas from theories, professionals, and other resources, consider the ideas you gain from potential students in the context of all other ideas you're using to design and develop the online instruction.

Theoretical Orientation

One rather common question occurs when designing online instruction: Should a particular theory guide design and implementation? Many different views have been expressed, ranging from those who think that theories are quite useful to those who think that theories are not helpful because they do not take into account practical realities of online learning contexts. Based on our functional relevance standpoint, we offer ideas for you to consider, but we will not pretend that there is one correct position about the use of theories. In brief, we will propose that it could be appropriate to use theories in some contexts more than other contexts or with some facets of instruction without relying on theories for other facets. Theories, research findings, practical information, and so-called wisdom of the profession (e.g., knowing previous customary ways of doing things) all can be very helpful in organizing online instructional design plans. For example, theories can stimulate or facilitate insights and variations in ways to think about online learning.

At the core of instructional theories are their respective epistemologies (or, philosophies about the nature of knowledge). Various frameworks

have been used to describe how respective theories compare regarding epistemology, with some people suggesting that they might be both complementary and competitive while others contend that there exists a continuum from objectivist to constructivist views. The objectivist perspective is that knowledge is observable and measurable. Instructional theories based on this assumption tend to be prescriptive, that is, the theory specifies particular strategies to help the instructor transmit knowledge to the novice learner and strategies that aid the learner in acquiring this knowledge. The assumption of constructivism is that knowledge is the making of meaning about a phenomenon and this meaning-making involves either personal or social agreement. The constructivist approach to instruction uses strategies such as collaboration, authentic context, and diverse perspectives to aid the learner's understanding (Bednar, et al., 1992; Cronin, 1997; Jonassen, 1999; Wilson, Jonassen, & Cole, 1993).

In a sense, we need to consider both the potential value that we might derive from theories and research findings and any costs (time, frustration, incompatibility) involved—particularly any costs that may be imposed on our student end-users. We should not do so simply to proclaim that our design is based on good theory. Using good theory can obviously be a good idea when it is reasonably clear that theories we have selected enhance learning. But, theories collectively cannot address all aspects and attributes that exist in practical situations. Functional relevance can serve as a framework within which to decide whether particular theories or research findings support the design and development of training for the types of skills desired for a particular situation.

One can make the case that applying learning theories to online design after judicious consideration of costs and benefits constitutes a value-added decision. For example, by identifying constructivism with online design, we recognize that constructivist approach in teaching fits with the unique characteristics of online learning en-

vironments which promote positive and active student learning. Head, Lockee, and Oliver (2002) described the facilitating functions of the nonlinear, associative structure of the Web in promoting learners' knowledge association. According to Miller and Miller (1999, 2000), the nonlinear, associative structure can be used to provide more accurate representations of experts' knowledge structures or to permit learners to build their own representations of knowledge (Ayersman, 1995; Wilson & Jonassen, 1989; Yang, 1996).

Discussions about the relative merits of different theories, and sharply different views about whether instruction should or should not be driven by theories, have occupied the attention and interest of researchers and practitioners. Thus, this chapter can not address all issues involved in such matters. However, from the standpoint of functional relevance, we propose that one or more theories should be applied to online instruction depending on the extent to which such theories offer some added value for the online instruction of interest. It may be possible, and even desirable in some situations, to apply so-called competitive approaches in our online instruction.

Previously, in this chapter, it was acknowledged that some designers consider objectivist and constructivist approaches to be incompatible with each other, often asserting that you have to choose one approach or the other. But, with careful attention to overall design requirements, it is plausible that certain aspects of our online instruction could benefit from applying objectivist procedures and other aspects could benefit from constructivist procedures. This can be accomplished successfully by observing that different components of online instruction can be identified and that those components may have contrasting design requirements. Moreover, it seems unlikely that any one theory will address all aspects of our instruction. A functional relevance perspective could be helpful for designers in identifying and making decisions about such responsibilities as the following: (a) make reasonably certain that

procedures within each component make sense to students, (b) provide students with transition instructions and support so that they can move successfully from one component to another, and (c) help instructors and students to recognize how the various online instruction components “fit together” and collectively have been designed to enable students to attain the respective purposes, goals, and benefits to be derived from that online instruction.

Social Presence

Social presence is an important concept for on-line instruction, but too often its significance and impact seem to be ignored or minimized. *Social presence* refers to the extent to which one feels that certain other persons are either both physically and psychologically present or feels the sensation of their being “socially present,” even though said persons are not with us physically. Connectedness is one term that sometimes is used in discussions about social presence. Think for a moment when you were in the same room with another person but the other person seemed to be oblivious to the fact that you were in that same room. That is the kind of situation where you most likely felt that you were not at all connected with this person, and you may even have wondered whether there was any social presence between you and this person. If this person is an instructor of a face-to-face classroom course you are taking, your feelings probably would depend on the size of the class or on other factors. As one member of a class with several hundred students you might have mixed feelings, but as one of only five students, you probably would not feel very happy.

How we perceive other people, and how they perceive us, has been of interest in psychology and other disciplines for at least half a century. Earlier terms for this area include personal perception, interpersonal perception, social perception, and other terms related to communications theory. Some of the earlier work focused on implications

when people do not have accurate perceptions of each other. However, for several decades it has been recognized that how one perceives another person may be more important than whether or not such a perception is accurate. For example, Sundland (1960) found that patients’ outcomes were correlated with their person-perceptions of their psychotherapists along relevant dimensions; however, the extent to which those person-perceptions were accurate was not correlated with their outcome. Snelbecker (1967) found that college students’ perceptions of psychotherapists in a laboratory analog were correlated with their perceptions of two therapists. Both of those studies used Barrett-Leonard’s (1959) idea of Relationship, which was based on Carl Rogers’ theory concerning person-perceptions of patients.

Online instruction designers might want to examine contemporary instruments and research findings both to inform their practice. At least with instructional design of some online courses, it may be important for designers to examine the extent to which students’ views regarding social presence could help identify what students expect with regard to social presence. It is important to note that the studies previously mentioned were conducted in psychotherapy relationships decades ago. However, lessons from studies of those relationships do raise some possibilities today. First, how students perceive social presence matters in online instruction may be important, no matter how accurate they are. Second, it seems plausible that online students’ personal attributes might influence their perceptions and feelings regarding social presence and also influence designers’ plans for creating instruction that is functionally relevant.

Although the term social presence is not always used, there is growing concern that increasing use of automated resources generally in society might be having an adverse impact, partly because of reduced interactions with an actual person. This concern has been expressed about various instances in society today where people are using technology resources as a replacement of person-

to-person interactions. For example, James (2006) suggested that the automated systems that make banking activities readily available as needed may actually be creating emotionally detached customers. One recent major study (Katz, 2006) suggests that, despite their proficiency with technology, today's college students do not necessarily prefer to have more than moderate levels of technology in their college courses. More directly related to online instruction, Reio and Crim (2006) expressed their concern about the lack of personal connection among learners while engaging in asynchronous online learning. They pointed out that the online educators were overly enthusiastic about the features of asynchronous learning and overlooked the factor of social presence, which may result in overall learner dissatisfaction with online learning.

These contemporary observations, along with earlier views, suggest that there may be insufficient attention given to social presence (Baer, 2000; Hill, Raven, & Han, 2002). Hill et al., pointed out that "explanation for high dropout rates and dissatisfaction with distance delivered courses may relate to a lack of a perception of community in courses" (p. 384). Tu and McIsaac (2002) emphasized that it is essential to explore the social presence in online classes, the relationship between media and the social-cultural construction of knowledge. Many commercial Web systems like Web CT and Blackboard include built-in tools to accommodate and facilitate education-related communication—such as synchronous and asynchronous online chat rooms. However, many online courses continue to create "cyber cubicles," where learners are separated from each other and where the level of communication is limited to "logon" without meaningful social communication among learners. Good quality effective online instruction involves more than introducing cutting edge technology. It involves building functionally relevant components such as those that address social presence issues, meaningful communication, and so forth, to create a

positive and socially supportive environment for learning. A recent effort in this direction is Yang's (2007) STEP model, which includes scaffolding, transaction, evaluation, and presentation. The STEP model underscores the importance of establishing social presence in online learning. It reflects the effort of designers and practitioners to build functionally relevant components in online learning by enhancing learner self-awareness in online learning environment, facilitating social comfort of expressing and sensing affect, and providing effective social navigation.

Learner Characteristics

Students who engage in online instruction often come with different motivational demands. Carr (2000) pointed out that some students attended the online courses because of external motivation such as job promotion, while others attended the online courses for internal motivational reasons such as self-improvement. Thus, online instructional design should attend to both external and internal motivation demands. Some students enrolled in online courses became very frustrated because the courses were poorly designed and failed to address students' internal and external motivational demands associated with the online courses (Carr, 2000; Hill et al., 2002). A design issue in online learning is how to address the differing motivational demands that each learner brings to a learning experience.

In most real life situations, people may share a common interest in some event (e.g., an observation or activity) while concurrently having considerable differences in the perspective they bring to that event. Despite such common interest, it does not necessarily mean that all of these people will have similar perspectives about that particular event. This same co-occurrence of shared common interest along with diverse perspectives can involve (a) preparing good online instruction, (b) writing a good book chapter, (c) designing good research studies, (d) practical application of some

theory, or (e) even attending a sporting event. Thus it is not unreasonable to expect diversity and common interests among students who are intended recipients of the online instruction.

Similarly, students enrolled in online courses or some role in making decisions about online learning can be expected to share some common interest but also have co-occurring perspectives with very different views about what constitutes quality of online learning. In addition to the intended beneficiaries of this online instruction, other people with some interest in and views about the topics addressed in the online instruction could include: the authors and designers of the topics, instructors or employers of potential recipients, and various theorists or researchers who focus on online learning.

We suggest that, of all these potential perspectives, too often the intended beneficiaries' perspectives about the online instruction are not adequately considered. More often, it seems that the designers' and other professionals' perspectives predominate. This is not surprising because designers and developers are so busy dealing with their online instruction responsibilities and pressures—typically also while wondering about potential critics' views about the technical standards that are supposed to be met in good quality online instruction.

Why is it important to place the emphasis on clients' or learners' perspectives (instead of mainly designers' perspectives)? Simply stated, if the needs and expectations of those intended beneficiaries are not met in a reasonable manner, it is quite likely that this online instruction will be judged to be either deficient or even a failure. Functional relevance suggests that we need to maintain our focus on the intended beneficiaries of the online instruction from inception of the idea, iterative tests and revisions of the online instruction. That includes not only design and development processes but also follow-up evaluations and implications for making any changes in this present offering or in future online instruction.

In recent years, certain commercial design firms regularly involve intended learner groups or other targeted end-users throughout the design and development process. Although such firms recognize that additional costs are involved, this practice is accepted because it can help ensure that online learning will have higher prospects for success. A key question is: By what cost-effective ways can we obtain reasonably valid information about potential students' characteristics? As a start, let us acknowledge that designers should not be expected to recognize all possible motivations and expectations of students. Available funds, time-frames, and administrative requirements need to be considered when making design plans. Although a first inclination might be to survey potential students, it is usually best to start with pertinent existing information. Such available information could be valuable in designing, conducting, and analyzing surveys of potential students.

In established institutions with ongoing classroom courses and online courses, some useful information may be readily available. Reviews of literature about distance learning for the particular subject matter area may yield some other helpful insights about matters that should be considered for our online course. In the case of a new course, at many institutions this information about students would be required and carefully reviewed before the new course proposal was approved. Thus, it would be very important to obtain all pertinent documents about the new online course. When an online course is replacing or extending an established classroom course, helpful ideas could be obtained from current students or accessible students who previously completed this or similar courses.

Along with these ways for seeking information about learner characteristics, at some point it may be advisable to use a combination of procedures for collecting new information. One approach is to alternate between using interviews or focus groups and surveys. For example, one possibility would be this: (a) after having reviewed available

information, formulate a series of questions and interview or hold group discussions with potential students. A goal here would be to ensure that we're asking reasonably appropriate questions. These interviews and focus group discussions could help guide identification and formatting of appropriate questions; (b) conduct surveys (in class, mailed surveys, or online surveys) of potential students; (c) conduct interviews or focus groups to help clarify and interpret survey results as well as to get answers to questions that only emerged during or after the surveys were conducted.

This information about potential students can be compared and integrated with ideas expressed by the experts. This should result in making decisions so that our resulting online instruction can be more relevant to how our intended online students function.

CONCLUSION

The chapter calls attention to an important aspect in the design of online instruction: that online instructional process will more likely be effective if and when they fit with and are perceived by students as being functionally relevant for their education, work, or other personal contexts. Designers typically must cope with many different—and sometimes competing—responsibilities. They must address subject matter requirements and expected outcomes, provide effective and efficient means for attaining designated educational standards, make professional decisions about cost-effective means for using technology resources, and comply with numerous other conceptual, administrative and practical matters. However, it is a key thesis of this chapter that those efforts may not be so successful if intended students ultimately do not recognize that the resultant online instruction is consistent with their needs and expectations.

It is suggested that unnecessary deficits may exist in online instruction causing students to have unanticipated problems that may cause serious

downtime in learning. For example, problems may occur when technology resource instructions are confusing or not clear, when incompatibilities exist between technology resource requirements and students' available equipment or software, with subject matter content that is different from what students had expected, or when students are not familiar with some particular pedagogical procedures.

The concept of functional relevance focuses on learners' perspectives and perceptions as to whether instruction might be relevant for and fit with the way(s) that students function in their work, studies, personal lives, and so forth. It is proposed that teachers, trainers, and other educators become aware of the functional relevance aspect of their designs and programs. Doing so could help improve and enhance the design and development of successful online instruction. In particular, such efforts can lead to online learning outcomes that intended learners will view as being more relevant to their prior knowledge and as being compatible with they function in their studies, work and personal lives. Those efforts may facilitate students' application and extension of their online learning.

FUTURE RESEARCH DIRECTIONS

Two general directions can enhance our ability to design and provide better online learning: (1) study and classify the nature of respective approaches to designing online learning, (2) create ways to incorporate learners' perspectives throughout the design-development-dissemination process.

1. For good reasons, novices initially are encouraged to focus on only one or a few approaches because trying to learn too many different approaches could be counterproductive. But, with greater knowledge and experience, they will learn about "new" approaches and wonder if some might be

preferable in certain situations. Snelbecker (1999) suggested that facilitating such advanced proficiency in design might benefit from psychotherapists' experiences with their Society for the Exploration of Psychotherapy Integration (SEPI). SEPI helps psychotherapists learn psychotherapy approaches' strengths, weaknesses, and situations where each can be especially helpful. A SEPI-type group could help instructional designers study and discuss merits of design approaches.

2. To create functionally relevant online learning, it is important that intended learners' perspectives be considered throughout the design-development process — from initial ideas through design-development-evaluation-revision, and during follow-up studies in various settings.

Of course, some of this work already is included in most (if not all) instructional design-development approaches, such as doing needs assessments of intended students, and getting reactions of students at various stages. Research could help clarify cost-effective ways (a) for identifying the nature of potential constituent groups, (b) detecting the range of views within each group, (c) discerning similarities and differences in perspectives of constituent groups, and (d) most importantly, research especially is needed to identify cost-effective means whereby we can integrate these groups' perspectives *throughout* the instructional design-development process.

Snelbecker, Miller, and Zheng (2004 & 2006) have reported ways that two commercial design groups began incorporating intended end-users' perspectives throughout the design process from conception of products and continuing throughout development and release of the new products. For example, end-users participate along with graphic designers, information scientists, and other professionals who traditionally designed and

developed such products and services. Instead of waiting until products are ready for "Beta testing" the trend now for some design companies is to have end-users' views made a part of the entire design-development process.

There is need for studies on: identifying the kinds of people who might benefit from proposed online learning, obtaining and understanding the perspectives of constituent groups, clarifying similarities/differences among constituent groups, and indicating ways potential students' perspectives can be *synthesized* with information more conventionally used during design-development of online instruction.

There is long-term and continuing need for this research. Snelbecker (1974) described the need to synthesize information from various resources to design effective instruction, and proposed the importance of focusing on practical matters along with theory. Milsum (1966) explained: "When the biologist, social scientist, and indeed natural scientist collaborate with the engineer on these large new system's problems, their classical roles as analyzers of existing systems in contrast to the engineer's role as the synthesizer of previously non-existing 'hardware' systems needs reappraisal" (Milsum, 1966, p. vii).

Chapter 2.11

Self-Regulated Learning: Issues and Challenges for Initial Teacher Training

Manuela Delfino

Institute for Educational Technology - Italian National Research Council, Italy

Donatella Persico

Institute for Educational Technology - Italian National Research Council, Italy

ABSTRACT

This chapter assumes the importance of developing Self-Regulated Learning (SRL) competences in students in order to cope with the challenges of today's and tomorrow's society. To achieve this, it is claimed that it is crucial to train teachers who are aware of what SRL is and are able to support their students in developing these abilities. This chapter proposes examples drawn from a course in Educational Technology where SRL competence has been promoted through reflection on cognitive, meta-cognitive, emotional and motivational aspects of learning, as well as through modelling teaching practices that tend to shift the locus of control from trainers to trainees.

DOI: 10.4018/978-1-60960-503-2.ch200

INTRODUCTION

Teaching is a very hard job. It has always been hard, but it has become even more difficult and crucial in the so called knowledge society, where the major assets of its citizens do not lie in the amount of information and skills they possess, but in their ability to acquire knowledge and competence and in the way they can make use of both.

In this view, the aim of education is not to make learners know all there is to know about a given subject, but rather to make them able to build, enrich and nurture their own knowledge. Hence, what teachers should do is provide their students with some very basic and carefully chosen notions and concepts and with the ability, the will, the conceptual and technological tools needed to elaborate on them. This is why teach-

ing is so difficult: because it is about empowering people, putting them in charge of their learning and teaching them how to control it by making them aware of how to choose the best learning strategies. But there is even more. Today we do not want to leave anybody behind, neither do we wish to mortify talents or betray excellence. This entails achieving personalised learning, thereby giving each learner the chance to fully exploit their potential. And this makes teaching even more difficult, in that it requires decisions about how to foster learning for each student, by adapting, controlling and assessing the effectiveness of the teaching and learning process.

However, there is some good news: learners can, and should, help in the realization of this process. They can, and should, become aware of their learning styles, learn to evaluate their results, exploit ICT to acquire, evaluate and elaborate knowledge. Teachers will have to provide scaffolds for learning by modelling how to carry out authentic tasks, by offering situated learning opportunities; by providing chances for learners to collaborate and therefore support each other in this process.

But how can we train teachers for such a hard job?

According to Paris and Winograd (2001) the best way is by using, with trainee teachers, the same approach we expect them to use with their students. They claim that it is a frequent paradox that teachers are often trained with methods that contradict the principles they are being taught. Teachers naturally tend to replicate the same teaching approach they have experienced. This accounts for their resistance to the educational use of technology, their tendency to engage in perfunctory curriculum delivery, their focus on contents rather than on learning methods.

In this paper, we will use the case of a course in Educational Technology run by the Institute for Educational Technology of the Italian National Research Council for the Post-Graduate School

in Secondary Teaching of the University of Genoa to discuss and exemplify the following points:

- If the aim is to train teachers about Educational Technology, then Educational Technology must be used to do so;
- It is impossible to teach future teachers all there is to know about Educational Technology: a much more sensible approach is to identify some basic concepts and to lay the bases for further autonomous professional development;
- Awareness about the importance of self-regulation in the teaching profession should also be promoted, because instructional design in education cannot be reduced to rigid decision making procedures;
- If teachers must empower their students and make them able to become better and more autonomous learners, they will first need to learn to self regulate their own learning. To this end, they should receive explicit training on what self-regulated learning is, how it can be promoted and what its relationships with the use of Educational Technology and with the most popular learning theories are.

THEORETICAL FRAMEWORK

The theoretical framework of this chapter lies at the crossroads between two fields: the psychological theories of Self-Regulated Learning (SRL) and the interdisciplinary sector of Networked Learning (NL).

When we talk about the importance of developing a learner's ability to successfully cope with the challenges of today's and tomorrow's society, we acknowledge that this ability involves cognitive, meta-cognitive, emotional and motivational aspects. The theory of SRL subsumes research on these aspects in one coherent construct emphasising

ing the interplay taking place among them when learning is the focus.

NL, on the other hand, is the term we will use to refer to learning on the Web and with the Web, that is by using both its online resources and its interpersonal communication facilities. In the following we will set the scene for this paper by discussing the respective contributions of research in SRL and NL to the field of teacher training. We will also focus on the interplay between these two fields, with emphasis on those aspects that are relevant to the aim of the paper, that is, advocate the importance of SRL in teacher training, both as an aim and as a content, and provide examples of how theory can be bridged into praxis, as well as of the role that can be played by NL in this process.

Self-Regulated Teachers for Self-Regulated Learners

SRL takes place when learners are in full control of their own learning, that is they plan, monitor and evaluate their own learning processes, from a cognitive, meta-cognitive, emotional and motivational point of view (Zimmerman & Schunk, 2001; Boekaerts, Pintrich & Zeidner, 2000; Schunk & Zimmerman, 1998). In principle, this entails learners being able to set their own learning objectives and pursue them by choosing optimal learning strategies and suitable media, according to their learning styles and pre-existing knowledge. They will also be able to regulate the whole process, possibly re-adjusting their own decisions based on effective self-evaluation strategies.

SRL is therefore a very desirable set of competences for students who are to become autonomous citizens, and educators should pursue its development.

SRL competences develop through practice, and teachers can support such development by modelling effective behaviour and by planning the teaching and learning process in such a way that SRL strategies are increasingly adopted by students while teachers' support decreases accord-

ing to scaffolding and fading techniques (Collins, Brown & Newman, 1989).

Obviously, teacher training programmes should aim to raise awareness of the need to nurture students SRL and to develop such competences among teachers. The case of pre-service teacher training is particularly interesting and critical because trainees' SRL competences may be quite well developed in connection with their own disciplines, but some important components are often lacking: the awareness of the importance of supporting their development among their students, the teaching skills needed to do so and the competences required to self-regulate their own learning in a technology rich environment. While the first two points should be among the aims of any teacher training programme, the third point is one of the primary aims of teacher training in Educational Technology.

Networked Learning and Teacher Training

NL is used here to identify "the use of internet-based information and communication technologies to promote collaborative and co-operative connections: between one learner and other learners; between learners and tutors; between a learning community and its learning resources, so that participants can extend and develop their understanding and capabilities in ways that are important to them, and over which they have significant control" (de Laat, Lally, Simons & Wenger, 2006).

According to the aforementioned definition, NL comprises both learning through Information Problem Solving tasks and Computer-Supported Collaborative Learning (CSCL). The distinction between these two areas is quite blurred, the difference lying mainly in the fact that the first appears to focus more on use of the Web and its online resources to retrieve, evaluate and reuse information in a critical way (Brand-Gruwel & Gerjets, 2008; Walraven, Brand-Gruwel &

Boshuizen, 2008), while the second is mostly inspired by socio-constructivist views of learning, and concerns the way people learn together with the help of computers (Stahl, Koschmann & Suthers, 2006; Koschmann, Hall & Miyake, 2002; Koschmann, 1996). CSCL enables, on the one hand, distance learning students to participate in collective activities and achieve shared goals, and, on the other hand, tutors and teachers to effectively scaffold and support students in learning together (Strijbos, Kirschner & Martens, 2004). In this field, written asynchronous interactions are central, since they have the potential to activate collaboration and meta-cognitive processes.

In spite of the strong resistance initially shown by trainees (Wood, Mueller, Willoughby, Specht & Deyoung, 2005; Uzunboylu, 2007), NL is being increasingly used in teacher training, and there are many reasons for this. One is that the large cohorts of trainee teachers are often characterised by very different backgrounds and expectations, so they need to be addressed with a very flexible and personalised approach, which cannot easily be done face-to-face, let alone in a transmissive way. Another is that teacher training is mostly about problem solving in instructional design, and therefore requires reflective practice and the possibility of looking at problems from several perspectives, which is better done through discussion among peers and with experts (Gray, Ryan & Coulon, 2004; da Ponte, Oliveira, Varandas, Oliveira & Fonseca, 2007).

The Interplay between SRL and NL in Teacher Training

SRL in NL contexts imposes demands that are peculiar to this kind of environment (Whipp & Chiarelli, 2004) and have to do with the ability to strike a balance between individual and social aspects of knowledge construction. For example, in CSCL learners should be pro-active and goal orientated without disregarding the importance of peer contribution to the discussion, they should

be able to control emotions but also disclose them to contribute to the formation of a pleasant social climate, they should seek support and feedback but also provide it when needed and they should negotiate decisions and share achievements.

Networked learners, especially novices, should not be left alone in such a powerful but complex and unfamiliar world. To this end, the figure of the online tutor is of crucial importance. The roles of the online tutor have been widely investigated (de Laat, Lally, Lipponen & Simons, 2007; Conrad, 2004; Salmon, 2004; Berge & Collins, 1996) and include, among others: providing guidance and support to participants, especially at the beginning of a new learning experience; facilitating access to the learning environment and providing help with its use; mediating between the instructional design decisions and the spontaneous dynamics of the learning group; helping individuals to work collaboratively towards the achievement of common goals; stimulating discussion on specific contents; promoting cohesion and favouring a positive social climate among students.

As Goodyear, de Laat and Lally (2006) put it, learners, on their side, have to (re)learn “to become active learners, need time to develop confidence to act as constructive learners, and exercise autonomy. [...] Students also need to act as a community, where they take on active responsibility for educational processes as well as managing cohesion, well-being, trust, emotion, spirit and motivation within the group” (p. 216).

The design, investigation and evaluation of NL environments as well as the way they support the development of SRL among trainees can be made more systematic if we refer to an adaptation (Delfino, Manca & Persico, 2007) of the Community of Inquiry model (Garrison, Anderson & Archer, 2000). The original, well known model was based on three dimensions (i.e., the *cognitive*, *social* and *teaching presence*): through these components the model aims to provide a way to understand and analyse the intertwining of several factors in a Community of Inquiry. Enriched

by a fourth element, *meta-cognition*, the model was used to design our courses in Educational Technology. The four components of the learning experience - the cognitive, the social, the teaching and the meta-cognitive – also provide a structure to discuss, in this paper, the choices made by the course designers. In particular, we will discuss the decisions made about the learning objectives, the contents and learning styles (the cognitive dimension); the course structure and the teaching/learning strategies adopted (the teaching dimension); the participants' interactions and the emotional/motivational factors involved in building the online community (the social dimension); the reflection on the learning process and on its effects (the meta-cognitive dimension).

INSTRUCTIONAL DESIGN CHOICES TO TRAIN TEACHERS ABOUT EDUCATIONAL TECHNOLOGY AND SRL

The course in Educational Technology was addressed to trainee teachers and run yearly from 2001 to 2006, involving a total of more than 600 trainees. The objective of the course was promoting the development of educational design competences, with special focus on the evaluation and selection of learning strategies, techniques, tools, and on the infusion of Educational Technology in the school context. Even though some of the contextual constraints remained the same every year (e.g., number of participants; short duration of the course; limited amount of resources available; great differences among trainees as regards expectations, interests and background), the course design changed according to the changing needs and features of the target population, and to the experience gained during the previous versions (Delfino & Persico, 2007). For this reason, in the following, we will refer to the different “versions” of the course, meaning the various formats it took in the six years of delivery.

The instructional design choices made for this course are discussed in the next sections, with particular reference to those aimed at the development of SRL and collaborative abilities. We will start with our view on how the subject can be dealt with, bearing in mind that it is a large and fast moving field. Then we summarise the delivery modes adopted in the various versions of the course. The subsequent sections are devoted to the cognitive, teaching, social and meta-cognitive components according to which the course was designed.

Training Teachers in Educational Technology

“Educational Technology is the study and ethical practice of facilitating learning and improving performance by creating, using and managing appropriate technological processes and resources” (AECT, 2004, p. 3). This is the latest definition of *Educational Technology* diffused by the Association for Educational Communications and Technology (AECT). It emphasizes different aspects of educational practice (through the verbs *facilitating, improving, creating, using, managing*) without disregarding the role of theory and research in the field (concepts summarized in the word *study*).

The double nature of this subject entails that the course programme should strike a balance between opportunities for the development of operative abilities (i.e., knowing how to do things, using and managing processes and resources) and for reflective practice, performance improvement and competence building. The key role of practice in Educational Technology is emphasized in all versions of our course by including extensive hands-on experience in their programmes. This choice also derived from the belief that Educational Technology cannot be taught without using Educational Technology, because future teachers should be trained with methods and tools that are

similar to those they are expected to use with their own students.

Furthermore, to develop know-how about what kinds of technology suit different contexts, trainee teachers should be given the opportunity to become acquainted with different forms of technology and to reflect on their educational limits and potentials (Cox, Preston & Cox, 1999; Pope, Hare & Howard, 2002; Brush, Glazewski, Rutowski, Berg, Stromfors, Van-Nest, Stock & Sutton, 2003; Dawson, Pringle & Adams, 2003; Ertmer, 2003). This can be done by emphasising the importance and the nature of the educational processes triggered by technology and by focusing on methodological and educational aspects rather than analysing in detail specific tools, that are likely to become outdated in a short time.

Delivery Mode

In accordance with the earlier considerations, CSCL was included among the training methods of our course, for a number of reasons. Firstly, CSCL competences are highly valued for technology integration in schools. Secondly, collaborative forms of Computer-Mediated Communication (CMC) are capable of fundamentally reshaping teachers' professional development (Pachler & Daly, 2006) since they increase teachers' acquaintance with the different Web services and hopefully encourage their future participation in communities of practice, one of the most promising means of Teacher Professional Development (Fusco, Gehlbach & Schlager, 2000). Lastly, very few of our trainees had experienced CSCL before and they therefore needed to try it out first hand to become aware of the pros and cons of its use in education.

While the first version of the course, held in 2001, was entirely face-to-face, with lessons alternated with laboratory activities, from the second year the course included a distance learning component based on a socio-constructivist approach and therefore it relied heavily on task-based group

work. The distance learning component gained importance with time: in the second year it was an optional three-week online module; in the third and fourth years it was a ten-week online course that students could choose as an alternative to the face-to-face one; in the last two years there was no option but a blended course. The blended scheme chosen for the final versions of the course entailed, for the first time in the course history, that all students had to take part in online activities.

Distance communication among participants - students, tutors and experts - took place within a special configuration of the Centrinity First Class[®] CMC environment. Interactions were mostly asynchronous, though synchronous communication in the form of chat was occasionally used.

The Cognitive Dimension: Learning Objectives, Contents and Learning Styles

Instructional design techniques suggest that decisions concerning the learning objectives of a course, in an academic context, should derive from the learning needs and take into consideration both the features of the target population (size, age, motivation, prerequisites, etc.) and the requirements and constraints imposed by the context in which the training is to take place (times and settings, tools and resources available, etc.).

The nature of the subject matter also influences the design of the course. Educational Technology, in fact, is a wide and complex domain, hard to cover in short courses like the one in question. According to Issroff and Scanlon (2002), it includes a set of pedagogical and methodological skills needed for a competent use of the various strategies, techniques and media in teaching. It was therefore necessary to provide a general idea of the field and its contents, but also to identify some infeasible concepts to be dealt with in greater detail than others, posing the basis for subsequent autonomous learning.

When learners are adults, or graduates as in the case of our trainee teachers, it is desirable that they have a say in the overall objectives of the courses they take, even if their lack of competence in the domain might limit their ability to do so. In our case, to find a good balance between the institutional aims of the course and the students' expectations, interests and desires, we found it very useful to:

- Provide students with a course guide, sent by e-mail a few weeks before the beginning of the course and containing information about the course (its objectives, structure, contents, method and the assessment criteria). This helps students to plan their learning and arrange the environment;
- Monitor students' expectations towards the course and their previous knowledge/experience in the field of Educational Technology year by year, by using ad hoc questionnaires and informal interviews. This also helps students to become aware of their expectations, recollect ideas about previous learning experiences, and activate prior content knowledge;
- Devote some time, at the beginning of the course, to discuss these expectations and competences and negotiate the course objectives and approach with the students;
- Offer the trainees a number of options as to sub-objectives and topics to be dealt with, and differentiate the activities proposed (e.g., individual vs. group work; compulsory vs. optional; based on discussion and knowledge building vs. based on tasks; etc.), so as to give them the chance to identify those that best match their personal goals within the course general aims;
- Provide different ways to achieve similar or alternative learning objectives, so that learners can choose the learning strategies according to their favourite learning styles.

Nevertheless, some types of choices should not be left to the students at the beginning of the course but postponed to a later phase.

First of all, high level choices concerning learning objectives and contents require some competence on the subject, so they can only be made by people with previous knowledge of the domain. This does not mean that the students will never be able to make them but rather that they need to be gradually guided towards this aim. To this end, students can be supported through tools such as advance organisers in fully fledged online courses (McManus, 2000) or face-to-face sessions in blended courses. The role of these tools is to provide an overall picture of the content so that students can make informed choices as to what and how they would like to learn in more detail. This is particularly helpful when there is not enough time for the lecturer to completely cover a subject and the domain is a rapidly changing one. In the online versions of our course, the overall theoretical introduction was taken care of through readings and discussions moderated by competent tutors. In the blended versions, the face-to-face lectures provided the general picture of the topics covered in the online modules, while these served the purpose of carrying out in-depth analysis of one or more examples.

Secondly, choices regarding learning strategies, methods and tools require awareness of one's own favourite learning styles and of the pros and cons of each option. Among our trainee teachers, this awareness is unlikely to be well developed, at least in connection with technology use. However, since Educational Technology is the topic of the course, the ability to make informed choices in this respect is also one of the aims of the course. In particular, among the various possible methods, we wished them to appreciate the pros and cons of online collaboration. This is why we concluded that all our students should try online learning at least once, and specifically CSCL.

The Teaching Dimension: Course Structure, Social Structures, Tutors' Roles, Learning Evaluation

While deciding the activities to be carried out online, many decisions about the course structure, the social structures, the tutors' roles and the evaluation criteria must be taken, being aware of their reciprocal influences.

The balance between the institutional aims of the course, its method and the students' expectations, interests and desires can be achieved by giving the course a modular and flexible structure, where different modules pursue different objectives and students can choose which topics to investigate, with what methods, as well as how deeply they want to investigate them. While this is hardly feasible face-to-face, especially with a large audience, it can be done online, by proposing open learning tasks (i.e., tasks that can be further specified by the students themselves) and by splitting the whole cohort of students into small groups, working under the guidance of experienced tutors.

In our course, for three years, even the choice between the online and the face-to-face mode was left to the students. However, there are drawbacks concerning the management of such options. On the one hand, the more freedom of choice the students have, the more the design and the tutors should be flexible and considering the investment required to design learning activities, especially online, it is desirable to limit the effects of these fluctuations. On the other hand, the students' choices are not necessarily the best ones from the point of view of the learning outcomes (e.g., extrinsic motivation can prevail over intrinsic motivation, and the easiest option is likely to be chosen instead of one that is perhaps more promising but more demanding).

In addition, the balance between choice and imposition changed in time, during each course. The initial activities were, in fact, carefully planned and pre-defined: start date, end date, who does what, by when, with whom, were decisions taken

by the course designers. As the course progressed, though, more freedom was granted and the activity structure was more flexible. The learning materials changed too: during the scaffolding activities tutors provided students with analytical grids and detailed worksheets, aiming to show a possible way to accomplish tasks, as the course progressed, however, they granted learners more and more responsibility, letting them decide how to organize their documents and what to produce in the reification phase.

Since our students had to learn how to handle group dynamics and to experiment their future teaching role, they were encouraged to practice different roles, and in particular to act as moderators and facilitators of online activities. This was achieved through role-play techniques where students were invited to take up various types of pro-active roles in a group, such as strongly characterised teachers (e.g., the technology enthusiast, the technology detractor, the bureaucrat, etc.) while discussing strengths and weaknesses of an online resource. Previous research seems to support the hypothesis that role playing fosters SRL fairly well, compared to other strategies (Dettori, Giannetti & Persico, 2005). However, it was felt that facilitation roles should be first modelled by the tutors before asking students to do the same.

Designing the teaching dimension also entails decisions aiming to define the social structure of the community, including the size and composition of groups as well as their reciprocal interactions. In order to obtain a lively exchange, heterogeneous groups of seven/eight people were established and different learning strategies were adopted in each module. Among these, an alternation of individual and group work was aimed to consolidate and assess specific topics dealt with during face-to-face sessions or covered in educational materials; dialogical, argumentative and peer review strategies were adopted to carry out critical analysis of different learning resources; the collaborative production of artefacts within the framework of the role-play activity was chosen

to achieve thorough understanding of different technology enhanced learning methods.

Most of these decisions were taken during the instructional design of the course, while others were left to the tutors. These were choices that had to be taken on the basis of the information that tutors constantly receive from the monitoring process. Examples of these decisions are those depending on the tutors' sensibility to the students' emotional and cognitive status. The consequence is a need for close orchestration between the work of the instructional designers and the tutors: a lack of understanding of the course design principles by the tutors might, in fact, endanger the whole design effort. It is no coincidence that in our courses the tutors often took part in the design of the course. In this way, not only did we take advantage of their invaluable contribution to the course set up, but we also made sure they really shared its design principles.

Finally, methods and criteria for learning evaluation should be mentioned. The central issue pertains the need to harmonize the socio-constructivist approach with the requirement of a summative evaluation of learning which is peculiar to the academic context. In the solution adopted for our courses the final summative evaluation took into consideration both qualitative and quantitative elements related to participation to each online activity (Anderson 2004a; Benigno & Trentin 2000). The criteria informing learning assessment were made clear from the beginning of the course. Although this point is a general principle in education, it is particularly important in online collaborative learning. Usually the quality and regularity of participation in the collaborative activities is assessed by the online tutors and informs the final assessment, together with the calibre of the products of the working groups. In our course, this type of assessment, based on the individual contribution to the group work process (MacDonald, 2003) was combined with a more traditional type of assessment, based on the production of an essay or an oral exam.

To some extent, we let students choose on what basis they wanted to be evaluated, hoping that this assumption of responsibility further fostered SRL. Forms of self-evaluation were encouraged as factors belonging to the meta-cognitive dimension but were not taken into account for summative evaluation.

The Social Dimension: Emotional and Motivational Factors

The social dimension "relates to the establishment of a supportive environment such that students feel the necessary degree of comfort and safety to express their ideas in a collaborative context" (Anderson, 2004b, p. 274). To reach this purpose, special attention was given, especially at the beginning of the course, to familiarization and socialization activities, considering them as crucial components, able (a) to increase the sense of togetherness among participants and, consequently, to increase the quality of learning and the achievement of instructional objectives (Rovai & Jordan, 2004; Aspden & Helm, 2004); (b) to establish a suitable social climate; and (c) to develop the emotional and motivational aspects of SRL (Delfino, Dettori & Persico, 2008). Although much of the responsibility concerning the regulation of social dynamics is entrusted to the tutors' sensibility, the importance of keeping in mind the social aspects when designing online courses should not be underestimated (Anderson & Elloumi, 2004).

The measures taken to foster social presence were deemed particularly important due to the high number of participants and to the fact that only some of the participants had met before the course. In particular, the sense of belonging developed in the blended versions of the course seemed stronger than in the online versions, perhaps because face-to-face meetings allowed its strengthening by acting on participants' identity, recognisability and participation. This was achieved, for example, by allowing identification of colleagues through

the use of badges, by inviting students to sit in the classroom according to areas corresponding to the online workgroups, etc.

The online activities usually started with some ice-breaking playful tasks, aimed at encouraging students to socialise or at least communicate with colleagues in order to get used to the environment and to familiarize with the basic rules of CMC. Furthermore, they were provided with a common Café area devoted to non-course related discussion. Sometimes, students used this area to talk freely about the course and its components.

An interesting way to encourage socialisation and expression of emotions is the use of metaphoric expressions and figurative language, as a stimulus to manifest and share the emotions involved in any new learning experience. A study based on transcript analysis (Delfino & Manca, 2007) revealed that many of our students made spontaneous use of metaphoric expressions to disclose their feelings and support peers in the emotional control of the learning experience. For this reason, the following years we decided to exploit the potential of metaphors more systematically by adopting an explicit spatial metaphor as a way to foster the students' sense of belonging to a community, to provide a framework for role assignment, identity, and responsibility and as an encouragement to manifest and share emotions (de Simone, Lou & Schmid, 2001). The activity proposed was based on the metaphor of navigation. Participants were invited to choose the kind of boat they wanted to use for their metaphorical voyage (the course), to say why they had chosen that particular kind of boat and their feelings and their expectations about the trip. Afterwards, each group of sailors had three weeks to negotiate and decide on a name for their boat, a motto and a symbol, thus practicing in a simple way methods of online collaboration. In the conclusive activity, they were required to say if they had changed their mind about the original choice, if they wanted to join another boat and another crew, and why.

The Meta-Cognitive Dimension: Reflective Practice

The meta-cognitive dimension deserves special attention when SRL is one of the training objectives (Dettori & Forcheri, 2004; Paris & Winograd, 2001). In particular, in our course, it was regarded as an essential element and therefore made explicit in the design principles because the course was addressed to trainee teachers, and the very nature of their future work requires the acquisition of critical thinking skills in the field of education through in-depth analysis and reflection on learning processes (Parsons & Stephenson, 2005), including their own.

The meta-cognitive component of the course consisted of critical discussions on the approach adopted in the course, on its contents, on the students' expectations, on the relevance of Educational Technology within their training. Furthermore, the fact that for the majority of our trainees (about 90% per year) this was the first exposure to CMC in formal learning activities made it advisable to focus on the peculiarities of this type of learning process.

In parallel with the contents-related main stream tasks, another activity was devoted to the analysis of "what" and "how" participants were learning. Since they were generally free to choose the topics of conversation, some of them gave their feedback on the course method, others focused on the concept of online social presence, yet others gave their opinion on the development of pragmatic and rhetorical skills.

The conclusive phase of the meta-cognitive reflection process took place during the final part of the course and was aimed at reflecting on acquired skills, difficulties, satisfaction or dissatisfaction as to expectations and commitments for the future.

The importance given to the discussion within the group and to the collaborative approach is the consequence of the belief that the teaching skills to be developed within the course are complex,

demanding, and may be best acquired through experience and reflection on it. The tutors, recruited from researchers in the field of Educational Technology and in-service teachers, proposed discussion topics based on authentic or realistic learning situations (van Weert & Pilot, 2003). For example, regarding topics such as instructional design, trainee teachers need to become aware that there is not one right-or-wrong choice since each decision is characterized by pros and cons that a good teacher should be able to detect and evaluate. To this purpose, both self-evaluation and peer interaction are more effective than listening to or reading the expert's opinion, whose point of view is too often assumed as correct.

At the meta-cognitive level, even if face-to-face sessions can be very useful (especially to solve latent conflicts or uncertainties about the method), online discussion is often even more effective, possibly because so many participants, overcoming the distance in space and time, could reflect on and react to each others' postings. The storage of postings in the form of a threaded discussion developed over time, also provided a useful support for reflection (Åhlberg, Kaasinen, Kaivola & Houtsonen, 2001; Thomas, 2002; Macdonald & Twining, 2002; Meyer, 2003). It was mostly through these meta-cognitive activities that participants become aware of what SRL is, how it can be promoted and what its relationships with the use of Educational Technology and constructivist learning theories are.

LESSONS LEARNT

The experience gained throughout the six years of this course, has provided us with a better insight, though not with clear-cut solutions, concerning teacher training in Educational Technology and the way it can be brought to enhance trainees' SRL competences.

We started from the assumption of the importance of first hand experience and reflective practice, in both areas. In addition, we realised that creating and managing a positive social environment in the learning community is a necessary condition for any learning to occur. There is no learning for pupils without an adequate process of socialization behind it, both with the teacher and among themselves. The same applies when collaborative technologies are introduced, and teachers must be prepared for that. A theoretical understanding of pros and cons of given educational software is not enough for teachers to feel at ease in using it in the classroom, they must also know what happens to someone to whom such an activity is proposed.

The changes made to the course aimed to offer flexibility and freedom without making the course too hard to run. Trainee teachers were given the opportunity to focus on the importance of social relations, on meta-reflection; to emphasize the chance to express feelings, moods, states of mind towards the learning processes; to play different roles within a community of learners; to reflect on the potential of language in social interactions, to learn how to self-regulate in order to promote effective self-regulation processes. While the course was in progress, we found that informal interaction among participants (e.g., that occurring in the Café area) via the online platform was as important as the formal learning activities. They were learning something meaningful even (and perhaps especially) when they were not working on a given assignment, but rather making use of the online platform for personal communications of various nature. In the context of a post-graduate training programme for teachers, some of their postings could be considered quite weird or out of place. However, they were not, because ultimately what participants were doing was just experimenting the potentialities of a Web-based collaborative environment, and that was among the objectives of the online course.

CONCLUSION

Technology is changing the way we work and the way we learn. In particular, at the same time NL requires us to become more autonomous in learning and more open to collaboration with peers. These two needs may appear to be contradictory, but they are not. More autonomy is needed because learning on the Web entails personal commitment, personalised goal-setting, ability to manage time and resources, successfully handle emotions and motivation, constructively deal with failures and self-assess achievements while facing information problem solving tasks. Better abilities to collaborate are needed because professional life is increasingly based on communities of practice, virtual or face-to-face, and teachers professional lives are perhaps even more dependent on this way of learning than others. In many countries, the problems teachers face in their work include isolation, lack of preparation to work with colleagues - especially those with different backgrounds, difficulties in dealing with students with different needs and learning styles, and last but not least, insufficient time, competence and disposition to use ICT effectively in their profession.

The educational polices of many countries are, at least in principle, already directing schools and individual teachers to a way of teaching that is more relevant to the outside world, but in many cases this is not enough. Filling the gap from theory to praxis is the difficult part, and teachers should not be left alone in doing it. Actually, in many cases good policy indications are interpreted by the establishment and translated into rigid rules, which are passively, and often reluctantly applied by teachers who do not share their final aim and their real sense.

Teacher training programmes should therefore become a priority and should generally invest a lot in SRL development of trainees, in particular when pedagogical and technological aspects are concerned. These objectives should of course go hand in hand with polices concerning teachers'

enrolment, investments in their preparation and support building among parents, legislators and institutions. The organisation of work in schools should favour, and not hinder, the achievement of these objectives, providing time, space and resources that can be used freely to these ends. If it is true that teaching is a hard job - but very crucial for any society, then consensus should be built around its role and recognition for it should be granted in all senses.

KEY TERMS AND DEFINITIONS

Computer-Mediated Communication: Communication process between humans through ICT.

Community of Inquiry: Virtual community for inquiry learning.

Educational Technology: Theory and practice of systematic design of learning processes and resources.

Instructional Design: Systematic approach to the design of learning processes and environments.

Networked Learning: Learning on the Web and with the Web.

Self-Regulated Learning: Learning process controlled by the learner from the cognitive, meta-cognitive, emotional and motivational points of view.

Teacher Training: Process aimed at making teachers more competent for their work.

This work was previously published in Handbook of Research on New Media Literacy at the K-12 Level: Issues and Challenges, edited by Leo Tan Wee Hin and R. Subramaniam, pp. 839-854, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 2.12

Individualized Web-Based Instructional Design

Fethi Inan

Texas Tech University, USA

Michael Grant

University of Memphis, USA

ABSTRACT

Adaptive (individualized) Web-based instruction provides mechanisms to individualize instruction for learners based on their individual needs. This chapter will discuss adaptive Web-based instruction, paying particular attention to (1) the implications of individual differences to Web-based instruction, (2) the adaptive methods that are available to designers and developers, and (3) the considerations for instruction design and development with adaptive Web-based instruction. The primary purpose of this chapter is to provide a framework to shape the development of future individualized Web-based instruction.

INTRODUCTION: STRATEGIES AND GUIDELINES FOR INSTRUCTIONAL DESIGNERS

Web-based learning environments have unlimited opportunities for educational uses, but there are numerous implementation challenges. Significantly, Web-based learning systems' content presentations, navigational methods, and instructional strategies may not be suited to all users (Brusilovsky, 1998; Song, 2002). Most Web-based instruction provides what the designers/developers consider to be the optimal interface and content presentation, expecting learners to fit into the system (Brusilovsky, 2001; Chen, Czerwinski, & Macredie, 2000; McLoughlin, 1999). Since Web-based learners typically work

alone and asynchronously, instructors/trainers are unable to provide the just-in-time modifications afforded in face-to-face sessions. If the user is not comfortable with the Web-based learning system, many instructional advantages can be lost (Metros & Hedberg, 2002; Oliver & Herrington, 1995).

While many challenges affect all learners, there is also a need for physically and visually challenged students to be appropriately accommodated and successfully integrated into the learning environment. Web-based instructional applications often neglect impaired learners. Through the use of assistive and adaptive technologies, impaired students could leave their isolation and become an important part of the learning community (Cavanaugh, 2002; Fink, Kobsa, & Nill, 1998). To overcome these barriers, an online learning system should be designed such that each individual's needs are identified, and appropriate guidance and support are provided during the learning process (De Bra, Brusilovsky, & Houben, 1999; Papanikolaou & Grigoriadou, 2004; Triantafillou, Pomportsis, & Demetriadis, 2003).

ADAPTIVE WEB-BASED INSTRUCTION AND INDIVIDUAL CHARACTERISTICS

Adaptive instruction means creating a learning environment and finding instructional approaches and techniques that conform to meet students' individual needs (Park & Lee, 2003). Adaptive Web-based learning environments (A-WBLEs) are one form of adaptive instruction that tailor individual differences in the online environment (Inan & Grant, 2004, 2005). In A-WBLEs, the fundamental focus is the individual differences of learners, because individual differences such as gender, prior knowledge, and learning styles have demonstrated significant effects on student learning (e.g., Chen & Paul, 2003). To provide a guiding framework, A-WBLEs (1) gather a learner's information and preferences, (2) build

an individual model based on the learner's preferences and knowledge, (3) apply adaptive methods to accommodate the learner based on the developed model, and (4) monitor the learner's actions and learning processes to provide new information to update the learner's model, granting a more effective and efficient system (Inan & Grant, 2004).

Although researchers agree on the influential effects of individual differences during learning, the question remains as to which variables should be considered when designing an A-WBLE. Many researchers consider learning style and cognitive style to be important characteristics to take into consideration when developing adaptive web-based instruction (Gilbert & Han, 1999; Magoulas, Chen, & Dimakopoulos, 2004; Papanikolaou, Grigoriadou, Kornilakis, & Magoulas, 2003). Brickell (1993) suggested the more enriched learning experiences occurred when the materials developed considered students' learning styles. Furthermore, Triantafillou et al. (2003) reported the majority of students were satisfied with the adaptations of learning strategies in relationship to their cognitive styles.

Another trait, students' prior knowledge and experiences, is also popular in designing adaptive systems (Brusilovsky, 2003; Foster & Lin, 2003; Weber & Brusilovsky, 2001). Students' prior knowledge contains their previous understanding of the content area and level of readiness for learning new content. Many studies have considered prior knowledge in Web-based instruction (e.g., Chen & Paul, 2003; Milne, Cook, Shiu, & McFadyen, 1997). Foster and Lin (2003) found students' acquisition of knowledge and skills were not just related to the presentation of the instructional tasks, but their prior knowledge and cultural background also played an important role. Similarly, Far and Hashimoto (2000) found a student's background knowledge and motivational state had a strong influence on learning outcomes. Moreover, prior technical knowledge may have an effect as well. Learners have different degrees of familiarity with Web browsers and communication tools,

which can affect their learning in an online setting (Magoulas, Papanikolaou, & Grigoriadou, 2003; Muir, 2001).

Additionally, a number of other variables have been considered in the design, development and implementation processes of adaptive Web-based instruction. These have included type of discipline (Chen & Paul, 2003), goals (Brusilovsky, 1998; Magoulas et al., 2003), affective and belief states (Hudlicka & McNeese, 2002), motivations (Far & Hashimoto, 2000), attitudes (Fink, Kobsa, & Nill, 1996), multiple intelligences (Kelly & Tangney, 2004), information seeking preferences (Stelmaszewska, Blandford, & Buchanan, 2005), media preferences (Carro, 2002; Danielson, 1997), language (Carro, 2002), gender (Milne et al., 1997), and disabilities (Fink et al., 1996, 1998).

ADAPTIVE METHODS

As suggested previously adaptive methods are techniques, treatments, and strategies used to make adjustments and variations in various components of Web-based instructional systems to accommodate individual needs and preferences that are stored in a student model. There

are several common adaptive technologies (i.e., adaptive interface, content and navigation) used by adaptive instructional systems, but all adaptation technologies are adopted from intelligent tutoring systems and adaptive hypermedia (Brusilovsky, 1996, 1998). Unfortunately, these methods limit adaptations to the Web-based environment, rather than instructional aspects (Carro, 2002). Inan and Grant (2004) proposed a broad range of adaptive technologies to improve the educational facets of adaptive Web-based instruction. Table 1 provides a summary of adaptive technologies with their educational implications.

Adaptive Content

Adaptive content is changing the contents of the Web page to a learner's goals, prior knowledge, and other personal information stored in the adaptive system (Brusilovsky, 1998, 2001). The contents of the page can be modified to better suit the needs of the learners based on diagnostic assessment of the individual (De Bra, 2000; Fletcher, 1992). There are many ways the same data can be presented to the learner. For example, the amount of the content (e.g., condensed, summarized, extended) or format of the content (e.g., audio, video, text)

Table 1. Summary of adaptive methods

Methods	Description
Adaptive content	Adjusting the organization, format, or amount of content
Adaptive sequencing	Ordering content in the most suitable way
Adaptive navigation and orientation	Changing the appearance and structure of navigations, for example, direct guidance, link annotation, or hiding links
Adaptive support and feedback	Providing intelligent help and feedback during the learning process regarding student actions
Adaptive learning activities	Providing a different instructional treatment for each user
Adaptive interaction	Adjusting interactions with content, learners, instructor, and interface to increase learner engagement
Adaptive assessment and grading	Applying different types of assessment procedures and grading options
Adaptive collaboration	Using system knowledge about different users to form collaboration groups
Adaptive interface	Changing the visual interface of the pages according to individual preferences
Adaptive social context	To maintain interest or user appeal by providing an adjusted social context
Adaptive learner control	Giving options to each individual to decide the system adaptation level

can be adjusted. Adaptation of content depends on several variables such as age, prior knowledge, study discipline, and learning styles. For example, a system could provide supplementary information if the student does not possess specific knowledge or interest. Comparative explanations may be presented to students who want to gain a different perspective (De Bra et al., 1999).

Adaptive Sequencing

Adaptive sequencing is ordering content effectively to provide a learner with the most suitable way to acquire knowledge or skills (Brusilovsky, 2003). Sequencing can be at a high level, that is, determining the order of topics or content to be presented, or at a low level, such as determining the order of learning tasks with examples and problems (Fletcher, 1992). Adaptive sequencing of the content can be arranged according to instructional strategies, a student's goals and preferences, or a student's observed actions and performances. Sequence of the content is mostly affected by the student's prior knowledge and nature of the content (Morrison, Ross, & Kemp, 2004; Wiley, 2001). For example, based on prior knowledge, rules or algorithms may be followed by examples (rule/e.g.) or the reverse (e.g./rule).

Adaptive Navigation and Orientation

Adaptive navigation supports the learner in cyberspace with orientation and navigation by changing the appearance of visible links (Brusilovsky, 1999). Adaptive orientation helps students to locate their current position and how to move to the next or previous position (Oliver & Herrington, 1995). Users with different knowledge levels of the content may appreciate different adaptive navigational support (Brickell, 1993; Weber & Brusilovsky, 2001). Navigational methods with restrictive approaches like direct guidance or hiding links are appropriate for learners with novice

knowledge or no knowledge of a subject. However, the most appropriate approaches for learners with reasonable knowledge are rich associative linking technologies, such as multiple link generations and link annotations to extend learner's options (Brusilovsky, 2003). Options such as site mapping menus, bread-crumb menu details, graphic organizers, and system feedback help to orient the learner within the learning environment, as well as guide the learner in negotiating the learning environment.

Adaptive Support and Feedback

Adaptive support is providing intelligent help during the learning process and giving extensive and creative feedback regarding the learner's actions and answers to questions (Brusilovsky, 2003). Pedagogical agents and intelligent feedback systems within instruction, as well as error recovery within the learning environment, can coach the learner. Although feedback can play an important role in a student's learning and attitudes, providing the same level and type of feedback to each student may not be as effective as adjusting help according to their individual needs. Some learners need to be encouraged or directed; some may only need approval to continue. Some students may perform better when their self-confidence increases. For example, to increase less confident and less motivated students, the system can provide simple and similar tasks that are likely to be solved correctly. When this type of student makes a mistake, instead of providing the correct answer, informative feedback or retry opportunities may be appropriate (Far & Hashimoto, 2000).

Adaptive Learning Activities

Adaptive learning activities include providing different instructional and motivational strategies to support learners and increase engagement in the learning process (Inan & Grant, 2004). In-

Instructional strategies are often selected based on content characteristics, available resources, and class size (Reigeluth & Curtis, 1987). Therefore, one instructional strategy may facilitate learning for one student but may inhibit learning for another (Jonassen & Grabowski, 1993; Triantafyllou, Pomportsis, Demetriadis, & Georgiadou, 2004). For example, several studies on cognitive style indicated that field dependent students learn better with group-based or collaborative learning activities, whereas field-independent learners do better with individualized learning activities (Chen, 2002; Liu & Reed, 1994). Similarly, the need for motivational strategies changes according to individuals. For example, allowing each learner to select and work on projects or tasks relevant to his/her expertise and interest can increase motivation and engagement to the learning process. On the other hand, if motivational strategies are not personalized and chosen carefully, these can even de-motivate learners (Song & Keller, 2001).

Adaptive Assessment

Adaptive formative and summative assessments provide learners with exposure to different types of learning tasks and problems in addition to targeting weaker skills. Furthermore, different assignment types can be applied to different users, such as individual assignments and group assignments (Muir, 2001). The type of testing can be adapted because some students are successful with objective testing. However, only providing objective test items does not ensure these students can express themselves with more open-ended assignments. Other attributes of testing, such as order and difficulty level of items, can also be adjusted (Weber & Brusilovsky, 2001). Traditional adaptive testing is applied in several familiar tests such as the GRE and TOEFL: If a student answers a question correctly, his score increases and receives a slightly harder question, whereas his score will decrease and receive a slightly

easier question next when he answers a question incorrectly (Schaeffer et al., 1998).

Adaptive Collaboration

Group-based or cooperative learning activities are appealing among educators due to their well-established benefits. Basically, these activities help students to create, learn, construct, and develop knowledge, attitudes, and values through interaction with others while developing interpersonal skills (Butzin, 2001; Hancock, 2004; Jonassen, 1995; Roschelle, Pea, Hoadley, Gordin, & Means, 2000). However, one of the challenges of collaborative learning is building the groups meaningfully. Adaptive collaboration can help instructors during generation of groups by making use of the system knowledge about students (Brusilovsky, 1999). This allows forming better matching groups where students have better chances to learn from each other. Other challenges to collaborative learning, such as group decision making (Socha & Socha, 1994) and group formations (Tuckman, 1965), still must be integrated within the instruction.

Adaptive Interface

Adaptive interface is changing the visual interface of the pages according to the individual's preferences (e.g., color, font style, font size, and scrolling) (Inan & Grant, 2004). The appearance of the text and images on the computer screen influences readability (Metros & Hedberg, 2002; Smaldino, Russell, Heinich, & Molenda, 2005). There are many ways in which the same data can be presented to the learner. A variation in information presentation includes items such as layout, organization, structure, appearance, and format (Magoulas et al., 2004; Oliver & Herrington, 1995). Furthermore, adaptive interfaces could be useful for exceptional learners, such as visually impaired students who may need magnification

of the text size or English language learners who may need translations into native languages. Technologies, such as cascading style sheets (CSS) and content management systems, allow for variations in control of Web page structures and content display. So, these may offer easier methods for development with multiple audiences.

Adaptive Interaction

Adaptive interaction is adjusting the type of interaction that is more suitable to the learner's model. Interactions can include: (1) learner-content, (2) learner-learner, (3) learner-instructor, and (4) learner-interface (Hillman, Willis, & Gunawardena, 1994; Moore & Kearsley, 1996). All types of interactions are critical in online learning (Shortridge, 2001), but each individual can have his/her own interaction preferences (Sabry & Baldwin, 2003). Sabry and Baldwin (2003) observed variation between learning styles and types of interaction used in the Web-based instruction. Furthermore, variations were revealed between communication preferences and the gender of students. Bostock and Lizhi (2005) reported females wrote more messages than males in discussion boards, showing more connected communication patterns and a concern for a greater sense of community (Rovai, 2001). Another serious concern involves non-traditional students. By examining use of a discussion board, Jun and Park (2003) indicated international students far less frequently initiated discussions or posted messages compared to American students.

Adaptive Social Context

Like adaptive interactions, adaptive social context can provide options for reducing transactional distance (Moore, 1993) and isolation within Web-based learning environments. A learning environment's convenience and climate helps students in developing a positive attitude toward the system

(Inan, Yildirim, & Kiraz, 2004; King, 2002). Therefore, besides providing content and information, some social activities could be provided according to user preferences. For example, some students enjoy publishing a personal home page. The Web-based learning environments can create a home page or blog space for each learner and allow them to enable or disable publishing or modifying their pages. In combination with adaptive social context, the system may also suggest study groups.

Adaptive Learner Control

One of the most appreciated features of Web-based instruction is its non-linear structure, where learners select content and move around by their own decisions and control (Chen & Paul, 2003; Federico, 1999; Khan, 1997). However, previous studies indicated that some learners may have problems taking control of their learning in an open learning environment (Chen, 2002; Song, 2002; Weber & Brusilovsky, 2001). For example, Ford and Chen (2000) indicated field dependent learners are more comfortable with the system having control, whereas field independent learners prefer to have control over the system. Similarly, McManus (2000) revealed that highly self-regulating learners perform poorly in most linear Web-based learning environments, where limited choices were available. These findings suggest that some learners might be able to decide which adaptive methods and level of adaptation is appropriate for their learning. Therefore, the level of control could be shared among the learner, instructor/trainer, and the system (Papanikolaou et al., 2003; Tsandilas & Schraefel, 2004). Adaptive learner control offers learners and instructors/trainers opportunities to individually or cooperatively decide the level of system adaptation (Inan & Grant, 2004).

INSTRUCTIONAL DESIGN CONSIDERATIONS FOR INDIVIDUALIZED WEB- BASED INSTRUCTION

When designing and developing individualized Web-based instruction, instructional design and development must consider two implementations:

1. The development of new adaptive systems
2. The updating or retrofitting of existing systems; each of these are discussed next.

Development of New Adaptive Systems

Following systematic guidelines or models throughout instructional systems development makes the system more reliable and effective (Briggs, Gustafson, & Tillman, 1991; Gustafson & Branch, 1997; Zheng & Smaldino, 2003). There are numerous instructional design models (e.g., Dick, Carey, & Carey, 2005; Morrison et al., 2004; Smith & Ragan, 2005). Although these models have been developed for different purposes, serve different populations, and describe different steps to achieve instructional products, they all include five core elements: (1) analysis, (2) design, (3) development, (4) implementation, and (5) evaluation (ADDIE).

Unquestionably, designing an adaptive instruction requires following an established model or process. We believe that the ADDIE framework can provide guidelines for development of adaptive Web-based instruction with revising and supplementing necessary steps. The central change in the framework is moving its focus from developing and providing a high quality instruction that “fits all learners” to one that “fits each learner.”

In addition to typical ADDIE processes, the *analysis phase* should include a collection of students’ individual characteristics, which would include elements of typical learning analysis but

may include more specifics, such as assessment scores, communication preferences, and collaboration skills (Aroyo, Bra, Houben, & Vdovjak, 2004; Brusilovsky, 2001; Foster & Lin, 2003; Gilbert & Han, 1999). The *design phase* now adds specifying adaptive methods, assigning roles to students and teachers, plus matching adaptive and instructional strategies to learner characteristics (Inan & Grant, 2005; Triantafillou et al., 2004). The *development process* incorporates generating a user model, content structure and prototypes of the adaptive system (De Bra, 1999; Magoulas et al., 2003; Papanikolaou et al., 2003). *Implementation processes* must include application of the system in the real environment, where instruction is adjusted to meet learner needs (Magoulas et al., 2003; Papanikolaou et al., 2003). Finally, *evaluation* brings in assessment of student learning, observations of student actions, formative evaluation of the system before it is completed, summative assessment of the system efficiency, and updates to the student model (Federico, 1999; Lee, 2001; Triantafillou et al., 2004; Weibelzahl, 2005). Table 2 summarizes the ADDIE framework for the development of A-WBLEs.

Updating or Retrofitting Existing Systems

The second type of implementation is updating or retrofitting an existing system. Today, almost all universities have one of the common course management systems. Similarly, corporate Web-based training has been dominated by learning management systems and learning content management systems. It would be overly optimistic to suggest that these non-adaptive systems will be replaced with adaptive ones soon. Therefore, if there is an opportunity to use an adaptive approach within these systems, there is a need to determine how to integrate adaptive functions with the existing systems. Two methods for integrating an existing system are described below.

Table 2. ADDIE framework for development of A-WBLEs (Note: ADDIE = analysis, design, development, implementation, and evaluation)

ADDIE Components	Strategies for adaptive system development
Analysis	Gathering: Collecting students' prior preferences, knowledge, skills, and attitudes, which are important factors in student learning in a Web-based learning environment
Design	Inference: Inferring and predicting what these collected data tell about student and parameters Matching: Specifying adaptive methods, assigning roles to students and teachers, matching adaptive and instructional strategies to learner characteristics
Development	Building: Generating a user model, content structure, and prototypes of the adaptive system
Implementation	Accommodation: Making adjustment on the system based on collected and inferred data Updating: Altering student model continuously according to collected and monitored data throughout the learning process
Evaluation	Monitoring: Observing student sequence, interaction, errors, pace Assessment: Formative and summative evaluation of system efficiency and student learning

- Patching adaptive functions:** Through a patching method, a new module with adaptive functions can be developed and linked to the old system by managing the systems on different Web servers (Richard & Tchounikine, 2004). This approach helps developers to maintain the existing course/learning management system functions, while incorporating new adaptive functions. This process may augment the existing instruction, but integrating two different Web-based systems under one interface may be too difficult or too costly.

One of the rare examples of this approach, experimental learning management system's (eLMS), Building Block aimed to interoperate with commonly available course management systems, developed by the VaNTH ERC project of Vanderbilt University and collaborating universities (Howard, Remenyi, Pap, & Garay, n.d.). Currently, the Building Block for Blackboard was developed to provide an interface that allows Blackboard users to access services provided by the A-WBLE (Howard, 2006)

- Implementation modification:** The other model for updating or retrofitting existing

systems—implementation modification—can be done by using the existing system's functions in a novel manner or by utilizing some functions and features of the system for a particular group of students to accommodate individual differences. For example, WebCT's selective release function allows instructors to modify instructional components based on student test scores and/or other student characteristics. Additionally, other popular encapsulated instructional modules, such as Macromedia Flash movies and Camtasia simulations, can build in adaptive methods for learners. But these modules require sophisticated programming to connect with the course/learning management system to report and update the student model.

CONCLUSION

The Web has become a widely available and used platform for educational purposes. Adaptive (individualized) Web-based instruction can provide a mechanism to understand each individual's learning styles, preferences, prior knowledge, and learning goals and provide different treatments for each learner based on their individual

needs (Brusilovsky, 2001; Inan & Grant, 2004). If implemented correctly, an adaptive Web-based instruction can improve student performance, as well as decrease learning time and usability problems (Gilbert & Han, 1999; Papanikolaou et al., 2003; Triantafyllou et al., 2003; Tsandilas & Schraefel, 2004; Weber & Brusilovsky, 2001). So the promise of A-WBLEs is attractive.

Developing and implementing adaptive Web-based instruction is a complex process, though. In addition to development costs and time, adaptive instruction has limitations and concerns, including instructor skills preparation, ethical concerns, development and update time, as well as costs (Brusilovsky, 1996; De Bra, 2000; Federico, 1999; Karagiannidis, Sampson, & Cardinali, 2001; Magoulas et al., 2003). Moreover, many adaptive educational applications have failed to incorporate valuable learning principles and instructional strategies (Carro, 2002; Park & Lee, 2003). In order for A-WBLEs to become viable, sustainable options to university faculty and corporate trainers, these issues must be considered in light of the various adaptive methods discussed previously.

KEY TERMS AND DEFINITIONS

Adaptive Assessment: Adaptive assessment offers different types of assessment procedures and grading options that provide learners with exposure to different types of learning tasks and problems.

Adaptive Collaboration: Adaptive collaboration means using system knowledge about different users to form collaboration groups.

Adaptive Content: Adaptive content means adjusting the organization, format, or amount of content based on learner's goals, prior knowledge, and other personal information stored in the learner model.

Adaptive Instruction: Adaptive instruction means creating a learning environment and finding instructional approaches and techniques that conform to meet students' individual needs.

Adaptive (Individualized) Web-Based Learning Environment: Adaptive Web-based learning environment provides mechanisms to individualize instruction (e.g., content, strategies, assessment) for learners based on their individual needs and preferences in the online environment.

Adaptive Interface: Adaptive interface is changing the visual interface of the Web pages according to individual preferences such as color, font style, font size, and scrolling.

Adaptive Learner Control: Adaptive learner control gives each learner the option to decide the system adaptation level and adaptive methods individually or cooperatively.

Adaptive Navigation: Adaptive navigation supports learner orientation in the online environment by changing the appearance and structure of navigations.

Adaptive Social Context: Adaptive social context means maintaining interest or user appeal by providing an adjusted social context and activities.

Chapter 2.13

The Virtue of Paper: Drawing as a Means to Innovation in Instructional Design

Brad Hokanson
University of Minnesota, USA

ABSTRACT

This chapter presents an argument in favor of using paper to conceive, plan, and describe instructional design projects. Such a simple medium has great capability and, as is well known, a tenacious ubiquity; our offices, practices, and lives are filled with paper. We will see how the attributes of paper help us in both social and cognitive ways, particularly as a medium for drawing.

PROLOGUE

It was a peculiarly beautiful book. Its smooth creamy paper, a little yellowed by age, was of a kind that had not been manufactured for at least

forty years past. He could guess, however, that the book was much older than that. He had seen it lying in the window of a frowsy little junk-shop in a slummy quarter of the town (just what quarter he did not now remember) and had been stricken immediately by an overwhelming desire to possess it.... Winston fitted a nib into the penholder and sucked it to get the grease off. The pen was an archaic instrument, seldom used even for signatures, and he had procured one, furtively and with some difficulty, simply because of a feeling that the beautiful creamy paper deserved to be written on with a real nib instead of being scratched with an ink-pencil. Actually he was not used to writing by hand.... He dipped the pen into the ink and then faltered for just a second. A tremor had gone through his bowels. To mark the paper was the decisive act (Orwell, 1948, p. 23).

DOI: 10.4018/978-1-60960-503-2.ch213

In this passage, Winston is about to engage the simplest, most immediate medium—pen and paper. His creative process will be unencumbered by layers of technology involving complex skill sets, which, even when mastered, place their own restrictions on their user and become to some extent autonomous. Central to this act is his own intellect, and he recognizes the danger and importance, the intent of the mark, and its ability to connect with others.

INTRODUCTION

However we use a notation system, a visible language must build on our human experiences. We choose the media and which technologies we work with, and we make those choices based on our social and cognitive practices. Winston Smith's use of paper embodies human attributes that are politically rebellious: the capacities for private notation and independent thought.

Our current challenges are not so much in the technological systems we use, but in how people conceive, develop, and disseminate ideas through media. The choice is not how to use a new technology or software to visually notate our process of instructional design, but rather how to use visual notation to innovate and improve instructional design and education. Communication, creative thought, and interaction in complex processes must be addressed by meeting the needs of the human element of design.

KNOWLEDGE WORK AND VISUAL NOTATION

The focus of our effort is instructional design, the creation of materials for and the structuring of instruction itself. For our purposes here, instructional design is the knowing use of technology for the assistance of learning, and more recently,

specifically the use of computer- and Internet-based technologies in the service of learning.

Instructional design can be described as “knowledge work” as described by Peter Drucker (1999) and others, and this description may help us understand the use of paper in the field by comparison with other professions. Knowledge work is a classification of work that involves the generation, development, and implementation of ideas. It can be described as work where the true means of production is the knowledge of the worker. Other fields engaged in knowledge work include the law, surgery, and architecture. Knowledge work is generally complex, quite often socially grounded, and involves complicated technical issues. Knowledge work often requires significant education or training, and the work is generally done in organizations and/or teams. Designing, including instructional design, is knowledge work.

Many of the activities of knowledge work are verbal and visual. They involve sharing, recording, notating, and creating ideas—most supported by some technology, the most ubiquitous being paper. There remains, as we shall see later, a continued use of paper in this electronic age. Knowledge work, particularly design, is tied to the use of paper because paper allows visual notations more easily than other media. It is faster, simpler, more immediate, and less separated (or mediated) from our thoughts.

Later in this chapter, architecture will provide a good comparison to instructional design for its use of notation systems: it has similarly complex technical issues (of building and construction); it is socially based, often practiced within a firm and with clients; and it addresses theoretical and philosophical issues in application. While architecture may result in visual form more than most instructional design, it still provides a strong analogy for an examination of design methods and tools as applied to instructional design.

The general field of design can be said to have evolved from craft when need arose to separate the work of creation from the work of production. Within design, visual notation is needed to create, direct, and communicate. “It is, above all else, the separation of designing from making and the increased importance of the drawing which characterizes the modern design process” (Lawson, 2000, p. 241). Drawing, what first developed as a means to direct others in the making of the end product, has also evolved other purposes, notably to support the imagination. The word design, of course, derives from a Latin word meaning “to mark” or draw.

Design as a profession and as a practice is methodological, purposeful, and goal oriented. It examines the entire problem, seeking a broader understanding, rather than small improvements addressing known problems, as does craft. Both craft and design seek applied solutions; the crafts person creates the result, while the designer directs others in doing so generally through visual means. Advances through craft will be incremental, i.e. minor continued improvements in efficiency or detail; advances in design work may be significant changes or substantial improvements. Currently, much instructional design is craft based, seeking detailed changes in the end product, and often building from existing models of instruction. For greater innovation and invention to occur, however, changes in the design process are necessary.

PAPER

Throughout history, visual notation systems for information recording, conveyance, and investigation have been tied to various media, most frequently paper. Since its broad production and use, paper has helped fuel the development and communication of the world’s knowledge.

Over the past twenty years, electronic communications methods and media have rapidly developed—newspapers, books, and whole librar-

ies are now accessible online, and many people work using computers, particularly in knowledge and information fields, while management, communication, and production in instructional design is done principally on computers.

THE GOAL OF THE PAPERLESS OFFICE

The computer and information revolution have significantly changed our work habits and our understanding of information. The concept of “atoms vs. bits” (Negroponte, 1999), of analog vs. digital, and advanced vs. appropriate technology all pressed us forward to embrace computer technology. Not using the latest technology in the workplace is considered laggard or Luddite. As knowledge workers, we are centered in the use of computers, and paper is *passé*. The conversion, quasi-religious, is not complete:

Yes, I’ve been to the crossroads and I’ve met the devil, and he’s sleek and confident, ever so much more “with it” than the nearest archangel. He is casual and irreverent, wears jeans and running shoes and maybe even an earring, and the pointing prong of his tail is artfully concealed. He is the sorcerer of binary order, jacking in and out of terminals, booting up, flaming, commanding vast systems and networks with an ease that steals my breath away. ... Do we know what we’re doing? Do people understand that there might be consequences, possibly dire, to our embrace of these technologies, and that the myth of the Faustian bargain has not become irrelevant just because we studied it in school? (Birkerts, 1994, p. 211)

The “paperless office” remains as a broadly held belief; however, in real life, the use of paper remains important in the workplace.

Computer technology was supposed to replace paper. But that hasn’t happened. Every country

in the Western world uses more paper today, on a per-capita basis, than it did ten years ago. The consumption of uncoated free-sheet paper, for instance—the most common kind of office paper—rose almost fifteen per cent in the United States between 1995 and 2000. (Gladwell, 2002)

If we examine our own work experience through reflection and the work habits of others through research, we can see the continuing use of paper for knowledge work and the reasons for its persistence. For example, while we use e-mail constantly, the promise of paperless communication has not been achieved. In truth, as organizations install e-mail systems, paper use increases on average by 40% (Sellen & Harper, 1997). With e-mail, we use *more* paper. Why?

WE KNOW HOW PAPER IS USED IN OUR OWN EXPERIENCES

Our own work experience can provide a base for understanding the role of paper in the knowledge workplace. We understand first hand the use, ubiquity, and commonality of paper. The management of “paper” is considered a hallmark of modern professional travail; the clutter of our homes comes significantly from paper; organizations seek to decrease the use of paper and encourage its recycling. We print documents to read and edit, guilty about our use of the world’s resources, and about our failure to fully achieve digital literacy.

In general, knowledge workers make a series of choices that take advantage of how to use media. More often than not, we make rational and understandable choices to use paper. For example, we print out e-mail to have a handy record of a communication. We write numbers, names or ideas on available pieces of paper. The grocery list is put on the back of an envelope, a phone number on a sticky note, and contact information is embellished on the back of a business card. We print out docu-

ments to read and annotate; our well-read books are marked up and personalized, the notations becoming part of the cognitive record of reading.

Some of these choices are due to the simple physical attributes of paper that are easily recognized. Paper is (among other characteristics) generally inexpensive, lightweight, light in color, translucent, durable in most situations, easy to use, easy to mark, and readily available. These physical attributes help determine for what it can be used, i.e. its capabilities or *affordances*.

Affordances, per Gibson, are those capabilities, properties, and attributes of a tool or medium that “...make possible different functions for the person perceiving or using that object” (Gibson, 1979, p. 24). We often make choices about media use by weighing various affordances, choosing media with a perceived relative advantage for our own use.

For example, we chose to write the grocery list by hand on a used envelope instead of on the laptop because it is lighter and more transportable, more easily carried to the grocery store. While it is possible to carry the laptop to the store, we quickly understand that it would be easier to use a lighter weight scrap of paper to help remember grocery items. We mentally and often unconsciously weigh these attributes when we pick up a piece of paper.

Imagine the process of writing the list on one’s laptop to illustrate an alternative choice: go to the laptop, start the laptop, start the word processing program, write the list, visit the refrigerator to check current supplies, start the printer, print the list, close the program and laptop. One could chose to carry the laptop to the grocery store in lieu of printing the list, but that would raise additional difficulties.

We often know it is much easier to use paper without going through a conscious decision making process. We use paper because it has the capabilities we need for the tasks we are performing. It does what we need it to do simply.

AFFORDANCES OF PAPER FOR KNOWLEDGE WORK/DESIGN

Within the scope of simpler tasks, we understand what works well, knowing needed skills and effort. We use what is easy and cheap, paper, the affordances of which stand well apart from our digital tools. There also are more complex or sophisticated affordances of paper that are tied to knowledge work, particularly is how we use paper as individuals and within groups to understand and think.

- **Navigation:** The tangibility, the physicality, of paper helps one navigate and understand a document. Through spatial understanding, through representation of (textual) location, and through a physical gauging of location, we understand the structure of a document. One can understand, visually and haptically, progress in reading a large document or the ease with which one could read a thin children's book. We can find summarizing arguments in many books at the end, and the initial challenge of the author at the beginning. We know the main body of the book contains supporting information in greater detail.
- **Cross referencing:** Spatial flexibility allows the easy comparison of multiple documents, cross referencing between multiple pieces of paper. Multiple documents can be arrayed on a surface and easily cross-referenced, even between paper and electronic sources.
- **Annotation:** Paper based documents can easily be annotated using textual or symbolic notation, using pen or pencil. These marks vary from structural reorganizations to textual comments to visual representations, often all within the same document and using the same marking system.

- **Manipulation:** Paper allows for the multi-dimensional display and reorganization of documents. For example, paragraph five can be physically put at the end of the report, or an image can be located for connection to the text. The manipulation of paper materials is grounded and first hand. For example, we can examine the difference between paper collage and digital collage. There are real limits to a paper collage. One must budget unique resources, and creation is tied to real constraints of paper, cutting, shaping, and gluing. This is contrasted to the weightless world of the digital creation, which is unlimited and, in the end, without gravity. The paper collage is, however, immediate, personal, and unique.
- **Placeholding:** Paper documents serve as cognitive aids to memory; they remain as left until addressed. They are a constant reminder of tasks undone.
- **Portability:** Paper is portable and can be carried to various locations untethered to one's workplace, e.g. away from one's computer. It can be read in the park, handed to an airline ticket agent, or presented to a flight attendant when "all electronic devices must be turned off". Is it not place bound, tied, at the least to an Ethernet wire or a battery pack.

These capabilities of paper do not mean that other digital systems are not useful; these observations mean that the use of paper is often part of the complete process of idea and document development: a document may be initialized and finalized on the computer, but in the process, it may be converted back and forth to paper many times.

Yet, if the computer is the canvas on which documents are created, the top of the desk is the palette on which bits of paper are spread in preparation

for the job of writing. Without these bits of paper ready to hand, it is as if the writing, and more especially the thinking [italics in original], could not take place in earnest. (Sellen & Harper, 2002, p.1)

These affordances can be contrasted to computer-based electronic systems; all of the tasks could be accomplished using a computer. But all would require substantial investment in technology, skills, and cognitive effort. The tasks would be divorced from direct human intervention and not grounded in the real world. Computers and most software packages separate users—through interfacia such as keyboards, mice, screens, and requirements to learn and often extensively develop skills—from the act of creation.

While paper has substantial value for text-based communication and notation, it is also well suited to use to convey visual images or notation. Paper, broadly defined, is a surface for making marks that require little experience; a separate program or marking tool is not required. Most people have sufficient skill in non-textual visual representation, i.e. drawing, to accomplish rudimentary representations and to decode visual images (Goldschmidt, 1999). This is often more efficient than text alone. The hand, unlike computer programs, has never had a significant division between writing and drawing, between textual notation and visual notation. While skills may vary, the medium is not forcing the use of word or image on the page; a mark is a mark, whether text or image, or visual notation.

EMPIRICAL EVIDENCE OF PAPER SUPPORTED KNOWLEDGE WORK

Sellen and Harper (2002) found that knowledge workers employed paper in ways that were complex and sophisticated, and which also illustrated some of the nature of knowledge work. Their research involved observing work in air traffic control, financial management, and policing.

Authoring, reviewing, collaborating, and interacting socially were all supported through the use of paper, even when electronic media for communication were available and well understood.

Authoring, an important component of knowledge work, is well supported by paper. As noted, digital technologies may be used for the finished product, but the actual composition of ideas is done through a combination of paper and digital technologies. We write, compose, draw, and create on paper. We may implement those ideas through other media—digital software, oil paint, buildings, and sculpture—but we make our initial authoring choices generally on paper. Even authors who extensively used word processing software move back and forth between print and electronic versions of their work.

Knowledge workers also tend to review the work of others on paper, both for approval and for their own understanding. We understand information through the formation of our own knowledge, and part of the formation of our knowledge often occurs by marking written text.

Similarly, knowledge workers often plan their work using paper, where a lack of imposed structure affords ease and flexibility in jotting down notations, making diagrams, marking emphasis, or connecting ideas. Word processing, by comparison, focuses one type of information and is structured for written documents on a page. The diagram sketched by hand into the paper document is easy; that same diagram in an electronic document requires many additional steps and substantially more skill in software use.

Collaborative activities are also often more easily undertaken through the use of paper. Paper allows the sharing of a common document and making of multiple and diverse marks on it. Knowledge workers can pass around a draft, or even copies of a draft, for annotation and review. Paper often provides the media to record ideas, plans and discussion for working groups. Examples of collaborative paper or paper-based activity in the workplace include the large paper

easel pads used to record and archive ideas in team brainstorming sessions, or sticky notes used to plan staffing or procedures.

Finally, paper is often used as a reason for added, informal interpersonal meetings, greasing the wheels for further creativity. Written documents, such as a report or a memo, are often delivered in person. This provides an opportunity to review the materials with the intended audience and to increase creative social interaction in the workplace. Such documents could often be sent by other means, such as e-mail, but the personal meeting is valued more highly than electronic expediency.

One of the most developed paper-based collaborative systems is the A3 Report used by Toyota. “These single page data-dense reports are used as part of a process to gather information, share information, make comments, track progress and graphically represent the improvement process” (Liker and Meier, 2006, p. 201). The A3 Report method involves using one side of an A3 sized piece of paper. “It allows only the most critical information to be shared with others for careful evaluation of the thought process used, as a means of requesting support or advice, and for arriving at a consensus.”

Initially, A3 Reports were developed as a standardization choice allowing worldwide communication through a single, simple format: “... this was the largest size paper that could fit in a fax machine: 11 × 17 inches” (Liker & Meier, 2006, p. 203). While the documents could be done in electronic form, the use of paper allows for easy distribution, broadly distributed use, and allows input from all. They are dynamic and collaborative documents, not frozen and uni-directional Power-Point presentations (Sobek & Jimmerson, 2004).

A3 reports are a hallmark of the “lean” management movement. These single pages of A3 sized paper are used for planning, communicating, generating new ideas, and resolving problems. Use of the single sheet for planning reports forces conciseness, summarization, and organization

of thought. The reports, consistent with Toyota management principles, are highly structured, yet created to encourage ongoing input, including editing and marking, by others.

The value of the A3 report is that it ensures communication, either formalized or incidental. Reports are duplicated and presented to others for input. The development of the A3 document is often done in teams or collaboratively; reports can be printed or posted for review, and are easily folded for inclusion in a notebook. Informal annotation of the A3 reports by others, including on the factory or shop floor is encouraged as part of the ongoing process.

DRAWING AS A MEANS TO DESIGN

Much of our understanding and use of paper is for text; most of our communications efforts are centered around words and writing. However, beyond the linear use of one symbol system, writing is an entire array of ways to communicate more effectively and expressively. Drawing, a visual notation system, is central... and common to all design fields. Historically, humans have relied on drawing to communicate.

Drawing is a kind of Universal Language, understood by all Nations. A Man may often express his Ideas, even to his own Countrymen, more clearly with a Lead Pencil, or Bit of Chalk, than with his Tongue. And many can understand a Figure, that do not comprehend a Description in Words, tho' ever so properly chosen. (Benjamin Franklin, 1749)

Central to the use of paper is the ability to generate graphic images or diagrams easily. For the architect or artist, these images are essential to their creation: Drawing, or “making marks,” is an act of decision and exploration. Designers make marks, adjust symbols, manipulate forms, and from that manipulation and iterative design

process develop new and better ideas (see for example, Waters & Gibbons, 2004).

How we view visual notation, drawing, is an important key to advancing instructional design. If we use it solely to communicate, we will limit its effective use. Communication with colleagues and clients is an important use of visual notation, to be sure, but more importantly, drawing can serve other functions in our design process. It is where we can generate ideas, its principle role in many other design fields.

Why is drawing effective in the development of ideas? Visual form is instantly recognizable, and at the same time encourages interpretation. The generation of visual forms allows the abstraction of ideas and the summarization of complex concepts. One can scribble a drawing, change it, and reinforce one's thoughts. It is "media-as-environment," a place for the development of ideas (Meyrowitz, 1999, p. 45).

REASONS FOR DRAWING

In the design fields, drawing or visual notation is central to the design process and is used for a variety of purposes, ranging from the presentations to the public and reviewers, to the cognitive efforts of individual practitioners.

A drawing is like a theatrical scrim, a gauzelike screen whose properties change dependent on lighting conditions. Like a scrim, a drawing is both opaque and translucent, a filter between the drawer and viewer; drawer and object, between ideas conceived and their two-dimensional manifestation. A scrim and a drawing both prevent as well as allow view, asserting their presence with varying authority and in different ways. When the back light turns on, the scrim disappears. In a similar way, drawings dissolve and open a world of rich possibilities. (Fraser & Hemni, 2000, p. 18)

Both Lawson (2004) and Fraser and Hemni (2000) describe multiple functions for drawing in the architectural design process; drawing is used to plan, to communicate, to convince, and most importantly, to ideate (See Figures 1-3). Each of these modes of drawing can be applied to use in the field of instructional design. These types of drawings include:

- **Public communication:** Most design work in architecture is very public; public reviews are common. Many drawings in the design fields are used to present work and communicate intent to outside parties. In architecture, plans are reviewed by government agencies, clients, and communities. These drawings can be described as presenting a positive and finished image to the public (Lawson, 2004). Drawings may be used to support marketing of buildings, securing public approvals, or in convincing a client of the project's value.

Within instructional design, there currently is less use for representation of design work, as often the preference is to have non-working digital models for presentation of early stages. In architecture though, the economics of physical

Figure 1. Thinking drawings by the author

construction compared to the cost of producing a digital prototype encourages visual and often animated representations.

One other comparison for the field of instructional design would be movie production. The development of movies is based on an extensive series of drawn visual representations, story boards, and iterative representations as the cost of final production is quite high. Most animated movies such as Disney/Pixar's *The Incredibles* (Walker, 2005) are extensively developed on paper in hand drawn form prior to the computer-based rendering of the final product.

- **Work communication:** Drawings are extensively used to communicate within the field of architecture. These may take the form of diagrams, representations of data, or representations of ideas. The value of this type of drawing or visual notation is beginning to be well understood in the field of instructional design (cf. Botturi, 2006). Design teams in all areas need to communicate structure, sequence, and organization of their work; visual representation and notation can provide a better understanding than by text alone.
- **Vendor communication:** Drawings are commonly used to communicate directly with those providing services or products; within architecture, some drawings have the legal force of contract and are literally called "Contract Documents." As more of the actual production work in instruction design is done by outside vendors, communication will become a higher priority. Much of this communication will be verbal, but visual notation and communication will also be increasingly valuable.
- **Development testing:** Many ideas cannot be fully understood unless represented visually and those ideas are often explored through drawings. Understanding complex and intricate technologies can be assisted

through the use of drawing. For example, the efficient layout of clothing patterns on milled fabric is important for cost effective production; developing hypothetical layouts of furniture in visual form by interior designers helps to understand room use; and urban designers use visual models to understand the ramifications of zoning laws. If verbal annotation is helpful, diagrams, visual representations, or mapping is more so.

In the virtual world of technology-rich instructional design, the real world limits of room layout, fabric width, and neighborhood density are not immediate concerns. However, early development of screen designs could benefit from rapid visualization through hand-based drawings, and hand drawn maps are a good starting method for Web site design.

- **Research drawing:** Architects and others also use drawing as a means to understand observed phenomena. The "grand tour" of Europe, undertaken as part of formal studies in architecture, is often documented with drawings in a sketchbook. Not mere drawing practice, this custom helps the architecture students cognitively engage and internalize what they see.

Most travelers today carry a camera and forsake the personal time and engagement of drawing what they see, yet for most the cognitive residue of taking a photograph is minimal while the understanding gained by drawing one's observation is long lasting. In Japan, hikers still climb Mount Fuji to paint the sunrise. Again, the reflective experience is of considerably greater value.

Drawing as a tool to research and understanding is not limited to architects and tourists. Early scientists, including Sigmund Freud, used drawing as a means to understand and develop ideas.

In the latter part of the 19th century, German researchers considered drawing to be instrumental to scientific discovery, both as a way to capture the microscopic detail of nerve cells, for example, and to illustrate theories of how the brain might work. (Gamwell, in Carey, 2006)

For example, Darwin's drawings were essential to his seminal work in *The Origin of Species*. And the recorded anatomical observations of Leonardo da Vinci are early examples of the use of drawings for research. Mechanical or electronic reproduction of visual images does not require the same cognitive effect as the engaged and personal representation.

- **Sketching as visual thinking:** The most important aspect of drawing is its ability to help create and develop new ideas. This type of drawing, called "study sketching" by Goldschmidt (1999), and "design drawings" by Fraser and Hemni (2000), occurs in many fields. It is finding answers to complex problems through visual representation, and is "...practiced by individuals who attempt to conceive of a new entity, be it a work of art, a building, a technically-oriented invention or novel artifact, or a scientific concept" (Goldschmidt, 1999, unnumbered). Many design fields such as architecture, graphic design, and industrial design have active histories of design sketching. This process is drawing to invent, to generate the new, drawing to create.

This type of drawing is often intensely personal. It is a one-to-one visual conversation with oneself through the medium of drawing, and it is generally not meant for extensive communication. Such sketches can be decoded, understood, and valued by knowledgeable others, but their primary purpose is one of supporting thought.

The imperfect feedback (or "backtalk" per Goldschmidt, 1999) of media is an important component of the design process. Representing an idea through drawing is not always an exact science; through the vagaries of the media, the roughness of the paper or bleed of ink, or even through the inaccuracy of the hand, differences and changes occur. This can be a conversation as challenging as an engaging argument with a peer, and it is where ideas develop. Lawson (2004) calls these drawings "proposition drawings." "These are drawings where a designer makes a 'move,' or proposes a possible design outcome" (p. 45).

Designing, particularly within architecture, is often iterative, making a series of choices within a larger conceptual goal. This type of drawing becomes game-like, combative, an interactive argument, and, as often described, conversational. It is an interaction with a sheet of paper, akin to "thinking out loud," helping ideas and decisions emerge from the page, away from the brain, in a two dimensional use of symbols comparable to the leap to writing envisioned by Ong: Thought requires some sort of continuity. Writing establishes in the text a 'line' of continuity outside the mind" (Ong, 1982, p. 39). Drawing expands this capability in multiple dimensions.

This method of drawing is closely related to the concept of cognitive tools developed by Jonassen and others to describe the use of computer-based tools to investigate various hypotheses and directions. A spreadsheet, for example, can be used as a cognitive tool to define, structure quantitative relationships, and to iteratively advance various numerical scenarios. The use of drawing in design can easily fit within Jonassen's (1996) description of cognitive tools as "...readily available, generic applications; they are affordable; they are used to represent knowledge in content domains; they are applicable across different subject domains; they engage critical thinking in learners; they facilitate transfer of learning; they are simple, powerful formalisms; and they are reasonably easy to learn"

(p. 709). How parallel is Goldschmidt's description of the cognitive mechanism of drawing: "... this is a 'front edge' process in which partial and rudimentary representations are produced, evaluated, replaced by others if need be, transformed, modified and refined, until their maker is satisfied with the result" (1999).

As we have seen, the visual notation of architecture, drawing, serves a wide variety of needs, which can be compared to the work in instructional design. Drawing, i.e. paper-based, free flowing visual notation, has value on many levels, from public communication to private cognition. In both fields, ideas and concepts need to be explored and described in ways beyond simple text. Similarly to architecture, the drawing of instructional design must be free flowing, inventive, both personal and public, and easily used.

Visual notation must have both a cognitive and practitioner base in drawing, a basis gained by making marks *by hand* on surfaces, which occurs most easily and commonly on paper.

DRAWING ON PAPER

Media, of course, are needed to communicate and to support thought. The use of some technology is necessary to extend our thoughts to others. But the type and extent of media technology imposes change on the message and change on the process. Two things stand out: first, the cognitive load and communication skill required to use more complex technologies detracts from the capacity for thought. Using simple media allows greater concentration on the task at hand – design, information, communication, or invention.

Simpler media also impose less of their own structure on the interchange and allow a freer form of idea development. Software is an indispensable tool of instructional design, but any software, as a medium, structures the results, "perfecting" ill-formed ideas in its own likeness (Drucker, 1999).

Figure 2. Thinking drawings by the author

Figure 3. Preliminary site concept drawing for Cambridge Community College, Minnesota, USA. Courtesy Hokanson/Lunning Associates, Inc., architects.

For example, a word processor often completes or re-spells words; presentation programs such as PowerPoint utilize wizards to summarize presentations, limiting expression and communication (Tufte, 2003), and desktop publishing programs make some layouts easier to use than others, encouraging their use.

If the meaning of Goethe's Faust, of Van Gogh's Landscapes, or Bach's Art of the Fugue could be transmitted in discursive terms, their authors should and would not have bothered to write poems, paint, or compose, but rather have written scientific treatises. (Von Bertalanffy, 1965, p.44)

Media biases communication, whether the media is computer-based software or oral speech (Innis, 1951). The clearest, easiest, and least biased use of visual notation (for the foreseeable future) will occur through the use of drawing directly on paper.

CONCLUSION

We have seen, through both our own experiences and through research, that paper continues to be an important component in knowledge work, the work of thinking, invention, design, and innovation. This will be the important work of the coming century, and it also includes instructional design. Paper will continue to be used for a number of reasons, both common and complex. In modern society, it is always present, inexpensive, light weight, flexible, and relatively stable. We note things on scraps of paper or in more developed notebooks, on agendas, on programs, and on napkins and note cards. It also has value in more complex ways; it remains less mediated than computer-based communication as fewer processes are needed to use and understand it. Further, paper provides abilities in the areas of editing, annotation, collaboration, and manipulation that remain more difficult on the computer; and it supports close interpersonal contact in meetings, conveyance, and personal delivery, i.e. it encourages face-to-face social interaction.

Our ideas come from our use of media. While the other tasks of visual notation or drawing that are primarily representational are important to the process, the generational aspects of any notation, whether drawing or writing are paramount;

drawing is a cognitive tool, unmediated through a computer.

Perhaps the most critical element in the use of drawing or visual notation is the ability to generate ideas, to create within this simple medium. Ideas are created through various processes, through thinking, working, communicating, and experimenting. They are not birthed fully formed. Highly developed programs and media short-circuit the process and pre-structure the results. Ideas need an environment, a medium that allows their formation like a cloud of matter coalesces into a planet; an environment for the growth of ideas.

While Einstein was able to mentally generate images, most mortals require some sort of cognitive assistance and some exploration with an external medium. Few humans can completely envision the results of their ideas, whether that is quantum physics, mathematical examples, or designing a new bathroom. This envisioning must occur with ease, with the tools at hand, with the least mediation. That is why Sellen and Harper (2003, p. 185) have written that "the reality [is] that the workplace of the future [is] full of paper." And it's marked with the results of our thinking.

As we develop a common symbolic language for instructional design, we may learn from the work of Christopher Alexander, architect, and author of *Pattern Language* (1971). The book extensively explores hundreds of architectural elements in diagrammatic and photographic form. Ideas for houses, cities, rooms, and spaces are examined and diagrammed as a means to understand the richness of architecture. Far from a template for design, it can be better used as a descriptive observation of the built environment, an artifact from Alexander's own observations. What was most important was the making, not as a product for codified reuse

While there are a number of computer-based notational systems in use, there remains no common system for instructional design. The development of any notational system must be more than a one-off program; it must be based in the human

process of design and development, and its use must be easy, inexpensive, shared, and widespread to be of value. Designers will need to use the system on an informal and unmediated manner. They have to be able to use it without a computer, anytime, anywhere, and at a moment's notice.

Such a system will evolve bottom up, through usage by drawing, much as the rules of writing have evolved from informal oral speech: "The rules of grammar in natural human languages are used first and can be abstracted from usage and stated explicitly in words only with difficulty and never completely" (Ong, 1982, p. 7).

Visual notation in design must encompass many tasks. It will be used for communicating with other team members, but will also be used to plan out tactics and set goals as a decision recording method, to define components created by others, to present ideas and progress to clients, or to develop ideas for the invention of new forms of instructional design. What is not needed is a canned set of symbols, like logos, icons, templates, or emoticons, but a broad-based development of representational or generational skills: skills at conceptualizing, summarizing, editing, communicating, organizing, ordering, and structuring for instructional designers. In simpler terms, instructional designers need to draw to plan, to conceive, and to communicate.

ABSTRACT

LDL (learning design language) is an educational modeling language which was conceived to model collaborative activities. It has roots in social sciences, mainly linguistics, sociology and ethnomethodology. It proposes seven concepts that allow instructional designers to build the model of a collaborative learning activity. It has both a visual and a textual notation, the latter being computer-readable. This means that the produced models can be easily operationalized and executed in an existing virtual learning environment. This chapter introduces LDL, its concepts and the graphical notations associated with each of them. The methodology proposed to

facilitate the modeling is also presented. Its use is illustrated by the example of the planet game, which was practically tested with other research teams as a benchmark/competition during the ICALT 2006 conference.

INTRODUCTION

Learning design language (LDL) is a language intended for use by instructional designers. It has been created to allow them to describe and specify learning activities on the Internet. Lots of activities may take place on the Internet—like a treasure hunt between groups of children, a training session to improve reading, a discussion between a teacher and students, an examination, etc. So, the focus is placed on collaborative activities, as the LDL

DOI: 10.4018/978-1-60960-503-2.ch214

authors are convinced that learning can no longer take place without considering and enhancing the interactions between the learners.

The ambition of the LDL authors is twofold: on the one hand, we want to provide instructional designers with simple means to build the formal description of whatever kind of learning activities (such as the ones previously mentioned, for example) and to combine them. On the other hand, we want the teachers to be able to transform easily these formal descriptions into effective online activities, without any intervention from computer science specialists. These activities will involve services and digital resources available on the teachers' school network and on the Internet.

We did not take into account the division of labor that usually occurs between the instructional designer and the teacher. On the contrary, we have considered that, in order to be exploited by an instructional designer, the language should allow the designer to describe activities as if she or he were a teacher and had to solve some of the problems encountered by teachers preparing lessons. Examples of these problems include determining the theme of the activity, gathering adequate documentation, defining some attainable learning objectives, evaluating the duration of the activity, proposing a division of the activity into sessions, indicating the way students will be arranged during learning sessions, defining individual work sequences and positioning them in the overall activity, defining the way and the means to measure the students' progress. They concern learning and pedagogy, of course, but also logistics, organization and evaluation.

This is an important preparatory task, which may be more or less precise, more or less detailed. It guarantees the teacher being able to conduct the activity once it has begun while keeping control of his or her objectives. Improvisation, on the other hand, is more risky. It is probably limited to the best teachers, in the same way that rally-style driving is restricted to the best drivers. It supposes a complete mastery of pedagogy.

After this preparatory phase, the teacher will be in charge of adapting the activity designed by the instructional designer. The teacher will consider the following:

- The students to be involved in the future activity, because the teacher knows their skills and their work practices,
- The personal objectives defined for each of these students,
- The technical context in which the teacher is operating.

Using LDL during the preparation phase leads the instructional designer to create a *scenario*. A scenario is a codified and formal description of a future activity. It can be considered as a specification of this activity. Designing a scenario to specify an activity consists in describing:

- Where the activity will take place,
- Who the participants in the activity will be,
- What the participants' interventions will be,
- How and when these interventions will be connected throughout the activity,
- The rules the participants will have to comply with,
- What the consequences of the participants' reactions, actions and points of view on the activity will be and how they will be able to express these points of view.

The distinction between a scenario and the activity modeled by this scenario is the same as the difference between a recipe and the future dish whose preparation is described by this recipe. If the ingredients used by the cook are actually the ones mentioned in the recipe, and if the way the dish is prepared is in conformity with the instructions in the recipe, then the tasting of the dish should go off well. In particular, if the codification proposed by LDL is respected, then a computer will be able to interpret a scenario. Thus the teacher will be

able to operationalize it in a technical computer environment.

To support the description of a scenario, a graphical notation was defined. This enables the instructional designer or teacher to represent the scenarios produced more easily and comprehensibly. Once these representations have been produced, they are translated into a corresponding XML binding in conformity with the LDL syntax. (These bindings are not provided here as they are of no use in helping the reader understand the models or the notation.) They are the computer-readable representations of the scenarios. They are also a way of representing the scenarios in a normalized format suitable for exchanges and operationalization.

LDL does not describe the actual nature of the services and resources used by the learners and teachers during the ongoing activity. Neither does it describe the functionalities of these services. The transformation of a scenario, in which services and resources are described in an abstract way, into an actual online activity, in which actual services and resources are involved, is carried out during the operationalization phase. It is supported by learning design infrastructure (LDI), a global infrastructure which has been developed in relation with LDL to deal with both the operationalization and the execution of scenarios.

The authors of LDL think that teachers and instructional designers, who design activities for the teachers, should not have to concern themselves with the technical features of the computer tools they use. That is not their problem. They should be allowed to forget about it so that they can concentrate on the specification of the activities they intend to carry out with students. They have to suppose that the technical environment will be able to adapt to their needs. This is a strongly-held position of the LDL authors, which has had a huge impact in defining LDL and developing LDI. Indeed, LDI is in charge of seeking, finding, and building the technical environment best adapted to the teachers' needs.

What follows is a description of LDL. Before the description, the background of the language will be presented. This will explain the origin of the language and will position it in the field of VIDLs. We will then categorize the language according to Botturi et al. (2006) classification. Next, a detailed description of LDL concepts will be given. For each of them, a definition will be provided together with some examples and the notation proposed to instructional designers to represent the concept in the activity modeling process. After that, the methodology defined to model learning activities with LDL will be described. The use of this methodology will then be exemplified in the planet game example. This example is a case study which was proposed as a modeling and implementing challenge during the last International Conference on Advanced Learning Technologies (ICALT) (Vignollet et al., 2006). It will be introduced just before describing how LDL was used to model it within the LDL methodology. Finally we will present the first results obtained, the strengths and the limitations of LDL and the future work.

THE ORIGIN AND BACKGROUND OF LDL

Modeling Collaborative Activities

The definition of LDL follows upon research we conducted in the domain of CSCW (computer support for collaborative work). Such research works asked the following questions: What are the essential properties of a groupware so that it effectively supports group activities while taking into account the social aspects of these activities? On which model should these tools be built?

The answer was to propose a model for group activities: the participation model (Martel, 1998; Ferraris et al., 2002). This model is grounded on properties that are inherent in the nature of collaborative activities. These properties were analyzed

and revealed by research in social sciences. We have considered the following ones:

- Activities are *situated* in various contexts (social, cultural, technical, geographical, etc.) (see Suchman, 1987; Fitzpatrick et al., 1995; Garfinkel & Sacks, 1972). Thus it is necessary to consider both the *places* of the activity and the *roles* the participants will have in these places. Roles are relative to the location of participants: i.e., they are also situated (see Chapter XIII).
- Activities are *unforeseeable*. They are built gradually as they proceed (see the works on activity theory by Vygotsky and Leontiev). So it is impossible to produce an *a priori* description of what an activity will be. Such a description can nevertheless be useful to support collaboration in CSCW tools but *if and only if* it can be revised *in situ*, according to what actually happens in the ongoing activity (Suchman, 1987).
- Collaborative activities suppose the existence of a *compromise* between the interests of the group and those of the individuals, between the dependencies that stem from relationships among individuals and their autonomy. Each individual must be able to negotiate her or his commitment to the activity (Martel, 1998). This was inspired by Goffman's theory (Goffman, 1981).

In addition, we were inspired by works in linguistics, mainly the dialogue models of the University of Geneva (Roulet et al., 1985) that attempt to explain the succession and the interweaving of conversational exchanges. Indeed, we have drawn a parallel between a teaching activity and a conversation. In a conversation, locutors speak to their interlocutors, who make an interpretation of what is said and may react in turn (Austin, 1955). Just like a conversation,

we consider an activity as *a set of exchanges and interactions* between the users involved (the participants). As in a conversation, the exchanges are *structured* and *scaffolded* by rules. And as in a conversation, every exchange involves at least two participants: an *addresser* who acts and whose actions are aimed at an *addressee*.

A Socio-Constructivist View of Learning

Contemporary pedagogical movements attach great importance to socio-constructivism, a learning theory developed by Lev Vygotsky at the beginning of the 20th century (Vygotsky, 1934). This theory rests on the idea that knowledge acquisition is facilitated by the various social interactions a learner may have during her or his learning process.

This point of view seems to be shared with problem-based learning proponents such as Savery and Duffy (1996). These researchers also state that cooperation influences learning. Indeed, generally in their approach, learners, grouped in teams, are expected to collaborate, helped by their teacher, to explain phenomena underlying a problem.

Both theories thus state that learning activities are intrinsically cooperative: they are based on interactions which are richer and more complex than the traditional face-to-face exchanges between a teacher and her or his learners.

THE IMS-LD PROPOSAL

The main proposal in the domain of learning design languages is IMS-LD, which was a result of the work conducted at OUNL (Koper, 2002). It is based on a theatrical metaphor. Indeed, it considers a learning activity as being a succession of "acts" (in the theatrical meaning of that word) that leads to the realization of the "drama" which occurs between learners and teachers. Modeling

such an activity is thus a matter of modeling the alternating or the sequencing of the exchanges that occur in the class.

The main contribution of this approach is to put forward this learning flow modeling, considering that the learning flow reflects the activity in an overall way. However, even though EML has been adopted by IMS, there remain barriers to its adoption. We mention in what follows the barriers which are particularly significant to our purposes. They led us to choose to develop a new LD language instead of using IMS-LD.

A Complex Language

The first barrier is the complexity of the IMS-LD language. Several researchers and end-users (teachers, instructional designers) share the point of view that IMS-LD is complicated, in particular because of its high number of concepts. Consequently, only someone who knows it well can handle it and capture its subtleties. For instance, it is very difficult to define the appropriate properties. Even if the associated best practices try to offer a method, it is still extremely difficult to use for instructional designers, and quite impossible for teachers to use (Le Pallec et al., 2006).

Indeed, as IMS-LD (EML in fact, its ancestor) has been designed to industrialize the creation of distance learning activities, it is not dedicated to teachers organizing learning activities in their classes. It operates as though the modeling phase has to be dealt with by an instructional designer who has a discussion with the teacher and who translates into IMS-LD the informal description of the learning activity the teacher has produced. However, once the modeling has been done, the teacher and the instructional designer have to discuss the formal model produced. This requires the teacher to be able at least to understand, even if she or he cannot produce, the model in a general way. If the language is too complex, this may not be possible

Difficulties in Modeling Collaborative Activities

Miao et al. (2005) have done an interesting and deep analysis of the capacity of IMS-LD for formalizing collaborative learning scenarios. They have pointed out five major difficulties, among which is the difficulty of modeling varied forms of social interactions. They show evidence that by using IMS-LD “it cannot be clearly modelled whether and how people collaborate” (see p.3 of Miao et al.’s paper).

As Hernandez-Leo et al. also noted this problem, they have proposed an extension of IMS-LD (see Chapter XX). But, as Harrer mentions in Chapter XIV, this extension at service level rather than at activity level cannot appropriately capture the characteristics of social interactions.

These difficulties were also reported by Caeiro (see Chapter X). They put forward that the theatrical metaphor is not suitable to model collaborative learning situations when they are not a succession of acts, in the theatrical sense. This led them to propose the poEML language.

No Concept Dedicated to the Activity Observation

All of the actors in the field of education are in agreement about the fact that an educational activity is characterized by its unpredictable nature. Le Pallec et al. (2006) claim that “a large part of scenario can only be defined during runtime” and “in learning science, models are driven by learning events to detect and to react upon” (Le Pallec et al., 2006, p. 2). In fact, teachers are usually able to give prescriptions of an activity, but they know that they will have to take into account the learners’ reactions and what will happen during the activity to adapt it as it proceeds.

IMS-LD does not include a semantically-founded concept which could capture these reactions and the events coming from the ongoing

activity. This is probably due to the theatrical metaphor which intrinsically does not take the reactions of the actors into account. Indeed, actors are supposed to play the part without deviating from the original text. So there is theoretically no need to consider these reactions and what is going on. Everything should go on according to what is written in the author's original text.

The IMS-LD "property" concept could be used to try to capture these reactions. However it has not been defined for that purpose but to be computational. That is probably why it is so difficult to use it to capture reactions and points of view of the participants. Moreover, it cannot be used to capture what is going on in the activity.

Learning Tools Confronted with Virtual Learning Environments

Learning tool designers were concerned very early on by the modeling, or, more exactly, the orchestration of these tools. They tried to describe and formalize the ways of interacting with them, taking into account the specificity of the learning activities they wanted to plan. This is true in all learning contexts: lifelong learning, school-based instruction, etc. This is for instance what Gueraud and her colleagues propose in FORMID (Gueraud et al., 2004), which implements learning activities that include the use of simulations in the electricity field.

However, the deployment of virtual learning environments (VLE) leads one to reconsider their proposals. Indeed, learning tools are now included in the VLE and can interact with other services (Durand & Martel, 2006). Then teachers or instructional designers populate the VLE with several resources, including instructions, learning tools, documents, case studies, etc. All these resources can be considered as small pieces of learning scenarios. Only the sequence which orders these elements is missing.

Towards the Creation of a New Language

In 2003, we were facing the following situation:

- We needed a language enabling one to describe collaborative learning activities and their learning flows,
- We wanted the language to take into account the unforeseeable nature of learning activities,
- We wanted the language to consider the situated and interactive nature of collaborative activities,
- We wanted the language to be computer-readable so that it would be possible to automate the construction of an adapted VLE and the delivery of learning activities via this VLE starting from the activities' description,
- The incipient IMS-LD standard language did not meet our requirements.

So we decided to define a new LD language, based on the participation model. As this model had been improved and validated—it had been used to specify and develop successfully one of the very first extant VLE in France, which has been used daily since 1999 at University of Savoie by more than 15,000 users (Martel et al., 2004)—the challenge sounded possible.

LDL was thus created in 2003 by Christian Martel, Laurence Vignollet and Christine Ferraris from "scenario Team" in collaboration with Pentila corporation (<http://www.pentila.com/>) and Jean-Pierre David and Anne Lejeune from LIG-METAH (Laboratoire d'Informatique de Grenoble—METAH Team). The related infrastructure LDI was specified by "scenario team" and Pentila corporation, and developed by Pentila corporation.

POSITIONING LDL TOWARDS BOTTURI ET AL.'S CLASSIFICATION

LDL can be considered as a *finalist communicative* language, in reference to the framework presented in Botturi et al. (2006). In the same paper, they have also defined a classification scheme for ID languages. According to this classification, LDL can be categorized as:

- **Stratification:** (layered) LDL proposes seven different concepts to describe the model of a learning activity. All these concepts are linked with each other in an information model (a meta-model).
- **Formalization:** (formal) LDL combines a graphical notation and a textual one. Indeed, the instructional designer is supposed to use the graphical notation to create a scenario. The resulting diagrams have then to be transformed in a corresponding LDL-XML binding, so that a computer will be able to make the scenario run on an existing VLE. The binding is of course formal as it is expressed in XML according to the LDL grammar. As the transformation is supposed to be carried out automatically in the future (this is not the case currently), the graphical notation requires precise syntactical rules.
- **Elaboration:** (Specification) The language has been primarily defined to build the specification of a learning activity. The specifications built have the particularity of being computer-understandable. They can be transformed automatically into machine-code in order to automate the delivery thanks to technology.
- **Notation:** (Both visual and textual) Initially, there was only a textual notation (an XML binding). We have added a graphical notation, assuming it would help teachers and instructional designers in

building the scenarios. This still has to be validated.

- **Perspective:** (multiple) If we consider only the textual notation of LDL (i.e., the XML binding), the perspective is single. If we consider both the textual and visual notations, it is multiple. In fact, several views are required for some of the LDL concepts, for instance the *position* one (see Figure 13 and supplementary Table 1).

LDL: SEVEN CONCEPTS TO BUILD A SCENARIO

To build a scenario using LDL, the instructional designer has to analyze the activity to identify:

- « Who »: Who takes part in the activity?
- « Where »: Where does the activity take place?
- « What »: What is done during the activity?
- « How » and « When »: In which order do we play and under which constraints (when does it start and when does it stop)?

To those “classical” concepts, LDL adds two other, more original ones (Martel et al., 2006a):

- The « reactions » of the participants: What is the participant’s evaluation of the difficulty of an activity? What is his or her point of view on a document? How does a participant view his or her place in the activity?
- The « rules of the game » of the activity: What is allowed? What is not? How could we take into account the participants’ reactions to adapt the activity?

LDL concepts are detailed below. For each detail, we provide a definition of the concept together with its UML representation (which positions the

concept relative to the others within the LDL meta model), some examples and the corresponding LDL graphical notation. This notation is intended for instructional designers. We have defined it in order to prevent instructional designers from having to use the XML notation. The objective is twofold: (1) to provide instructional designers with a graphical notation which is much easier to handle than XML and (2) to provide both teachers and instructional designers with a more user-friendly means of communication. The reader who is not familiar with UML will be able to find a good UML primer in Chapter IX of this handbook.

The Roles

The roles represent “classes of” participants who take part in the activity. In activities, participants have coherent interactions. A set of interactions reflects a “thematic” role.

Definition

The activity’s participants are represented by the role concept (see Figure 1). A role is the set of interactions a participant can have with others taking part in the activity.

It is characterized by a name (the role’s name), chosen by the instructional designer because of its relevance to the activity to be modeled.

Examples

Participants who write a course for their students, annotate their work and mark their examinations are teachers; participants who read the course, do the exercises and take the examination are the learners; participants who write an article for an online newspaper’s readers are writers.

Figure 1. Role model (UML representation)

Notation

The Figure 2 gives the graphical notation of the roles. This notation is taken from actors’ notation in UML.

The Arenas

The arena is the place where the activity takes place: a service or a content. A forum, a search engine or a chat room are considered as service arenas. A course, an exercise, a photo album or a Web site are content arenas. This referencing to real space guides the modeling and delimits the interaction perimeter. Participants interact in these arenas through the interactions specified by their roles.

Definition

Places where activities take place are arenas. An arena refers to a service or digital content which supports the participant’s activity. It is defined

Figure 2. Role notation

at least by a name and may contain other arenas (see Figure 3).

Examples

The library is an arena where participants can search for a book; the amphitheater is the place where the teacher gives a lecture: it is the lecture's arena. The usual arena used by participants for asynchronous online discussion is a forum.

Notation

The Figure 4 gives the graphical notation of the arena called "Forum to discuss the lecture."

The Interactions

The interactions represent what is done during the activity. They specify the exchanges the participants will have during the learning activity. They usually consist of verbal communication, document exchange and collaborative productions. They are situated: they occur in contents or via services. So they depend on the capacity of the

places where they occur (for instance, a content can be read, a forum can offer communication functionalities, etc.)

Definition

Any exchanges which take place between the participants during the activity are called interactions.

In its simple form, an interaction is characterized by (see Figure 5):

- An identifier,
- The *action*, which describes what is done during the exchange,
- The roles of the participants involved in the exchange,
- The arena in which the interaction takes place.

An interaction always takes place between at least two participants, represented by their roles. The initiator is called the *addresser*, the one to whom the action is addressed is called the *addressee*. Addresser and addressee represent the respective places of the interaction's participants (here we have transposed the duality that exists in conversations between locutors and interlocutors). The association called "*involves*" which appears in Figure 5 between the "role" and "interaction" concepts thus needs to be divided into two more precise associations which consider these respective places: the ones appearing on Figure 6.

Furthermore, LDL allows the specification of start-up and stopping conditions of interactions, using *rules*. The rules are described further.

Examples

"The teacher provides a document to the learners," "the project leader sends an alert message to the members of her or his working group," "the learners answer a question given by the teacher"

Figure 3. Arena model

Figure 4. Notation of an arena

Figure 5. Interaction model

Figure 6. Addressers and addressees during an interaction

are just a few examples of interactions which can happen between an activity's participants.

Students doing an exercise and sending it to their teacher are the addressers and the teacher is the addressee. Sometimes, the addresser and the addressee are identical and correspond to the same participant. It is for instance the case when a learner reads a document for her or his own information. It is also the case when a participant uses a search engine to find information.

Notation

Interaction notation consists of four constituents: its identifier, the action's name, the roles involved and the arena where it takes place. This is expressed by the notation presented in Figure 7 (R1 and R2 correspond to the name of the roles).

This notation has to be completed with the rules that express the start-up and stopping of the interaction. They are referenced by a diamond, which symbolizes a condition, as shown in Figure 8.

Figure 7. Notation of the interaction I

Figure 8. The interaction *I_talk* referencing its start-up and stopping rules.

The Structures

How and when the interactions are connected throughout the activity is captured by the structure concept.

Definition

During the activity, interactions are played either sequentially or in parallel. In LDL, the structures describe these sequences.

A structure is characterized by (see Figure 9) a title, which identifies it in a unique way within a scenario, the list of the interactions, and the type which defines the interactions' organization. LDL distinguishes two types of structure, which correspond to two different manners of linking the interactions:

Figure 9. Structure model (types are represented using sub-class notation)

- A *sequence* structure means that the interactions will be executed one after the other, sequentially;
- A *parallel* structure means that all or some of the interactions will be executed in parallel. With this type of structure, the instructional designer could, if necessary, indicate the maximum number of interactions that the participant has to perform. By default, this number is equal to the total number of interactions which corresponds to the progress in parallel of all the interactions.

Like the interactions, the structures contain information on their conditions of start-up and stopping. These conditions are also expressed by rules. Finally, a structure can include other structures.

Examples

A *sequence* structure will allow one to express that an alert will be sent to tutors as soon as the teacher gives the specified document to learners. A *parallel* structure will make it possible to express that the learners must carry out three exercises, in any order, that they will have to choose from the list of the five proposed.

A more complex structure could be for example: the learners read the instructions, they can then play a learning activity, and finally, they have an assessment to perform. In this example, three steps are sequentially performed. The first one and the last one are simple interactions. The second one corresponds to a more complex activity where, for instance, the learners can, in parallel, read the lesson, discuss with their peers and do exercises.

Notation

The *sequence* structure is represented vertically and the *selection* structure horizontally. If the number of interactions to be performed is limited, this number is mentioned in brackets.

Figure 10. Sequential structure notation

In Figure 10, we represent the main structure of the last example above: a sequential one which starts automatically and specifies that the reading interaction called *I_ReadingOrders* is followed by the learning structure called *S_Learning*, and closed by the assessment interaction called *I_Assessment*.

Figure 11 shows the “*S_Learning*” structure, a structure where three interactions can be played in parallel: the “read the lesson” interaction (*I_ReadingLesson*), “discussion” interaction (*I_Discussing*) and the “exercise” (*I_Exercising*) interaction.

The Rules

The rules correspond to the rules of the game of the activity.

Definition

Rules are used to express the start-up and the stopping of interactions and structures. They are production rules of the form: *If condition Then action*. The conditional part of a rule is a logical expression using the connectors OR, AND and NOT. The action can be the start-up or the stopping of a structure or an interaction.

Examples

Rules make it possible to express for example that a discussion can begin when all the learners have read the instructions and that it will stop when the teacher gives the signal.

Notation

A reference to the rules is added to the structure and interaction notations, as shown in Figures 8 and 10.

The Positions and the Observables

The conditions of the rules depend on the reactions of the participants. LDL includes a concept, that of *position*, which allows one to specify these reactions and thus to adapt the activity according to them. The value of a position is tested in the conditional part of a rule.

Figure 11. The parallel structure called *S_Learning*

Table 1. Examples of position

Position Id	Title	Value	Type	Taken by	On
P_stop_act	I stop the learning activity	True or false	declared	teacher	The learning activity
P_vote	my evaluation of this work is	an integer between 0 and 20	declared	teacher	The learner work
P_is_inside	I am present	True or false	observed	learner	The group space

Definition

The position of a participant is the means of expressing the participant's reactions, perception and points of view on an ongoing activity. It is characterized by (see Figure 12):

- An identifier,
- A title, which expresses the semantics of the position,
- A value,
- A type: *declared* or *observed*,
- The role of the participant who takes the position,
- The arena on which the position is taken.

Two types of position exist, depending on how the value of the position is obtained. A *declared* position means that its value is given explicitly by the participant involved. The value of an *observed* position is assigned by the system which deduces it from observation data on the activity's

progression. The instructional designer will have to define which aspects are to be observed. These aspects are called the *observables*.

Examples

A teacher can choose to interrupt a working session to allow learners to play games. This is a *declared* position taken *by* the participant having the “teacher” role *on* the “learning activity” arena. Its title may be “I stop the learning activity.” Its value may be “true” or “false” and may vary as the activity proceeds. Another *declared* position allows the teacher to give a mark to the work of the learner. The presence or the absence of the students in the digital space shared by the group is an *observed* position. Table 1 shows the complete descriptions of these three positions.

Notation

Positions are represented by:

- A hand symbol for a *declared* position,
- A magnifying glass symbol for an *observed* position.

The role of the participant who takes the position is specified under the symbol.

In Figure 13, the discussion can begin when all the learners have read the instructions and it will stop when the teacher gives the signal.

When appearing on an interaction representation (such as in Figure 13), positions are not

Figure 12. Position model with the links to other concepts

Figure 13. Interaction notation supplemented with positions

completely specified. Thus their definition has to be supplemented by fulfilling a table like the one presented in Table 1.

Please note that the rules are the means to personalize activities. For instance, a rule can be defined to propose complementary lessons to a learner who has declared that she or he is not able to do an exercise (her or his position to the arena “exercise”).

The presentation of LDL and its concepts is now complete. The next three sections are devoted to the presentation of the methodology we have defined to help the instructional designer build a scenario with LDL. The methodology is of course subordinated to the LDL language. After this presentation, we will apply the methodology to an example.

THE METHODOLOGY

The proposed methodology distinguishes two steps clearly. Step 1 aims at building an informal scenario. Step 2 aims at formalizing this informal scenario.

Step 1: Building the Informal Scenario

Usually, a learning design begins with a more or less precise idea of a learning activity described in a narrative way. For instance, the teacher and

the instructional designer could intend to propose an activity on the subject of planets and their organization in the solar system. In this example, the objective could be to enable the learners to discover that the differences between the distances of the planets from the sun can be explained by their properties. Another objective could be to allow the learners to acquire knowledge in the field of astronomy: the difference between a planet and a star, the notion of orbit, physical mass, etc.

To build a scenario, the instructional designer will first of all take into account the learning objectives of the teacher. Existing reference lists of skills will also be taken into account. Then the learning design consists in thinking about how the learners could individually or collectively use the resources during the activity. In other words, it is the construction and the description of interactional arrangements in which resources are used to facilitate effective learning. If possible, this learning has to be assessable.

Step 2: Formalizing the Informal Scenario

One only has to observe a group of learners working to become aware that the slightest educational activity is complex, and that its modeling could be quite difficult to carry out. In fact, a learning activity often conceals a myriad of interwoven activities, whose relationships are confused. Within this myriad of activities, we distinguish four types:

- The first type is obviously the *learning type*. Activities of this type are the heart of the learning. Learners manipulate the resources put at their disposal. They produce contents related to the learning objectives. They work individually or collaboratively.
- The second is the *observation type*. During activities of this type, the teacher observes the ongoing learning activity. The objective of this kind of activity is twofold. First,

they are intended to help the teacher perform a formative assessment of the learning activity, for each participant. Second, they can allow the supervision and the regulation of the progression of the activity. Usually, teachers are the only participants in this kind of activity.

- The third is the *assessment type*. Any learning activity is preceded, associated with or followed by at least one assessment activity. This is the place and time to assess the knowledge of the learners. The place of the assessment activity in the overall learning flow depends on the kind of assessment desired by the designer (diagnostic, formative, summative, etc.) (Durand & Martel, 2006).
- Finally, we consider the *organizational type*. Activities of this kind are dedicated to organization problems. It is usually the time and place where the resources and tools are made accessible, and the orders are given to the learners. If needed, it is also the time and place where groups of learners are created. Finally, it is the time and place in which the other activities are started.

We regard these four kinds of activities as basic elements that constitute every learning activity to model. The overall learning activity results from the combination and the interrelations of these activities. Being activities *per se*, they can be modeled as independent scenarios. Building the formal scenario of a learning activity is thus no longer a matter of defining a unique scenario, which encapsulates everything. It becomes a matter of defining *at least four scenarios*, corresponding to the four different kinds of activities identified. As a consequence, it becomes a matter of describing the relationships between these scenarios. It is also a matter of describing each scenario in terms of the concepts proposed by LDL. Thus the current step of the methodology consists in: (1)

identifying the activities and their relationships and (2) modeling each identified activity. These two phases are presented in the next two sections.

FORMALIZING THE INFORMAL SCENARIO (PART 1): IDENTIFYING THE ACTIVITIES AND THEIR RELATIONSHIPS

At this stage of the methodology, the instructional designer has to:

- Analyze the overall activity to identify the activities that constitute it and that correspond to the four types of activities mentioned above: organization, learning, observation and assessment;
- Define the relationships between these activities.

Identification of the Activities

It is easier to begin with the identification of the learning activities, as most of the time the information provided in the informal scenario concerns learning. The identification of the observation activity is next, followed by the assessment activity. Then comes the identification of the organization scenario, as it may start the other activities. The description of what usually happens in these activities (see previous section) may help.

Identification of the Roles Involved

The “identification” phase has to be completed with a description of who is to be involved in each activity by identifying their *roles*. For each activity, the instructional designer identifies the main roles of the future participants. For instance, the teacher is the role of the observation activity. For each activity, she or he also has to define the *participation modes*.

Identification of the Participation Mode

“Participation mode” is the overall way participants will exchange and interact in an activity. It describes the kind of situation a teacher wants to carry out with his or her students. It allows *individual* participation in an activity to be distinguished from *collaborative* participation.

In individual participation, participants have individual activities and no relationship with each other. This is the case, for example, of an examination in which, by definition, learners have to work on their own. Figure 14 presents the notation proposed to describe individual participation.

On the other hand, in collective participation (see Figure 15), participants work and interact together. They are supposed to act in the activity as interdependent and engaged partners sharing a common goal. For example, teachers may ask students to work in a group of four to read texts about “instructional design,” analyze them and produce a synthesis of their readings. In each group engaged in this activity, members work jointly. They will produce a unique synthesis.

In collaborative participation, we distinguish *frontal* situations from *open* ones. In frontal situations, participants have individual activities but no relationships with the other participants, except with the person having a particular role who oversees, stimulates, coordinates and controls. This person has a central position in the ex-

changes and in communication. This is the case for example of a course at university in a lecture hall: the teacher is in front of the students giving a lecture and the students are allowed to ask questions; to do that, they have to raise their hand to ask to speak. Figure 16 presents the notation proposed to describe such frontal situations.

In open situations (see Figure 17), participants can cooperate freely with their peers or with the teachers. It is the case for example of a panel session in which participants are invited to discuss and express freely their opinions and points of view.

In real educational practices, these various forms can be combined with each other to produce hybrid educational situations that can evolve over time. Figure 18 is an example of such a case. It combines individual participation for participants having a role (represented on Figure 18 with a black head) with open situation for participants having another role (represented on Figure 18 with a white head). It could be the case, for example, of a panel session with attendees. On the one hand, participants having the “attendee” role have an individual activity: they listen to the discussion and may take some personal notes. On the other side, participants having the “speaker” role are involved in an open situation: they are debating on a given subject.

Figure 14. Notation for individual participation in an activity

Figure 15. Notation for collective participation in an activity

Figure 16. Notation for a frontal situation

Figure 17. Notation for an open situation

Definition of the Relationships Between the Activities

Once the instructional designer has identified the activities, the roles involved and the participation modes for each of them, these activities have to be positioned by the designer with respect to each other. This means that the designer has to:

- Define the learning flow; and,
- Define the objects the activities may share (arenas and positions).

Figure 18. A hybrid situation.

These elements are presented in what follows, together with the notation proposed to represent them.

Defining the Learning Flow

The definition of the learning flow leads to both the building of the activity schedule (specification of the order according to which activities will have to be performed) and the definition of synchronization points between these activities. We have defined a notation to represent these two dimensions. For the schedule, the instructional designer may use the notation proposed in Figure 19 to represent activities which are connected sequentially. The notation proposed in Figure 20 is for those activities which proceed in parallel.

The synchronization points allow the instructional designer to deal with the start-up and the

stopping of activities. Two activities may start in an asynchronous way. If so, they will have different start-up conditions. This is represented by the notation proposed in Figure 21.

On the other hand, they may start simultaneously. This means that they share the same start-up rules. This is expressed by the notation presented in Figure 22.

Finally, the instructional designer may want to express synchronization at the end of activities. Figure 23 shows the notation proposed to express this in the case of three activities A1, A2 and A3: A3 cannot start until A1 and A2 are over.

Defining Shared Objects

Activities may share some objects. Two kinds of objects can be shared: arenas and positions. Two activities may share an arena if their respective participants need to have interactions in the same arena. Let us consider the example mentioned previously (concerning collective participation) in which groups of students work on the production of a synthesis on instructional design theories.

Figure 19. Activities performed sequentially

Figure 20. Activities performed in parallel

Figure 21. A1 and A2 start asynchronously

Figure 22. A1 and A2 start synchronously

Figure 23. Synchronization between activities

Imagine that in the learning activity, students have at their disposal a forum to support their discussion about the synthesis they have to produce. The observation activity and the learning activity will have to share this forum, as the teacher involved in the observation activity will have to be able to observe it. The notation proposed for the sharing of arenas is given in Figure 24, on the example of a shared forum.

In the same way, activities may share positions. For example, imagine that an assessment activity is going on. The teacher wants to propose an adapted remediation activity to the students whose marks are not as good (this is a learning type activity). To do that and to adapt the remediation to the students according to the obtained mark, the two activities will have to share the marks (see Figure 25). It is an “observed” position given by the teacher in the assessment activity. It will be used in the remediation one.

Figure 24. Two activities sharing a forum

FORMALIZING THE INFORMAL SCENARIO (PART 2): MODELING EACH ACTIVITY

Until now, the instructional designer has focused on the identification of the activities and their relationships. She or he has built an overall view, positioning the activities with respect to each other. It is time now to change the focus and to go deeper into each activity. That means building a model, i.e. a scenario, for each of them.

An LDL scenario needs the definitions of the structures, interactions, roles, arenas, rules, positions and observables suitable to the activity to be modeled. We recommend defining these concepts in the following order:

- First, identify the learning flow of the activity. This leads one to make an inventory of the structures and the interactions they organize. At this stage, the instructional designer only needs to identify the interactions in a general way (only their names). This will give a first, overall view of the expected activity.
- Second, give a more precise specification of each interaction. That means identifying the roles and the arenas involved in each interaction.
- Third, complete the specification of the interactions and structures with the definition of their start-up and stopping conditions. This supposes modeling the corresponding rules.

Figure 25. Notation for two activities sharing a position

- Fourth, define the positions. The conditional part of the rules tests the values of the positions. So, from the exhaustive list of rules, one can obtain an exhaustive list of positions to be defined.
- Last, define the observables. The instructional designer has to define for each “observed” position the associated observables.

The description of the methodology now is completed. With this approach, the instructional designer has all the material required to model a learning activity: a language, allowing a model of the targeted activity to be built, and a methodology for explaining how to handle the language and how to carry out the modeling process. The next section shows an example of how LDL and its associated methodology were used to create the model of the planet game case study.

APPLICATION OF THE METHODOLOGY TO AN EXAMPLE

We have chosen to show the use of LDL and the methodology with the planet game example. This example was proposed as a common case study to work on within the workshop entitled, *Comparing Educational Modeling Languages on a Case Study* (Vignollet et al., 2006) we organized during ICALT’2006. Each research team engaged as a competitor (they were 9) had to study a given real situation (the same for every team: the planet game), had to at least model this situation by using its own models and languages, and was asked to implement it as an activity running in a web learning environment.

The methodology recommends building the informal scenario first. Thus we begin by presenting the informal scenario of the planet game. Note that we will not provide the complete specification, as this would be too long. We will just show a part

of it, which illustrates the approach satisfactorily. Additional information can be found in Martel et al. (2006b) or at <http://ld.pentila.com>.

Step 1: The Planet Game Informal Scenario

The Context

The chosen activity is part of a real lifelong learning scenario in astronomy. The students have the same problem to solve. They are grouped into two teams. Each team has only a part of the knowledge and data required to solve the problem. So, they must collaborate.

The Proposed Activity

The activity objective is for learners to acquire knowledge in the field of astronomy. More precisely, they have to classify the planets with respect to their distance from the Sun (from the nearest to the most distant).

The strategy used by the teacher to reach these objectives is to propose a game for the learners. The latter are grouped into two teams (Team A and Team B). Resources and services will be available to help the learners in acquiring new knowledge, in exchanging with their team members, and in negotiating.

The Game Rules

Clues are distributed among teams. Team A knows some planets’ properties, taken from an expert interview it has at its disposal. Its members can deduce the planets’ order, but not the planets’ names. Team B knows the planets’ names and some properties taken from another expert interview. However, many properties are missing. Each team can use a chat room to enable its members to have discussions (about the problem to solve, the clues they have, etc). Each team also has at its disposal

a shared whiteboard allowing its members to list the already discovered information.

The teams have to cooperate using a forum to negotiate the exchange of clues and information. The teacher has access to the forum, and can participate in the discussions. She or he can also add new clues to either of the expert interviews. When she or he decides, the exchanges are stopped. Then, each learner fills in a questionnaire about the planet classification. The winner is the first who gives the right associations (the planets in order from the sun). The activity finishes when a winner is nominated.

Step 2-Part 1: Identifying the Planet Game Activities and their Relationships

When analyzing the informal scenario above, we notice that the four kinds of activity mentioned in the methodology section (organization, learning, observation, assessment) actually exist in the planet game. For the learning activity, it is obvious. The informal scenario explicitly includes a lot of information about this activity. The learning objectives are listed, together with the way to reach these objectives (analysis of the clues, discussion in the chat room, negotiation with the other team, etc.). The aim is clearly for learners to acquire knowledge about the organization of the solar system.

The informal scenario also mentions the interventions of the teacher in relation with the learning activity. Indeed, the teacher has to observe the teams while the learning activity proceeds. She or he may observe the team members' exchanges, their productions, the way they use the clues, etc. This is an activity *per se*, during which the teacher may identify the difficulties encountered by the learners, may put new clues at their disposal, etc. This is the observation activity.

The assessment activity is also clearly mentioned. It consists in a summative assessment

which occurs at the end of the learning period. It aims at checking the level and the solidity of their knowledge.

Finally, there are some elements which are related to organization which are possibly less explicit. The most evident one is to set up the two teams. To be carried out, the planet game requires this step. It also requires the teacher to prepare some instructions intended for learners, to put them at the learners' disposal, together with the useful resources (interviews, clues, shared whiteboard, chat room, etc.), to organize the course of the activities in time, etc.

These activities are represented graphically in Figure 26, together with the learning flow between them (the schedule and the synchronization points). Note that the learning activity appears twice, once for each team: they correspond to the same scenario.

The description of the relationships between activities has to be supplemented by the definition of the shared objects: arenas and position. The ALearn1 and ALearn2 learning activities share the forum which supports the negotiation of the exchange of clues. This arena is also shared with the AObs observation activity, as the teacher involved in the observation activity has to be able to at least observe what happens in it (see Figure 27).

Furthermore, the two learning activities and the observation one share the "end of the learning activities" position. This position is a decision of the teacher to be made explicitly in the AObs activity. Indeed, the teacher observes the two ongoing learning activities and chooses the time to stop them, when the learners have worked enough and have acquired enough clues and knowledge. Thus the AObs activity has to share this position with the two learning ones. As a consequence, these two activities will be aware of it and will be able to end. Note that it is also shared with the AAssess activity, as the end of

Figure 26. Activities, roles and relations between activities are identified

Figure 27. ALearn1 and AObs activities share the “clue negotiation” forum

ALearn1 and ALearn2 coincides with the beginning of AAssess.

Step2-Part 2: Modeling Each Activity of the Planet Game

We have chosen to describe the organizational one (though only part of it). It is easy to imagine the design of the others, in the same way. The first step is the identification of the “Learning Flow,” represented by the structures and the interactions.

The Structures and the Interactions

The main structure is a sequential one which combines four interactions:

- Read the instructions, called I_ReadInstructions
- Choose a group, I_ChooseAGroup
- Distribute clues, I_DistributedClues
- Start the learning activity, I_StartLearning.

Figure 28. The main structure with the interactions

This is noted as shown in Figure 28.

This identification leads to the determination of roles.

The Roles

Table 2 places the AOrg activity's roles in relation to the interactions that define them. It also provides the place of the role within the interaction: being an addresser or an addressee.

The Arenas

Now, the places where the activity takes place have to be identified. They can be more or less abstract. To find them, the instructional designer has to answer the following question: Where the interaction from role X to role Y takes place? What is the support of the interaction? In which space does the interaction take place?

In the example, the arenas are:

- I_ReadInstructions is done into the Instructions,
- I_ChooseAGroup is done in a questionnaire,
- I_DistributeClues is done in a group space,
- I_StartLearning is done in an activity.

Rules

The distribution of clues can start when the learners have chosen their group. A rule has to be defined. Let us call this rule R_distrib_start. The conditional part of R_distrib_start checks the

position of each learner. Its action part starts the distribution activity.

Positions

For each rule defined, there are related positions. The ones associated to R_distrib_start is a declared one. It is specified in Table 3.

Observables

The P_Group-Chosen position is an observed one. It is associated to an observable: the response provided by the learner in the questionnaire.

FIRST RESULTS AND CONCLUSION

As mentioned in Botturi et al. (2006), each design language was developed with a specific use framework in mind. For LDL, the use framework is the modeling of learning activities and the execution of the produced models (i.e., the scenarios) on existing VLE. As computer scientists, we have taken an engineering approach, moving toward the constant refinement of the language. We have made the deliberate choice of focusing on the expressiveness of the language and on the development of software tools enabling one to easily transform the models into actual activities running on VLE. Indeed, we think that it is of paramount importance that instructional design-

P_Group-Chosen	I have chosen a group	True or false	observed	-	learner	The questionnaire

ers and teachers are able “to see” what happens when a scenario is executed. So they can give some feedback. And this also enables learners to be involved in the evaluation process.

This has an important impact on the results we can present here. We provide results about the modeling capacity of the language and related to the experiments which were conducted with learners. But results related to the actual use of the language by instructional designers or teachers are still missing to date. This is commented on below.

Experiments Conducted

LDL’s maturity can be evaluated by taking into consideration experiments already carried out: the three main ones are described here. They enabled us to improve the expressiveness of the language and to make the infrastructure more robust.

A Famous Scenario of the Internet: The Treasure Hunt

A first experiment took place which brought together 40 participants at a workshop held during the 2005 occurrence of the annual summer school of the French “Technology Enhanced Learning” research community (Lejeune et al., 2005). The chosen activity was an example of a treasure hunt. This type of activity is very widespread and numerous examples can be found on the Internet.

We used LDL to build the scenario and LDI and its associated player to operationalize, execute, play and follow the resulting activity. This experiment enabled us to validate the concepts of the model. It also allowed us to improve the

robustness of the infrastructure, with 40 users playing simultaneously.

The Project “Shared Virtual Laboratory” (SVL) of the Kaleidoscope European Network of Excellence

The objective of this project was to provide researchers in ICT in Education with an integrated environment to collect and share experimental trails. This environment, developed by Pentila corporation, includes:

- Workspaces in which experiments can take place,
- The LDI infrastructure and the associated player,
- A trails repository.

TPELEC (French acronym for “practical work in the domain of electricity”) was one of the experiments conducted to improve the developed environment. It concerns learning in the domain of electricity. The learning scenario’s goal was on the one hand to destabilize the misconceptions and incorrect reasoning of learners, on the other hand to use the detected misconceptions for remediation, progression and building of new knowledge. To carry out the TPELEC experiment, LDL was used to create the scenario and its possible adaptations when misconceptions are detected. LDI was the operationalization, execution and observation infrastructure.

The TPELEC scenario was experimented with in classrooms in 2005-2006 (six experiments in three schools, with a total of 120 learners aged 14

to 16). As the teachers were involved in the experiments and could see the scenarios as they run, they gave some interesting feedback. In particular, they became aware of the modeling capacities of LDL. This stimulated their imagination and led them to produce new, richer scenarios. These scenarios will be formalized, operationalized and experimented within a new project that has been recently funded by the Kaleidoscope Network of Excellence. For a more in-depth description of the TPELEC experiment and its results, you can read the corresponding Kaleidoscope report (Kaleidoscope D7.8.1, 2006).

From a learning design point of view, the purpose of this work was to test the observation points: from their specification in LDL to their implantation and use in LDI.

The Planet Game

The previously presented planet game was tested by researchers during the ICALT 2006 conference. It allowed us to improve the capacity of the language to model different kinds of activities and led to the development of the methodology.

Qualities of LDL

We here want to highlight what constitutes, in our opinion, the main strengths of LDL. To do that, we will refer in particular to some of the “desired properties” proposed by Harrer in Chapter XIV. We also provide some limitations of the language.

A Theory-Based Language

LDL is activity-centered. It was conceived to model collaborative activities. It is grounded on social theories which explain what is inherent in these activities. It thus integrates concepts which enable to take these inherent features into account, mainly their unforeseeable, situated and interactional nature.

Simplicity

LDL comprises a small number of concepts, which facilitates its appropriation. This meets Harrer’s “familiarity / intuitive intelligibility” desired property. One may object that “arena,” “position” or even “interaction” are not that familiar to instructional designers or teachers. That is probably true. But the questions corresponding to the LDL concepts (who? where? what? how? etc.) should compensate for the relative unfamiliarity. And the number of questions should be small, as the number of concepts is. We are currently exploring ways of dealing with this problem through the development of an authoring online tool dedicated to instructional designers and teachers. In particular, we are considering the possibility of using metaphors to translate LDL concepts into corresponding concepts available in these metaphors. For example, in the “classroom” metaphor, the arenas could be the blackboard, the lesson, the poster, the video projector, the story book, etc., i.e. any resources or objects available in a classroom which are quite familiar to instructional designers and teachers. This should facilitate the use of LDL.

Expressiveness

The experiments conducted have improved LDL expressiveness. We were able to model different learning situations and activities of various kinds (learning, observation, assessment, organization). This is probably due to the neutrality of the underlying metaphor. Indeed conversation perfectly corresponds to activity and has the same inherent properties.

Support of Different Granularity

LDL also meets Harrer’s “support of different granularity” desired property thanks to the activity-centered point of view and to the “arena” concept. Arenas are places where activities take place. An

activity occurring in an arena can be described by means of a single interaction (for example, the interaction “to discuss about the lecture” taking place in a “forum” arena). But it could also be described by a more complex specification defining what may happen in the arena (for example in the forum, there may be a moderator; contributors may add new discussion subjects; a contributor may post something new; etc.). And this is a complete scenario (Martel & Vignollet, 2007). The grain of the activity to model has changed.

Future Works

LDL’s expressiveness has been improved during the conducted experiments. Nevertheless we cannot claim that LDL can be used to model any kind of learning. And this is true for all design languages. To try to obtain evidence to support that claim, it is necessary to continue the improvement with a set of informal scenarios to model, which could be considered as a benchmark. We suggest dividing the effort of the building of this benchmark between LD language designers. The work currently done by the English Joint Information Systems Committee (JISC) on the evaluation of IMS-LD within the IMS Learning Design for Practitioners (LD4P) project could be the basis of this benchmark.

Furthermore, we have not yet considered the evaluation of the perception of LDL’s usefulness and the associated methodology by end-users. This is a very difficult problem to deal with, as there are a lot of elements and variables to consider, which are tightly intertwined (Botturi, 2005). Some promising approaches have begun to clear it up, for examples chapters XVIII, XIX and XXI of this handbook and Botturi (2005). If we want to make such an evaluation, we need to make some experiments with practitioners (instructional designers and teachers), giving them the role of “scenario designer.” If we wish to do that in the best conditions, we in fact have to provide an online authoring tool to support both the design

process and the translation of the diagrams produced into LDL code. This tool has to be simple and intuitive enough to be used by end-users, as the learning activity management system (LAMS, Dalziel, 2003) authoring tool for instance. It has to support the graphical notation that we have proposed and the methodology. We have specified such a tool. It is currently under development and should be operational by summer 2007. This will allow us to start a validation phase, which will be supported by learning scientists, instructional designers and/or teachers.

ACKNOWLEDGMENT

We would like to thank the engineers of the Penttilä Corporation for their work on the LDL project.

ABSTRACT

Modern computer gaming technology offers a rich potential as a platform for the creation of compelling immersive training systems, and

there have been a number of game-based training systems developed in recent years. However, the field is still in its infancy. Improved understanding is needed on how to best embed instruction in a game and how to best use gaming features to support different types of instruction. Further, the field is inherently inter-disciplinary, requir-

DOI: 10.4018/978-1-60960-503-2.ch215

ing instructional system designers, software developers, game designers and more, yet there are no established development methodologies to ensure effective coordination and integration across these disciplines. The authors introduce a collaborative effort that is investigating how to improve the craft and science of game-based training. They present their experiences in creating a flooding control training system for the U.S. Navy Recruit Training Command, and discuss the inter-disciplinary development issues that they encountered. They present the lessons they learned and their views on how to advance current methods to support the consistent production of effective game-based training.

INTRODUCTION

Computer games of various kinds have been used for education and training purposes for over two decades with varying degrees of success (O'Neil et al., 2005; O'Neil & Perez, 2008). As computer gaming technology has matured and increased in capability, the opportunities available for delivering immersive learning experiences have increased (Bonk & Dennen, 2005; Hill et al., 2006; Hussain et al., 2008; Johnson et al., 2007; Roberts et al., 2006), and so has the challenge of creating experiences that are pedagogically effective (Diller et al., 2004; Hussain & Ferguson, 2005). A training game is imbued with a purpose - to provide experiences which lead to specific gains in the student's knowledge and/or skills. A good training game will consistently balance the instructional goals with the goal of motivating the player. However, a poorly designed training game will sacrifice one or more fundamental elements of the gaming experience in order to attempt to satisfy the training goals, or will sacrifice effective pedagogy in order to attempt to keep the game compelling. The former may be a great training system, and even a great simulation-based training system, but doesn't pass muster as a game-based

training system since the players don't enjoy it. The latter may be a great game, but doesn't pass muster as a training system since it does not produce the desired learning outcomes. Developers of game-based training systems know this, but achieving this synergy between instruction and engagement is a poorly understood art.

The challenges facing us as a discipline are:

- 1) An enhanced understanding of the elements of game design and pedagogical design that are crucial to game-based training and how to balance those elements effectively,
- 2) An enhanced understanding of how to assess the success of a game-based training application, and
- 3) The creation of development methodologies that lead to repeatable successes, especially for non-commercial training programs that are limited in the scale of effort that can be supported.

We introduce the initial results of a multi-disciplinary effort sponsored by the Office of Naval Research to directly address the issue of how to best create effective educational immersive computer games. The team for our project included researchers and content developers from the fields of instructional design, story-based training and entertainment, movie production, human performance assessment, game engines, commercial games, game-based training systems, simulation and modeling, intelligent tutoring systems, graphic design and modeling, system integration and educational science. As professionals in our respective fields, we each brought different perspectives on the interactions of different aspects of gaming and pedagogy to the table.

Our effort had two mandates. The first was to conduct applied and empirical research on tools and methods for enhancing the art and science of educational games. In particular, our initial focus was on identifying extensible design and development methods that support efficient cre-

ation of training games with strong pedagogy and embedded assessment. The second mandate was to create prototype training systems for the Navy that met real training needs and embodied sound pedagogy. The customer for our first training prototype was the U.S. Naval Service Training Command. The goal of this prototype effort was to provide training on how to perform effective flooding control aboard a simulated naval ship. The Flooding Control Trainer that we developed is intended for use at the Navy's boot camp to augment the classroom-based and hands-on instruction that is currently provided to over 40,000 recruits per year.

In a seven month period, our team members worked closely together, with subject matter experts and with our Navy customer to produce a prototype that met our customer's needs and was effective. We present here a description of the process that we followed, the tensions we encountered during the effort, and the lessons we learned on how to work in an interdisciplinary manner to achieve an instructionally strong and enjoyable outcome. We discuss our next steps in the project to refine and formalize our process, as well as our thoughts on where the field needs to focus going forward to ensure longevity and success as a discipline.

BACKGROUND

From a theoretical perspective, games hold promise as effective teaching devices because they can provide instructional environments that embody key principles derived from learning science. For instance:

- Interactions that facilitate player engagement in a *compelling task environment* should facilitate learning. Practicing in this type of environment is consistent with notions about the development of expertise (Bransford et al., 1999; Chi et al., 1988;

Glaser, 1989) and anchored instruction (e.g., Bransford et al., 1990; CGTV, 1992; CGTV, 1997; CGTV, 2000). The game world provides a context in which appropriate mental models are developed and refined through repeated exposure to important cue patterns.

- Games provide an excellent *model-based world* to foster reasoning. Students are able to manipulate variables, view phenomena from multiple perspectives, observe system behavior over time, draw and test hypotheses and compare their mental models with representations in the external world. These features are consistent with the model-based reasoning concepts advocated by learning researchers (Cartier & Stewart, 2000; Gentner, 1983; Leher & Schauble, 2000; Raghavan et al., 1997; Raghavan et al., 1998; Stewart et al., 2005; Zimmerman et al., 2003).
- Game-based tasks are expressly designed to help players *progress toward goals*. Moreover, the goals are concrete, specific, and timely. The vast literature on goal setting in instruction suggests that this characteristic property of games should enhance learning (Locke et al., 1981; Locke & Latham, 1990; Schunk & Ertmer, 1999).
- Interaction frequency is very high in games. These often require decisions and inputs by players several times a minute. Thus, games provide a *highly active learning* environment, the kind of environment associated with effective instructional system design (Chi, 2000; Mayer, 2001; Rothman, 1999; Vogel et al., in press).
- Well-designed games provide the player with constant successes. Many small tasks are embodied along the way in the pursuit of a greater goal. The result is that the game generates a feeling of constant accomplishment, a feature likely to *enhance self-efficacy*, which has been consistently

shown to improve learning and motivation (Bandura, 1977; 1986; Gist et al., 1989; Gist et al., 1991).

- Games provide a *continuous source of feedback* so that players know where they stand with respect to their goal accomplishment. This is crucial since feedback improves learning through both its informational and motivational qualities (Bransford et al., 1999; Salas & Cannon-Bowers, 2000).
- Game play tends to be *self-regulating*, an important feature of effective learning. Players are motivated to accomplish the next challenge and they know where they stand relative to their goals (Kanfer & Ackerman, 1989; Kanfer & McCombs, 2000; Pintrich & Zusho, 2000; Schunk & Ertmer, 1999; Schunk & Zimmerman, 2003).
- *Engagement and immersion* are high in well-designed games. Literature is beginning to investigate these concepts as psychological states associated with effective performance and learning (Csikszentmihalyi, 1990; Gerhard et al., 2004) and to examine what contributes to them (Baylor, 2001; Gerhard et al., 2004; Moreno & Mayer, 2004).
- *Challenge and competition* are hallmarks of good games. These features have been found to be motivational under certain conditions (Epstein & Harackiewicz, 1992; Reeve & Deci, 1996), and may be useful to motivate learning.
- Perhaps due to factors listed above, *time on task is very high* for games. It is not uncommon for players to spend hours a day on engaging games, and to continue interacting with a single game for years. From a strictly time-on-task perspective, we would expect that learning would be enhanced when trainees engage quality learning content for longer periods of time.

Despite this promise, however, many game-based training applications suffer key deficiencies leading to poor learning outcomes, such as poor instructional design, poor (or no) performance assessment, limited training scope, low levels of reusability, and lack of appeal to students (Hussain et al., 2008; O'Neil & Perez, 2008). These problems are due in part to the limitations of current gaming technology - for example, commercial games typically do not provide the ability to capture the relevant performance data at the right level of detail for tracking and assessment of trainee performance. However, they are also due in large part to the fact that there are no clearly proven methods for the development of effective training games. Further, most organizations and companies developing game-based training systems have only a few years of experience doing so and their experience is usually limited to work on one or two systems. Generally, designers and developers apply methods that have been appropriated from other fields, such as general software development, simulation-based training, computer-based training, commercial game development, and intelligent tutoring systems. The lessons learned from these ad-hoc approaches to game-based training development are rarely shared. Hence, insights are lost, pitfalls are re-encountered, and useful community-wide guidelines are not formed. Further, different development teams contain expertise in different fields, and hence some elements of game-based training design tend to be emphasized at the cost of others.

Our project team was a highly multi-disciplinary set of experts, each with varying degrees of expertise with game-based training, but all with deep knowledge within their core disciplines. The development team included members from seven different organizations that together provided expertise in game-based training, educational science, commercial game development, instructional design, human performance assessment, story-based training, simulation-based training,

computer-based training, military training systems, graphic design and modeling, animated movie development, entertainment and media production, intelligent tutoring systems, game engine development, agile software development methods, and systems integration.

Collectively, these experts brought to bear a rich subset of the practices currently used for developing game-based training. The key practices that we chose to start with based on preliminary discussions included:

- The manner in which the system will be used impacts instructional design choices, so pay close attention to requirements gathering.
- Remain focused upon learning objectives throughout system design and development.
- Develop the story outline early on, base it on the learning objectives, and iterate as system design proceeds. Taken to an extreme, one of the teammates believed that “It all starts with story.” According to Jerome Bruner (1990), plots are a creation of “transactional relationships” between reality, memory, and imaginary/narrative worlds. Transactional connections help learners use what they know in order to contextualize what is unknown, meaning that since the human brain needs story to provide context. An effective story provides a basis for addressing requirements and framing all content development in order to produce a consistent and compelling product.
- Incorporate assessment needs as early as possible during system design and development. Post-development efforts to graft assessment on a system not designed for it lead to significant problems in capturing the type, quality, and quantity of data required for effective assessment.

- Agile development methods work very effectively in fast-paced game-based training development efforts.
- Early involvement of all stakeholders in design and ongoing involvement during design and development iterations leads to a more robust product and helps avoid significant pitfalls.
- Keep the customer involved throughout to ensure the product meets stated and unstated requirements (and adapts to meet changing requirements).

DEVELOPMENT PROCESS

In March 2008, our team began the development of a game-based training prototype. Over the course of seven months, we followed an agile development methodology to iteratively create and refine our instructional design, and develop and refine our initial product prototype, which we delivered successfully at the end of September. During our effort, we encountered a number of issues, many of them due to tensions caused by differing perspectives of the project stakeholders based on their backgrounds and relative priorities. All key issues were resolved, practically-speaking, to result in a product that met our customers’ needs and satisfied the immediate goals of the project. However, a number of the tensions remained as background issues and recurring discussion themes. In this section, we summarize the key tasks of the project in a roughly chronological manner, and identify the key tensions that occurred along the way. Figure 1 illustrates the project milestones that are discussed in more detail in this section. The following section expands upon these tensions and identifies the methods used to address them and/or the lessons learned from our experience.

Our project, a three-year effort that started in February 2008, had two mandates - to conduct applied and empirical research into tools and

Figure 1. Timeline of project milestones

methods for enhancing the state of the art and science of educational games, and to ensure that these developments would have long-term value to the Navy. In order to achieve the latter mandate, we created a prototype training system for the Naval Service Training Command (NSTC) to enhance the Navy's Recruit Training Command (RTC) curriculum. Our NSTC customer has a background in educational science and deep knowledge regarding the training needs and culture at RTC. From RTC, we drew upon the training staff as subject matter experts (SMEs). Thus, the stakeholders of our effort included our transition customer (NSTC), our program manager (ONR), the subject matter experts and the members of our team.

To support the first mandate, we identified a need for a game-based training test bed allowing the explicit control of diverse variables in order to empirically study the impact of gaming and instructional features upon learning outcomes. This test bed capability formed an additional requirement for the initial training system we created. The focus of the paper is the process we followed

in developing the training system product and our lessons learned from that effort. We describe certain interim and final elements of the product to support our discussion. However, a complete description of the final product is not given.

Selection of Training Requirements, Domain, and Gaming Platform

In developing our training product for RTC, our initial step was to identify the specific training needs. At RTC, recruits currently undergo six weeks of intensive training on fundamental navy skills and end their training with an intense exercise called Battle Stations 21 (BS21). BS21 is a real-life simulation environment in which recruits are exposed to seventeen simulation scenarios during a single night. The facility is a building designed to give recruits the experience of being aboard a ship, and contains a simulated dock, a simulated exterior of a destroyer, and several floors that simulate different decks of a ship.

The goal of our effort was to provide supplementary training to augment the current classroom-

based and hands-on instruction in order to produce better prepared sailors. While overall performance of recruits in BS21 is excellent, students frequently exhibit key errors in several of the BS21 scenarios due to training gaps on those skills. Our requirement was to provide a compelling virtual training system to address some of those gaps.

At this earliest stage of product development, past experience has shown that it is critical to fully involve the customer. With any training system, the focus of the training must be driven by customer requirements, and the requirements must have a direct relationship to the learning outcomes desired. With any training application, it is important to choose a training domain that is suitable for the type of training possible with the technology used, or, alternatively, to choose the right type of training technology for the type of training desired. In our case, the customer desired an initial product delivery as soon as possible and wanted the product to provide immersive training geared toward single players. The customer desired that the training address a domain that would have high payoff in terms of improving recruit performance in BS21, but also wanted the application to provide familiarization with operating within a (virtual) ship environment. Within those constraints, we had a fair amount of leeway.

In initial discussions with our customer and with SMEs, four key training domains were identified as high benefit: controlling a flooding situation, standing a bridge watch, handling rope and navigating within a ship. Of these, it was determined by all stakeholders that handling rope was the least appropriate for an immersive gaming environment. Navigating within a ship was determined to be of secondary importance in that it could be embedded within training focused on either of the other two domains.

In these early discussions with the customer, it quickly became apparent that the high-level goals of the customer and the project could be best attained by leveraging an existing, open-source

game-based simulation prototype developed for the same customer. That application was based on the game engine Delta3D and contained a high fidelity representation of the ship interior of BS21 with a first-person perspective (see Figure 2). The drawback to the application was that it had minimal pedagogical infrastructure and minimal gaming elements. The advantage of the application was that it would avoid the need for an intensive graphics development process, and, since it was open-source, would allow us to add the pedagogical elements we needed. One of our team members had been the software developer for that application, which also provided us with immediate expertise. From the customer's perspective, reusing the application would justify earlier investments. Further, the customer already knew its strengths and weaknesses and was able to give us specific feedback on what he wanted improved for our product. The earlier application did not, however, contain virtual characters. Preliminary task analysis determined that it would be pedagogically appropriate to provide flooding control training without virtual characters since those skills can be performed by a single individual alone in real-life situations. Bridge watch, in contrast, inherently involves a team of people and thus the application would require augmentation with simulated characters to provide effective training. The bridge watch domain was deemed too risky to meet our aggressive development schedule.

The final choice of training domain for our initial product - flooding control - was made in early April for practical reasons based on the nominal choice of training platform and the customer's view of which domain would have higher product acceptance at RTC. The process of making this decision revealed one of the first key tensions in the project:

- The basis for technology decisions – pedagogical or technological

Figure 2. Available 3D simulation environment of BS-21 interior

Knowledge Acquisition

Once the choice of the flooding control domain was made, we undertook the task of knowledge acquisition for the flooding control domain. The knowledge acquisition methods we employed included a traditional, formal cognitive task analysis (CTA) as well as a subject matter analysis focused upon the potential elements for flooding control game scenarios, termed here a scenario element analysis. The analyses were based upon reviews of training materials in use at RTC, observations of recruits performing the flooding control scenario (and others) in BS21, and discussions with SMEs. In mid-April, a SME session was conducted face-to-face with six trainers from RTC. During this session, the questioning was led by our instructional designers, but representatives of most team members were also present and contributed to the discussions. This session, as well as a couple of follow-up face-to-face and teleconference sessions, provided two initial products.

The first was a traditional breakdown of learning objectives and the identification of expected behaviors, common errors, and consequences. The CTA determined that there were four key categories of learning objectives—those related to communication, situation awareness, appropriate

decision-making, and leadership. The communication learning objectives, for example, included reporting a situation immediately, communicating relevant information, and reporting when an action is completed. Decision-making objectives included maintaining watertight conditions, requesting permission before taking action as appropriate, and performing proper containment procedures. In addition, the CTA determined that there were certain skills that the recruits were expected to know based on the current curriculum, certain skills that it would be desirable for them to know if training could be enhanced, and certain skills that were very important in real-life, but that were beyond what could be expected of a normal recruit.

The second product was a breakdown of the elements of the flooding control mission that suggested the potential structure, actions, and variations for a simulated flooding control scenario. The scenario element analysis determined the typical timeline involved in a flooding control mission and the specific elements of the different phases of the mission that suggested the potential actions and variations to be included in a simulated scenario. These phases were broadly captured as: the discovery phase (the actions surrounding the event that identifies the need for flooding control), the preparation phase (actions in getting assigned

and ready to combat the flood), the transit phase (actions taken en-route to performing flooding control), the casualty combat phase (the procedures and options available while trying to control the flood), and the completion phase (what actions are performed at the end of the situation). These phases summarized the SMEs' views of the typical way in which a flooding mission occurs and what they felt needed to be reinforced with the recruits. Within each phase, a number of activities, possible actions and scene variations were identified. For instance, in the transit phase, additional hazards could be encountered, such as additional leaks, additional flooding locations, unsecured items in hallway, injured personnel and watertight doors not closed appropriately. During different phases, inappropriate setting of a watertight boundary could lead to various complications, including allowing a flood to spread or trapping a shipmate. In addition to multiple phases of a mission, the scenario element analysis identified multiple roles involved in different phases of a flooding control mission, including a first-on-scene sailor, a damage

control (DC) team leader or member, and damage control central (DCC). The SMEs indicated that the recruits should be taught certain skills associated with certain roles, even if they would typically not be in those roles for some time.

The products of the CTA and scenario element analysis were then merged to form a third product that mapped the learning objectives in context across the phases and roles (e.g., Figure 3 shows one of 26 learning objectives mapped). This product was prepared by May 1 and provided inputs to our story development process.

During the knowledge acquisition process, several tensions arose, including:

- Identifying all the learning objectives versus selecting the objectives to be addressed in the first game prototype
- Balancing cognitive elements with experiential elements

Figure 3. Learning objectives and common errors in context of flooding mission phases and roles

Learning Objective	Expected behaviors (enabling objectives)	Discovery Phase	Preparation Phase	Transit Phase	Casualty Combat Phase	Completion Phase
Communication - Demonstrate they know (a) whom to contact and (b) what to say and (c) how to listen and repeat back						
Report situation immediately	Use best available means to communicate Report hazards upon discovery Report new factors in situation immediately	Role: First on scene Specific objective: Notify someone of the flooding situation immediately Expected behavior: Report flooding immediately upon discovery. Use best available means to communicate (phone, yell, send messenger) Common errors: Do not communicate. Ignore problem, isolate location without permission, combat casualty on own. Consequences: No one else knows. Leak/flood progresses quickly and DC has less time to get there. Scenario variations: Individual injured or dies while combating. Individual electrocuted due to unperceived electrical hazard. Ship capability reduced. Ship sinks.		Role: DC team member Specific objective: Report any hazards en route to flooding area. Expected behavior: Report hazards upon discovery Scenario variations: Additional leaks, additional flooding locations, unsecured items in hallway, injured personnel, watertight doors not closed appropriately	Role: DC team member, DC team leader Specific objective: Keep DCC informed of any changes in situation. Expected behavior: Report new factors in situation immediately Scenario variations: Additional leaks, additional flooding locations	

Story Development

Great stories share at least six elements that set them apart from “scenarios” or “case studies”. They are: setting, characters, conflict/resolution, plot, voice, and emotion. Compelling stories, and those experienced in game environments in particular, are often called “immersive.” However, immersion doesn’t just happen; it takes purposeful effort on the part of the storymakers or designers. To achieve a great story, one must be intentional about combining the six elements in a way that will draw the audience (in the case of a game, the players) into the story so that they can see themselves as part of it. To do this, the story must be easy for them to relate to. To be successful as a learning environment, it must also create an “envelope” that will carry the learning tasks so that the learner literally “embodies” them.

Generally, fodder for narrative development in a learning product can be gathered in early conversations with the customer. In our effort, during the knowledge acquisition process, we determined through discussions that the basic objective of our initial product would be to teach recruits the steps required to stop (or mitigate the flow of) a leak on board a ship. We were thus able to begin to zero in on some of the key story elements from the beginning. For instance, from these early discussions, we knew the following about the eventual story:

- The story *setting* would be on (some type of) a ship.
- At least one of the *characters* would need to be a sailor on board that ship.
- The *conflict to resolve* would be a leaky pipe or breach in the ship’s hull that the sailor would need to fix or at least mitigate the effects of.
- The *plot* would need to include some sort of potential flooding scenario.

- We believed that the *emotion* of fear could be used to engage the learner as a crisis ensued. We also believed that the Navy values of “Honor, Courage, and Commitment” that were instilled in recruits during basic training could be used to provide motivation to overcome the fear and lack of initial skills, competence, and confidence to perform the mission.
- Voice, or who the “teller” would be, was not established until later.

On May 6-7, we held a two day story conference. We came together as a team of instructional designers, programmers, writers, and artists to begin to create the metastory for the game. Our customer participated and provided subject matter expertise as well as general guidance. The instructional designers kicked off day one by reviewing the learning objectives with the group so that we would stay focused on those throughout the day. The group was led by experienced story development facilitators through activities chosen to help us experiment and “play” with character development, setting, and plot points that would drive the learning objectives involved with a flooding scenario. It was important to develop a metastory that would be believable and that a new recruit would identify with as well as one that would set us up for the kind of conflict or crisis that could incorporate other possible disaster prevention/recovery scenarios (e.g., fire fighting) over time.

During the discussions, our customer emphasized the need to reinforce the pattern of “look-report-do” when training recruits. This led us to focus upon the situation awareness, communication, and decision-making learning objectives, and to de-emphasize leadership. To further focus the story, our customer in particular and the team in general prioritized all the enabling learning objectives based on training requirements and perceived utility.

After the story conference, the story developers used the notes from the two-day event and developed a draft of the metastory which included several possible game levels. During the first pass at the story, we decided that the background story (“backstory”) would be told in the third person by a narrator that was not a part of the story itself. This backstory eventually became the introductory movie or “intro cut scene” of the game.

During story development, a key tension was:

- Story first versus design first

Game Design

On May 29-30, we held a two-day team meeting to flesh out the specific training scenarios for our product. A representative from the customer attended, but no SMEs did. Using the learning objectives and story construct as a basis, the team brainstormed on how we wanted to provide training within the game. We made the decision to couple a guided discovery instructional strategy with an adventure-style gaming strategy. Following a common gaming approach, we decided to create a game with multiple levels of increasing difficulty. Based on the scenario element analysis, we decided to structure each level as a single mission, possibly with some “twists” to add to the sense of adventure. To support our instructional and gaming objectives, we identified a general mechanism for using dialog and messages from game characters to provide mission objectives, story and adventure elements, and instructional guidance and feedback. To avoid the need for animating the non-player characters, we designed the game in such a way that these characters would be elsewhere in the ship, out of view. Further, we incorporated the capability to provide students with opportunities to fail, possibly catastrophically, depending upon their errors.

Early on, we realized that we would need a tutorial level to train students on how to play

the game. This is a standard mechanism used in commercial games to bring players up to speed. The instructional designers deemed it important that this tutorial level would introduce the basic instructional mechanisms to lay the foundation for how the game would deliver its training. The game designers emphasized that the tutorial level should reinforce the mission metaphor to introduce the gaming strategy and to set student expectations. The story developers encouraged the incremental introduction of story elements throughout all levels, including the tutorial level. We converged on a tutorial level design that met all these goals.

Using the multiple levels of expertise identified in the CTA and our earlier rankings of the relative priorities of different learning objectives, we fleshed out the basic enabling learning objectives for the initial game levels. By the second day, we had designed the outline of tutorial level and three training levels of increasing difficulty. For each level, we identified which behaviors we wanted to assess, the key story developments, potential instructional scaffolding, desired immersive elements (such as sounds, lighting and game objects and effects), and the general flow of the gameplay.

At this point we captured and prioritized all the desired instructional and gaming capabilities. We determined that the initial prototype would focus on the tutorial mission and the first training mission (“Mission 1”). This provided the basis for the software requirements and the launching point for further instructional design.

The tension revealed here was:

- Gaming strategy versus instructional strategy

Initial Instructional Design

Following our May 29-30 meeting, the instructional design process began in earnest. Our instructional designers, assessment experts, and

Figure 4. Potential game levels produced during game design session

Story Development: Approaching area of operation, prepare for underway replenishment (UNREP)
Tutorial Level
Inspection: Inspect and secure repair locker
Objectives: Game mechanics, Communicate using phone.
Assess: Time taken. No failure and no negative feedback. High guidance.
Story Development: Ship collides with oiler during UNREP
Mission 1 Level
Investigate and Repair: Assess and repair leaking pipe
Objectives: Communicate with DCC, Maintain watertight integrity
Assess: Intent and accuracy of actions
Feedback: Guidance primarily in response to errors. Negative feedback and potential catastrophic failure
Mission 2 Level
Repair Complex Flood: Assess and repair multiple leaks
Objectives: Establish boundary, Apply appropriate repair, monitor and report situation, prioritize decisions, dewatering
Assess: Intent, accuracy of actions and effectiveness of decisions
Feedback: Low guidance, multiple ways to fail, complete success possible but order of decisions matters
Mission 3 Level
Rescue: Combat flood and ensure safety of equipment or personnel at risk
Objectives: Maintain safety of ship. Assess and report changes
Assess: Appropriateness of decisions
Feedback: Low guidance, complete success not possible – hard choices necessary, multiple “passing” mission completion states

game developers worked iteratively to identify the specific instructional elements of the proposed “Mission 1” game level based on our cognitive task analysis and our guided discovery instructional strategy.

An initial instructional design was developed by mid-June that elaborated on the learning objectives associated with each level and suggested the general instructional approaches to be used in the product. The guiding principles of this initial design were to:

- Address objectives in story, rules, consequences
- Design consequences to dispel misconceptions
- Provide feedback to promote learning
- Use scaffolding to guide players and allow them to experience actions beyond their level to reinforce learning objectives
- Use gaming technologies to facilitate the development of mental models

The instructional approach was a holistic design for providing part-task training within the context of the whole task. It specified multiple forms of feedback for alerting players to deficiencies and providing opportunities for players to demonstrate skills again in similar but not necessarily identical situations. It attempted to carefully control variations to ensure that the player did not just learn the game mechanics, but also understood the underlying facts, concepts, or principles.

The initial design also identified a general approach for assessment within the game. The types of assessment envisioned included completion of tasks, accuracy, time taken and steps taken. The intent was to assess learning objectives throughout the game by the actions the player would take. These assessments were also expected to affect play. The player’s actions could be limited until he or she demonstrated a predetermined level of mastery. A final performance assessment would be given at the end of the game that would detail strengths and weaknesses. In this final assessment, the player would be informed of how well

Development of Game-Based Training Systems

he or she did on each of the game performance criteria and how to improve performance in the future. Drawing upon the CTA, the scenario event analysis, and the basic game level design, the initial instructional design identified a series of key scenario events, the associated learning objectives and the associated assessment requirements (see Table 1).

The design specified several different types of feedback to be used in the game, such as:

- Natural consequences would be used, when possible, to indicate the effects of the player's action. The player would be made aware of the relationship between their action and the consequence (e.g., the player must know that turning the valve cuts off the water supply for fighting a fire).
- Hints would be given to reinforce or correct declarative knowledge, for example

Table 1. Mission 1 level scenario constraints and learning objectives

EVENT	ENVIRONMENTAL REQUIREMENTS	LEARNING OBJECTIVES	ASSESSMENT REQUIREMENTS
Readiness Set Readiness condition is set as a result of ship-wide "event" –General Quarters	• Alarm sound • Lighting effect • Announcement over the sound system	Decision-Making • Respond to readiness condition Situation Awareness • Report to proper location	Learner immediately leaves for general quarters assignment
Navigate Ship (recurs throughout game) Learner navigates within the ship	• Circle X, Y, & Z doors to open/close • Limit space to task area – Control where they can go. • Phone on wall in destination compartment or passageway	Decision-Making • Comply with restrictions on doors Situation Awareness • Identify location Communication • Ask permission before opening door	• Used phone to ask permission for opening doors • Opened/closed correctly • Path taken • Used phonetic alpha/num • Repeated back instructions • Located the proper compartment, as ordered • Reported location
Detect Flooding Situation Learner encounters flooding situation in a compartment	• Pipe w/ slow, obvious water leak • Other pipes not leaking • Identifier for compartment location	Situation Awareness • Conduct assessment • Recognize flooding cues • Identify location • Identify type of pipe leaking Communication • Ask permission before opening door, entering compartment;	• Asked permission to open door • Did not enter the compartment without permission.
Report to DCC (recurs throughout game) Learner reports to DCC	• Phone to use • Way to conduct two-way communication. Phonetic alpha/num • CCOL that can be read.	Communication • Communicate relevant information • Listen and repeat back instructions • Listen and acknowledge or correct repeat back Situation Awareness • Locate CCOL • Recognize equipment and material settings in CCOL	• Reported correct pipe/liquid type • Reported correct location • Corrected errors from DCC • Repeated back • Look at CCOL and used CCOL information correctly • Reported contents of the room
Minimize/Contain Leak Learner is ordered to repair/contain the leak	• Repair locker (to select & open) • Containment equipment (jubilee, shoring equip) to select from	Situation Awareness • Find repair locker Decision-Making • Perform proper containment procedures • Select appropriate equipment • Use proper technique for attaching patch	• Located repair locker (path taken) • Opened locker • Selected correct equipment (# of attempts, order of selection) • Placed patch and & tightened with wrench

- by telling the player the general rule or protocol.
- Catastrophic failures that immediately stop the game would be used to emphasize critical errors made by the player.
- Game scores would be used to provide feedback on the key behaviors to be developed and to reward the attainment of desired learning outcomes

Finally, the design specified several possible types of scaffolding to consider, including:

- Limiting the play space and/or choices offered to avoid cognitive overload and focus attention on key cues in the environment
- Providing hints that focus on the facts, rules, and or steps in a procedure
- Providing just-in-time information, particularly at novice levels, when the player is not expected to know that information or when that information is not critical to achieving the learning objective
- Modeling or demonstrating procedures using gaming techniques or incorporating embedded videos
- Providing advance organizers, such as a schematic of the ship to aid navigation
- Providing characters to guide the player in decision making when a player has been unsuccessful after several attempts
- Providing access to “mini-games” as needed to increase proficiency in basic skills

Following a traditional game technique, the notion of a “score” was initially suggested as a form of implicit feedback, and the use of specific warning messages in response to student errors was suggested as a form of explicit feedback and guidance.

During this initial instructional design process, two key tensions were revealed:

- Directive instruction versus guided discovery
- Feedback for learning versus feedback for motivating gameplay

Assessment Strategy

To accomplish the task of embedding effective assessment in our game, our design process dictated that we begin by examining the damage control domain - a broad class of activities of which flooding control is a part. Working closely with the instructional design team, the assessment experts identified the key constructs and relationships that formed the sub-domain of flooding within the damage control domain and mapped these constructs and relationships into a Flooding Ontology (a visual representation of the constructs and that make up flooding and how those constructs are linked). The ontology was divided into three broad constructs –Situation Awareness, Communications, and Decision Making—as these encapsulated the cognitive and behavioral elements relevant to addressing a damage control situation aboard a ship. The goals and objectives of the training, along with the assessments, would be designed around these core concepts and relationships. Given this general Flooding Ontology, the specific elements relevant to the Mission 1 level were identified based on the initial instructional design (e.g., see Figure 5).

With this ontology completed, we drafted a preliminary set of functional game requirements necessary for player performance to be sufficiently assessed. These requirements were specific features that needed to be represented in the game to serve as indicators of performance. They included elements the player could use to communicate with Damage Control Central (to assess communication skills), opportunities for the player to choose from a variety of apparatus the appropriate one to contain the leak (to assess content knowledge and decision making), and

Figure 5. Partial flooding ontology with mission 1 related elements (in gray)

opportunities for the player to interact with different types of doors under various material readiness conditions (to assess the player's understanding of readiness conditions and adherence to permission protocols).

Based on the initial instructional design and the general approach to gameplay, we proceeded to flesh out the detailed automated assessment strategy to be applied. The key learning objectives were mapped to key assessment requirements. We then identified, for each assessment requirement, the specific metrics that were possible to determine automatically in the game. These were tied as appropriate to specific scoring computations or feedback actions. The final assessment strategy incorporated the pedagogical objectives while respecting the need to have assessment fit in naturally with gameplay. The game score was defined to be monotonically increasing (i.e., total score could only increase in value, and would not decrease due to errors). The second iteration of instructional design, incorporating an assessment and feedback strategy for all learning objectives, was completed in mid-July.

In our assessment strategy, we attempted to identify behaviors that could lead to a failure of the mission. These serious errors would produce

a demerit that interrupted gameplay to provide important feedback. Table 2 provides an example of the assessment strategy for a single learning objective (i.e., Follow safety protocol), showing implicit feedback in response to accurate behavior via a change to the game score, as well as explicit "demerit" feedback in response to errors. Many of the details of the assessment strategy changed during subsequent refinements.

As the detailed assessment strategy was being developed, preliminary instructional logic was also created to identify when to capture data for assessment of player performance, as well as to identify possible situations for performance-based feedback opportunities. The logic for several of the behaviors involved in a flooding control mission was captured by mid-July using flowcharts such as that in Figure 6. The motivation behind these initial flowcharts was to capture an "ideal" trainer by working forward from the ontology and recommended functional assessment requirements to produce a guided discovery instructional strategy that would also support effective assessment. Consideration of gaming strategy, story and mission flow were left as future integration exercises. The logic allowed for multiple attempts to accomplish tasks while providing different guid-

Table 2. Sample specification of assessment and feedback for a learning objective

Skill Area	Learning Objective	Assessment Requirements	Metrics	Positive indicator	Negative indicator	Game Score Feedback Effect - Success	Numerical/ Aggregate Metric	Scoring/ Feedback Effect - Negative
Decision-Making	Follow safety protocol	Did not enter the flooding compartment without permission.	Intent	Asked for permission to enter a room in which student had (incorrectly) reported flooding	Never ask for permission to enter a room	0		
			Accuracy	Asked for permission to enter the actual flooding room	Enter flooding compartment without asking permission	10 points if student enters the room after requesting and receiving permission	1 count per flooding compartment; 1 count per "first" entry into flooding compartment; 1 count per correct request to enter flooding compartment	Demerit: A demerit is issued if the student enters the flooded compartment without receiving permission.
			Multiple instances (flooding compartment)	N/A - only one flooding compartment in this level				
			Multiple occurrences (Over time)	Only keep track of requests prior to the first entry into the flooding compartment			Accuracy percentage: Total correct request / Total flooding compartment	

Figure 6. Preliminary guided-discovery instructional logic for obtaining appropriate permission before opening doors (light gray = direct instruction, dark gray = implied instruction, black = goal achieved)

ance and constraining user actions depending upon the errors made (and amount of error repetition).

After mid-July, a collective effort was made to resolve the different representation formats preferred by the instructional designers, assessment experts and game designers and to integrate the various aspects of the product design. The most commonly agreed-upon format was the use of flowcharts. Using the preliminary instructional logic flowcharts (e.g., Figure 6) as a starting point, new flowcharts were defined for the key learning objectives of the mission 1 level. Figure 7 illustrates a flowchart specifying the instructional logic for “Following safety protocols”, as determined by donning the appropriate personal protective equipment (PPE). Each flowchart provided a specific set of rules indicating under which circumstances specific guidance messages (dashed border, light-gray), positive reinforcement messages (dotted border, light gray) or negative feedback messages (solid border, light

gray) should be given. These flowcharts integrated the assessment strategy and basic character interactions to identify the instruction, scoring, and dialog to be implemented in the game. New flowcharts covering all key situations in Mission 1 were completed in mid-August. During this revision, a second score mechanism was added to keep track of penalties associated with errors. Specifically, when a negative feedback message was given in response to an error by the student, a negative demerit score value was decreased by some amount. The demerit score (trapezoid) and positive score (hexagon) were separate values. The possibility of mission failure due to a high total demerit score (e.g., -1.0) was also introduced.

During the development of the assessment strategy and the associated instructional design revisions, two key tensions arose:

- Developing an objective versus developing methods for assessing attainment of that objective

Figure 7. Complete instructional logic for learning objective of “following safety protocols: Don appropriate personal protective equipment (PPE)”

- The right documents for sharing knowledge

Software Development

By mid-June, a software requirements document and an initial software design document were completed that identified the key changes needed to the existing simulation in order to support our desired training game design. In addition to supporting the instructional levels we had designed, we adopted an additional requirement to adapt the gaming infrastructure so that pedagogical elements of the training would be specified as much as possible using a data-driven approach rather than implementing a hard-coded game. The goal of a data-driven approach was to facilitate rapid changes to instructional content.

An aggressive agile development schedule was determined with four end-of-month deliverables: the first at the end of June and the last for

our final product at the end of September. The first deliverable would incorporate a basic mission flow (incorporating a briefing screen and a debriefing screen) and include some preliminary user interface elements (such as feedback and information windows). The second deliverable would provide an end-to-end walkthrough that exercised basic missions and basic forms of all interface elements. The third deliverable would include the data-driven infrastructure and all key graphics and animations needed to support the tutorial and main mission. The final deliverable would have a fully functional tutorial and the main mission.

In particular, the data-driven design adopted was as follows. A mission would be comprised of multiple tasks. For each task, specific trigger events would initiate it, and completion of the task would in turn initiate one or more other tasks. The specific tasks in a scenario and all details

concerning each task, such as its triggers and its description, were specified in the scenario data file. Further, a mission could contain multiple “score” objects, each maintaining a distinct value representing user performance. A score object could be triggered by direct player actions, such as dialog choices or entering a room, as well as by indirect actions, such as completing a task. The score object would contain specific feedback messages to provide to the user upon being triggered (e.g., via a “demerit” message or an instructional guidance message), and would maintain internal state reflecting the number of times triggered. The message could vary depending upon the number of times triggered. The specific score objects and all details concerning them, such as their triggers and messages, were specified in the scenario data file.

The key tension of the software development were

- Hard-coded versus data-driven implementation

Introductory Movie

In late June, as we iteratively refined our story, we realized that our product would be particularly enhanced by the incorporation of an introductory movie scene that would present the backstory and lay the foundation for motivating the student. The use of introductory movies and cut-scenes within and between game levels is a powerful method used in commercial games to enhance the player’s sense of immersion in the game. For our product, we determined that the introductory movie needed to:

- Motivate the desire to play
- Motivate the desire to serve in the Navy
- Introduce the backstory
- Promote the Navy core values of Honor, Courage, and Commitment
- Introduce the ultimate game objective

- Orient the student’s approach to playing the game

The introductory movie design was captured in a table that divided the script into small one- or two-sentence segments to facilitate the association of dialog with the appropriate on-screen visual. The team met via phone conference to discuss what should be seen while the narration was spoken. In order to hasten development and save money it was decided that characters would only be seen when absolutely necessary to the story. Likewise, we decided that in order to allow the learner to relate to the game character, the player would not be identified as male or female and that any time the learner had to “speak” it would be via text only. This meant that the learner would not ever see or hear himself or herself as a character in the game. This kept the player “generic” and allowed the learner’s imagination to fill in the gaps. Thus, a player could be immersed in the game without the necessity of choices of character art or voicing.

An artist then created storyboards (sketches) for the intro movie. The sketches were scanned and placed into the draft of the script. This document was shared with the larger team (including the subject matter experts) and feedback was incorporated into successive drafts. To stay true to story and reality, we decided it was necessary to have one non-player character (the officer of the deck who welcomed the learner aboard). Once the storyboard and script were approved by the development team and SMEs, the artists began to create the art and animations for the movie. For maximum effect, a 3D modeling approach with realistic ships and naval scenes was used. After a number of iterations with frequent SME feedback on the accuracy and suitability of our models, the graphic rendering of the movie was completed.

In parallel, a narration and sound script for the scene was finalized with inputs from several team members and from our SMEs. This process also involved the creation of a “scratch track” of

the narration of the introductory movie that was reviewed by our customer. Once the intro video was created, it was passed to our sound production team. Professional voice talent was used to record the narration for the movie, and the audio for the movie was finalized and enhanced with sound effects and music to add to the drama. The introductory movie was then incorporated into the game to be played before the tutorial mission.

There were minimal tensions raised during the development of the introductory movie. However, since the development of the movie was a substantial task, it was important to ensure that it was general enough to accommodate further story refinements in the game itself. During development, the specific wording used in the narration was varied slightly several times to reflect changes in the specific missions (particularly in the mission briefings).

Iterative Review, Refinement, and Testing

The instructional design, game level design, introductory movie, and software design were all refined in an iterative manner after the end of July. Efforts were conducted in parallel and discussions on one aspect of the product often involved team members working on other aspects. Customer design and product reviews were held bi-weekly (on August 4, August 17, September 4, September 17, and October 8). Three rounds of product testing with test subjects were held both before and after the initial product release. A pilot usability test was held on September 18, an end-user usability study on October 22-23, and a pilot validation study on November 17. Following each review and test, desired improvements were identified based on feedback and observations. These were then prioritized based on the importance of the changes and time/resource constraints.

In particular, four instructional elements were iterated upon and refined right up until the beta release in mid-September: instructional objec-

tives, assessment methods, dialog content, and mission debriefing.

On-going refinement of the instructional objectives of Mission 1 led to the following final set of objectives being approved by the customer on September 15 (see Figure 8). For each broad skill category (Situation Awareness, Communication, Decision Making), several terminal objectives were defined. For each terminal objective at least one enabling objective was defined.

In the final implementation, the student's performance against every terminal objective was assessed automatically via the student's actions in the game and choices in dialogs. Dialog interactions formed a key method for assessing user performance against a variety of communication and situation awareness learning objectives. These assessments were context-sensitive (i.e., the same dialog choice may be correct or incorrect depending upon prior user actions). As shown in Table 3, a single dialog interaction could result in errors against different objectives (e.g., reporting appropriate versus accurate information), and different types of feedback (e.g., dialog responses versus demerits).

The mission was comprised of multiple tasks, and the student's actions were interpreted in the context of the current sub-task(s). At the end of the mission, the student was provided a debrief that summarized their performance against every terminal objective on a three-point traffic light scale (green, yellow, red). An analogous design was adopted for the tutorial mission, though with a much reduced set of terminal and learning objectives.

Tensions that arose during the iterative refinement process included:

- Designing for the novice while keeping the gamer happy
- Balancing revisions to instructional design with meeting software deadlines
- Gaming strategy versus instructional strategy

Figure 8. Final instructional objectives: skill areas - terminal objectives - learning objectives

MULTIDISCIPLINARY TENSIONS AND LESSONS LEARNED

The Basis for Technology Decisions - Pedagogical or Technological

The tension revealed by the intertwined choice of training domain and gaming platform concerns

the weight that should be given to pedagogical or technological factors when making decisions about which training technology to use. In our case, the decision was made primarily for technological reasons, and not for pedagogical ones. For instance, the view of the instructional designers and assessment experts was that the domain should have been chosen first, the cognitive task

Table 3. Assessment and feedback based on students' dialog choices

Dialog choice	Assessment	Feedback
"DCC, this is Seaman Taylor. I'm dressed out and ready to help."	Incorrect	Dialog response from DCC: "Seaman Taylor, DCC. I asked you to go to compartment 1-80-1-Q and report when ready to enter. Get on it!"
"DCC. I am at space 1-80-1-Q. Request permission to enter and inspect."	Error against 'Report Appropriate Information to DCC' learning objective	Dialog response from DCC: "Sailor, this is DCC. Who is this?" and Demerit (e.g., "A proper report should include your name and all relevant information about a situation." and 0.1 demerit score change)
"DCC, this is Seaman Taylor. I am dressed out and ready to enter 1-80-1-Q. Request permission to enter and inspect compartment."	Correct if student is actually reporting from a phone near 1-80-1-Q. If reporting from wrong location, then error against 'Report accurate information to DCC' learning objective	"Seaman Taylor, DCC. Aye. Permission to enter and inspect 1-80-1-Q granted. Report situation as soon as possible." Dialog response from DCC: "I am not showing you near that space. Go find 1-80-1-Q and call me from the nearby phone." and Demerit (e.g., "You made a bad report. The DCC trusts you to be the eyes on the scene. Reassess the situation and give the DCC a better report." and 0.3 demerit score change)

analysis performed next, and then, based on the key learning objectives identified, the technology choice should have been made that would best suit those objectives. Thus, choices such as 3D immersive versus 2D interactive environments, single-player versus multi-player, simulated characters versus no characters, and so on should, in principle, have been driven by pedagogy. The lesson learned is that the practical considerations of customer preferences, schedule, and available resources can significantly impact these choices.

Identifying All the Learning Objectives versus Selecting the Objectives to be Addressed in Level 1 of the Game

The multi-disciplinary approach to instructional design had a clear effect upon the decisions made on how to sequence training in the game. The instructional designers, assessment experts, game designers and story developers all agreed upon a layered approach in which the training was broken up into multiple levels of increasing difficulty. The challenge was determining what was meant by “increasing difficulty.” Everyone had a slightly different understanding of how the learning objectives might be linked to form a beginning level scenario that would be both engaging and prepare the target audience for a live simulation of the entire flooding process. Many interesting, collaborative discussions occurred in refining exactly what would occur in the earliest missions.

The instructional designers envisioned a layered approach focusing on the key steps in the flooding control process in all levels, but varying the complexity of the skills expected. In order to allow the students to experience the entire process in earliest levels, instructional designers advocated that some of the smaller steps in the process be provided to the learner or that the environment be structured in such a way that the player would not have to demonstrate more specific skills until higher levels of the game. Their primary goal was

to build a foundation to ensure that players had a basic understanding of what happens in a flooding situation, and to reinforce all the key process steps in all the levels. The story developers encouraged the idea that not all information about the situation needed to be provided at the beginning, and that an incremental introduction of new story elements to provide context for new learning objectives over successive levels would be effective. The game designers wanted to keep the early levels simple and slowly build up the complexity of the gaming skills needed over multiple levels. Unlike the instructional designers, they did not feel that all aspects of the process needed to be present in every level (i.e., certain levels could focus upon certain elements of the process). The assessment experts were concerned primarily with cognitive overload and wanted to ensure that new skills and information were introduced in an incremental fashion over successive levels.

The decisions regarding which learning objectives to focus on in the first level were made with the intent of satisfying these goals as much as possible, and multiple refinements were needed over time to reach consensus. For example, there were several potential learning objectives pertaining to the rules for opening and closing doors under various readiness conditions. In our developed ontology all possible types of doors and hatches and appropriate entry rules were presented. In a classroom, these rules would likely be learned and tested with a paper and pencil test. An embedded tutorial addressing these rules was possible; however, we did not want this to be our primary instructional target for the beginning level of the game. To do so would burden the learner with information overload and require many permutations for mastering the distinctions governing the handling of different types of doors when in reality, given the readiness condition already set by the collision, most doors would require the same treatment. We resolved the issue by limiting the kinds of doors visible to the player so that the correct procedure would be technically

correct while presenting limited cognitive load. Thereby, the learner could focus on the larger steps required to identify, report, and combat the flood. This solution managed the cognitive load appropriately, maintained cognitive and physical fidelity, kept the learner engaged in the story and prevented negative training.

A lesson learned from this key tension is to maintain communication and seek mechanisms for closer collaboration. Presenting the learning objectives and developing an ontology are critical to developing the appropriate story, rules, and consequences in the game. Instructional designers are accustomed to look at the relationships among objectives in terms of the development of student knowledge and skills and designing for a scaffolded progression based on skill level. Further research is needed to determine whether and when, for game-based training: every skill must be taught from the bottom up in level 1; levels should provide part-task training; or hybrid solutions will be effective. There is more than one way to develop skills, and gaming technology offers unique opportunities to develop skills that are not available through the use of other instructional media. We can select skills on which to focus in a specific scenario and manipulate the physical fidelity of the environment to meet the instructional design. In a game, this can mean restricting the environment or game space or sequence of events or having other characters perform tasks that are beyond the expectations for the level 1 player. There is a fine line between selecting tasks that would be fun but not expected to challenge the learner, and selecting tasks that would confuse or distract the learner at level 1.

Balancing Cognitive Elements with Experiential Elements

A difference in perspective between the instructional designers and the game designers was the basis for understanding and characterizing about the domain. During the knowledge acquisition

process, the instructional designers gravitated towards a focus upon the cognitive elements of the domain (via a CTA) while the game designers gravitated towards a focus upon the context in which learning would occur in the domain (via a scenario element analysis). The goals of a CTA and a scenario element analysis are different. The former is focused on performance and associated knowledge states. The latter is focused on identifying the environmental contexts in which simulated activities occur, the steps of and interactions among those activities, and the possible variations in the details of those activities or contexts. Both analyses were conducted with collaborative discussions among team members. However, there were frequent misunderstandings of how to characterize the domain. Eventually, it became apparent that the two analyses were capturing complementary information. The exercise of merging them (e.g., Figure 3) resulted in several interesting discussions in which some previous misunderstandings were resolved. One benefit was that additional enabling objectives were identified. For example, in the context of the transit phase, an enabling objective for reporting a situation immediately is reporting any hazards encountered en route to the flooding area. On the downside, the merged document was difficult to follow for team members who had not directly been part of the knowledge acquisition process.

The lesson learned is that both the cognitive and context aspects of a domain are critical for game-based training and each leads to different ideas on how to structure the learning experience in a game. More investigation into effective methods for characterizing and refining the two domain aspects is needed.

Story First versus Design First

In our effort, a lot happened very quickly. There was a general feeling that the story development (i.e., the StoryJam™ held on May 6-7) occurred too early in the process since the learning objec-

tives from the CTA were not fully understood and had not yet been prioritized. However, without the forcing function of trying to develop a focused story to support the training, the necessary type of filtering and prioritization of the objectives may not have occurred in a timely manner. Throughout the successive refinements of the instructional design and game design, the basic story elements established at the early meeting provided positive guidance that encouraged convergence of ideas and consensus on decisions. The story decisions were also remarkably stable. For example, the supporting backstory and story elements used in making decisions in the May 29-30 game design meeting were largely present in the final design several months later. The participation of SMEs as well as the customer in the StoryJam was instrumental in establishment of a credible story.

Further research is needed to identify the best way to time and use the story development process to positive effect in game-based training development. However, a clear lesson learned is that a collaboratively developed story facilitates collaborative decision-making during subsequent development.

Gaming Strategy versus Instructional Strategy

The key area of difficulty reflecting the multidisciplinary conflicts in the team was the relative emphasis of instructional elements and gaming elements. There are many different types of computer games and there are many different ways to structure instruction. In developing game-based training, open questions include what type of game is best suited to a particular instructional strategy as well as what type of instructional strategy is best for a particular type of game. When choosing a gaming strategy, one is typically choosing a particular suite of game mechanics (interactions the player may have within the game) and a particular type of event flow. Likewise, when choosing an instructional strategy, one is typically choosing a

particular suite of instructional interactions with the student and a particular organization to those interactions.

A general methodology for determining how to provide game-based instruction for a particular domain is to map the enabling objectives to specific game mechanics and specific encounters within each level to ensure that the game player is learning what the designer has set out to instruct. During the knowledge acquisition process of our effort, we discussed a variety of possible game mechanics for various enabling objectives. In fact, the SMEs would occasionally proactively suggest a means for how they would “teach this in a game.” In our case, these initial characterizations of the instruction led to an early choice of two “complementary” strategies - guided discovery instruction using adventure style gaming. Guided discovery instruction uses implicit and explicit interventions to encourage and focus a student’s exploration of the training domain to achieve the learning goals. Adventure style gaming uses carefully placed hints and clues to encourage the player to continue to explore the game world and achieve the adventure’s goals.

This choice led to a lot of synergy at the beginning of the design process. Instructional designers would suggest a need for an intervention, and the game developers could easily map this into an event furthering the adventure. However, as the instructional design process progressed, issues of how to embed new instructional elements often turned into discussions of how the “gameplay” might be adversely affected. Issues that caused the greatest tension were the instructional designers’ and assessment experts’ desires for increased guidance and feedback explaining all the student’s mistakes as they were made, explicit didactic information on every element of relevance in the scenario (e.g., a help lookup facility), and increased scaffolding, such as the use of a compass-like aid to assist in navigating around the ship. Their goal was to reduce the student’s cognitive load and to ensure that the student formed good mental models

as early as possible during training. Countering this, the game designers wanted to minimize the amount of non-embedded information (i.e., not delivered as a natural part of interacting with the environment and other characters) to reduce negative impacts on the player's immersion and to maintain the sense of adventure. After many discussions and necessary compromises on everyone's part, we succeeded in resolving most issues to produce a final instructional design and game design that supported one another.

Hence, the two related lessons learned are that linking gaming strategy to instructional strategy can lead to good synergy of design and a compelling experience, but that an early choice of gaming strategy can lead to difficulties in trying to incorporate incompatible instructional elements later on.

Directive Instruction versus Guided Discovery

Expectations for the design of directive instruction and discovery learning are not the same. Our task was to pull the best elements of each into an engaging game that fosters learning through guided discovery. Just how much guidance is required in guided discovery? Which are the elements that must be more closely guided? When is there no harm in letting learners play until they get it right versus when must one guide them so they are not bogged down by details that are insignificant and detract from learning (i.e., avoiding situations in which the learner becomes overwhelmed with less important details and misses the key learning opportunity)? A prime example was in reading the compartment identifiers, or "Bull's Eyes", which indicate the location and type of compartments. We purposefully focused the player's attention on two of the elements in the four element series of number and letters that defines a compartment identifier. The goal was for the player to learn to use the two elements well enough to navigate fore and aft and to recognize which side of the ship

they were on. Once these tasks were mastered the additional elements could be addressed. In the game, however, how long should the player wander before being guided to information that will help him or her reach the intended destination?

The lesson learned is to use the cognitive task analysis to focus on identifying the actions a student must make to carry out a task as well as the typical wrong paths a student can take. In experiential learning, we include these actions in the environment and make some of them options – deliberately selecting these to promote successful task development while not overwhelming the student.

Feedback for Learning versus Feedback for Motivating Gameplay

Games offer opportunities for players to see the consequences of their actions in ways other instructional methods do not. Feedback in the form of natural consequences of actions can be powerful; the trick is to ensure that the feedback is driven by the learning objectives and emphasizes the cause and effect relationship between learners' actions and the consequences so they understand what has happened and why. Consequences of actions in games often provide the "wow" effect garnering the player's attention but not always making clear exactly what the player did to give rise to them. For example, one of the early feedback responses considered was to have a Chief non-player character yell at the player's character when certain key mistakes were made. This kind of feedback was not necessarily appropriate from a chain of command perspective and did not support the learning objective. However, from a gaming/story perspective, it added some emotional stress and made the experience more exciting. Providing the player with appropriate consequences resulting from his or her actions had to be carefully considered as part of the entire gaming/instructional strategy. The experiential aspect of the game environment opens possibilities that should continue

to be explored while maintaining the instructional focus. Decisions about which type of corrective feedback to provide immediately within the game and which to provide in the post-game debrief remain important questions for research.

The lesson learned is that finding innovative ways to provide feedback that promotes reflection requires concerted effort, ongoing discussion, and continued research. The game design must examine the intended outcomes and the paths people take that compromise those outcomes. We can then devise strategies to promote awareness and reflection, such as by setting up distractions to entice players into making common errors and providing feedback to help them refine their thinking.

Developing an Objective versus Developing Methods for Assessing Attainment of That Objective

A game story line must be developed so as to create situations that challenge learners with respect to the learning objectives and that provide opportunities for learners to react and receive feedback on their actions. Therefore, the objectives as well as the assessment strategy need to be developed first in the development of the game. In formal schooling, assessments often occur after a learning event (e.g., end of module test). As a team with such a short development cycle, it was easy to slip into this way of thinking. Also, team members had differing expectations about the role of assessment and even about the meaning associated with it.

Assessment is another area where gaming technology offers new possibilities for learning. Using both time to complete and path taken are possible options in addition to “correct” actions. One promising discussion focused on assessing intent and accuracy as one way to understand reasons for a player’s actions and to tailor future trigger events so as to hone skills appropriate to that player’s needs. This kind of assessment

also has implications for the type of feedback provided. Van Merriënboer and Kirschner (2007) for example make the following recommendations for assessing intent and accuracy:

- If the learner makes an error that conveys an incorrect goal, the feedback should explain why the action leads to an incorrect goal and should provide a hint or suggestion as how to reach the correct goal. .
- If the learner makes an error that conveys a correct goal, the feedback should only provide a hint for the correct step or action to be taken and not simply give away the correct step.

The lesson learned is that objectives and assessments must be linked at the outset of the development process.

The Right Documents for Sharing Knowledge

A key challenge throughout the effort was conveying our thoughts and ideas to each other in an effective manner. Most stakeholders in the effort tended to think and operate at a different level of abstraction or with a different focus. Further, different stakeholders entered with different preconceptions about the motivations of other stakeholders. Exacerbating this quintessential inter-disciplinary communication issue was the fact that our team was widely distributed geographically. Despite roughly monthly face-to-face meetings and frequent discussions by telephone, numerous misunderstandings would arise and persist.

The knowledge sharing issue was particularly revealing in the documents that we generated to share our instructional design ideas. Every single performer had a different preferred format for capturing their ideas, even if the general type of document was similar. For instance, each of

us had a different view about what a storyboard entailed. This confusion led to various persistent misconceptions. For instance, the game designers tended to conclude that the instructional designers were seeking to provide learning that was linear in nature due to the list or table formats they used to capture instructional events.

At several points during the effort, attempts were made to integrate the different perspectives and create a single format that met the needs of all performers. During knowledge acquisition, a table format merging the key CTA information and the scenario element analysis was created (see Figure 3). During development of instructional and assessment logic, a rich flowchart format was used to draw together inputs from several sources (see Figure 7). During the specification of the dialog, three different formats were explored (a dialog tree, a storyboard with optional paths, and a linear list with linked dialog fragments), but ultimately the actual dialog implemented in the game prevailed as our means of discussing and reviewing dialog content.

There is a strong need for effective collaboration mechanisms in a diverse game-based training development team. While we identified some collaborative document formats, further research and refinement is needed to find those communication means that are most effective for game-based training design.

Hard-Coded Versus Data-Driven Implementation

In the field of game-based training, there is always a tension between implementing exactly what is needed for the specific instruction and implementing general game mechanics which can be used to support a variety of instruction. In many cases, the former approach is used, leading to a system that requires significant effort to adapt. Due to our broader project goals, we adopted the latter approach. In addition to a data-driven

task mechanism, several data-driven feedback mechanisms were implemented.

The software development iterations during July and August were focused on implementing a data-driven infrastructure and basic support for the game mechanics we wanted in our initial prototype. By the end of August, a preliminary implementation of the tutorial and Mission 1 levels had been implemented. However, further revisions to the instructional content continued right up the end of September. These revisions were easy to incorporate into the system, and we made numerous revisions to the instructional content without slipping our software deadlines.

A key lesson learned was that the focus on a data-driven approach to specifying the instructional logic in the game greatly reduced the stress of making changes to the game and avoided the need for any significant re-factoring of the code.

Designing for the Novice While Keeping the Gamer Happy

Aside from age, Navy recruits are the very embodiment of diversity – 40,000 recruits each year who come from every conceivable background. It was essential that our training system be accessible to everyone from super users to computer neophytes and be effective with everyone from expert gamers to non gamers. However, since our target population truly are novices in the domain of Navy skills, it was critical that the instruction be delivered at an appropriate level and not be overly challenging. In making our instructional design and game design decisions, there was an ongoing tension between designing for the novice and ensuring that the game was usable and appealing to a very broad population. This tension revealed several lessons learned.

The interface of the game needed to be simple to accommodate the broad range of users. Further, a simple interface is a common trait of many good games. However, in our effort, being simple was

often at odds with being comprehensive. The more instruction, data, feedback, interventions, and details we added, the more complex the interface became and consequently, the less usable. In the end, we decided to postpone some instructional interventions in order to maintain a simple, clean interface.

Dynamic interaction is the most obvious quality of games. After all, if one can't interact, a game reduces to a spectator experience. However, what types of interactions are appropriate for novice game players, while retaining appeal for the experienced gamer? In our game, the player assumed the role of a Seaman recently assigned to his or her first ship. By making the role in the game reflect the near future for all recruits, issues of experience in gaming were partially avoided (e.g., all the recruits are new to being aboard a Navy ship, so navigating around a ship effectively requires diligent attention to details in the environment). Further, we made actions in the game reflect real-world actions. Since these actions (e.g., navigating within a ship, repairing a leak using correct procedures, communicating properly with a superior officer) are not typical of a commercial game, both the inexperienced and experienced gamer still needed substantial learning in order to do it right.

Each mistake made by a player creates a brief teachable moment where corrective guidance can make a huge difference. However, the right level of guidance to give to a novice can conflict with the degree of freedom expert gamers expect. Our approach was to provide both non-interruptive and interruptive feedback of varying detail depending on the nature of the mistake made while keeping the player immersed in the story as much as possible. Minor errors would result in some guidance provided in a small pop-up window that was not intrusive. Conversely, when the student made a critical error, a demerit would interrupt gameplay visually and aurally with a specific message about the error. For both hints and demerits, the initial

message would be somewhat general. If the error was repeated, subsequent messages would be more detailed.

These decisions were borne out by results of product testing across all a variety of users. For instance, a student's first demerit stops mere button-clicking behavior and leads quickly to increased attention by both gamers and non-gamers.

Balancing Revisions to Instructional Design with Meeting Software Deadlines

In addition to our data-driven approach, another key contributor to our success was the use of an agile software development methodology. A particularly relevant aspect of agile development is frequent deliveries. One of the key tenants of agile development is getting working iterations of the software into the hands of stakeholders as early and as often as possible. With six geographically distributed groups, frequent releases helped mitigate communication issues and maintain a cohesive vision for the product.

As in many software products, the requirements provided by the customer may change over time. In our case, there was an increasing emphasis placed upon the depth of training to deliver. Initial requirements were for a skill practice environment with limited guidance. Later requirements were for a training environment with limited assessment that could produce some validated learning outcomes of certain skills. The final requirements, determined several months into the project, were for a training system with focused guidance, general assessment on all key skills, comprehensive feedback in response to errors, no negative training, and no irrelevant elements that would produce validated learning outcomes across most skills taught. Our agile approach to software development, iterative approach to instructional design and frequent interactions with

the customer enabled us to accommodate these changes in requirements.

Although key to our success, the agile method was not without issues. In fact, it caused some interesting tensions and challenges among the team. In order to produce frequent releases, software development moves extremely quickly. Yesterday's ideas become tomorrow's implementation. This put an extra burden on quick turn arounds and the rapid iteration of ideas and forced the team to focus on what's important. Ideas that fell into the "could-be" or "might be nice" categories quickly got pushed aside by "must have" and "critical" requirements. Whenever an idea cropped up, it was immediately weighted for its instructional or gameplay value and then balanced against the rest of the to-do items. The most important items always got done and the rest got set aside for another day. The result was a game that was delivered on time and within budget, met all customer needs, and passed the usability tests with flying colors.

FUTURE RESEARCH DIRECTIONS

In the next two years of our project, our plan is to investigate further issues related to the development of game-based training and to build upon the lessons learned so far to identify design and development methods that support consistent and effective outcomes. We plan to create additional refinements of the flooding control training system, as well as to create additional training systems in other domains for the same customer. These development efforts will inform and be supported by efforts to create better authoring and assessment tools for game-based training (e.g., of which our data-driven infrastructure was an early step). To ensure that our advances are well-founded, we will conduct a variety of empirical investigations into the effectiveness of different gaming features for training, and the interaction between different gaming and instructional approaches.

The field of game-based training is at an interesting crossroads as it moves from a poorly understood cottage industry to a well-founded discipline of its own. The multifaceted nature of game-based training is both its strength and its weakness - no other medium can provide as rich and varied learning experiences, but few other instructional mediums are as difficult to get right. There is a need for increased communication across practitioners to share processes, mechanisms, and lessons learned. We believe our continuing efforts in this project will provide seminal contributions towards formalizing game-based development methodology.

CONCLUSION

Conducting research on instructional games begs the question, "How can games be made instructional *and* engaging?" A critical battleground for this debate is the learning objectives and how they are used during design and development of the game. Respecting the role of learning objectives was an easy point of agreement for the team in the abstract. However, it was difficult to reach a common understanding of what that meant in terms of game play, story, actions, dialog choices, feedback, guidance, and the game environment. Instructional design based on learning objectives can limit distractions that overload the player with extraneous information that interferes with learning. However, the objectives alone do not guarantee focus on relevant information. Structuring the story must work in concert with treating the consequences of errors to help the player develop a mental model of what actions lead to the desired outcomes. The interactions between the player and the game must maintain the player's sense of immersion while also ensuring that the experience remains focused on the skills being taught. Finding the balance between adhering to the learning objectives while maintaining the characteristics

associated with a game was a persistent challenge that revealed itself in a variety of ways.

A second key battleground for this debate concerns the processes followed in producing an appropriately instructional and fun game. In general, the agile approach adopted in this effort resulted in ongoing priority conflicts between the instructional, gaming and story mindsets. The instructional designers by nature preferred a more traditional waterfall approach in which all key decisions regarding learning goals, content selection, and specification of instructional methods and strategies would be made prior to involving considerations about the story, the technology, and the gaming style. Their concern was that that key components, affordances, and experiences in the training system necessary from a pedagogical and assessment standpoint would be undermined or inadequately represented if instruction came second. The gaming developers by nature preferred clear direction on the basic interaction modes desired for instruction and the basic structure of a game level so that the associated software interfaces and graphics could be created in a timely manner, and were content to leave easy-to-change data details (e.g., the specific dialog and instructional messages, or sequencing of activities within a level) as part of an iterative refinement process led by the instructional designers. Finally, the story developers by nature preferred a strong early investment in coming to agreement on the basic story in order to ensure that successive iterative refinements of the instructional design or technology could be shaped to maintain a powerful story. From their vantage point, powerful stories create powerful experiences that invite participation while information and data, on the contrary, invite critique. The danger of ignoring the story aspect of a learning game at any stage of the process is that achieving a powerful story becomes difficult.

Of the many lessons learned in this effort, most involve the challenge of effective communication among professionals from diverse backgrounds.

It is important to clearly articulate each team member's priorities as early as possible and work together to devise methods for sharing and integrating information that will accommodate any competing priorities. From this, specific critical paths and components must be identified that, if organized and prioritized correctly, can inform the overall design and development approach. Since the process of combining the craft of game design and the science of learning has yet to be established, the lessons learned from this project may serve to inform the process and lead to an efficient and effective model for the development of games for learning.

ACKNOWLEDGMENT

The research reported in this paper was conducted under the management of Dr. Ray Perez under the Office of Naval Research contract number N00014-08-C-0030. We would like to thank our customer Dr. Rodney Chapman, Chief Learning Officer of the Naval Service Training Command, and his staff for their active participation in refining and guiding our product design, and Lt. Greg Page from the Recruit Training Command for his assistance in providing subject matter expertise. We would like to thank Dr. Ray Perez and Mr. Paul Chatelier of the Potomac Institute of Policy Studies for identifying opportunities for putting our research efforts in context of the Navy's current needs. We would like to thank Steve Greenlaw of Intelligent Decision Systems, Inc. for providing subject matter expertise. Finally, we would like to thank the software designers and engineers who contributed to the development and testing of the product: Chris Rodgers and Brad Anderegg from Alion Science and Technology, Rachel Joyce and Julian Orrego of UCF, and Erin Panttaja, Todd Wright and John Ostwald of BBN Technologies.

ABSTRACT

Instructional video game development is occurring in both the commercial game development and the instructional design/development communities, but regularly in isolation from one another. While many proclaim that game-based learning offers an instructional revolution, the empirical results on instructional effectiveness have been mixed. These mixed findings may be due to the contrasting approaches utilized within these two communities. These communities dif-

fer with respect to prioritizing goals and design/development processes. However, the creation of an effective instructional video game—one that both motivates and teaches—is dependent on the successful partnering of these communities. Accordingly, this chapter elucidates the commonalities and differences in the development goals and approaches of these communities and discusses how best practices of each community should be blended for optimal instructional video game design. This chapter also includes relevant experiences from an instructional PC-video game development project, illustrating challenges faced

DOI: 10.4018/978-1-60960-503-2.ch216

and new opportunities afforded via a collaborative development effort.

INTRODUCTION

With traditional instructional methods, such as formal classroom instruction, one fundamental challenge can be motivating students to fully engage in the instructional content. PC-based instructional video games have become an increasingly popular instructional medium, as many proclaim that video games engage and motivate learners in ways that traditional instruction hasn't in the past (Gee, 2003; Herz & Macedonia, 2002; Prensky, 2001). Further, some proponents of instructional video games suggest that today's learners (and game-players) are wired differently than learners of the past, and that game-based learning leverages this difference, capturing their motivation to learn (e.g., Prensky, 2001).

While many assert that game-based learning offers a new revolution in instruction (Gee, 2003; Herz & Macedonia, 2002; Prensky, 2001), the empirical results concerning its effectiveness with respect to student knowledge acquisition and retention have been mixed to date (Hays, 2005). Thus, utilizing this engaging medium may help alleviate the concern of low student motivation; however, motivation alone is not a sufficient condition for learning. This suggests that the important question for instructional game developers is not whether a learner is fully engaged in game play; rather, is the "engaged" learner actually learning the instructional objectives embedded in the video game or merely playing the game? In short, both student motivation and pedagogical structure are necessary determinants of the effectiveness of instructional video games.

The development of instructional video games represents new territory. Experts in the instructional design/training development community have typically developed tools used for instruction, while commercial game development experts

have mastered the development of video games for entertainment purposes. Video games designed specifically for instructional purposes represent a gray area, with training game development occurring in both communities but many times in isolation from one another.

It is possible that the demonstrated mixed effectiveness of instructional video games (e.g., Beal, 2005; Hays, 2005) can be attributed to the contrasting approaches utilized within these two communities. Many believe that the commercial game development and instructional design/training development communities differ greatly with respect to their fundamental goals (i.e., entertainment versus learning) and processes involved in design/development (i.e., game development versus instructional design processes).

The creation of an effective instructional video game—a game that motivates and also successfully teaches the intended instructional objectives—is dependent on the successful partnering of these two communities. While these communities may hold different goals or definitions of a successful development initiative, these goals are not incompatible. Further, while on the surface these communities may appear to utilize unique design/development approaches, these two communities actually embrace complementary approaches. Accordingly, the purpose of this chapter is to elucidate the commonalities and differences in the development goals and approaches of these two communities, and discuss how the best practices of each community should be blended for optimal instructional video game design.

The remainder of the chapter is organized as follows. First, the overarching development goals of both game developers and instructional designers are described. This includes how these goals differ, as well as overlap. Next, is a description of the different developmental processes that game developers and instructional designers are likely to follow in product development. Again, differences and similarities in the product development processes of both communities are highlighted.

Further, to illustrate the challenges faced and new opportunities afforded when these two communities partner in the development of an instructional game, examples from experiences during the development of a training game called ELECT BiLAT are provided. This game-based training tool was designed to provide U.S. Army officers instruction on preparing for and conducting bi-lateral, cross-cultural negotiation meetings. Specifically, in ELECT BiLAT, learners are confronted with a series of scenarios that involve meetings with leaders in an Iraqi village. In order to successfully accomplish their mission, learners must correctly plan and execute these meetings, thereby demonstrating proper cultural, negotiation, and decision-making skills.

ELECT BiLAT is based on a commercial game engine and includes interactive computer-generated characters and automated instructional feedback/coaching. Although ELECT BiLAT uses a 3D game engine, it is not a first-person-shooter game; in fact, there is no shooting in the system, and most user interaction is accomplished through a menu system. Figure 1 displays a sample screen shot from ELECT BiLAT. In this portion of the game, the learner is engaged in a negotiation

meeting with the local police chief. The choices of available actions (for the learner) are selected from the menu at the lower left corner of the screen, and the computer-generated character verbally responds to the learner's choice. In the lower right window, there is an on-going printed transcript of the interaction, along with hints and coaching from an intelligent tutor built into the game.

The ELECT BiLAT project described here has been sponsored and managed by the U.S. Army Research, Development, and Engineering Command's Simulation and Training Technology Center (STTC). The development of ELECT BiLAT was a collaboration between the University of Southern California's Institute for Creative Technologies and three U.S. Army research agencies (STTC, the Army Research Institute for the Behavioral and Social Sciences, and the Army Research Laboratory—Human Research Engineering Directorate). In order to maximize the potential success of both the development and implementation of this instructional game, this collaborative effort brought together multiple researchers and practitioners in the fields of game design, human factors, and instructional design, along with U.S. Army trainers and students. Ad-

Figure 1. Screenshot of ELECT BiLAT, depicting a negotiation meeting with the police chief (©2007 University of Southern California. Used with permission)

ditional details about ELECT BiLAT can be found in Hill et al. (2006).

DEVELOPMENT GOALS

Commercial game developers and instructional designers do not have incompatible goals for product development (e.g., instructional video game development); however, their priorities may be a bit different. At a general level, both game developers and instructional designers want to develop a successful product; however, the standards with which these groups measure success differs. For game developers, if the game results in a high sales volume and users want to play it, they are successful. Thus, the primary goal of a commercial game developer is to maximize player enjoyment and motivation to continue playing the game. For instructional designers, they are only successful if the students learn the instructional content. It doesn't matter how much the learners enjoy the game and want to continue playing if they are not learning as a result of game play. Accordingly, the primary goal of an instructional designer is to assure that the student has achieved mastery over the learning objectives.

Both the primary goal of the game developer and of the instructional designer are critical to the success of an *instructional* video game, in that a successful instructional game must maximize player motivation/engagement, as well as knowledge acquisition and retention (see Figure 2). Further, to ensure that both goals are optimally achieved, the utilization of a multi-disciplinary team, consisting of both game developers and instructional designers (as well as team members with other qualities like training domain subject matter expertise, graphic artists, and product management) is critical. Game developers are skilled at designing games that are engaging and have motivating and intriguing story lines (Dickey, 2005); whereas, instructional designers are skilled at structuring information within a learning environment so that learning will take place (Branson, 1978; Dick & Carey, 1990). Both skill sets are required for development of an instructional video game.

A multi-disciplinary team may initially struggle in the process of instructional game development because of their varied world view of product development. The initial struggle can be minimized through clarifying each others' objectives, common terminology, and processes for meeting their overarching goals (i.e., motivation

Figure 2. A depiction of the overlapping goals of commercial game developers and instructional designers when they work together to build an effective training game

or learning). During the development of ELECT BiLAT, there was a realization that the two communities possessed different operational definitions for the same term. For example, on the instructional design side, the term “content” relates to the information/domain to be trained (e.g., negotiations and cultural norms). On the game development side, “content” relates to objects that appear on the screen (e.g., buttons, characters, and background items). Another example of a term that needed clarification was training support material. The instructional design view was that background information on the training domain was the primary component of supporting material, while the game development view was that supporting material consisted of mainly instructions on how to use the game. To assist in minimizing such misunderstandings of “common” terminology used, a list of shared vocabulary was developed—a comprehensive list of terms and definitions that the different partners used. Discussing and clarifying the differences provided a means to communicate more clearly across specialties and to better understand each community’s goals and objectives for the project. This also helped to mitigate some of the challenges of bringing together individuals from fields that have distinct cultures (Finholt & Birnholtz, 2006).

While the fundamental goal of game developers and instructional designers may not be identical, they do share the desire to avoid the same obstacles to success (see Table 1). No game developer or instructional designer wants an uninteresting and confusing product that is easily forgotten. Thus, one way to help circumvent this initial difficulty in collaborating is to shift the focus of the team to minimizing obstacles to training game success. For example, if during the development process the instructional designers realize that the game, as currently conceptualized, fails to teach all aspects of the intended set of competencies, then the game developer (and team) should take that as an opportunity to modify properties of the game to more effectively link it with the learn-

ing objectives. Conversely, if a game developer observes that the training game appears to be a little boring, then the team can work together on alternative ways to engage the learner and maintain learner attention.

Just because the primary goals and objectives of game developers and instructional designers are not identical, does not mean that they are incompatible. By working together during the development process, they can achieve both goals—a training game that is motivating to play and maximizes acquisition and retention of the instructional content. Each group must be aware of the other’s perspective (likely through extensive communication) and respect the other’s position while working toward the common goal of developing an effective training game.

DEVELOPMENT PROCESSES

In this section, the general approaches that the two groups take toward product development are described (see Table 2). The terminology used for the various steps of design/development across the gaming and instructional design communities are explained, followed by a discussion of how the operational definitions of some of the terms vary between these groups. The goal is to illustrate that while these two groups have distinctly

Table 1. Examples of goals and obstacles for commercial game and instructional designers

	Primary Goal	Objectives	Obstacles
		Engaging	Lack of Interest
Games	Motivation	Playability	Confusion
		Challenge	Boring
		Skill Acquisition	Skill Degradation
Instruction	Learning	Mastery	Confusion
		Attention	Lack of Interest

Table 2. A comparison of the five steps in the development processes of instructional designers and commercial video game developers

→→→ Development Process →→→					
	<i>Step 1</i>	<i>Step 2</i>	<i>Step 3</i>	<i>Step 4</i>	<i>Step 5</i>
Instructional Design	- Analysis	- Design	- Development	- Implementation	- Evaluation
Computer Game Design	- Choose goal/topic - Research	- Design - Storyboard	- Program - Playtest	- Deliver	- Post mortem

different design/development steps, they share many similarities.

The instructional design approach tends to be structured rather linearly with respect to product (instructional system) development. While the specific processes used by instructional designers may vary to some extent (e.g., Branson, 1978; Dick & Carey, 1990; van Merriënboer, Clark, & de Croock, 2002; Winston, 1968), with some processes involving an iterative component, for the most part, the linear approach seems to be the norm when applied. For instance, a commonly used approach for instructional systems design is captured by the acronym ADDIE, which stands for the steps of: analysis, design, development, implementation, and evaluation. These steps are well known by instructional designers and frequently utilized to guide their development of instructional software.

In the commercial game industry, there is also a fairly standard process for developing a product. Many game developers have previous experience with software development; this is why the computer game development processes often share many similarities with well-known software development processes (Boehm, 1988; Royce, 1970). Generally, the first step is to choose a goal/topic/theme for the game, followed by the steps of research, design (preprogram & storyboard), program/playtest, delivery, and post mortem (Crawford, 1997). For commercial game development, many of these processes tend to be very fluid, with multiple steps being worked on at any one point in time and with continual revisiting of any given step. This iterative process may

include potential users playing paper-based and software-based prototypes, with feedback being used to make modifications to the design. Also, the first “working” version is not thought to be the final version, but a work in progress. There tends to be a good deal of testing, continued modification, and retesting until the developers are ready to “go gold” (i.e., have a final version ready to deliver to users).

The steps and processes used by game developers share many features with those used in the instructional design approach, in that they both have analysis, design, development, implementation, and evaluation phases. The remainder of this section describes in detail the similarities and differences between the processes used by these two communities, and provides examples of how game developers and instructional designers can effectively combine their efforts throughout the development of an instructional video game.

Step One. For an instructional designer, the “analysis” phase involves identifying what needs to be learned (Branson, 1978). The primary aspect of this is to specify explicit learning objectives. This also includes determining the current knowledge base of the intended learners, as well as the gaps in their knowledge, skills, and abilities that need to be addressed by the training to be developed. For a game developer, the first step involves making decisions about: (a) the type/genre of game they plan to build (e.g., first-person-perspective, multi-player), (b) the development and delivery platform to utilize (e.g., licensing an existing game engine versus creating a new one), and (c) who will be their target audience. In the design

of an instructional video game neither of these “analysis” decisions needs to supersede the other; and it is suggested that all of these decisions are valuable and should be explicitly considered.

One clear parallel between the worlds of game developers and instructional designers is the analysis/research of the intended audience. Game developers may ask questions about their target audience, the complexity of the set of rules governing game play, and the game’s story line. Whereas, instructional designers may ask questions about the intended trainees, such as their current level of understanding of the topic of instruction (as well as the intended mastery level post-training), the ability of the students to use the training technology, and how this fits into their broader curriculum. Both sets of questions address who the targeted end user will be. Understanding the characteristics of this user in turn will facilitate the development of the most effective training game—one that meets the needs of the learner.

The choice of game genre is another important decision for both commercial game developers and instructional designers intent on creating a training game. From the commercial game perspective, the choice of game genre is often driven by factors such as the expertise and experience of the design team, with teams playing to their strengths. Marketing and sales concerns also play a role in this decision. As an example, not only is a company with a history of producing sports games likely to be better at producing sports games than other types of games, this company is also more likely to have a greater understanding of the sports gaming market. If such a company were to decide to create a strategic war game, they would face a number of challenges—both in the development and sale of a new title. With the exception of a few highly popular franchises (e.g., *Star Wars*), game purchasing behaviors are more likely to remain within genre than between genre (Horn, 2006).

For the instructional designer, there are two key aspects to the decision of game genre: (a)

game-training content match, and (b) learners’ prior video game experience. With respect to the former, the training content of a game can be intrinsic or extrinsic to the game genre. An intrinsically instructive game is one in which the training content is a fundamental aspect of the game mechanic—for example, using a flight simulator to train pilots. Research suggests that by selecting a game with similar attributes to the training domain, less effort will be required for the learner to transfer what is learned in the game to the real-world context where they must apply those lessons (Auffrey, Mirabella, & Siebold, 2001).

An extrinsic training game is one for which the training content is not directly related to the underlying game mechanic, but instead uses the game as a way to deliver unrelated content. Prenksy’s *Straight Shooter!*, a first-person-shooter game designed to teach bankers about derivatives policies and practices, is a good example (see Prensky, 2001, pp. 248-253). If the training content is particularly well suited for a particular game genre (e.g., a flight simulator for some basic flying concepts and skills), it is often advantageous to use that game-training content match. However, even when there is a clear game-training content match, the decision to develop that particular type of game is not necessarily warranted. As an example, consider attempting to train infantry squad leaders. While it may seem natural to use a first-person-shooter, if the goal is to train decision-making and strategy it may be better to rely on a more strategic (perhaps even turn-based) game-style in order to encourage more deliberative thought. In short, one needs to seriously consider the knowledge and skills to be trained before selecting the game genre of the instructional game.

In selecting the genre of a training game, it is also useful to consider the prior video game experience of potential learners; as aforementioned, the analysis of who will be using the training game is critical. If the users are not familiar with a particular game genre, then there may be time wasted trying to teach the learner how to use the game

interface, sacrificing time devoted toward learning the training domain. Further, research suggests that learners who have previous experience with video game genres similar to the training game are more likely to demonstrate positive training outcomes, such as enhanced training performance, training satisfaction, and time spent engaging in the training game (Orvis, Horn, & Belanich, 2006; Orvis, Orvis, Belanich, & Mullin, 2007).

For ELECT BiLAT, on the instructional design side, the analysis step/phase started with interviews of Army instructors and other subject matter experts (SMEs) to understand the targeted training domain and typical gaps in trainees' knowledge, skills, and abilities (Hill et al., 2006). A set of learning objectives was developed to clearly identify what should be learned by the students. There was also a discussion about the game technology that would be most appropriate for the target group of learners. Since the target learners were Army officers with considerable years of military experience (typically in their 40s), it was noted that these individuals were not typical gamers (Belanich, Orvis, Moore, Horn, & Solberg, 2007). Thus, a training game involving complex movements through a 3D world would likely be foreign to many of them and require a good deal of up-front training on the game technology, with little added value to training the instructional domain. Accordingly, the decision was made to simplify the game mechanics and interactions with computer-generated characters as negotiation meeting partners. There was a focus on more familiar types of buttons and menus in the user interface to best meet the needs of this group of learners. On the game development side, the choice was made to use the rendering capabilities of a 3D game engine to provide an engaging environment for the training that would immerse the students in the training scenarios. All of this minimized the time needed to learn how to use the training game, allowing more time to be spent learning while engaging in the game.

Step Two. For both instructional designers and commercial game developers, the design phase includes developing a plan that will accomplish the goal of making a successful product. Instructional designers frequently accomplish their overarching goal of maximizing student learning by breaking down what needs to be taught into small chunks and then organizing these instructional chunks in a structured, sequenced way (i.e., an organization scheme that leads a learner toward mastering the learning objectives) (Bransford, Brown, & Cocking, 1999; Branson, 1978; Moreno & Mayer, 2002). Typically, commercial game developers would work toward accomplishing their overarching goal of maximizing player motivation/engagement by creating a general story or path that they want the player to experience as part of the game, filling in details as they proceed. This process would end with the development of paper-based storyboards which include the sequence of events that are likely to occur during the game experience and what the different game screens would look like to the user.

In short, instructional designers tend to take a bottom-up approach, starting with small chunks and organizing them into a whole. Conversely, game developers tend to adopt a top-down approach, working from a general story idea/theme and progressively adding detail. These processes do not need to be incompatible; in fact, they can be integrated. For example, instructional designers can first develop their learning chunks/nuggets. Then, the game developers can utilize this information to develop a general story line that will include all of the learning chunks. Both groups can then work together to fill in the gaps so that there is a meaningful organization of chunks within the story line.

In fact, it can be argued that the story line and the teaching points *must* be fully integrated; building the instructional content into a story line is key for an instructional game (Dickey, 2006). Research has shown that learners are more likely to learn

information in an instructional video game when it is integrated into the story line or progression of the game versus information that is superfluous to the overall flow of the game (Belanich, Sibley, & Orvis, 2004). There are several techniques for aligning instructional content with the game story line (see Dickey, 2006). The practical take home point is that story development and training domain development should not occur in isolation. The instructional content must be fully integrated into the overall story line of the game to maximize effectiveness.

One caution when developing a story line is that even if it shares an overall theme with the training domain, it may not match up well with the specific teaching points/learning objectives that are required. For example, playing a game like *Rollercoaster Tycoon*TM may make a player aware of some of the aspects of building and maintaining a theme park that the player wasn't aware of before. However, it won't teach a person the engineering skills of building an actual rollercoaster or the accounting/business practices of running an actual theme park.

To avoid this issue during the development of ELECT BiLAT, active collaboration between the instructional designers and game developers was critical, as well as seeking input from training domain content experts. First, instructional designers identified the tasks and learning objectives that were to be trained, and made sure that they were integral parts of the immersive story line (Hill et al., 2006). This involved performing a detailed task analysis, identifying the skills and behaviors necessary for planning and engaging in bi-lateral meetings. This task analysis was based on interviews with Army instructors and other SMEs, a review of Army doctrine, and a review of the published literature on culture and negotiations. Results from the task analysis were later fed back to the SMEs and instructors to ensure that it accurately represented the training domain. Further, in order for the game developers to build an engaging but realistic story line for the training

scenarios, direct questions were asked to the SMEs, such as "When you are engaging in *Task A*, what are the most important aspects to be aware of?" In addition, some examples of critical incidents pertaining to this task were requested (i.e., real-world situations of when they had effectively/ineffectively engaged in the task) (Anderson & Wilson, 1997). These "important aspects to consider" and SME-provided critical incidents were then woven into the story line, paired with the identified skills and concepts to be trained.

Another important variable to consider in the design phase is the level of challenge that will be most appropriate for the training game. This is important on an instructional level, in that you want to push learners to gain new knowledge and skills; however, you also do not want to overwhelm the learners by asking them to perform tasks that are well beyond their current mastery level (Bowman, 1982; Garris, Ahlers, & Driskell, 2002; Rieber, 1996). The appropriate level of challenge is also important on a motivational level, in that to maintain high levels of motivation, the task being performed should be neither too easy as to become boring, or too hard to be frustrating (Belanich, Sibley, & Orvis, 2004; Crawford, 1997; Csikszentmihalyi, 1990; Malone & Lepper, 1987).

With ELECT BiLAT, we knew it was possible that some of the target learners might possess limited prior experience with the training domain; therefore, starting the game at a high challenge level would have been problematic. However, it was also critical to include scenarios that would challenge those with greater levels of prior experience, as well as learners that had improved their knowledge and skills over the course of using the game. Accordingly, a series of progressively more difficult negotiation scenarios were developed and used in the game (Hill et al., 2006).

The design phase is critical for instructional video game development success, and will require game developers and instructional designers to communicate their *wants* and *needs*. Because the product is in the conceptual stage at this point, it

is not that easy to clearly explain what is required and why it is important across the two communities. Simple prototypes or examples from products that share similar features can help in this interchange of ideas. With ELECT BiLAT, the game developers created a paper-based prototype to show instructional designers (and later potential users and Army instructors) how the training game would work. From these “show and tell” sessions with users and instructors, the game developers and instructional designers gathered extensive feedback (in terms of engagement of the story, ease of use, and if the game adequately captured the instruction domain). This feedback was used to improve the design and update the prototype. Over time, the prototype was iteratively refined and tested until the major game-play elements and instructional components were deemed sufficient and fully integrated.

Step Three. During the development/programming step, the plan (created during the previous step) is used to produce the actual video game. This is where the programmers start typing out computer code, working to implement the plan. In order to minimize any misunderstandings as the paper plan is being translated to software code, it is important that the plan is clear, both in terms of instructional content and motivational game features (e.g., realism of graphics, usability of interface, challenge level presented).

As with any plan, once it is put in motion there are often modifications that need to be made. While both instructional designers and game developers tend to use iterative development models (to some capacity), there are some differences in the kind of feedback that loops back into the development process. For instructional designers, feedback is typically provided by someone in the role of an instructor. This feedback entails the aspects of the instructional tool that they think would be effective for teaching their students, as well as what components need modification. Ideally, instructional designers are able to obtain some level of in-class evaluation using a pilot group

of learners (e.g., whether through cooperative agreements with instructors intending to use the instructional tool or through individuals recruited to participate in a focus group).

Game developers typically involve people from the actual target audience to play-test alpha and beta versions of the game. The game developers observe the play-testers using the game and ask for their opinions about different aspects of the game (e.g., Is it fun? Is it challenging enough? Did they find the storyline interesting? What worked and what didn't?). Play-testing is very important because the best way to determine if intended users will enjoy the game is to have them play it and then capture their feedback (Salen & Zimmerman, 2004). In addition to using such a pilot group of play-testers, commercial game developers are often able to glean feedback from the player community through alpha and beta versions which have been released to the public. This feedback, while valuable, typically focuses on issues that are of concern to experienced, highly motivated players—making it a bit more difficult to predict the types of problems that novice game players may face.

Commercial game developers attempt to get as much feedback as they can at this point in the product development process because they typically do not have the opportunity to make significant revisions once they go to the delivery phase. (It should be noted that while game patches have become relatively common among computer games, they have been historically difficult or impossible with console games. This is starting to change as the newest generation of consoles typically have Internet access.) Conversely, instructional designers are expecting to also get feedback at a later stage (i.e., Step 5—Evaluation) and this information is frequently used to make further revisions. In short, game developers have a tendency for a shorter feedback loop for each iteration of the game. Further, they will develop segments of the game and get feedback on their development all within this step. In contrast, instructional design-

ers have a tendency for a longer feedback loop in that they will develop the training tool (Step 3), formally evaluate how well the training worked (Step 5), and use the results of this evaluation to update/revamp the training tool.

With ELECTBiLAT, an iterative development process with both short (within step) and long (across Steps 3-5) feedback loops was used (Hill et al., 2006). Examples of short feedback loops include when the game developers/programmers would demonstrate their work for the team and make quick modifications based on feedback received. Also, when the software was at a stage to be play-tested, a pilot group—representing the population of instructors and students in which the training was intended—were asked to try out the instructional game and give extensive feedback both in terms of instructional content and playability/engagement. An example of a long feedback loop includes the iterative delivery of versions of the game to individuals in the U.S. Army course where the game was to be implemented. During this roll out, multiple versions (based on the suggested feedback) were delivered and formally evaluated for instructional impact (i.e., did they learn?), usability, and motivational factors. The cooperation and patience of Army instructors during this process was critical. The detailed, expert assessment that instructors, students, and other SMEs were able to provide enabled both incremental and significant improvements relatively quickly. Had this tool been created by a team without direct access to the target group of learners/instructors, this type of user feedback (across Steps 3-5) would likely not be available.

Step Four. In Step 4, the end user gets to actually use the game. For instructional designers, the term implementation is used because the instructional tool is often part of a course or some larger curriculum. When used as part of a course/curriculum, there is the possibility that guidance on the instructional tool will be provided to the learner by an instructor or someone else who provides this support function. Learners are not

necessarily expected to utilize the tool independently. In contrast, with entertainment games, the term delivery is used because it is expected that the system will stand on its own. Game directions are important and needed to guide users. However, if users have questions that go beyond the provided directions, gamers are usually more than willing to search around for answers. For example, users may go to gaming Web sites or read other material that may provide the answers they seek.

It is important to note that in both the instructional and entertainment domains, there is a need to provide sufficient guidance regarding *how* to use the game. Further, the guidance provided may need to be expanded with an instructional game. For example, there typically is a need to provide support to not only the learner, but also the instructor, who may not have expertise with computers or video games. This “train-the-trainer” effort plays an integral role in the success or failure of an instructional video game, as an otherwise excellent training game can fail if it is not effectively implemented in a course (Belanich, Mullin, & Dressel, 2004).

Several pitfalls can lead to poor implementation/delivery of training games. Belanich, Mullin, and Dressel (2004) described various obstacles to successful training game implementation. One of the main reasons for ineffective implementation is that the game is not clearly integrated into the curriculum of the course. For instance, learners are never explicitly told the purpose of this instructional tool or what they should seek to achieve by engaging in the game. Without a reason as to why the learners are devoting effort to play the game, students may wonder, “What’s the point?” It should be clear to students what they are expected to gain from playing the training game (i.e., the learning objectives to master and/or competencies to be developed). Also, if the instructor does not know how to use the training game (e.g., maneuver through the user interface), this can lead to wasted time as the students have to learn how to use the game on their own. Furthermore, the students may

gain the impression that the instructor doesn't really know the instructional material. Clearly, proper implementation is critical for a training game to be fully effective.

With ELECT BiLAT, the intended implementation was for the game to be used as an in-class exercise (to take only a few hours) as part of a two-week course. First, the instructor would highlight some of the topics to be addressed within ELECT BiLAT. The instructor would also go through some of the procedures that the students would have to complete as they were progressing through the game. Then as the students used ELECT BiLAT, the instructor would be available for assistance. Fortunately, the lead instructor had been involved in early discussions and demonstrations of the game and was motivated to provide feedback, which were critical to making the implementation of the game successful. There has been discussion regarding the best way to ensure that this knowledge is available to students in other contexts (e.g., contexts with less active/knowledgeable facilitators or no facilitator), and future versions of ELECT BiLAT will include additional support information. Among the solutions being discussed is the inclusion of a video introduction to the game and its interface. This is a key area which must be considered if gaming savvy instructors will not be available at the implementation site.

Step Five. For instructional designers, the evaluation phase is not necessarily the end. Based on the results of the evaluation, they are likely to revamp the design and may go through another cycle of development. Because there is often an instructor overseeing the use of the training tool, the instructional designers might get feedback from the instructor's perspective. If there is a formal evaluation conducted, which is not always the case (Hays, 2005), student feedback may also be available.

With game development, there are different avenues to gather feedback on the success/failure of an effort. The evaluation of a commercial game may rely on sales data and player critiques on game

Web sites. If the game is successful, there might be a second version—only “bigger and better,” with new features. If the game is not successful, they may chalk it up as experience and develop a completely different game. The market response to entertainment games is relatively quick—if gamers are not satisfied, a game will not sell well. Additionally, the gaming community has evolved to a point where there is a good deal of feedback provided via online forums, magazines, and so forth. With instructional games, sales often rely on slower procurement processes, with decisions often being made not only by instructors, but by other administrators.

The challenge of evaluating the effectiveness of an instructional game, both in terms of accuracy and time, may not enable the development team to assess market satisfaction quickly. This can significantly delay the feedback loop. A combination of the aforementioned methods to evaluate the effectiveness of an instructional game might be most appropriate. This evaluation should address both instructional (did learning occur) and motivational (was it engaging to the learner) aspects of the instructional game.

The evaluation of ELECT BiLAT has been ongoing, and has relied on measures of learning, performance data logs, student feedback/satisfaction, and instructor feedback. Again, because of a close relationship with the course instructors, detailed feedback was provided which influenced subsequent updates. The initial results indicate that the students are learning due to this implementation. There is always room for improvement, and based on the initial evaluation, additional modifications are currently being made.

CONCLUSION

Instructional designers and game developers may be quite different, and their experiences and priorities might, at times, appear to be at odds with one another. However, when developing instructional

games, they do share a similar overarching goal—to build a successful product, and in this case, a successful instructional game. Remaining focused on this common goal as the priority should assist these two communities in bridging their diverse perspectives and expertise in order to develop the optimal instructional video game.

Throughout this chapter, it has been argued that the critical determinant of the success of video games as instructional tools lies in the willingness of commercial game developers and instructional designers to work with one another, as well as their ability to successfully integrate their central goals and design/development processes. The primary implication of this work suggests that a collaborative team with members of different specialties working together is essential for achieving the goal of building a game that is both instructional and motivating to use. Unfortunately, according to Squire (2005), who conducted a series of case studies of video game-based learning product development, organizations may use interdisciplinary game development teams, but they do not include instructional designers as part of the team. A typical team includes program managers, graphic artists, and programmers—no instructional designers. Without specialists who understand how to provide instruction, it isn't surprising that many instructional games do not effectively teach the intended instructional objectives (Hays, 2005).

To provide insight into how a successful merging of these two communities can be accomplished, relevant research in both game development and instructional design has been presented, and practical lessons learned from experiences during the development of an instructional video game were provided. A mutual understanding is key to successful partnerships, and this requires consistent communication and a respect for the skills and attributes that partners with different backgrounds bring to the team. Game developers may benefit from understanding and incorporating

several processes used by instructional designers (Bransford et al., 1999; Dick & Carey, 1990; Moreno & Mayer, 2002). Likewise, instructional designers may benefit from understanding and incorporating several processes used by game developers (Bethke, 2003; Crawford, 1997; Salen & Zimmerman, 2004; Squire, 2005). In short, communicating and understanding the commonalities and differences of the expectations and processes of their partnering community should facilitate their successful collaboration. Further, the unique elements of each community's approach should be blended for optimal instructional video game design—an instructional video game which is both intrinsically motivating and pedagogically sound.

ACKNOWLEDGMENT

Statements and opinions expressed in this chapter do not necessarily reflect the position or the policy of the United States Government, and no official endorsement should be inferred. The ELECT project described here has been sponsored and managed by the U.S. Army Research, Development, and Engineering Command's Simulation and Training Technology Center. The chapter authors (from the Army Research Institute) would like to express their appreciation to the partners who collaborated on ELECT BiLAT (i.e., STTC, the Army Research Laboratory—Human Research Engineering Directorate, and the Institute for Creative Technologies).

KEY TERMS AND DEFINITIONS

ADDIE: The ADDIE model is commonly used in instructional systems design. The acronym stands for analysis, design, development, implementation, and evaluation. The output of each stage serves as the input for the subsequent stages.

Instructional System Design: The practice of creating and organizing media in a way that enables individuals to learn effectively. Instructional system design incorporates a variety of disciplines

including education, psychology, information technology, graphic design, and others.

Iterative Development: A model of system development in which the ability to rework and revise aspects of the software is scheduled. In this approach, the developer benefits from prototype evaluation during the development process.

Learning Objective: A specific, measurable task (or class of tasks/actions) a learner should be able to perform as the result of training. It should include the conditions under which the task should be performed as well as the criteria by which performance will be judged.

Subject Matter Expert (SME): An individual with a high level of knowledge in a particular domain—subject matter to be taught. Although an

SME typically may not have an expertise in training or instructional design, he or she can play an integral role in the design of instructional games.

Spiral Development: An iterative model of system development in which software is built in progressive phases. In each phase, a prototype of the software is reviewed by the customer and evaluated prior to further development. Following the review, another prototype is built and evaluated. This process continues until the final product is delivered.

Storyboard: A graphic means of presenting the story line of a video game, movie, or cartoon. In serious games, this depicts the plot of the video game in which learning objectives are embedded.

ABSTRACT

While utilizing GPS-enabled handheld computing units, we have developed and studied augmented reality (AR) curricula to help middle school students learn literacy and math. In AR, students move around an outdoor physical environment, interacting with virtual characters and artifacts on their handheld computer. These invisible objects and characters provide clues to help solve a mystery, guiding the students through a process of inquiry and evidence building. The first AR curriculum we developed, *Alien Contact!* is based on a scenario where aliens have crash landed near the students' middle school. Students, working in teams, learn math and literacy skills in the course

of determining why the aliens have come to earth. This study describes the design heuristics used during the initial development and deployment of *Alien Contact!*, the results of two formative evaluations of this curriculum, and the impact these findings have had on revising our design heuristics for a subsequent AR curriculum about beached whales, called *Gray Anatomy*.

INTRODUCTION

Researchers are starting to study how AR modalities for learning aid students' engagement and understanding (Dunleavy, Dede, & Mitchell, in press; Klopfer & Squire, 2008; Klopfer, Yoon, & Perry, 2005; Klopfer, Yoon, & Rivas, 2004). This article explores the background of AR, describes

DOI: 10.4018/978-1-60960-503-2.ch217

the Handheld Augmented Reality Project (HARP) at Harvard University, explains the results from formative evaluations of the first AR curriculum created through HARP, and delineates how the lessons learned from this evaluation impacted the development of a subsequent AR curriculum.

THEORETICAL FRAMEWORK

The theory that learning occurs most effectively in authentic setting is not new. Hendricks (2001) stated that complex social interactions are at the heart of learning. Brown, Collins, and Duguid (1989) more precisely defined this thinking through their belief that individuals' interactions with their social teams lead to their adoption of learned behaviors. This phenomenon, which Hendricks called situated cognition, is different from practices in traditional educational settings. There is ample research to substantiate that social interactions are important for accomplishing challenging learning tasks. Bandura (1977), Vygotsky (1978), and Scaife and Bruner (1975) found that observation of and assistance from others at times precedes and always interacts with human cognitive development. Bandura (p. 12) highlights the importance of "symbolic, vicarious, and self-regulatory" processes in social learning. As compared to a psychological view where learning is a matter of an individual "performing responses and experiencing their effects." Bandura elaborates on his theory that learning is a social process, explaining that we learn everything vicariously before we learn it directly because it is the only way we can "acquire large, integrated patterns of behavior without having to form them tediously by trial and error. The harder the task to be learned, the more we must learn it through observation first.

Hendricks (2001) found evidence to support the idea that practices based on situated cognitive theory can have significant impacts on immediate learning. Klopfer et al. (2004) focused on the use of

technology to facilitate situated learning environments—particularly through the use of handheld and wearable computing devices. Through the use of *participatory simulations* they found that students were more motivated, engaged, and excited by the process of participatory learning than they are by more traditional means of learning.

Motivation concerns the selective direction, energizing, and regulating of behavior patterns (Ford, 1992). It is central to persistence in learning and to producing positive outcomes (Ryan & Deci, 2000). Vygotsky (1978) found that, even before behavior sets in, through motivation we decide where we direct attention. There are different types of motivation, and they have different impacts on learning and sustaining learning (Ryan & Deci). Extrinsic motivation ranges from, at one end, a sense that our behavior is controlled by others who do things to regulate our behavior, to the other end, where we have a sense that we are in control of our own actions and get support from outside actors but little direct regulation of our behavior (Ryan & Deci). Most of the incentives to succeed academically in postsecondary education are designed to stimulate various forms of extrinsic motivation. For example, in a competitive classroom, some students' suboptimal performance, made explicit through student rankings and bell curves, serve as extrinsic motivators for other students to achieve.

There is strong evidence that cooperative learning is better for stimulating intrinsic motivation than competitive learning (Gehlbach, 2007). Classrooms that focus on cooperative learning make students responsible for one another's outcomes (Gehlbach). Social learning approaches may be more likely to foster intrinsic motivation, the form of motivation most likely to positively influence persistence, because it is the most self-directed form of behavior regulation and taps into our innate desire and capacity to seek out challenge and explore (Ryan & Deci, 2000). Later research by Klopfer et al. (2005) substantiated these earlier findings as to the impacts of simulations. More

recently, Rosenbaum, Klopfer, and Perry (2007) placed their participatory simulations within the context of augmented reality.

AUGMENTED REALITY

Squire and Jan (2007) define augmented reality as “games played in the real world with the support of digital devices (PDAs, cellphones) that create a fictional layer on top of the real world context” (p. 6). Squire and Jan focus on place-dependent AR games, which require participants to come to specific locations to work through the game. Alternatively, place-independent AR games are designed to overlay game elements on a map of any physical location.

In AR environments, students interact with virtual and physical objects, people, and environments. Unique capabilities of AR include the amplification of real world environments, the ability of team members to talk face-to-face while interacting simultaneously in the virtual environment, and the capacity to promote kinesthetic learning through physical movement through sensory spatial contexts. In the form of AR that we studied, students utilize GPS-enabled wireless devices that allow them to engage with virtual information superimposed on the physical world. For example, a student may be guided by a map of Washington DC on their handheld to walk to the Lincoln Memorial. When they arrive, an image may appear of the memorial itself containing architectural specifications, or a movie may become accessible that talks about famous events in history that have occurred at this location, or they will be asked to perform a particular task. By infusing digital resources throughout the real world, augmenting students’ experiences, improving their recognition of patterns, critical features, background information, and reinforcing what they are learning through multiple sensory experiences (i.e., hearing about the memorial from an expert, seeing it with their own eyes, and even

possibly touching a feature of the memorial itself while seeing that feature explained up close on their handheld device). Unique capabilities of AR include the amplification of real world environments, the ability of team members to talk face-to-face while interacting simultaneously in the virtual environment, and the capacity to promote kinesthetic learning through physical movement through sensory spatial contexts.

In addition, the current software developed to facilitate the delivery of AR curricula allows authentic team interactions and collaboration. This is due to the fact that the technology provides individuals within a team of students the ability to take on different roles within the augmented reality environment, thus allowing each individual to interact with the virtual elements in different ways than their teammates. While students may arrive at the same physical location as their group, a different artifact, interview, or task will appear on their handheld device than on their teammates who holds a different role. This is more authentic as a collaborative tool due to the fact that individual students within a team must collaborate and share information in order to progress through the game. The frequently seen suboptimal practice that team work is *turned over* to an individual student within the team to complete is not possible with this pedagogical approach; each individual must participate for the team to be successful.

THE HANDHELD AUGMENTED REALITY PROJECT

HARP is part of a three-year federal grant through the U.S. Department of Education Star Schools Initiative. HARP is a collaborative effort between Harvard University, the University of Wisconsin, and the Massachusetts Institute of Technology to study the efficacy of AR technology and curricula for the instruction of math and language arts at the middle-school level.

Lessons Learned about Designing Augmented Realities

This project has as its primary objective to design and study engaging and effective augmented reality learning environments using wireless handheld computers equipped with GPS receivers. In order to do this, HARP personnel have developed an AR curriculum called *Alien Contact!* and a subsequent curriculum called *Gray Anatomy* that incorporates many of the lessons learned from formative evaluations of the earlier curriculum.

ALIEN CONTACT! CURRICULUM

We designed *Alien Contact!* to teach math and literacy skills to middle and high school students (Dunleavy et al., in press). This narrative-driven, inquiry-based AR simulation is played on a Dell

Axim X51 handheld computer and uses GPS technology to correlate the students' real world location to their virtual location in the simulation's digital world (Figure 1).

As the students move around a physical location, such as their school playground or sports fields (Figure 2), a map on their handheld displays digital objects and virtual people who exist in an AR world superimposed on real space (Figure 3). When students come within approximately 30 feet of these digital artifacts, the AR and GPS software triggers video, audio, and text files, which provide narrative, navigation, and collaboration cues as well as academic challenges.

In *Alien Contact!* the students are presented with the following scenario: Aliens have landed on Earth and seem to be preparing for a number

Figure 1. Dell Axim & GPS receiver

Figure 2. Students exploring school grounds

Figure 3. Handheld display of digital objects on school grounds

of actions, including peaceful contact, invasion, plundering, or simply returning to their home planet, among other possibilities. Working in teams (four pupils per team), the students must explore the augmented reality world, interviewing virtual characters, collecting digital items, and solving mathematics and literacy puzzles to determine why the aliens have landed. Each team has four roles: chemist, cryptologist, computer hacker, and FBI agent. Depending upon his or her role, each student will see different pieces of evidence. In order to successfully navigate the augmented reality environment and solve various puzzles, the students must share information and collaborate with the other members of their team. As students collect this data, they will discover different possibilities for why the aliens may have landed. It is up to the students to form hypotheses based upon the data collected. At the end of the unit, the students orally present their findings as a team to the class and support their hypothesis with data collected in the field (Figure 4).

In order to keep the game space uncluttered, only the current and next interactions are shown on the map at any one time. This reduces confusion pertaining to the order of the game, and clarifies where the students should progress to next. This is done through a *triggering* mechanism built into the game development editor. Each

character or object with which the students interact activates the next character or object to appear in the progression and deactivates the previous character or object.

In its full form, *Alien Contact!* is a six-day, multidisciplinary curriculum that includes two days dedicated to playing the game, and four days interspersed to introduce concepts, allow for analysis and synthesis of data gathered during the game days, and enable students to develop and present their hypothesis for why the aliens have come to Earth. This curriculum is based on Massachusetts state standards and fosters multiple higher-order thinking skills. In designing this unit, HARP personnel targeted concepts in math and literacy typically difficult for middle school students to master. Using the spring 2005 8th grade MCAS test as a reference to determine high-need areas, project personnel focused primarily on aspects of ratio, proportion, and indirect measurement (Math Standard 6.M.3, 8.M.4, 8.N.3) in combination with how English vocabulary has been influenced by Latin and Greek languages (ELA Standard 4.18, 4.21, 4.24). However, other Math and ELA standards are embedded within the unit, such as reading graphs (Math 6.P.6, 8.D.2) and conducting team discussions and presentations (ELA 2.4, 3.8, 3.9, 3.11, 3.13).

This game also aligns with other standards. The Partnership for 21st Century Skills, a state-level, public-private partnership geared at making U.S. public education relevant in the 21st century, has recognized education's role in building social capital through education and how challenging this will be. The Partnership for 21st Century Skills believes key skills students need include: global awareness and civic literacy; communication and contextual learning; and leadership, ethics, and social responsibility (Hardy, 2007). The Organization for Economic Cooperation and Development (OECD) has included new measures in its Programme for International Student Assessment (PISA), a 42 country comparative study conducted every three years on the skills that 15-year-olds

Figure 4. Students presenting their hypothesis

are developing in school. In 2003, PISA added a problem-solving section to its international assessment designed to assess cross-disciplinary, problem-solving skills. In future iterations of the problem-solving skills section, PISA plans to include an assessment of collaborative problem solving skills (OECD, 2008).

In addition, the game content and structure are designed to allow for multiple entry points on which teachers may build in future iterations (Dunleavy et al., in press). The design allows teachers the flexibility to emphasize: (1) different academic standards; (2) different content areas (math, ELA, science, social studies/history); and (3) different current events (energy crisis, oil shortage, global nuclear threat, cultural differences).

This design rationale is three-fold: (1) build in multiple entry points for teachers; (2) build in mathematical and linguistic patterns that, when recognized, reveal the ubiquity and mystery of mathematics and language; and (3) build in multiple layers of complexity that will engage and challenge students regardless of ability and will provide teachers opportunities for differentiation. As students engage in the mathematics and literacy of the content, the curriculum attempts to capitalize on some of the inherent properties of these fields that are fascinating (e.g., mapping latitude and longitude, ancient languages, and cultures) regardless of the standards that are targeted.

AR in general and *Alien Contact!* specifically incorporates several elements from popular video games that increase learning and engagement: (1) narrative and setting; (2) differentiated role playing; (3) master goal divided into subtasks; (4) interactivity; (5) choice; and (6) collaboration. In *Alien Contact!* the narrative and setting is the unfolding saga of the aliens' interactions with Earth. To infuse this situation with challenge and invite curiosity, each student's differentiated role is presented with an alternate, incomplete view of the game space. For example, when presented with a piece of alien spacecraft debris, each team member is given a different dimension of the

wreckage to measure or a unique clue as to how to measure it. If the students do not collaborate, they will not be able to solve the problem and advance to the next stage of the game (Figure 5).

The master goal of the curriculum unit is to discover why the aliens have landed. However, in order to collect sufficient evidence to form a hypothesis, the students must successfully complete multiple subtasks requiring math and literacy skills. Throughout the scenario, the students interact with virtual characters, digital items, and each other to navigate the game space. Choice and collaboration are embedded within the entire unit. Finally, the entire scenario is open ended, with multiple possible explanations for why the aliens have landed.

FORMATIVE EVALUATION

During the fall of 2006 and the spring of 2007 early iterations of the *Alien Contact!* curriculum were implemented for the purposes of conducting formative evaluation of the format. As there was no existing design for developing in-practice AR curriculum, much of this formative evaluation was intended to develop the heuristics for developing appropriate and effective AR curricula. The methodology and results of this pilot formative evaluation are described in depth by Dunleavy et al. (in press); however, for clarity purposes,

Figure 5. Students collaborating to measure a physical object used in the AR gamespace

the methodology and findings of this study are described here.

Utilizing a multiple case studies design, a series of data collection techniques were implemented at three sites (selected through convenience sampling) in order to gather in-depth information on how students and teachers perceived the AR curriculum. These data sources (including observations, formal interviews, informal interviews, and Web site postings) provide rich, contextual data that allowed for triangulation of results.

These data were qualitatively analyzed within each site using a structured-coding scheme that followed an initial open-coding process. The initial open coding resulted in 30 descriptive codes, which were then analyzed iteratively using pattern matching analysis. The analysis from each case study was then used for cross-case analysis to determine if there were similarities across implementations in usage and perceptions.

RESULTS

Through the analysis of case study data from the initial formative evaluation, Dunleavy et al. (in press) documented high student engagement during the implementations of the *Alien Contact!* AR curriculum. According to Dunleavy et al. “high motivation and engagement seems logical and almost a given during an activity that has students go outside with handheld computers and search for clues about aliens, it was nonetheless a critical threshold that needed to be reached during this first year of the AR design development.”

Students and teachers reported several factors that played a role in motivating them throughout the curriculum implementation. Among the most common factors mentioned by both teachers and students were the use of the GPS-enabled handhelds themselves, the ability to collect data outside, and the interdependence of the roles within the team dynamic. In addition, teachers focused

on how the AR curriculum engaged previously disengaged students (Figure 6).

However, in addition to the increased motivation, Dunleavy et al. (in press) also found significant logistical limitations in implementing AR curricula. In particular, hardware and software issues, particularly due to GPS errors, interfered with the seamless integration of this technology. Another issue dealt with the substantial management and technical support required to maintain the instructional process and the technology—a problem deemed to be *prohibitive* in any effort at scalability. Also of concern were findings of substantial cognitive overload on the part of students involved with the AR curriculum. Students and teachers indicated that learning the technology while also trying to work relatively complex content problems caused confusion and led to some students giving up before completing tasks.

Another result from the research was the discovery of unanticipated competition between teams. Due to the linear nature of the learning path (that is, all students moved from one character to another in an identical and predictable progression), student teams were able to visually see where other teams were within the progression. Therefore, each team had the sense that they were either *ahead* or *behind* other teams in the game space. This led to student teams hurrying through the activities in order either keep pace or pass other students, whom they viewed as their

Figure 6. Students engaged in the AR game

competition. As would be expected, this resulted in students missing valuable information within the game space.

An additional unanticipated finding was a desire on the part of the students to know the *right* answer. As would be expected with students at the middle-school level, especially with those accustomed to commercially available games designed to provide closure, participants expressed a strong desire to know why the aliens were actually here at the end of the game (this was usually articulated through the focus group interactions). In most cases, the ambiguity of the game's multi-hypothesis nature was difficult for these students to accept.

It is important to note that current implementations of the *Alien Contact!* curriculum are validating the findings from the formative evaluation—particularly where the issues of technical and logistical support are concerned. Students appear to be motivated by the AR curriculum; however, competition between student groups is present in nearly every implementation, and the issue of having the right answer continues to persist.

FURTHER EVALUATION

Building upon the formative evaluation conducted by Dunleavy et al. (in press), further research is being conducted to study the impact that *Alien Contact!* has on academic achievement and affect. Through a pre-test/post-test, control-group design, it will be possible to draw preliminary conclusions about how effective this version of an AR curriculum can be in an educational setting.

Data for this analysis is being collected during the spring of 2008. The control curriculum is identical to the *Alien Contact!* AR curriculum in terms of content, however, it is played inside using a board game rather than outside using the handheld computers (Figure 7).

MODIFICATIONS BASED ON FORMATIVE EVALUATION

HARP personnel responded to the results from the formative evaluations to better design a subsequent AR curriculum called *Gray Anatomy*. This section will describe the initial version of this new curriculum and the changes that were made to our AR design template based on the findings of the formative evaluations discussed previously.

Gray Anatomy

Gray Anatomy, just as is the case with *Alien Contact!*, is a scenario-based AR curriculum. As the game begins, students are presented with a scenario in which a gray whale has beached itself. Working in teams, the students must interview virtual characters, inspect virtual objects, and work through mathematics and language arts problems to determine what occurred and why the whale beached.

Similarly to *Alien Contact!*, this curriculum also focuses on middle-school, Massachusetts state math and language arts standards. In this case, the math standards revolve around data analysis, statistics, and probability (MCAS standards 6.D.1 and 8.D.3) and the ELA standards include thematic

Figure 7. Students playing the boardgame control curriculum

identification and support (MCAS standards 11.3 and 11.4), understanding a text (MCAS standard 8.19), and support hypotheses with evidence from text (MCAS standard 8.24). Additional standards that are touched upon are numbers and number sense (MCAS math standards 8.N.10 and 8.N.11), vocabulary and concept development (MCAS ELA standard 4.17), formal and informal English (MCAS ELA standard 6.6), questioning, listening, and contributing (MCAS ELA standard 2.4), and oral presentation (MCAS ELA standards 3.9, 3.11, and 3.12).

As with *Alien Contact!*, this curriculum incorporates the previously mentioned video game characteristics that increase learning and engagement. However, several substantial changes have been made to the game play in response to the results from evaluating *Alien Contact!*'s design.

Cognitive Overload

The most difficult of the concerns identified by evaluations of *Alien Contact!* was the issue of cognitive overload. Due to the fact that the overload was caused by difficulties synthesizing several tasks, each of which was relatively complex in and of itself and was dependent on the individual student, it was difficult to develop solutions to address the problem. For this reason, several steps were taken to mitigate complexity of the tasks required in the *Gray Anatomy* curriculum.

The first step taken was to limit the number of characters or objects that any student would interact with during a given time period. Initially, the *Alien Contact!* curriculum incorporated far too many characters and objects. Through the formative evaluation conducted by Dunleavy et al. (in press) as well as lessons learned through subsequent implementations of the AR curriculum, we determined that between five and six items or characters per AR session is optimal for progressing through the game in a timely, efficient, and effective manner. For this reason, each of the two

game days involved with *Gray Anatomy* include a maximum of six interactions.

In addition in attempting to limit the scope of the interactions that any individual student might have, we also made efforts to limit the opportunities to misunderstand directions for given tasks. The *Alien Contact!* curriculum depends to a great extent on providing written textual directions to students. In many of these cases, the content required at least one scroll to complete the reading of the directions. Following several of the principles of game design for effective learning laid out by Gee (2003), it was decided to focus on using multimedia for the delivery of directions and content through the game. According to the work of Gee, by leveraging the technological capabilities of the handheld computers themselves, the AR games pace can effectively provide multimodal meaning (i.e., use materials other than text to provide meaning). In addition, by providing materials in other formats than simply through text, the curriculum can address semiotic principles (i.e., identifying and appreciating the interrelations between multimedia elements in a complex system) (De Oliveira & Baranauskas, 2000).

More tangentially, in response to a perceived need for greater clarity throughout the game, a new design paradigm was implemented for *Gray Anatomy*. As HARP staff did not have any previous experience designing AR curricula, this first effort was done without a roadmap. In essence, project staff designed the process for developing an AR curriculum through the process of developing the AR curriculum itself. Based on lessons learned from this *bootstrapping* design strategy, a more structured development process utilizing a storyboarding approach was implemented for the development of *Gray Anatomy*. This process involved multiple meetings among HARP staff during which the broad strokes of the story involved with the curriculum were outlined. In these meetings, we decided that there would be various possible theories to why the whale would

have beached, one of which would be a *correct* response. Documents were developed to guide the formulation of these different theories, and each member of the HARP team designed one set of evidence that can confirm or deny individual theories using these guides to assure consistency across the different answers.

Competition

The other major unanticipated issue seen throughout our evaluations of *Alien Contact!* was the competitive interactions among the student teams when playing the game. As was discussed earlier, this was generally due to the fact that all students followed the same path of characters and objects, and thus each team could see which other teams were ahead or behind them in that progression. On its face, competition is not necessarily a negative thing to build into a game; however, in this instance, it did have negative repercussions. Because of the competition, students who wished to *win* would rush through the individual interactions that make up the game and would miss important information that they needed to progress through subsequent characters or to identify possible support data for individual hypotheses.

In order to undercut this competition across teams, the HARP staff developed a nonlinear path through the game. Instead of each character/object triggering the next character to appear along a proscribed path, an entry-point character will trigger all of the other characters in the game. This entry-point character will direct the students on the scope and sequence of the game playing experience and will inform them that each team must visit all of the other characters within the game space during the course of the AR event. The path through which the students progress can be determined by them, thus making it less likely that student teams will see other teams as ahead or behind them.

Modifications Based on Other Considerations

In addition to the modifications that were made based on our evaluation findings, there were also several modifications that came about due to informal analysis of the *Alien Contact!* curriculum and implementations that took place after the formative evaluation was conducted.

Flexible Roles

The first change occurred due to difficulties that were caused by the hard coding of four roles within the *Alien Contact!* curriculum. As was mentioned previously, students were placed into teams of four, with each of the students within a team taking on one of four roles (chemist, cryptologist, computer hacker, and FBI agent). However, the relative inflexibility of this system caused difficulty when there were a number of students that was not divisible by four. What would be done with any *excess* students? In implementations of *Alien Contact!* these additional students would be allocated to teams and would duplicate one of the four roles (thus a team might have two chemists). Obviously, this is not optimal due to the fact that the content was developed to assure that each of the students within a team would receive unique information that would need to be shared with other members of the team in order for the team to be successful. Having two students playing one role, although expedient, created a situation where the additional student was not necessary to the team's success.

In order to combat this situation, *Gray Anatomy* was designed with a flexible role structure. The AR editing software and the needs of the curriculum design still dictated the hard coding of roles within the game space. However, HARP personnel decided that two different versions of the game would be created. The first version would have three students in each team. Each of these three

students would take on one of the following roles: marine biologist, oceanographer, and reporter. The second version of the game would entail two students pairing together to play the game. These two students would play the game as the marine biologist and oceanographer.

In keeping with the design paradigm used within *Alien Contact!*, the reporter would receive unique information within the three-person version of the game. The fact that this information would be necessary to progress through the game effectively created the problem of how to allocate the reporter's information to the participants within the two-person version of the game. The solution for this was to have the reporter incorporated as a character the paired students would interact with within the game space itself. Thus, each of the two students would still be receiving all of the information that any student working within the three-person version would see, while allowing the flexibility to accommodate any number of students without the need of duplication of roles.

Correct Answer

Another issue that was present within most of the implementations of the *Alien Contact!* AR game was a desire on the part of the students to know the correct answer to the question of why the aliens had come to earth. Manifesting itself within the focus team interviews that followed the full implementation of the curriculum, students asking for the *right* answer lead to discussions of the need to use data to support hypotheses in ambiguous situations. Although this is a valuable lessons for students to learn, and one that *Alien Contact!* attempts to convey, one of the strengths of many commercially available games is that they build to a climax and then offer closure (whether this is on a small scale based on individual tasks within a game or on a larger scale as the structure of the entire game). For this purpose, HARP personnel decided that *Gray Anatomy* would include such a correct answer.

This, however, presented its own unique challenge, as there is no explanation widely accepted in the scientific community as to why whales beach themselves. In a game based on having students answer this question, it is not appropriate to offer a solution as correct if the wider scientific community cannot support such an assertion. Such an act would provide students a false sense of the real world and would be impossible to support ethically.

The solution that the HARP staff decided on was to have a series of "crackpot theories" that were viable sounding, but which each had a "fatal flaw" that made them impossible to have actually caused the beaching. Thus, whichever theory was not fatally flawed could be seen as the correct answer to the simulation. HARP staff developed three theories, two of which are fatally flawed. These theories, along with the corresponding characters used to support or debunk them, make up the suite of interactions that each team of students has over the course of two days of outdoor AR interactions.

Redesigned Control

In order to do rigorous research into the efficacy of both AR curricula as an instructional strategy, we use a pre-test/post-test control group research design. As such, a board game version of the AR game is developed to act as the control curriculum to determine what value, if any, the technology adds. All content was the same as would be found in the AR curriculum, and the team dynamics remained the same. This board game consists of an 8x8 checkerboard, around which student teams move game pieces. Each of the 64 squares on the checkerboard corresponds to an envelope on a tri-fold poster demonstration board. According to where they were in the game, the team is directed to open a particular envelope, which holds cards that deliver the role-based content for that interaction. In addition, the teams are directed to

move their game pieces to the corresponding next square on the checkerboard.

Using the version of the board game initially developed for *Alien Contact!*, HARP staff determined that the design of the board game made it unnecessary to interact with the actual checkerboard for all but the most ancillary activities. In order to make the interface more interactive and engaging, the board game portion of this control curriculum was redesigned. The new version of the board game includes a foam board image of a neighborhood with puzzle-piece shaped, yellow spaces interspersed throughout the image. As students move through the game, they receive puzzle pieces that show them with whom or what they were interacting with next and in which envelope that character's or object's information would be found. This redesign dramatically improved the *feel* of the board game and has created a situation where the students need to interact with the board, making the control curriculum more similar in its format to the AR curriculum.

Shorter Curriculum

Another modification made to the curriculum template for *Gray Anatomy* was to switch from a six-day to a five-day schedule. The *Alien Contact!* curriculum follows a staggered indoor/outdoor pacing. As was discussed earlier, four of the six days within the *Alien Contact!* curriculum are dedicated to work in a traditional classroom setting. Each day immediately following the two game days are dedicated to analyzing and synthesizing the data that were gathered during the gameplay. This had the consequence of creating an awkward schedule that required more than one academic week for completion.

This awkwardness of the schedule led to a switch to a five-day curriculum plan for *Gray Anatomy*. Rather than having an analysis and synthesis day following each of the two game days, there is only one analysis day following

two straight game days. It is postulated that this change will have dual benefits. The first benefit is to create a schedule that works within a single academic week. The second benefit is to create a more focused analysis opportunity.

Curriculum Focus

Another issue that has been addressed for *Gray Anatomy* was the focus on integrating the different content areas more meaningfully. *Alien Contact!* can be implemented as a math curriculum, an ELA curriculum, or a combination of math and ELA. The decision to split the combined curriculum and only implement that math or ELA content areas was made in order to facilitate the ability to recruit individual teachers for the project. If a math teacher wished to implement *Alien Contact!*, however, there was no corresponding ELA teacher to conduct those sections of the curriculum, so it would be more difficult to recruit teachers. The focus for Gray will be on an integrated math and ELA curriculum rather than on separate math and ELA. This is in line with skills that students need in their future work, which is interdisciplinary. It also significantly reduces logistical problems or need for so much technical support of setting up two different games.

Teacher Involvement

Finally, there is discussion about how to get the teachers themselves more involved in the delivery of the curriculum rather than having it be something that the research team comes in and does. It was never intended that the research team would teach the content itself, as the future of AR lies in its ability to be a seamless part of the learning environment run by the in-service teachers. With implementations of *Alien Contact!* it has been necessary for the research team to play a relatively large role in managing the content. In order to mitigate this for *Gray Anatomy*

implementations, the game will be played fully with teachers before the students play so they themselves are engaged in situated learning and learn the process involved. This has the indirect benefit of getting buy-in from the teachers both for the technology and for the process of situated learning. Second, the HARP team is considering ways (both technological and non-technological) to have teachers gather feedback from students after the first outdoor day so they can more closely track individual student's progress and give them formative feedback to improve their experience for the second outdoor day.

CONCLUSION

The development and deployment of AR technologies is still in its early stages. Since these types of curricula incorporate nascent technology, taking the long view about their potential for student learning is appropriate. As Dede (2005) asks when discussing the learning styles associated with "Millennial" students, "What new forms of neomillennial learning styles might emerging media enable?" (p. 8). We know that students will increasingly bring learning strengths and preferences to the classroom derived from the ever more sophisticated and pervasive use of cell phones. This trend implies that instructional designs merging physical and virtual environments hold great promise for building on learners' emerging skills and inclinations. Our early research is promising in demonstrating AR can enhance student motivation, involvement, and excitement; and our current studies are examining the extent to which learning outcomes are enhanced over comparable control curricula.

As a field, instructional designers are at the beginning of identifying best practices for developing effective AR curricula. Systematically building on findings from early studies such as our work will not only improve later AR cur-

ricula, but also may lead to improvements in the technology itself, particularly as AR moves to its eventual target device, the cell phone. By migrating this emerging interactive medium from custom, school-supported PDA/GPS technologies to standardized, commercial-provider-supported, cell phone technologies, educators can realize the advantages of using ubiquitous, powerful devices students could bring from their homes to classroom settings.

AR can reach its full potential only when this leveraging of student-owned technologies is realized. Any instructional design that depends on school-based personnel maintaining and managing complex, custom sets of equipment has inherent weaknesses. Maintenance and management is time consuming, and the equipment is prone to obsolescence; the total cost of ownership by the school system is substantial when this includes initial purchase, maintenance, technical personnel, and replacement costs. Beyond those issues, if educators are responsible for equipment evolution, this will dramatically slow the advance of AR technologies. Compared to large telecommunications companies rapidly enhancing their equipment to gain market share in the lucrative cell phone market, educators have neither the technical capacity nor the competitive incentives to rapidly improve AR devices.

We estimate that, within a year or two, the next generation of cell phones can deliver the types of AR developed in our studies. Such a migration in AR infrastructure will require a substantial shift in how teachers and administrators treat cell phone usage in school settings. At present, many educators see cell phones as a barrier to effective instruction because of their potential to distract students' attention and to facilitate cheating. Once schools go beyond banning cell phones, or reluctantly accepting smart phone technology as a necessary evil, to instead developing ways to incorporate these powerful devices for the improvement of student learning, then educators

will have a commercially supported learning infrastructure with which students are already familiar and fluent, paid for and maintained external to education, and available for learning inside of classrooms and out. AR is a fulcrum for leveraging this evolution.

Section III

Tools and Technologies

This section presents an extensive treatment of various tools and technologies existing in the field of instructional design that practitioners and academics alike must rely on to develop new techniques. These chapters enlighten readers about fundamental research on the many methods used to facilitate and enhance the integration of this worldwide phenomenon by exploring software and hardware developments and their applications—an increasingly pertinent research arena. It is through these rigorously researched chapters that the reader is provided with countless examples of the up-and-coming tools and technologies emerging from the field of instructional design.

Chapter 3.1

Cognitive Architecture and Instructional Design in a Multimedia Context

ABSTRACT

Our knowledge of human cognitive architecture has advanced dramatically in the last few decades. In turn, that knowledge has implications for instructional design in multimedia contexts. In this chapter, we will analyse human cognitive architecture within an evolutionary framework. That framework can be used as a base for cognitive load theory that uses human cognitive architecture to provide testable hypotheses concerning instructional design issues. Human cognition can be

characterised as a natural information processing system. The core of such systems can be described using 5 principles: (a) information store principle, (b) borrowing principle and reorganizing principle, (c) randomness as genesis principle, (d) narrow limits of change principle, and (e) environment organizing and linking principle. These 5 principles lead directly to the instructional effects generated by cognitive load theory. Some of these effects are concerned with multimedia learning. The particular ones discussed in the chapter are the split-attention, modality, redundancy, element interactivity, and expertise reversal effects.

DOI: 10.4018/978-1-60960-503-2.ch301

INTRODUCTION

Instructional design recommendations not based on our knowledge of human cognitive architecture are likely to be limited in their effectiveness or may even have negative consequences. In this chapter, we will use an evolutionary approach to human cognition (see Sweller 2003; Sweller 2004; Sweller and Sweller 2006). Evolution by natural selection can be used to determine categories of knowledge that humans are particularly adept at gaining because we have evolved to acquire that knowledge. Furthermore, the basic logic that underlies evolutionary biology is shared by human cognition and so can be used to analyse our cognitive processes. Those cognitive processes, in turn, determine the effectiveness of particular instructional procedures. We will begin by discussing two categories of knowledge from an evolutionary perspective.

BIOLOGICALLY PRIMARY AND BIOLOGICALLY SECONDARY KNOWLEDGE

Geary (2007) divides knowledge into biologically primary knowledge that we have evolved to acquire easily and automatically and biologically secondary knowledge that relies on primary knowledge but that we have not evolved to acquire. Examples of activities driven by primary knowledge are listening and speaking our first language, recognising faces, using general problem solving techniques and engaging in basic social relations. We have evolved over millennia to acquire massive amounts of knowledge associated with these activities easily, quickly and without conscious effort. We can acquire biologically primary knowledge simply by being immersed in a normal human society. Explicit instruction is unnecessary.

In contrast, biologically secondary knowledge tends to be associated with a more advanced stage

of development of civilization. It has only been required since the rise of civilisation and so we have not evolved to acquire specific examples of biologically secondary knowledge. We can acquire such knowledge using biologically primary knowledge but it is acquired relatively slowly and with conscious effort. In contrast to biologically primary knowledge, biologically secondary knowledge requires explicit instruction and conscious effort on the part of learners. The bulk of knowledge acquired in educational institutions such as schools consists of biologically secondary knowledge.

HUMAN COGNITIVE ARCHITECTURE WHEN DEALING WITH BIOLOGICALLY SECONDARY KNOWLEDGE

There is a basic logic associated with the acquisition of biologically secondary knowledge and that logic is identical to the logic that underlies the processes of evolution by natural selection. Both are examples of natural information processing systems (Sweller & Sweller, 2006). There are many ways of describing that logic. In this chapter we will use five basic principles.

Information Store Principle

In order to function, natural information processing systems require a massive store of information used to govern activity. In the case of human cognition, long-term memory provides that store. The well-known work of De Groot (1965) and Chase and Simon (1973) on the knowledge chess masters have for board configurations taken from real games provides evidence for the importance of long-term memory for most facets of cognition, including problem solving. A genome provides the same function for evolution by natural selection.

Borrowing and Reorganising Principle

Acquiring a massive store of information requires an efficient acquisition procedure. In the case of the human cognitive system, that procedure involves borrowing and reorganising information from the long-term store of other individuals by imitating what they do, listening to what they say and reading what they write. The information obtained is combined with previous information resulting in reorganisation. Findings based on cognitive load theory provide evidence for the importance of the borrowing and reorganising principle (e.g. Sweller, 2003, 2004). How cognitive load theory suggests instruction should be organised to facilitate the borrowing of information is discussed below. During sexual reproduction, evolution by natural selection uses the borrowing and reorganising principle to allow a genome to acquire large amounts of information that is necessarily reorganised during the process.

Randomness as Genesis Principle

While information is best acquired by using the borrowing and reorganising principle, that information must be created in the first instance. In genetics, random mutation is the ultimate source of all biological variation and so is the genesis of all biological novelty. In human cognition, information is created via the randomness as genesis principle during problem solving. In order to generate a problem solving move, we must use a combination of information held in long-term memory and a random generate and test for effectiveness procedure. If at any point while solving a problem, two or more moves are available to us, and if we do not have information in long-term memory indicating which move might be best, we must randomly generate one of the moves and test to see what effect it has. To the extent to which information is not available in long-term memory, no other procedure has been

identified to generate moves other than random generate and test. That process is the ultimate source of all novel information we create just as random mutation is the ultimate source of all biological variation.

Narrow Limits of Change Principle

Since the creation of novel information requires a random generate and test procedure, mechanisms are required to ensure that randomly generated information, most of which is dysfunctional, does not destroy the functionality of the information store. Our cognitive system achieves this end by ensuring that all changes to the store are small and incremental by requiring information to first be processed by a limited capacity, limited duration working memory. Evidence for the limited capacity of working memory comes from the well-known work of Miller (1956) while evidence for its limited duration comes from Peterson and Peterson (1959). It must be emphasised that the limitations of working memory only apply to novel information to which the randomness as genesis principle applies. Changes to a genome require random mutation, are governed by the epigenetic system and also are slow and incremental.

Environmental Organising and Linking Principle

The limitations of working memory disappear when it processes organised information from long-term memory. When dealing with familiar information, working memory has neither capacity nor duration limits. Evidence for the altered characteristics of working memory when dealing with well-learned information comes from Ericsson and Kintsch's (1995) work on long-term working memory. We can hold huge amounts of familiar information in working memory for indefinite periods. That material can be used to organise information from our environment and link our activities appropriately to the environ-

ment. It provides the ultimate justification for our cognitive system. Similarly, the epigenetic system determines how information stored in DNA is used to govern biological activity.

INSTRUCTIONAL CONSEQUENCES

There are instructional consequences that follow from the manner in which our cognitive structures are organised to process information. The first and most obvious implication is that the purpose of instruction is to alter the information store – long-term memory. If nothing has changed in long-term memory, nothing has been learned. The second implication is that the best way to alter long-term memory is via the borrowing and reorganising principle. Wherever possible, we should present information to students rather than have them search for the information themselves. The third implication is that when presenting information to learners, we should organise that information in a manner that takes into account the characteristics of human cognitive architecture. For instruction to be effective, the narrow limits of change principle is paramount. Instruction has to be designed in such a way that the limitations of working memory are overcome by, for instance, minimising extraneous cognitive load. By minimising unnecessary working memory load, essential information can be stored in long-term memory and in turn, that information will increase the effective capacity of working memory via the environmental organising and linking principle. That principle permits humans to readily engage in very complex activities.

Cognitive load theory has used this architecture to devise a variety of instructional procedures. Some of those procedures are directly concerned with the presentation of information within a multimedia framework. In this chapter, we focus on three cognitive load effects concerned with aspects of multimedia presentation of information: the

split-attention effect, the redundancy effect and the modality effect.

The Split-Attention Effect

Split-attention occurs when learners have to mentally integrate two or more sources of physically or temporally disparate information and each source of information is essential for understanding the material. The working memory load imposed by the need to mentally integrate the disparate sources of information interferes with learning. Consider a conventionally structured geometry worked example consisting of a diagram and its associated solution statements (see Figure 1). The diagram alone does not communicate the solution to the problem. The statements, in turn, are incomprehensible until they have been integrated with the diagram. Learners must mentally integrate the two sources of information (the diagram and the statements) in order to understand them. This process can be cognitively demanding, especially for a novice learner, thus imposing a cognitive load that is extraneous simply because of the particular format used.

Research into split-attention was initially conducted by Tarmizi and Sweller (1988) who looked into the effectiveness of worked examples on learning geometry. Previous research had demonstrated that worked examples were highly effective for learning algebra (Cooper & Sweller, 1987; Sweller & Cooper, 1985) and in other mathematical-related domains (Zhu & Simon, 1987). However, Tarmizi and Sweller found that in comparison to conventional problem-solving strategies, worked examples did not enhance performance in geometry. They argued that the requirement due to the format of the worked examples to mentally integrate the two sources of information (diagram and textual solutions) must have imposed an increase in cognitive load that prevented cognitive resources to be used for learning. In subsequent experiments, Tarmizi and

Figure 1. Conventionally structured geometry worked example consisting of a diagram and its associated solution statements

Sweller demonstrated that learners who studied integrated worked examples (see Figure 2) performed better than learners who followed a conventional problem solving strategy during acquisition.

Subsequent research sought to test the hypothesis that if multiple sources of information were integrated, the need for learners to engage in mental integration would be obviated thus freeing cognitive resources for learning. The Tarmizi and Sweller findings were replicated by Sweller, Chandler, Tierney, and Cooper (1990) in the domain of coordinate geometry, by Ward and Sweller (1990) in the domain of physics, by Chandler and Sweller (1991) using instructional materials designed for electrical apprentices, and by Sweller and Chandler (1994) and Chandler and Sweller (1996) investigating learning in a computer environment. This line of research has been extended to language learning. In a series of experiments designed to test the split attention effect, Yeung, Jin and Sweller (1998) found that explanatory notes integrated with reading pas-

sages, by reducing cognitive load related to search for meaning, improved reading comprehension for both fifth grade first language pupils and inexperienced learners of English as a second language (ESL). Together, these findings in different domains generate the expectation that training conditions comparing split-attention and integrated formats will yield results demonstrating the superiority of the integrated format. This phenomenon is known as the split-attention effect.

Various forms of different sources of information can lead to split-attention: text and text, text and mathematical equations, or different forms of multimedia. Any instructional material that contains more than one source of information is potentially a context for integrating split-source information. Split-attention will frequently occur in a multimedia context as there will always be at least two sources of information involved.

The split-attention studies mentioned so far deal with sources that are physically separate and have engaged learners in the visual medium only. Whether the cause of split-attention is text and a diagram, or computer and a manual, the different sources of information are physically separate in a manner that requires visual and cognitive search that imposes an extraneous load. However, physical separation is not the only form of separation that generates unnecessary cognitive

Figure 2. Integrated worked example

load. Multiple sources of information that must be integrated before they can be understood can also be separated in time, resulting in temporal separation. The consequences of temporal rather than spatial versions of the split-attention effect have been largely carried out by Mayer and his colleagues who have extended the effect to include sound (Mayer & Anderson, 1991, 1992; Mayer & Sims, 1994; Moreno & Mayer, 1999). This body of work demonstrates that learners who received information simultaneously, that is integrated narration and animation outperformed learners who received non-integrated instructions (narration and animation separated temporally).

In summary, the split-attention effect has been demonstrated in many studies using a wide variety of materials and participants under many conditions (see Ayres & Sweller, 2005 for a detailed review). The presence of this effect has implications for instructional design in a multimedia context where there will always be at least two sources of information.

Split-attention effect and instructional design. The split-attention effect has both theoretical and practical implications. From a theoretical perspective, the results provide evidence that minimising extraneous cognitive load benefits learning. From a practical perspective, the results provide some instructional guidelines for dealing with multiple sources of information. One guideline is that where instruction includes multiple sources of information that must be integrated in order to make sense, those sources of information should be both physically and temporally integrated in order to reduce extraneous cognitive load. This guideline should have the potential to improve multimedia instruction substantially. However, considerable care must be taken when physically integrating disparate sources of information as there are conditions under which simply integrating all text onto a diagram will have negative rather than positive effects on learning (see Ayres & Sweller, 2005).

One condition under which integrated instructions do not have positive effects on learning is when the multiple sources of information are intelligible in isolation. For example, physically integrating a diagram with statements that merely redescribe the diagram has negative, not positive effects on learning due to the redundancy effect (see next section). If all sources of information are intelligible in isolation and redundant, elimination of redundancy rather than physical integration should be undertaken. Thus, analysing the relation between multiple sources of information prior to physical integration is important.

Another condition under which integrated instructions are not beneficial is when the learning materials do not involve high element interactivity (e.g. Sweller 1994) where element interactivity refers to the number of elements that must be simultaneously processed in working memory because they interact. Low element interactivity material consists of elements that can be processed individually because they do not interact. Since the elements can be processed individually, they impose a low load on working memory and such material is described as having a low intrinsic cognitive load. In contrast, the elements of high element interactivity material, because they interact, must be processed simultaneously in working memory if the material is to be understood. Such material has a high intrinsic cognitive load. A diagram and related text that have few interacting elements and therefore are easily understood are unlikely to impose an extraneous cognitive load due to split-attention. There is no real benefit in physically integrating the different sources of information as they can be easily learned even when presented in a split-source format.

A further factor to consider when integrating different sources of information is learner characteristics that interact with material characteristics. Material that is not intelligible in isolation and high in element interactivity for low knowledge learners may be intelligible in isolation and low

in element interactivity for learners with more knowledge. For high knowledge individuals, physical integration may be harmful because of the redundancy effect (Yeung, Jin & Sweller, 1998).

The Redundancy Effect

The redundancy effect occurs when additional information presented to learners results in negative rather than positive effects on learning. It can be obtained in one of two ways. First, when identical information is presented in two or more different forms or media, such as pictures and words, or words in both auditory and written form, if one of these forms is redundant then the elimination of that form may result in enhanced learning resulting in the redundancy effect. Second, when additional information is presented in an attempt to enhance or elaborate information, if the additional explanations or elaborations are redundant then the exclusion of that additional information may enhance learning providing another example of the effect. There is overlap between these two forms in that the same information presented in a different medium may be essentially an elaboration. Nevertheless, the distinction is real in that some elaborations use the same medium while others use different media. In both instances, the effect is the same: redundant information can interfere with learning.

The redundancy effect was probably first demonstrated by Miller (1937) and subsequently by various researchers (e.g., Reder & Anderson, 1980, 1982; Solman, Singh & Kehoe, 1992). However, these researchers did not explain the effect in terms of cognitive load theory. Cognitive load theory suggests that processing redundant information with essential information increases working memory load, which interferes with the transfer of information to long term memory. Removing redundant information eliminates the requirement to process information that is not essential to learning. Consider instruction on the flow of blood in the heart, lungs, and body. Frequently,

it will consist of a diagram of the heart, lungs, and body with arrows indicating the direction of the blood flowing the veins and arteries. In addition, text consisting of statements such as, "The blood entering the aorta is pumped back into the body", or "Blood from the lungs flows into the left atrium." In contrast to the geometry example given earlier, the diagram is self-contained and intelligible. It shows by means of arrows and labelling, that blood entering the aorta is pumped back into the body and that blood from the lungs flows into the left atrium. The text in this case is redundant since it merely repeats the same information albeit in a different form. In addition, when such redundant text is integrated with the diagram by being placed at appropriate locations on the diagram, the text is not only redundant, it is also unavoidable. Learners looking at the diagram are very likely to read the text as well. In contrast, if the text is below or next to the diagram rather than integrated with the diagram, it is much easier to ignore. Using the biology material mentioned earlier, Chandler and Sweller (1991) compared the performance of learners under the conditions of integrated instruction, split-attention instruction, and diagram without text instruction. The best condition was the diagram without text instruction indicating that redundant instructional material should be eliminated.

In contrast to inexperienced language learners, senior undergraduate students and high-ability ESL learners, when reading passages integrated with vocabulary explanations, found that the information about the meanings of many words was redundant but hard to ignore (Yeung, Jin & Sweller, 1998). Consequently, for those experienced learners, explanatory notes with an integrated format led to lower scores of reading comprehension in comparison with the conventional text plus a separate vocabulary list. It appears that, although explanatory notes using an integrated format within passages may be helpful for those learners with less expertise to reduce the split attention effect, this format may not be suitable for readers with high

language proficiency because of the redundancy effect. Diao and Sweller (2007) further examined the redundancy effect in the context of educational multimedia designed for learners of English as a foreign language (EFL). In their study, Chinese EFL learners using simultaneous presentations of spoken and written text reported having a higher mental load and produced lower scores in both word decoding and reading comprehension than did those using materials presented in written form only. The findings support an earlier study of Japanese EFL learners (Hirai, 1999), which claimed that the listening rate was far behind the reading rate for less proficient learners. When the aim is to teach novice EFL learner to read, such poor audio-visual correspondence may cause a redundancy effect in the presentations comprising both identical auditory and written text.

Since the Chandler and Sweller (1991) findings, the redundancy effect has been demonstrated in a variety of contexts. It is not just the diagrams and redundant text that can be used to demonstrate the redundancy effect. While diagrams are frequently more intelligible than the equivalent text, there are instances where any one of diagrams, the presence of equipment, or auditory information have been found to be redundant (see Sweller 2005 for experimental evidence). In other words, what is redundant depends on what is being taught.

Redundancy effect and instructional design. As is the case with the split-attention effect, the redundancy effect has been demonstrated in many studies using a wide variety of materials and participants under many conditions. In practical terms, the redundancy effect provides a simple guideline for instructional design: eliminate any redundant material in whatever form presented to learners and any redundant activity that instruction may encourage learners to engage in. However, this guideline alone does not indicate exactly what material may or may not be redundant. This guiding principle needs to be considered in conjunction with cognitive load theory. The theory can be used to provide guidance concerning the conditions that

determine redundancy and hence what material is likely to be redundant. For instance, in deciding whether text should be added to a diagram, the instructional designer needs to consider several factors. Is the diagram intelligible on its own? If so, the text may be redundant. Does the text provide essential information? If so, it is not likely to be redundant and should be retained. Is there a high level of element interactivity within the text, that is, to understand one element, one must consider many other elements at the same time? If so, as far as possible, diagrams should not be presented with the text to avoid the risk of overloading working memory. Another factor to consider is learner expertise. Whether information is high in element interactivity and whether it is intelligible on its own depends largely on the learner. Information that is intelligible for more expert learners may not make sense to novices who require additional explanatory material. In short, whether or not additional material is redundant can be determined by considering the cognitive load implications of that material in the context of learner expertise.

The Modality Effect

Studies documenting the split-attention and redundancy effects have provided evidence to indicate that the manner in which information is presented will affect how well it is learnt and remembered. Another effect that has important implications for instructional design, especially in multi-media learning is the modality effect. The modality effect occurs when information presented in a mixed mode (partly visual and partly auditory) is more effective than when the same information is presented in a single mode (either visually or in auditory form alone). For example, consider a typical geometry problem consisting of a diagram and associated statements (Figure 1). Conventionally, the diagram and the associated statements are visually presented. However, although the diagram has to be presented visually,

the associated statements can be presented visually or orally. There is evidence to show that students learn better when the associated statements are narrated rather than presented visually.

According to cognitive load theory, many instructional materials and techniques may be ineffective because they ignore the limitations of human working memory and impose a heavy cognitive load. This type of load is referred to as extraneous cognitive load and has been the main concern of cognitive theorists whose focus has been on devising alternatives to those conventional instructional designs and procedures that were developed without taking into consideration the structure of human memory.

Theoretically, there are two ways in which extraneous cognitive load can be manipulated. First, instructional procedures can alleviate extraneous cognitive load by formatting instructional material in such a way that minimises cognitive activities that are unnecessary to learning so that cognitive resources can be freed to concentrate on activities essential to learning. The split attention and redundancy effects discussed above fall into this category.

The consequences of extraneous cognitive load can also be alleviated by increasing effective working memory capacity. Working memory was initially considered a single entity. More recent research has indicated that working memory may consist of multiple processors rather than a single processor (Baddeley, 1992; Schneider & Detweiler, 1987). These multiple stores, processors, channels, or streams (the terminology varies among researchers) are frequently associated with the separate processing of visual-spatial and oral material. For example, Baddeley's model of working memory (Baddeley, 1986, 1992, 1999) divides working memory into a visuo-spatial sketch pad that processes visually based information such as diagrams and pictures, and a phonological loop that processes auditory information.

There is considerable evidence to suggest that the visuo-spatial sketch pad and the phonological

loop process different types of information independently, at least to some extent. If the two systems are relatively independent, the total amount of information that can be processed by working memory may be determined by the mode (auditory or visual) of presentation. It may be possible to increase effective working memory capacity by presenting information in a mixed visual and auditory mode rather than a single mode.

Low & Sweller (2005) provided a discussion of research evidence to support the notion that working memory can be subdivided into partially independent processors consisting of an auditory working memory system to deal with verbal material and a visual working memory system to deal with diagrammatical/pictorial information. Since the two processors deal with appropriate information independently to some extent, it is plausible that a mixed mode of presentation can increase the amount of information that can be processed in working memory. In a detailed review of the experimental literature, Penney (1989) provided two different lines of evidence demonstrating an appreciable increase in effective working memory capacity by employing both visual and auditory, rather than a single processor. One line of evidence shows improved ability to perform two concurrent tasks when information was presented in a partly audio, partly visual format, rather than in either single format. The other line of evidence demonstrates improved memory when information was presented to two sensory modalities rather than one. As previously indicated, the occurrence of increased working memory capacity due to the employment of a dual, rather than a single mode of presentation, is termed the modality effect. (See Low & Sweller, 2005 for a discussion of research demonstrating the modality effect).

If effective working memory can be increased by using dual-modality presentation techniques, theoretically, this procedure may be just as effective in facilitating learning as physically integrating two sources of visually presented information. The instructional version of the modality effect

can be considered to stem from the split-attention effect. It occurs under split-attention conditions when a written source of information that must be integrated with another source of visually presented information such as a diagram, is instead presented in auditory rather than visual mode. The instructional modality effect is obtained when a dual mode presentation is superior to a visual only, split-attention presentation.

Modality effect and instructional design. The instructional predictions that flow from the experimental work on the modality effect are straightforward. Assume instruction that includes a diagram and text that are unintelligible unless they are mentally integrated. A geometry diagram and associated text provide one of many examples. From a cognitive load theory perspective, the modality effect can be explained by assuming the memory load due to a diagram (or picture) with text presentation induces a high load in the visual working memory system because both sources of information are processed in this system. In contrast, the diagram and narration version induces a lower load in visual working memory because auditory and visual information are each processed in their respective systems. Therefore, the total load induced by this version is spread between the visual and the auditory components in the working memory system. In other words, integration of the audio and visual information may not overload working memory if its capacity is effectively expanded by using a dual-mode presentation.

Using the cognitive load framework as a theoretical base, Mousavi, Low, and Sweller (1995) tested for the modality effect using split-attention geometry materials consisting of a diagram and its associated statements. It is obvious that a geometry diagram must be presented in visual form. However, the textual information could be presented in either visual (written) or auditory form. A visually presented diagram and auditorially presented text may increase effective working memory and so facilitate learning over conditions

where visual working memory alone must be used to process all of the information. In a series of experiments, Mousavi et al. obtained this result. Audio-visual instructions were consistently superior to visual-visual instructions, demonstrating the modality effect. Furthermore, strong evidence was obtained indicating that the effect was due to working memory considerations, not merely due to the physical fact that auditory and visual signals can be received simultaneously while two visual signals (e.g. from a diagram and separate text) cannot be perceived simultaneously but must be attended to successively. The effect was retained even when the geometric diagram and its associated text were presented successively rather than simultaneously in both the audio-visual and visual-visual conditions. Remembering and using a previously presented statement while looking at a diagram is easier when the statement is spoken rather than written.

Tindall-Ford, Chandler, and Sweller (1997) replicated the basic, modality effect finding in another series of experiments with electrical engineering instructional materials. In addition, these experiments differentiated between materials that were low or high in element interactivity. Tindall-Ford et al. predicted that low element interactivity material with its low intrinsic cognitive load would not demonstrate the modality effect because increasing effective working memory would be irrelevant under conditions where the information that had to be processed did not strain working memory capacity. The modality effect was obtained with high but not low element interactive materials. In addition, assessment of comparative cognitive load using subjective ratings (see Paas & Van Merriënboer, 1993) indicated that cognitive load was higher under visual-visual than under audio-visual conditions, but only when the instructional material was high in element interactivity. Jeung, Chandler & Sweller (1997) found that the modality effect was enhanced when visual indicators were used to indicate to learners which parts of complex information were being

referred to by the spoken text. Leahy, Chandler and Sweller (2003) demonstrated the modality principle but also found that the modality effect could only be obtained under split-attention conditions where the information of both modalities was essential for understanding. The effect was not obtained under redundancy conditions where one modality could be understood in isolation and the other was redundant in that it presented the same information in a different form.

The importance of split-attention conditions (i.e. with both sources of information essential for understanding) rather than redundancy conditions (both sources of information independently intelligible) for the modality effect can be seen from the work on the expertise reversal effect. Expertise reversal occurs when instructional techniques that are highly effective with inexperienced learners lose their effectiveness and may even have negative consequences when used with more experienced learners. Information in a dual-mode presentation may become redundant when presented to more experienced learners. Kalyuga, Chandler, and Sweller (2000) demonstrated that if experienced learners attend to redundant auditory explanations, learning might be inhibited. In a set of experiments with instructions on using industrial manufacturing machinery, inexperienced learners in a domain clearly benefited most from studying a visually presented diagram combined with simultaneously presented auditory explanations. After additional training, the relative advantage of the narration disappeared whereas the effectiveness of the diagram-only condition increased. When the same students became even more experienced after further intensive training in the subject area, the diagram-only condition was far superior to the diagram with narration condition, reversing the advantage of the dual-mode presentation previously obtained.

The modality effect is especially important in the context of multimedia learning because the instructional medium involves different presentation modes and sensory modalities. Multimedia

instruction is becoming increasingly popular and findings associated with the modality effect that can be interpreted within a cognitive load framework can provide a coherent theoretical base for multimedia investigations and applications. Indeed, in a number of web-based instructional studies, Mayer and his colleagues have demonstrated that students performed better on tests of problem solving transfer when scientific explanations were presented as pictures and narration rather than as pictures and on-screen text (Mayer & Moreno, 1998; Moreno & Mayer, 1999; Moreno, Mayer, Spires, & Lester, 2001). According to the researchers, such results are consistent with dual information processing theory. When pictures and words are both presented visually, the visual processor can become overloaded but the auditory processor is unused. When words are narrated, they can be dealt with in the auditory processor, thereby leaving the visual processor to deal with the pictures only. Thus, the use of narrated animation reassigns some of the essential processing from the overloaded visual processor to the underloaded auditory processor. Unlike the earlier research that used book-based materials, the work of Mayer, Moreno and their colleagues used on-screen materials.

More recently, Brünken, Steinbacher, Plass, and Leutner (2002) replicated the modality effect in two different multimedia learning environments while using a dual-task approach to measure cognitive load. Learners' performance on a visual secondary reaction time task was taken as a direct measure of the cognitive load induced by multimedia instruction. Brünken et al. found evidence that the differences in learning outcome demonstrated by the modality effect are related to different levels of cognitive load induced by the different presentation formats of the learning material. Specifically, they found that an emphasis on visual presentation of material resulted in a decrement on a visual secondary task, indicating an overload of the visual processor. In further work, Brünken, Plass, and Leutner (2004) again

reproduced the modality effect while measuring cognitive load using a dual-task methodology. In this work, the secondary task was auditory instead of visual and there was a decrement in performance on the auditory secondary task when the primary task placed an emphasis on the auditory processor.

CONCLUSION

The split-attention, redundancy, and modality effects discussed in this chapter can be explained by cognitive load theory. In turn, instructional predictions that flow from these effects provide a theoretical base leading to practical applications for e-learning and multimedia presentations. The results associated with the modality effect provide a new instructional procedure. Under split-attention conditions, rather than physically integrating disparate sources of information, learning may be facilitated by presenting a written source of information in auditory mode. While care must be taken to ensure the auditory material is essential and not redundant and that the instructional material is sufficiently complex to warrant the use of a technique that reduces cognitive load, under appropriate circumstances, the instructional gains can be large.

FUTURE RESEARCH DIRECTIONS

To this point, cognitive load theory has primarily been concerned with the borrowing and reorganising principle – how instructors should organise visual and aural information to maximise learning. Less attention has been paid to the initial creation of information where the randomness as genesis principle has primacy. Human creativity has been recognised as an important field of study for a very long time. That recognition has not been associated with a commensurate advance in knowledge. Bluntly, the field of creativity has never been integrated with our knowledge of human cognitive

architecture and it can be argued, as a consequence, has been unable to generate usable information.

The cognitive architecture outlined in this chapter may have the potential to begin a rectification of this state of affairs. By accepting that the randomness as genesis principle is the source of novel information and by considering the interactions of this principle with knowledge held in long-term memory, it may be possible to generate instructional recommendations concerning human creativity. Theoretical work is commencing on this project.

Indiana University-Bloomington, USA

ABSTRACT

This chapter discusses the design and use of simulated teaching experiences contextualized through role-play in a multi-user virtual environment as a means of providing pre-service teachers with pedagogical and instructional experiences that are increasingly difficult for university programs to provide. It illustrates the underlying pragmatic theory of communication that supports this model of simulated experience as well as research methods that we suggest can aid in understanding the complex learning that stem from actor and student interaction. The goal of this chapter is to provide an instructional design model of simulated role-

play experience that emerged from a design-based research project as a means of supporting the development.

INTRODUCTION

Every Tuesday, Wednesday, and Friday, when the signal emits clearly from transmitters hidden on thousands of planets, moons, and asteroids and reaches Earth, a tall, blonde man named Calron logs onto the OTAK. Once in the computer system, his digital self materializes in the central world, which is filled with numerous other figures, representing children from several continents. Calron is not from Earth; he is from the distant

DOI: 10.4018/978-1-60960-503-2.ch302

world of Atlantis. A member of a secret Council, he seeks to improve the quality of life on both planets through scientific inquiry aided by his friends on earth.

Calron types greetings to several elementary and middle school aged students, calling them by name from his past experiences with them during the previous six months. He asks several questions about their learning activities in the space and how students think their work is helping people on both Atlantis and Earth. Students pester him with questions about the Archfall book, which introduces them to the story and problems of the world of Atlantis. He answers sometimes specifically, sometimes vaguely; taking notes about which students he has told what information, so that he and other members of the Council can refer back to it in the future. When students ask which Quests they should complete next as these are the main learning activities in the 3-D space, he nudges them towards those that he and the Council feel can best help the respective planets. Figure 1 presents an image of Calron as he appears in the book that accompanies the digital world.

Figure 1. Calron, a pedagogical agent and Atlantan Council member in Quest Atlantis

Calron is not really an alien from a distant planet. Instead a simulated character role-played by a pre-service teacher. The experience of being Calron embeds the pre-service teacher within what it is to be a teacher by simulating several of the roles and responsibilities of teaching. Being a Council Member provides learners with a live action digital simulation of the pedagogical roles that teachers engage in every day that range from coaching to facilitating and even dramatic acting. While the activity furthers student experience related to the narrative that supports the project, it provides a valuable set of interactions that will increasingly interact with their students in interactive digital spaces that simulate the learning environments that currently consist of whiteboards and desks.

The Challenge for Teacher Training

With the increased need for trained teachers that continues to trouble schools in many U.S. states (Matus, 2005) as well as countries worldwide, teacher training institutions are increasingly turning to distance learning applications to provide simulated field experiences that mirror those that students would traditionally receive by teaching with a mentor teacher in a physical classroom (Lehman & Richardson, 2004; Simpson, 2006). In addition, there have been calls by the government, professional teaching organizations, parents and the media to improve the training of teachers to include knowledge about the latest research findings and knowledge about best practices in education (NEA, 2004; PreventionAction, 2007). While the technological solutions continue to multiply, a number of problems exist that call for solutions that involve the use of digital simulations. The use of such simulations has shown some promise for providing rich, meaningful field experiences to pre-service teachers that can prepare them for their future work as day-to-day professionals and learners (Aldrich, 2003; Squire, 2004; Thiagarajan, 1996).

Viewing the development of a simulated digital teaching experience through the lens of pure simulation (or simulation games) can be aided by adopting a theoretical stance that does not accept a single historical, Kuhnian paradigmatic stance (i.e. positivist/empiricist vs. contextualist vs. relativist) (Bernstein, 1983; Hollis, 1994). This frees the designer or researcher from a view of a simulated experience that provides only a narrow glimpse into teacher or learner experience. Instead, this chapter proposes examining the design or educational value of a simulated experience employing a pragmatic theoretical view that takes communication as the core function of human activity can provide a holistic means of developing a more complete picture of teaching and learning. Early work in the area of pragmatic theory and research centered on the idea that the development of theory and its accompanying research should be geared towards the development of new means of teaching and learning that could be readily employing in educational settings (Dewey, 1925, 1938).

This chapter frames both a theoretical and methodological perspective for understanding, assessing, and teaching using simulated role-play from the pragmatic Theory of Communicative Action (CA) (Habermas, 1981a) in several ways. First, it identifies the core issues and problems inherent in many existing teacher preparation systems. Further, we explore and critique the splintered, underlying theoretical stances that guide the development of many face-to-face and simulated teaching experiences and explain the means by which the theory can provide a more holistic view of the nature of simulated experiences for teacher preparation, learning, and assessment. Finally, we provide an example of a simulated teaching experience and future directions for this form of simulated role-play experience in educational settings.

BACKGROUND

Issues, Controversies, Problems

Teacher Field Experiences

As the number of teachers needed in public schools increases, the number of available locations for pre-service teacher experiences has not concurrently increased (Simpson, 2006). While the use of digital simulations and other forms of technology such as computer-mediated communication, digital video, and video conferencing systems have shown some promise for addressing this shortage of face-to-face field experiences, Simpson (2006) notes several challenges to using field experiences delivered at a distance:

1. Field experience in distance delivered teacher education programs is brief; this may stem from administrative limitations such as a limited number of school sites. Others difficulties in these experiences come the fact that instructors have found it challenging to include all the relevant knowledge about pedagogical practices and specific area content knowledge (i.e. mathematics) that researchers have found necessary to ensuring a quality education for distance students.
2. Young (1998) notes that a central issue related to providing a range of pre-service field experience is that a consequence of many newly shortened programs is that experience is often in a single school and that this solitary experience can be an inadequate model for a future teacher.
3. It is also often difficult for teacher education institutions to find a sufficient number of schools in which to place their students and expert teachers with which to pair them.
4. While ensuring that there are sufficient schools for pre-service teacher, assuring quality experiences is yet another problem.

Ishler, Edens, & Berry (1996) and Howey (1996) found that educational institutions delivering pre-service teacher education have little supervision over local school sites. Therefore, ensuring that the mentor teachers are modeling best practice is difficult or not done. As they are limited to the use of local schools or schools within a reasonable traveling distance, those schools and teachers that may best model teaching are not used.

Reconnecting Theory and Practice

Work related to Jurgen Habermas' (1981a; 1981b) Theory of Communicative Action (CA) is geared towards developing practical means of understanding and improving what is at the center of the both this theory and teaching practice: human communication towards a goal. In instructional settings, such communicative goals range from those of the teacher such as conveying strategic content information (i.e. Lansing is the capital of Michigan), to eliciting responses from students that confirm understanding, and further into areas of negotiating or enforcing societal normative rules (i.e. you should not hit your peers). The learning goals that teachers have for their students may come from state curriculum or from personal goals established for individual students, but each is communicated either directly through such actions as writing them on the chalk board or implicitly through the goals of the specific activities and linkages to assessment.

These goals as communicative actions (i.e. discursive speech acts, textual discourse) generally have one of four purposes. The first goal is generally to convey objective, empirical knowledge or fact commonly accepted in the present as valid by society such as information found in standardized tests. However, this actually includes two different types of communication 1.) teleological or strategic action which relates to technical, in which empirical knowledge deemed by the individual

to be useful, is leveraged during 2.) constative speech acts or conversation to further develop and critique the theoretical understandings of speaker and hearer. A third possible goal is to provide socially valid normative understandings that have been generated through past consensus within socially or culturally shared experience such as social rules such as legal or moral conceptions through normatively regulated action. Lastly, the speaker may be attempting to express some internal state or "lifeworld" understanding towards the goal of taking some future action such as a direction to do something, known as dramaturgical action (Habermas, 1981a; Habermas & Cooke, 2002). According to Habermas, what underlies all of these different forms of communicative actions is intersubjective agreement between speaker and hearer. This theory has several implications for the development of educational simulations that are intended to provide pre-service teachers with practice geared towards the multiple communicative actions that they are expected to engage in within their future classrooms.

The Limits of Simulations with Communicative Action

The limitation that faces traditional simulations when viewed through the lens of Communicative Action is that only the pre-service teacher/student and simulated system are present. Why this is problematic is that the system cannot participate in conversation and critical discourse in which the validity of the assertions made by the student can be examined. Even more problematic is that the student must tacitly accept the validity of all claims made by the system because it remains static in the face of critique and cannot engage in a back and forth conversation towards consensus about the validity of the information communicated through the technological structure of the simulation.

For example, if the student teacher finds the system's communication about the appropriate

means for disciplining a child in the classroom to be inappropriate when they throw a piece of paper, the system often still only recognizes one correct, valid answer (i.e. give the student a verbal warning) because of the scripted nature of many educational simulations and simulation games. The participant in the simulation cannot engage in conversation with the system and state their critique of the communicated approach because the simulation engages in purely strategic action in which there are set rules for valid communication behaviors that, in a human, would have been accepted as useful knowledge for how to act in a classroom. The learner may imagine instances in which the proposed strategy for acting would be inappropriate; however, they have no recourse to conversation with the system about the validity of the required strategy. Their only option is to refuse to participate in the simulated experience.

This problem resulted in the idea that it should be possible to leverage technology to mitigate the major problems faced by student teachers in the current teacher training programs:

1. distance of the teacher from their pre-service experience,
2. the limitations placed on the amount of structured or unstructured communications,
3. the amount of critical impact they could have on the students in a limited time period, and
4. the possibility of a poor quality teaching simulated face-to-face instructional experience.

However, the question remained as to how the one could develop a simulated teaching experience that would provide pre-service teachers with a flexible system in which there were opportunities for the participant to engage with real students in to simulate the communicative actions that are present in day-to-day teaching.

Quest Atlantis: A Simulated Conceptual Play Space

An initiative within the National Science Foundation and MacArthur Foundation supported Quest Atlantis (QA) project was developed in order to provide students with a digital science-inquiry experience using a multi-user virtual environment (MUVE) (Barab, Warren, & Ingram-Goble, 2008; Barab et al., 2007). Within the foundational narrative that situates student activities and provides a rationale for students to work within the OTAK, a simulated computer simulation of the distant world of Atlantis, there are a number of characters who drive the learning activities and story which comes in the form of novels and comic books (Warren, 2005, 2006b). These characters introduce new meta-storylines, explain new digital developments within the 3-D environment, and provide brief background stories to situate the “Quests” that students complete in order to earn rewards and prestige.

The Need to Build Narrative Supports

One of the primary complaints from the 4th, 5th and 6th grade public school learners that emerged from informal and semi-structured interviews related to the narrative that supports QA. Specifically, they noted that there was a lack of interaction with the main characters that otherwise engaged them in the stories that framed the learning activities and drive their actions in the 3-D space (Dodge et al., In Press; Warren, 2006c). Therefore, it was determined that project team members should role play the six main characters a few hours a week to provide student participants with the opportunity to interact directly with the fictional characters as a means of enriching their experience with and knowledge of the supporting narrative as it evolved.

At the same time the team was developing the initial solution to this problem, the problem of a lack of suitable pre-service teacher sites for field

experiences was noted to the designers during an unrelated meeting. As a result of this limitation, many pre-service teachers in the state of Indiana were placed in schools out of state as far away as Cincinnati, Ohio, Louisville, Kentucky, and Chicago, Illinois. This resulted in round-trip travel times ranging from two to five hours in some instances. The challenge was mainly due to a systemic state geographical challenge that resulted in a lack of urban centers near teacher preparation universities. Those centers near the universities tended to be rural or lacked sufficiently high student populations to meet the need for mentor teachers and classrooms for field experiences. For those pre-service teachers that intended to teach in urban area, the opportunity to practice in such settings was lacking and further, many of the rural schools were burdened with high pre-service teacher to mentor teacher ratio (Warren, 2006a). This led to a large number of students who spent only a few hours in the classroom as students before they were given their own classes as professionals after graduation.

Upon this discovery, it was determined that in order to address both the need for student interaction with the fictional characters and pre-service teacher need for interaction with real students, it was determined recruit undergraduate students in the pre-service education program to work in a simulated field experience called The Council Actors.

SOLUTIONS AND RECOMMENDATIONS

Design Solution

In order to recruit teachers for the program, The Council Actors program was conceived as an independent study course to provide a simulated field experience to pre-service teachers. The main benefit of this solution was perceived to be that it would give the pre-service teachers an opportu-

nity to interact with students on a daily basis in a way similar to how they would once they had their own classrooms upon graduation in terms of developing effective communication. Further, through role-play, they would be able to experience the dramatics/acting as teacher/scaffolding student learning, which Habermas (1981a; 1981b) would frame as “dramaturgical action.” Actors also interact with and instruct students by providing both explicit, realistic expectations for acting in a safe, 3-D space while adding richness to student experience by communicating the story that drives their activity in the project worlds. Training the Council Actors was conducted by master teachers and project staff and was conducted similarly to mentoring that is commonly done in public schools and teacher education programs.

Requirements of the Council Actor Simulation

Council Actors were required to complete a number of weekly requirements in order to meet their own field experience needs as well as those of the students they would work with in the 3-D worlds. The following are the explicit requirements provided to Council Actors for working in the QA worlds that would provide them with high levels of contact with students while still ensuring coordination of teaching efforts across the team.

1. **Interaction:** The Actor will interact with kids or otherwise be in the space at least 6 hours per week.
2. **Feedback:** Actors will give feedback on Council suggested and Community Quests during their down time in the space.
3. **Staff Meeting:** Actors will attend a Council Actor staff meeting approximately one hour per week and engage in team planning.
4. **Council Meeting:** At least one time per month, all Actors will meet in the digital Council Chamber within Quest Atlantis for 30-45 minutes per week.

5. **Web logs (blogs):** The Actors submit blog entries for their characters 1-2 times per week under the guidance of two project members with expertise in this area. This allows them to approve all blog submissions and post them in the appropriate space while ensuring for narrative consistency.

In addition to these guidelines for role-playing the character and character responsibilities; there were also two other key guidelines or pre-requisites. These are: the Actor has reviewed the novel at length and has also reviewed the individualized character sheet for their particular character. The findings that stemmed from the staff meetings in which the Actors told their stories of interacting with students impacted each new iteration of the reified requirements document and provided insight into the building of tacit knowledge of the pre-service teachers and staff members over time.

Transfer in the Simulation

The Guide to Simulations and Games for Education and Training (Horn, 1977) defines the term simulation as a method of representing physical reality. Further, Horn also note that the essence of the social system interaction must also be represented, not just the physical. Therefore, simulations are used to replicate essential aspects of reality so it may be better understood and/or controlled. In addition, this definition sees user control as an important feature of a simulation, positing that the user must be an active participant in an experiential learning activity, whether physical, such as flying a plane, or social, such as engaging in a debate about substantive international topics in the forum of a simulated United Nations.

However, this may not be a complete conception as Baudrillard (1993) notes:

The systems of reference for production, signification, the affect, substance, and history, all this equivalence to a 'real' content, loading the

sign with the burden of 'utility,' with gravity – its form of representative equivalence – all this is over with...simulation, in the sense that, from now on, signs are exchanged against each other rather than against the real (Baudrillard, 1993, p.6-7). " At this point, differences between the real object and its reference or sign can no longer be discriminated between, making their value equivalent. (Baudrillard, 1994, p. 6)

If we accept this concept, then the reality represented by a simulation can be accepted as being the same as that in a different context outside the simulation. In a learning setting, this gains importance because it discounts the argument that both the classroom setting and the work students do in classroom contexts must be authentic in the sense that it is exactly the same as the work they will be expected to do in the future for it to be of value. From Baudrillard's argument, work completed by students in a simulation (e.g. as a flight simulator) and the work that students may complete in another context (e.g. flying a real plane) need not be an exact match and both have authentic value. This is because humans already understand the exchange of the real for the referential and value the practice of the referential equally in terms of future use. Therefore, learners do not need to complete the exact same task in order to perceive how the simulated task and accompanying practices have value. Thus, simulated experiences such as a role-play have transfer to alternate contexts and work activities.

The Council Actors simulation provides the pre-service teacher learners with control of the major features of communicative action ranging from the strategic in which they post web logs that are used to convey "facts" about the Atlantian planet just as they will write dates and events for the American Revolution on the chalkboard. The learners have control over what they choose to reveal, the instructional methods by which they convey information such as social norms, or negotiate meaning and understanding through

constative communication within the simulated space that is QA. By providing the pre-service teachers with control over the social system that in many ways mimics the learning and normative aspects of the classroom, we provide them with a simulated experience that leads to transfer to their future teaching experience. The Actors experience simulates many of the interpersonal conflicts that arise between students, rule enforcement, and pedagogical moments that are part of the everyday classroom.

Simulating the Council: Balancing Narrative and Learning

The role of a Council Actor was revealed to be complex as the Actors began to engage with students in the space. Therefore, as we reported our findings in the staff meetings, we determined that being an Actor would require a number of guidelines for pre-service teachers to follow in order to preserve the numerous narratives that exist in Quest Atlantis. This scaffold was necessary, not only for the narratives to remain intact, but also provided a structure to the overall experience and commitment required of the pre-service teachers.

In other words, while there were a number of different roles that the pre-service teachers were expected to engage in; there was also a need for a semi-structured experience for the pre-service teacher that they could refer back to in times of trouble. This highlights both a limitation and a key opportunity of using the role-play design in that the guidelines above are listed as minimums for participation. In contrast, the upper limits of the amount of time spent would be defined by the pre-service teachers as restricted by their other school and social commitments. With a different group of role-players, such as credentialed teachers hired to spend considerably more time in the QA space than the pre-service teachers can afford, it may be possible to substantially increase the potential interactions between the teachers, students, and narrative. This would then result in high satisfac-

tion among the QA student participants, but would eliminate the pre-service experience and benefit.

The Role(-play) of the Pre-Service Teacher

One important part that emerged was that the primary role of the pre-service teacher is to nudge students towards using the learning affordances (Gibson, 1977) of the space such as the text of Quests, Actor blogs, and other digital tools for learning. These encouragements provide students with the opportunity to interact with the narrative/characters, which they express an interest in doing through their constative communications with the Council Actors. These “nudges” can be used to direct students towards particular Quests that are of special interest to the Council Actors due to fictional events on Atlantis. These moments of interaction act as opportunities for the teacher actor to engage in the form of validity claim negotiation between teacher and student that we believe is necessary for understanding to occur. For instance, a typical interaction may emerge:

Calron:*So what is your favorite world in Quest Atlantis?*

Student:*I like Culture.*

Calron:*What do you like in Culture world?*

Student:*The stuff about music is my favorite*

Calron:*Have you looked at the Quest about Unidad's favorite song?*

Student:*No*

Calron:*I think it would be a good one if you like music*

Student:*Thks*

While this is a typical type of interaction in which the Actor pushes a student who may not be completing the main learning activity in QA, which are Quests, they also act in several other ways such as providing understanding of group norms by referring the I-BURST rules that govern behavior in the space while another role is to provide students with feedback. Council Actors review different learning activities such as com-

Simulating Teaching Experience with Role-Play

munity or teacher Quests and provide feedback that has a clear Atlantian view of the problem and solution, while still connecting their work to the real world and its impact on the distant world. They also have the opportunity to help guide class activities in conjunction with teachers. This allows the pre-service teacher, with the help of a QA staff member or teacher, to practice grading and giving feedback that are two important responsibilities of teachers on a day-to-day basis.

Tension: Non-Explicit Direction

A major challenge that emerged with this working within this form of simulated teaching experience is that Council Actors must avoid being overly explicit in their answers as it may lock the narrative in ways that makes it difficult to scaffold for other Actors or may limit future development. QA novels such as *Archfall in the Two Worlds, One Fate* series provide a good example of the non-explicit kinds of interactions that could serve as a model of the kinds of interaction that should be used when acting as a Council member. The novels act as strong references for Actor behavior, knowledge, background information, and context as the Actor seeks to provide students with learning experiences in the 3-D worlds. The cover of *Archfall* is presented in Figure 2 and showcases Kerbe and Alim, two of the Council members, surrounded by the Arch of Wisdom.

In instances where narrative-shifts may occur as a result of interaction with students, it is necessary for not only a detailed description of the situation to be kept; but for a decision to be made on whether to acknowledge the shift or to attempt to minimize it. In either case, the narrative would be used as the primary reference.

Tension: Providing Cognitive Challenge

Another major challenge was that Council Actors are expected to avoid overly didactic, explicit instructional interactions in which they tell students the answer to specific questions about how to complete a learning task. Cognitive challenge

Figure 2. Archfall cover image

questions rather than direct answers work better because they encourage students to critically examine their problem and seek their own solution. Questions such as: “Why did you decide to do that?” or “Have you thought about X?” serve as to challenge the student participants to come to their own conclusions and solutions without being led directly to them.

Tension: Empowering Learners Through the System

Finally, we wanted to avoid presenting the Council a group as all-knowing, perfect avatars of virtue lest we destroy one of the things that kids like about them which is that they are flawed and somewhat like themselves. There should be instances when the Council member just does not know the answer and recommends that the Questers ask their friends, their teachers, or explore more on their own. By engaging in strong instructional methods that empower the learners, we hoped that the pre-service teachers would learn how to encourage self-direction and ability to master the necessary skills to effectively communicate within the QA

system towards the goal of understanding their world through inquiry. One of the means by which we provided the Actors with guidance about these Council members was to develop “templates” or “style sheets” similar to those that are used in role playing games like White Wolf’s *Mage: The Awakening*. These style sheets provide the Actors with the core information about the character’s values, experiences that are in the background of the narrative, physical, social, and mental attributes, as well as their personal beliefs in relationship to the Social Commitments which are central to the Quest Atlantis moral and ethical system that supports student activity. Figure 3 shows part of Calron’s template that includes an example of this guide that is provided to the Actors.

RESEARCHING A SIMULATED TEACHING EXPERIENCE

While working to develop substantial methods for research into complex environments that include simulations, games, MUVES, and blends of these continues, we generated several suggestions for addressing issues of learning, attitude, and other important educational and psychological constructs relevant to the effectiveness of a simulated experience in this format. Empirical forms of research such as survey and pre-posttest methods should be employed to provide part of the picture of pre-service attitudes towards learning based on design methods, issues of self-efficacy, and understanding of instructional methods.

However, in order to provide a more complete picture when examining a role-play simulation, we recommend that other methods that can delve more deeply into the socially negotiated and individual experiences of the pre-service teachers should also be employed. These include, but are not limited to, qualitative methods that generate data which can be used to revise the design of such a simulated teaching experience and may provide a lens by which we can better understand and improve more naturalistic pre-service experiences in face-to-face settings. Most importantly, these methods center the researcher as a co-participant in the learning experience and therefore provide a means to empower the pre-service teacher in areas of student management, communication, and problem solving before they take over their own classroom. The most important research methods we employed were those that forced self-examination of Actors and sharing of those insights and challenges that emerged as we worked through the use of the simulated experience. The information that emerged from these discussions resulted in the highest positive impact redesigns to the experience over time and generated effective rule sets to govern role-play.

The Emancipatory Interest

In terms of social science research, the Emancipatory Interest is a concept that violates the underpinnings of traditional empirical research (Gall, Borg, & Gall, 1996), but was very important as we sought to include CA as a grounding theory for both the design of the learning experience for the pre-service teachers and staff as well as the research methods that were employed. The idea of observer as objective outsider is abandoned in favor of inserting the researcher, not only as participant-observer in the social learning and acting processes, culture, and immersive forms of life of the local community, but as an active proponent and advocate for effecting social change

and empowerment (Lather & Smithies, 1997; Leistyna, Lavanez, & Nelson, 2004).

From a researcher point of view, this becoming part of the community allows for honest communication by the participants of their individual understandings that bind their actions and knowledge of their meanings in the context of the social science perspective. Further, by engaging a dialogue between researcher-participant and study-participant, as well as the community, problems and solutions are identified and generated by the Council Actor members themselves, which leads to empowerment in the present context and empowerment to solve problems in future situations (Leistyna et al., 2004) and therefore transfer of the simulated experience to their prospective professional teaching experience.

The Emancipatory Interest fundamentally changes the purpose of research from observing or describing and then reporting a change made over time in a community to a purpose that involves the researcher empowering community members to identify and work towards solutions as they reacquire power from the digital system and reintegrate it into the community through purposeful communicative action. So, how do we study a simulated role-play from the perspective of both emancipating the participants and understanding the impact of such a design on the communicative actions that form the basis of instruction and learning?

Hermeneutic and Phenomenological Approaches

In order to address the idea that instruction and learning are communicative actions with the goal of emancipating both instructor and learner, there are several methodological approaches that can be leveraged. Two in particular are the hermeneutics and phenomenology (Bernstein, 1983). Both offer a number of benefits for social sciences research in terms of moving to a situated conception of

knowledge that are important for developing a simulated teaching experience like the Council Actors. First, these stances view knowledge as tied to context and situated within the individuals experience with it. Knowledge, understanding and experience occur concurrently and from these come meaning. “(U)nderstanding must be conceived as a part of the process of the coming into being of meaning” (Gadamer quoted in Bernstein, 1983, p. 125). Therefore, the process of research in social sciences from this perspective must study the process by which individuals come to understand situated knowledge and derive meaning from it.

Challenges to Such Approaches

However, both forms of research have both been criticized on a number of fronts including charges that they lead to relativism in which there is no fundamental truth or knowledge, they have a lack of usefulness for social science research due to their descriptive nature, and they require a substantial length of time to conduct a proper research study using such methods (Bernstein, 1976, 1983). The first and second criticisms are well-founded concerns as misapplied hermeneutic methods can lead to overly specific, completely relativistic information that adds nothing to the body of research knowledge. However, if such methods are used to describe the experiences and understandings of several people to provide a larger picture of the situation through the lived practices of the Council Actor pre-service teacher participants, the story of a culture and its forms of life may be used for formative and diagnostic purposes, much like more traditional, empiricist methods of research. The descriptive nature of hermeneutic research methods is more beneficial than Positivist paradigms for such diagnostic and formative purposes because it they allow for the identification of problems and solutions as conceived and phrased by the participants rather

than decontextualized yes or no answers to narrow hypothetical questions.

Further, in modern conceptions of these research methods, the researcher often becomes a part of the community and acts as a co-participant in the research and learning processes of the culture under study, which is important within the context of the Council Actors where the pre-service teachers and staff act as participant in, designer of, and researcher of the simulated experience. This helps to overcome the commonly perceived “Ivory Tower” problem in which the researcher is viewed as an outsider telling the community what is wrong and prescribing an alien approach to solve a perceived problem. In the context of hermeneutic research, the researcher is instead viewed as a co-worker who is developing solutions in conjunction with the local community and solutions are phrased in terms of what the community members themselves propose (Carspecken, 1996; Denzin & Lincoln, 2003). In the case of the Council Actors, the researcher is always also an Actor themselves who can act as a modeler of appropriate communication and teaching with students in the digital worlds.

FUTURE TRENDS

As the population of the world continues to grow, the need for trained teachers who can walk into the classroom and understand how to effectively communicate in order for students to learn and grow. Concurrently, the opportunities for pre-service teachers to engage with students before they take over their own classrooms continue to decline in many areas (Simpson, 2006). Role plays have already been found to be valuable as learning tools in military applications (Nieborg, 2005), flight simulations, and other instances in which there are fairly low-levels of complexity to the computers simulated behavior, because the artificial intelligence, while improving rapidly, lacks the responsiveness of true combat

or flight situations that become more complex exponentially in compressed time periods. This is also true in standard classrooms, especially with K-12 students who behave differently from day to day based on myriad factors that come from home, interpersonal relationships that implode in the hallway on the way to class, and the daily foibles of self-image that change with the surging hormones of the individual student.

In the future, providing pre-service teachers with simulated role-plays in which they act as the teacher acts can provide them with authentic expectations of the kinds of student behaviors, questions, and challenges that they will face in the classroom on a day-to-day basis once they take over their first class room. Just as we would prefer that the pilot of a \$30 million fighter jet has had experience overcoming the common and uncommon problems that arise mid-flight and can react effectively to the humans that fly the enemy fighters, we want our pre-service teachers to be prepared for the unpredictable human challenges in a situated fashion more closely mimics what they will encounter in a way that simulations are only now beginning to address. With our children's minds and education, we would prefer that future educators that may decide that teaching just is not for them decide this based on realistic expectations that stem from realistic interactions with students well before they take over their own classroom. As role-plays like this become more common, we can expect to find better trained teachers who are more readily able to start teaching on the first day of school and fewer who wash out of the profession after two years because they did not know how difficult it can really be to teach every day.

Every day, the number of communication tools splinter and rapidly expand in multiple forms where students use tools ranging from text messaging Facebook and Second Life to those we have not yet conceived. Each new form of structural communication (using technology as a vehicle) conveys information that allows students to rapidly coordinate their learning actions in groups,

negotiate understanding through interpersonal, constative speech acts, and come to understanding of their relationships to societal norms. These pre-service teachers, many of whom already use these tools themselves, will need to be experts at communicating with technology and understand how the tool deforms or alters student understanding so that they can adapt their own instruction to meet the needs of a new kind of student.

CONCLUSION

As the need for qualified teachers with real world experience working with students rises throughout the world and the opportunities for meaningful practice the art of teaching and interacting with students decline due to population shifts, increases, and declines, cost of training, and low participation of existing teachers in mentoring programs, the need for simulated teaching experiences will concurrently increase over the come decades. As this need increases, innovated instructional and learning methods are increasing access to student populations using communication tools embedded in online simulations and game products ranging from Second Life to Quest Atlantis that have their own existing or emerging storylines that require human support to maintain. Role play in these simulated learning environments provides opportunities for pre-service teachers to engage in meaningful pedagogical contact with the students that they may in the future teach so that they can understand the limitations, difficulties, and instructional affordances of technologies as a means of communicating meaningful learning experiences from a variety of educational paradigms from objectivism to contextualist or relativist world views.

Just as importantly, these simulated role-plays provide pre-service teachers with opportunities to understand how today's learners use technology to communicate. From a communicative action perspective, understanding how the structural

communications that are mediated by technologies like Facebook and Second Life deform or otherwise alter student knowledge and action is going to be increasingly important as they are further integrated in educational settings. Knowing how to overcome the misunderstandings that arise from technological mediation through pedagogical action is going to be one of the core skills of many instructors as technology plays an ever more important role in teaching and learning. By allowing the pre-service teacher to safely engage in the everyday communicative actions that make up teaching that range from negotiation and construction of knowledge to communication of student roles and norms, role play simulations have the potential to help mold instructors that are better prepared to face a rapidly changing classroom environment.

KEY TERMS AND DEFINITIONS

Field Experience: Activity that typically takes place in an authentic school or educational environment where an individual may practice and observe methods associated with a particular role—primarily applies to teacher field experience which is a requirement of the in-service teacher prior to graduation.

In-Service Teacher: Individuals who are licensed teachers and currently teaching.

Learning: The internalization of knowledge; may be directed (and therefore defined as instruction) or may be ill-structured and/or unanticipated in informal settings.

Narrative: Otherwise known as a retelling or story in which commonly includes elements such as plot, exposition (beginning), rising action (conflict), climax (turning point), falling action (wrap-up), and resolution (conclusion).

Play Space: An environment where incidental learning may occur, where meaningfully directed learning may occur; but where the majority of ex-

perience is ill-structured and without meaningful goals or objectives.

Pre-Service Teacher: Individuals in teacher education programs who have not yet been awarded their initial teaching license.

Role-Play: The act of portraying an entity other than oneself. An immersive role-play would require an investment into the character such as that of a professional actor in a particular part.

Simulated Character: A non-real character with a deeply developed back-story. Simulated characters include a core set of engagement and activity rules that encourage adherence to the ‘spirit’ of the character.

Simulation: An experience that interactively models some part of reality for a user.

Teacher Experience: The act and art of being in the role of a teacher. Activities are not limited to teaching, but also include mentoring, coaching, facilitating, reviewing and observation.

Virtual Worlds: Imaginary virtual persistent environments where individuals can use an avatar to interact with other avatars and virtual objects.

Chapter 3.3

Impact of Podcasts as Professional Learning: Teacher Created, Student Created, and Professional Development Podcasts

Kathleen P. King
University of South Florida, USA

ABSTRACT

Until now, research on podcasting in education mostly examined teacher created podcasts in K-12 and higher education. This paper explores podcasts in professional learning across several genres of podcasts. Using a popular typology of podcasts, teacher created, student created and professional development podcasts (King & Gura, 2007), this paper compares, contrasts and reveals the potential of multiple educational contexts and instructional strategies, formative instructional design, interdisciplinary strategies, formal and informal learning, and effective uses of data gathering methods. The significance of the study extends from not only the extensive reach of the data gathering and

production, but also the robust research model, formative and dynamic instructional design for staff development and recommendations for podcasting research strategies.

INTRODUCTION AND NEED

Since 2004, Internet-based new media formats have soared. Prolific Internet use has generated public desires and expectations to be *content creators*. Opportunities such as political and personal blogs and independent podcasts of all flavors as well as ever-popular YouTube® videos flash across users' screens and minds, creating the expectation of self as a new media communicator (Walch & Lafferty, 2006). It is through the recent

DOI: 10.4018/978-1-60960-503-2.ch303

advent of convenient and free Web 2.0 technologies, such as blogs, podcasts and vlogs, and Free Open Source Software (FOSS) (Rajendran & Venkataraman, 2009) that people of all ages and backgrounds are claiming their place and voice on the Web (Frontline, 2008). The great value of podcasting, a new media technology, for education is the ease of custom and inexpensive design, truly flexible, “anytime, anywhere” delivery format. Since 2005, anyone with access to a computer, Internet and a \$10 microphone can freely record, edit, and distribute audio content worldwide. Similarly, anyone with Internet access can hear these archived digital audios on computers or mobile devices, 24/7.

Widespread social and instructional adoption of podcasting has occurred since 2006, including adoption for formal and informal learning. With this increased use, educators and researchers need greater understanding of podcast-related instructional applications, data gathering opportunities, impact, scalability and scope of reach, instructional design, and research opportunities (eSchool News, 2008; King & Gura, 2007; Williams, 2008). For example, there are numerous free data gathering resources to couple with podcast use and yet no mention in the literature as to how schools might use it to demonstrate impact of their programs and services or instructors for formative improvement of curriculum, let alone recommended strategies for educators’ reporting of them. Research studies may also provide recommendations for the design of additional action- based research and inquiry in robust and systematic ways (Devaney, 2008).

By analyzing findings from three related podcast studies, this paper provides a macro research perspective and recommendations in these areas. The work collectively addresses the impact of podcasts on professional learning and uses King and Gura’s podcast typology (2007) as a framework for comparison and differentiation. This paper presents findings, discussion and interpretation of results for the following research questions:

(1) What is the use and potential for podcasting in multiple educational contexts? (2) What instructional strategies are used in the podcast? (3) How is formative instructional design utilized in the podcasts? (4) What interdisciplinary strategies are used? (5) What is learned about uses and formats of formal and informal learning? And (6) What effective uses of data gathering methods are recommended from these studies? The popular typology of podcasts, teacher-created, student-created and professional development podcasts is used in three studies examining the following productions: UEGE, TTPOD/PFT, and DLPOD (see Figure 1).

THEORETICAL BASES

Major theoretical underpinnings of this research include formative evaluation and continuous improvement of instructional design, research design and methods, podcasting and new media as instruction, podcasting typology, and informal learning.

Formative Evaluation Informing Instructional Design

Critical to the approach of this study is that educators can formatively design and evaluate instruction (Caffarella, 2001). Continuous improvement via data gathering, analysis and interpretation provides powerful means to proactively and dynamically chart the course of successful learning as many educators have demonstrated (Jonassen et al., 2003; Wlodkowski & Ginsberg, 1995). Broader and substantial research methodologies frame our thinking for instructional design, inquiry and data collection. These core frameworks include Denzin and Lincoln (2008a, 2008b) on qualitative research, Gall, Borg, and Gall (1996) on statistics and research design, and Hinchey (2008) on action research.

Figure 1. The three cases: podcasts studied

Research Methods (as a Theoretical Frame)

With action research as a vital model of research in many teacher education programs today, instructors engaging in instructional improvement using podcasts may go further and conduct action research inquiries. Even if research is not formally pursued, educators collect data and use student responses in informal research for guiding instructional design (Denzin & Lincoln, 2008; Hinchey, 2008). This article examines three different educational podcasting studies, therefore understanding the framework of research methodologies and decision making are important foundations for our discussion (Gall, Borg, & Gall, 1996).

In the field of instructional technology among diverse populations, action (Hinchey, 2008) and mixed-methods research (Creswell, 1998; Glaser & Strauss, 1967; Tashakkori & Teddlie, 1998) have been effective strategies across numerous studies (Jonassen et al., 2003). Analyzing the studies at hand for their research methods provides greater understanding of what educators currently do

for data gathering and research in educational podcasting. In addition, it provides a basis for recommendations for more systematic and deeper inquiry, which can improve student learning, and advance the field's future.

Podcasting and Instruction

Podcasting distributes digital recordings via Really Simply Syndication—feeds (RSS-feeds). That is, individuals record audio content with computers or digital recorders, post it on the Internet on a publicly available server, create XML script RSS-feed to string it together and deliver the episodes. Teachers and students, now podcasters, visit the podcast directories on the Internet and add their information to the searchable databases (King, 2008). Potential listeners visit the search for topics on the web or visit the directories, review descriptions, select and directly listen to or download the files.

Expert authors carefully and specifically applied the technical definition of podcasts to their work (Walch & Lafferty, 2006). They define

podcasts as audio (and video) new media products hosted on servers and scripted with an XML/RSS feed, utilizing push technologies. This definition distinguishes podcasts from web-based audio or video posts which are not syndicated, cannot be “subscribed” to, nor automatically delivered to listeners/learners.

Listeners may also port podcasts over to portable devices such as MP3 players, iPods, or some cell phones for mobile convenience (Richardson, 2006; Williams, 2008). This option allows listeners to choose not only *when* they want to listen, but also *where*. The rich podcasting medium reaches most people with Internet access; therefore, it provides a platform for instruction from diverse perspectives.

Essential to framing our research, design and teaching efforts are understandings of education in a pluralistic society (Greene, 1993), culturally responsive teaching (Wlodkowski & Ginsberg, 1995), and multiculturalism (Spring, 1997). When our learning space spans the globe and all 24 hours, learners may engage with people from any lifestyle who have access, thereby eliminating traditional boundaries of time, space, geography and class (Rajendran & Venkataraman, 2009). Therefore, greater skill in understanding and communicating with people different from ourselves emerges.

Podcasting Typology

King and Gura’s 2007 podcasting typology provides an effective means to differentiation among and compare educational podcasts. *Podcasting for Teachers: Using a New Technology to Revolutionize Teaching and Learning* (2007) identifies three major genres of educational podcasts: *teacher-created*, *student-created* and *professional development podcasts*.

Teacher-created podcasts represent those developed by teachers, especially for instructional purposes. These podcasts may include lectures or presentations recorded and posted as an episode in a class or subject series. In a more creative

pedagogical style, teachers may specifically plan, design and create podcasts for other instructional purposes. For example, they may develop supplementary classroom materials, distance learning, out of class or homework materials, tutorials, extension activities, etc.

Student created podcast are often developed as part of classroom assignments. From k-16 to workplace training and doctoral studies, they may be used in a plethora of ways. For instance, some teachers provide students opportunities to capture, archive and distribute their work as web-based audio or video projects, interviews, role playing or performances, historical narratives, presentations, simulations, etc. Indeed, creativity in student podcasting has been most widely seen in k-12 education, but is starting to emerge in higher education, albeit slowly. This trend may be due to different curriculum, professional development opportunities and classroom time. Nonetheless, with the growing number of Millennials or Digital Natives (Prensky, 2001) already graduating from our colleges, higher education needs to transform content expectations to be larger and in varied demanding media. Furthermore, we need post-secondary education to prepare students to be effective communicators, inventors, and analysts of digital media to guide our future. Assignments integrating critical thinking in the content area and developing innovative, creative, research grounded media exemplify the relevant learning possible with podcasts.

Professional development (PD) podcasts may be created by a variety of individuals, and organizations. These podcasting producers and hosts may include professional associations, teacher educators/professors, staff developers, schools, colleges and universities, non-profit organizations, or government agencies, and certainly teachers (that is “by teachers, *for* teachers”). Podcast-delivered PD affords much greater choice of time and space for engaging in professional learning. Indeed, the freedom shocks many educators and professionals, as they realize not only can they

choose what they want to learn, but schedule it at whim or will, and much of it is free. This new generation of PD is not much like the mandatory training or staff development we sat through previously. Instead, PD on demand allows the lifelong learner to be *in control*.

All of these forms of educational podcasting create a growing archive which is freely available. Individuals and organizations alike may select formal and informal staff development resources from this rich storehouse of content. Learning must be selected with a critical eye for credentials and expertise of the presenter. In addition, the relevance of content and integration of research, theory and practice are of prime importance for educational podcasts. However, examining these characteristics creates a vibrant, relevant opportunity for situated learning including critical thinking, lifelong learning and 21st-century learning skills (King & Gura, 2007; Partnership for 21st Century Skills, 2004; Richardson, 2006; Williams, 2006). Podcasting pursued in a contextualized, learner-centered manner can be a powerful platform for education.

Formal and Informal Learning

Familiar typologies of learning include formal, nonformal and informal learning (Coombs, 1989). By definition, informal learning is more learner-centered, goal oriented, and flexible. Informal learning's focus on context and learner is inherent to the possibilities of the approach (Schugurensky, 2000). What distinguishes informal learning is the learners' independence and connection to the contexts of daily life, including work (Livingstone, 1999; Schugurensky, 2000). The fields of adult learning and teacher practice have done much to research (Argyris & Schon, 1974), codify (Tough, 1971), and build awareness (Dewey, 1938; Livingstone, 1999; Polanyi, 1967; Tough, 1971) of this area. Instructional technologies such as new media used for professional development provide more rich opportunities for informal learning ac-

cess, use and research. Yet despite the trends of social adoption and the research opportunities, educational research has been slow to wake to this sleeping giant.

RESEARCH METHOD

This research used a cross-case, case study model, in a mixed-methods approach (Glaser & Strauss, 1967; Merriam, 1997). The case study analyzes research approaches, instructional technology innovation, and adoption. Additionally, the researcher has been podcasting for three years and thereby can be considered an expert participant observer (Creswell, 1998). She provides insight into development, use and opportunities for technology, context, and meaning of new media.

Specifically, this study was a quantitative-qualitative-quantitative sequential design (Tashakkori & Teddlie, 1998). In a Sequential Mixed Methods Analysis (SMMA), the study used 5/7 stages outlined by Onwuegbuzie and Teddlie (2003): data reduction, display, transformation, consolidation, comparison and integration. Data gathering methods included primary document examination and evaluation, collecting statistical data of podcast listener use from servers, hosting services, and statistical third-party services, blog comments, email comments, research articles and reports about the projects, website reviews, content from social networking sites, field notes, observations, and podcast directory rankings and links. Data analysis is tabulation, frequencies, and constant comparison for emergent themes pursued until theoretical saturation (Glaser & Strauss, 1967).

The three studies and length of production examined were, (1) a school leadership podcast (9 months), (2) teacher professional development podcast (3 years), and (3) student created podcast (1 semester). Figure 2 provides a comprehensive illustration of the analysis strategy. It reveals the three cases, and the sequence of data collection, and analysis.

Figure 2. Analysis strategy overview

Table 1 provides the reader with the details and table of information gathered for each podcast series. It shows the categories and results used for this study. It is provided here not only to reveal the early stages of data, but also as a model of data gathering and data display (Onwuegbuzie & Teddlie, 2003) for researchers and podcasters who desire to replicate or scaffold the methods presented in this article.

FINDINGS: ANALYSIS AND DISCUSSION

Mixed methods research and action research were the predominate models describing the research methods used by the podcasts examined. Because so much data are available in quantitative format, when fully configured and accessed, many people emphasize listenership. However, many early, non-educational podcasters (2005-2007) had a strong sense of audience and rely heavily on qualitative data. When a mixed method is used, it provides a

fuller realm of inquiry. Action research provides a dynamic interaction with context, learning and development. Examining Figure 2 reveals each study using a different approach: quantitative research, mixed methods, and combined mixed-methods approach for action research.

Findings and Preliminary Analysis

Perusal of the data revealed a more varied educational contexts that might be expected. Based on the podcast series descriptions, purpose, show notes, and review of their program format many indicators were found. The settings included: staff development, direct learner instruction, independent continuing professional learning, teacher education, and student research. That is, the two broad groups of users, educators and students, used the podcasts in different settings (and in different ways to be discussed later). Specifically, educators and school leaders used podcasts for their professional development through formal efforts by their schools or in degree study, but

Table 1. Comparison educational podcast research

also in their informal continuing professional development. In addition, students used podcasts in completing lessons by direct instruction: as they were instructed to create or listen to a podcast, or as a solution to find additional information.

Educational podcasters were able to incorporate multiple instructional strategies in even one podcast episode. This finding was again more complex than may be expected, but encouraging because of the possibilities for further development. Examples of incorporating new media in empowering formats for underrepresented constituencies examples include, but are not limited to, design formats of small group dialogue, peer learning, peer review, learner created media, class presentations which are designed as global resources and instructor created media; and genres of: critical reflection, historical narrative, debate, first person narrative, storytelling, performances, and role playing. These innovative educators were keenly aware of being able to use the multiple instructional strategies in order to reach a wider range of multiple learning styles and to deliver

the message in multiple modes (King, 2008; Kolb, 1984; Williams, 2008).

Educators using podcasting of these varied genres demonstrate the value of using multiple instructional strategies to reach students more effectively. This example is from one teacher planning for student created podcasts,

In designing the course I tried to be especially sensitive and accommodating to access and equity issues (King & Griggs, 2000) and not make assumptions about 24/7 access or over familiarity with technology. One way I addressed these variables was to design varied technology options required for assignments (King, 2008).

Emergent Themes

Instructional Design and Monitoring Data. Major patterns in dynamic, learner-centered instructional design through monitoring data for learning benefits were revealed in this study (Caffarella, 2001; Jonassen et al., 2003). Such practices include developing a unique reporting format illustrated

in Figure 3. Such reports integrate the research and instructional design thoroughly (action research) with statistics from multiple sources into one tracking file and a one-page snapshot report. The procedure of tracking the podcasts includes periodically gathering and downloading statistics, establishing an electronic filing and backup system to archive the data, consolidating the data, and distributing reports for programmatic and instructional improvement. Certainly such extensive data gathering practices are not the norm with traditional classroom instruction. However, the podcasting distribution system and foresight to utilize it can enable educators to include the practices into their existing instructional design routines.

One project (DLPOD) benefited from extensive prior experience of the producer. This project established a statistical reporting format from the start and the ease of production tracking was significantly different. Unfortunately, to our knowledge, no one in education has discussed or published such documents previously.

Instructional Strategies. The data also demonstrates educational podcasters using interdisciplinary strategies in their creations. While presenting content on educational technology professional development (the TTPOD series) for instance, podcast hosts also discussed, in-depth, math education, literacy education and financial literacy. Alternatively a sample student created podcast (UEGE) integrated theory, research and practice from health education, government, and philosophy.

In addition, while content standards may be easily and directly addressed with podcasts, other indirect benefits are very valuable for learners. Using these learning activities, instructors can assist learners to experience greater research skills and perspectives, validation, and freedom. Furthermore, dialogue and peer learning are powerful for critical pedagogy as these new media approaches explicitly shift the classroom focus from teacher to learner (King, 2008; Wlodkowski & Ginsberg, 1995). New media enables learners to articulate

Figure 3. Consolidated statistical monthly report

their views to their classroom and distribute them worldwide if desired (King & Gura, 2007, 2009). Alternatively, instructors can create a password protected mailbox to address learners' needs and sensitive discussions (King & Gura, 2008).

Emergent Model of Instructional Design. In considering the process of instructional design, Figure 4 illustrates a simple model which conceptually and practically guides teaching preparation and practice. While most educators use a required curriculum, they may discover additional digital and supplemental publisher resources. Building upon these and other free or FOSS media (USA Library of Congress Digital media, USA National Archives, Archive.org, Teachertube.com, Schooltube.com, etc) they may scaffold student learning to develop meaningful project based learning assignments. Using the Figure 4 model, assignments focus on student created content, such as student created podcasts, and include the full cycle of curriculum-foundation, student research and student evidence of understanding through digital media.

Contexts of Learning and Readiness. Podcasting for professional learning is pursued both in formal and informal learning settings. Therefore, while millions of downloads have occurred as educators independently decide to pursue their continued learning, some professors use the same podcasts as part of their curriculum, aka listenings, staff developers use them to deliver or extend formal learning (for example, UEGE, TTPOD).

In addition, many young adults are Digital Natives (Prensky, 2001) and use technology to communicate, socialize, and meet most of their needs with it. Undoubtedly, Digital Natives' early adoption of this technology contributes to informal learning podcasts in general like language learning podcasts, catapulting to the tops of the charts (for example, UEGE). Incorporating digital media into formal settings provides not only authentic vehicles for learning, but also provides a model and experience in using podcasts for learning purposes. In fact, in the UEGE and TTPOD data, student essays, survey responses, and listener blog and discussion board posts reveal that learners'

Figure 4. Instructional design for educational podcasting

formal learning experience using podcast transfer (Caffarella, 2001) to informal learning practices.

Educational Podcasting Research Model

Based on review of the reports and articles, I propose a model for educational podcasting research design, Figure 5. This model includes critical characteristics that aid in research design include (1) integrate research planning and instructional design, (2), decide on data gathering methods, and reevaluate periodically, (3) plan on periodic status/data reports- at least monthly, and (4) use the information for formative evaluation and improvement. This model includes detailed essential elements of sound instructional design (Caffarella, 2001) and research methodology (Denzin & Lincoln, 2008; Gall, Borg, & Gall, 1996).

For example, qualitative data from listeners such as blog comments, emails, VOIP messages, discussion boards, and social networking provide valuable data for instructional design and should

be planned for designed, data gathering routines, report protocols and analysis established from the start. TTPOD and DLPOD developed and sought these data sources vigorously to good benefit. Other formal instructional podcasts may be missing opportunities for organized research efforts in gaining direct audience feedback.

Podcasting Data Gathering Strategies and Sources. Extracted from this research, examples of free statistical tracking systems include: Feedburner PRO, PODPress (through the podcast blog site), individual server statistics, Google Analytics™, and varied extents of statistics from individual hosts such as LibSyn, Podomatic, Blubrry.com, etc. Other examples of data gathered at no cost were through the use of online surveys and website statistics trackers (Statcounter, for example) (see Figure 6). When coupled with listener data this information provides podcasters and instructors insight into how many people are listening, to what, and when (day); what content is most popular; geographical location, operating system used, time zone and URL entry point of

site visitors and listeners. Such approaches and results were evident in two of the studies reviewed.

Limitations of this Study

All studies have limitations based on their design and participant thresholds. In this research project, the limitations include that although it was a diverse set of educational podcast efforts, those studied were a convenience sample. This choice was necessary to use a unifying framework. Therefore, the author's podcasts were used, albeit this identity is disclosed, documented and described.

Establishing the boundaries of this perspective, one realizes that this is an innovative educator, well versed in instructional technology and focused on learner-centeredness, formative design and instructional research. Such an orientation provides an unusual context, but a rich source for exploring the potential of educational and research applications of podcasts with current resources. Many fields study the work of innovators in order to chart new approaches (Rogers, 2003).

Further Recommendations

Listeners engaged in using these podcasts for learning gained much from their colleagues' and podcasters' perspectives. The related blog and discussion board postings reveal impressive demonstrations of effort, depth of research, insight, public speaking, global awareness, voice, empowerment and initiative by formal and informal learners. Creating new learning communities is never easy, but using new media to support traditional classrooms can extend learning. In addition, building a virtual community of practice (Lave & Wenger, 1991; Marsick & Watkins, 2001) around a podcast resource can provide support and knowledge for educators who might have little of either. In the case of the podcasts studied here, they have variously used Facebook, blogs and now Twitter to cultivate such communities.

When using podcasts for formal and informal learning, learners are using "new media" for recreational and social uses. This technology has a great excitement and popular validation connected

to it at this time. Aside from the benefits of users' flexibility and control of time and space, educators may leverage the new media as an added attraction and incentive to engage reluctant learners. In the process learners also are invested in processes which facilitate instructional improvement. They are exposed to more content; they have access to repetition via rewind and replay functions, and depending on the instructional design perhaps engage in it more, and discover new opportunities for finding and using learning resources.

In these several ways, the podcasts enable us to deftly cultivate 21st-century skills (Partnership for 21st Century Skills, 2004, 2007). Through practice, exploration and extension assignments critical thinking, research strategies, information literacy, problem solving and collaborative learning skills may be easily incorporated (ALA, 2006).

EDUCATIONAL SIGNIFICANCE AND FUTURE RESEARCH

This research has provided greater understanding of what educators do and how they engage in formative instructional design, data gathering and research in educational podcasting. Both the reflective practitioner (Schon, 1987) and teacher as researcher (Hinchey, 2008) are familiar and essential models for professional learning because they are flexible and encourage data-supported choices in their approaches. This study provides significant connections among educational podcasting, research, instructional planning and instructional improvement in the context of continuing professional learning.

Further research is needed to continue to build upon these recommendations for more systematic and deeper inquiry which can improve student learning and advance the field further. Many free resources are available for tracking podcast listeners; educators urgently need to learn how to configure and use these services accurately and

to assist in instructional improvement, research and investigation. At this time, podcasters follow this basic process only inconsistently.

CONCLUSION

There are a multitude of opportunities to use podcasting for professional learning beyond the model of course casting which our universities seem to be enamored with today. Teacher-, and student-created, and professional development podcasts provide abundant opportunities for flexible learning which include many additional educational opportunities yet to be extensively explored. This study has revealed how one podcast series from each of three different genres of educational podcasts can extend learning experiences to many instructional strategies and learning contexts. It has revealed an interdisciplinary instructional design approach which can be used in formal and informal learning. Finally, the dynamic instructional design platform seen in these examples offers a foundation for research approaches, methods and recommendations. Still only four years into the world of podcasting, we know educational podcasting has only begun to explore its impact for professional learning.

Chapter 3.4

Modelling Spoken Multimodal Instructional Systems

Niels Ole Bernsen

NISLab, University of Southern Denmark, Denmark

Laila Dybkjær

NISLab, University of Southern Denmark, Denmark

ABSTRACT

The use of speech and spoken dialogue is a relatively recent addition to instructional systems. As, almost invariably, human instructors and students talk during teaching and training, spoken dialogue would seem to be an important factor in systems that emulate aspects of human instruction. In this chapter, the origins and state of the art of spoken multimodal instruction are described. Strengths and weaknesses of the speech modality, key roles of spoken dialogue in multimodal instruction, functional issues in current spoken teaching and training systems, commercial prospects, and some main challenges ahead are then discussed.

DOI: 10.4018/978-1-60960-503-2.ch304

INTRODUCTION

A key advantage of instructional systems is to enable instruction in the absence of a human expert or teacher. From pre-school kids to adults of all ages, everybody needs to learn and benefit from the expertise of others when doing unfamiliar tasks. The classical solution is to be helped by a *human instructor* who has two kinds of expertise: in the subject-matter in question and in effectively communicating or transferring the expertise to students. While this approach has worked for millennia, it suffers from the problem that expertise remains expensive and rare, relative to the number of those who wish to acquire or draw upon it. A language instructor in class, for instance, has little time for coaching each student individually.

An interactive instructional system, or *system instructor*, offers to supplement the human instructor's contributions to individual student learning and problem-solving. In the ideal case, the system's expertise, both subject-wise and pedagogically, is near-equivalent to that of a good human instructor. Since systems can be copied infinitely, this would enable students to work with an expert all the time, in class, at home, and elsewhere, and not just when the student has a human instructor's undivided attention in class. It is hardly controversial that removing the difficulty of access to expertise and dramatically reducing its price is a worthwhile technological goal.

The roles of speech, spoken dialogue, and conversation in instructional systems, most of which include modalities other than speech, are described and discussed. Characteristically, human instruction involves spoken conversation with students no matter whether spoken interaction is central to the instructional task or has an auxiliary role. In relative terms, speech is a newcomer in the field of instructional systems, which for a long time was characterised by typed text input/output. Spoken interaction is insufficient for most instructional purposes, however. Other interactive modalities are needed for optimising instructional effectiveness and efficiency. New modalities and modality combinations hold the additional promise of providing system instructors for *all* users no matter their perceptual or motor disabilities.

Instructional systems are defined (the second section), their history reviewed and the state of the art of spoken instructional systems are described (the third section), and conceptual architectures and component technologies are presented (the fourth section). Using a simple example, how to approach instructional systems analysis and specification is discussed (the fifth section) and a functional model of instructional interaction sketched (the sixth section). Since speech is not a catch-all for instruction, when (not) to use speech is asked and key roles of spoken dialogue are proposed (the seventh section). Examples of spoken

multimodal dialogue systems (the eighth section) and commercial prospects (the ninth section) are discussed, and some main research challenges are presented (the tenth section).

INSTRUCTIONAL SYSTEMS

By an (interactive) *instructional system*, an application whose main purpose is to teach or train the user or help the user solve a particular problem is understood. Although often combined in practical applications, these goals are somewhat different. A *teaching system* primarily teaches *understanding* of some subject-matter, such as the periodic system, basics of genetics, astronomy, planet geography, phases in the history of humanity, and so forth. A *training system* primarily trains *practical skills*, such as language skills, how to operate some artefact, play golf, or fly a commercial airliner. Teaching and training systems are aimed at long-term learning effects in the learner. By contrast, *problem-solving support systems*, such as one helping to install IP telephony on a laptop, rarely incorporate ambitions of producing long-term learning effects. If they help solve the problem at hand, they fulfil their purpose.

Aiming at long-term retention which largely depends on the amount of elaboration done on the education material, *teaching/training systems* typically focus on providing opportunity for solving or otherwise addressing as many and as different problems or issues as possible in the application domain. Key challenges in developing a good system are to make it *pose* the right challenges, *evaluate* the student's attempts to cope, *feed back* evaluations, *monitor* progress, *modify* challenge level depending on learning progress, and *stimulate* motivation to continue learning. *Problem-solving support systems* focus on system problem-solving because the user is challenged already and needs help. Problem-solving support systems thus partially reverse the roles described, so that the user poses the challenge, evaluates the

system's attempt to cope, and feeds back evaluations—but the system is still the expert.

Instructional systems need a *usable interface* for human-system interaction. In a sense, this is no different from other interactive systems like word processors or spreadsheet packages. Arguably, however, usability requirements are particularly sharp for instructional systems: nothing is more de-motivating to self-instruction than a system you cannot find out how to use; students often work alone or in small groups, lacking the usual support from colleagues at work when something is amiss; and students typically need all system functionality rather than the <20% functionality most word processor users actually use.

HISTORY AND STATE OF THE ART

Intelligent Tutoring Systems

Intelligent machines for educational purposes date back to Pressey's (1927) machine for multiple-choice tests. Computer assisted training and teaching dates back to around 1960. While the first computer-assisted instruction (CAI) or computer-assisted training (CAT) systems were fairly simple, one source of progress was incorporation of AI-techniques in the 1970s. This led Sleeman and Brown (1982) to coin the term intelligent tutoring systems (ITSs) to distinguish the new AI-based systems from simpler CAI/CAT systems.

One of the first ITSs was the WHY teaching system (Stevens & Collins, 1977) which tutors factors and causal relationships affecting rainfall. A later, well-known training system is Sherlock and its successor, Sherlock II, which tutor air force trainees in diagnosing and repairing electronic equipment (Lesgold, Katz, Greenberg, Hughes, & Eggan, 1992; Lesgold, Lajoie, Bunzo, & Eggan, 1992). These are just examples of the multitude of domains addressed by ITSs over the years.

Early Intelligent Tutoring System Interfaces

For many years, ITSs were basically GUI (graphical user interface) –based, using input from keyboard and mouse and output on screen. Screen output was to begin with typically static text and graphics followed more recently by dynamic output, such as video, animation, and virtual reality. Since human tutoring typically involves natural language interaction, GUI-based instruction also began to include typed student-system dialogue. This trend seems to have grown with advances that now enable rather sophisticated linguistic interaction.

Natural Language Interaction

Some early text-based dialogue systems are psychotherapist Eliza (Weizenbaum, 1966) and SHRDLU (Winograd, 1971), the latter enabling users to move blocks of different shape and colour around by using a vocabulary of about 50 words. Theoretical work on discourse and dialogue in the 1970s and 1980s (Grosz, 1974; Allen, 1979; Grosz & Sidner, 1986) has played a major role in advancing natural language interfaces. Spoken interaction began to gather speed around 1990. In the 1990s, most spoken dialogue systems enabled users to accomplish some task, such as making a flight reservation (Bernsen, Dybkjær, & Dybkjær, 1998) or checking bank information, but few systems were instructional. An example of the latter is the speech-only Circuit Fix-It Shop problem-solving support system (Smith 1991; Smith & Hip, 1994). The system helps debug an electric circuit and a main development goal was to model mixed-initiative dialogue. Research on spoken and multimodal interaction goes back at least to Bolt's (1980) system which combines spoken commands and pointing-gesture input.

Spoken Teaching and Training Systems

Spoken interaction made its way into ITSs in the late 1990s. For instance, Graesser et al. (2001, 2004) use talking-head output in their AutoTutor system but still rely on text input. AutoTutor teaches newtonian qualitative physics and computer literacy. The conning officer virtual environment (COVE) system is for training Navy officers to become better ship drivers (Roberts, 2000). Interaction is via graphics output and speech, the system using short spoken exchanges to coach the learner during simulation. The ship-board damage control trainer (Clark et al., 2001, 2005) also uses spoken interaction and graphics output. Students must contain the effects of fire, explosion and other critical onboard events, and receive spoken instruction and feedback. The system asks question on, for example, what to do in a particular situation and which steps to take. The user answers via speech and/or pointing to part of the vessel displayed on-screen. Teaching system ITSPOKE (Litman & Silliman, 2004) uses the WHY2-Atlas (VanLehn et al., 2002) text-based ITS as back-end. When given a problem in qualitative physics, the student types a natural-language essay answer. ITSPOKE analyses the answer and engages students in spoken dialogue to provide feedback, correct misconceptions, and elicit more complete explanations.

Since spoken dialogue systems began to go multimodal in the late 1990s, several dialogue research projects have explored spoken multimodal interaction for teaching or training. Compared to mainstream ITSs, the resulting systems tend to focus less on pedagogical aspects and more on interaction. For instance, several training applications using spoken dialogue with virtual humans have been developed at the University of Southern California. One is a mission rehearsal system for training critical decision-making skills in small-unit US Army leaders (Hill, Gratch, Marsella, Rickel, Swartout, & Traum, 2003). Another is a

negotiation trainer for military personnel who need good negotiation skills when going to war zones (Traum, Swartout, Gratch, & Marsella, 2005). Focusing on improving conversational abilities, these projects go beyond the strict task-orientation of most spoken dialogue systems, towards enabling a more open conversation within the domain. This is even more so in the European Hans Christian Andersen system for non-task-oriented conversation with the fairytale author about his life, person, and fairytales (Bernsen et al., 2004). Aimed at the 10-18 year olds, the system combines education and entertainment.

The Collagen (collaborative agent) project (<http://www.merl.com/projects/collagen/>) (Rich, Sidner, & Lesh, 2001), although fostered in the spoken multimodal tradition, goes a long way towards merging with the ITS tradition and its pedagogical emphasis. Collagen introduced a platform for building mixed-initiative assistants for a wide range of applications and with considerable software re-use. Underlying the platform is shared-plan collaborative discourse theory. The platform has been used for, for example, an agent that teaches how to operate a gas turbine and one which helps set up and program a video-cassette recorder (Rich et al., 2001). To bridge to ITSs, domain-independent pedagogical agent Paco has been developed and used for teaching students how to operate gas turbine engines (Rickel, Lesh, Rich, Sidner, & Gertner, 2002). Language training systems is another example of systems that draw on both traditions. The Colorado Literacy Tutor (Cole et al., 2003) is aimed at teaching students to read fluently and understand what they read. Talking animated head Baldi teaches vocabulary and grammar to autistic and hard-of-hearing children and helps them improve speech articulation and linguistic and phonological awareness (Massaro, 2005).

Speech in Commercial Instructional Systems

While many commercial instructional systems include text-to-speech output, there are still rather few that include speech recognition. Spoken output is primarily used to speak some text aloud. Although any text may be read aloud, most commercial instructional software providers who stress the availability of spoken output, use it for some kind of language training (cf. later). Similarly, most commercial instructional systems that recognise speech are aimed at language training.

Text-to-speech output is, for example, included in the reading, grammar, and vocabulary improvement programs from Merit Software (<http://www.meritsoftware.com>). A product from Kurzweil (<http://www.kurzweiled.com>) aims to ease and enhance the reading, writing, and learning experience of the visually impaired by speaking text aloud. Knowledge quiz software from Interactive Speech Solutions and Microsoft's Mobility Solutions for Education (<http://getccq.com>) ask questions in English while the question text is displayed in the application window. Spanish-speaking students may click a button to hear the question spoken in Spanish while still viewing the English text. Several systems from Caltrox (<http://www.caltrox.com>) use spoken output, including programs for learning multiplication tables, teaching kids to count, learn the alphabet or the spelling of words, and a text-to-speech program for training English pronunciation and vocabulary-building.

Several commercial pronunciation training systems use speech recognition, including Auralog's Tell Me More (<http://www.auralog.com>) and one from Protea Textware (<http://www.proteatextware.com.au>). These programs use the speech recogniser's recognition of the student's pronunciation of words and phrases as a basis for feedback on the pronunciation quality. Pronunciation training is used as an example in the fifth

section. Spoken dictation systems are also being used as a help for dyslectic students.

COMPONENTS AND ARCHITECTURES

In this section some basic aspects of components and architectures for ITSs and spoken multimodal dialogue are described.

Core Components of Intelligent Tutoring Systems

A typical ITS includes the following abstract components:

- The **student model** (user model) collects, stores, and updates information about the individual student for use by the teacher model. As a minimum, the model keeps track of how well the student performs over time
- The **teacher model** (pedagogical model) is a model of the teaching process adaptable to the individual student's needs. The model includes, for example, information about when to introduce a new learning topic depending on curriculum and student model information, and decides on the performance evaluation feedback to present to the student
- The **expert model** (domain model) includes information relating to what is being taught as well as a model of how an expert solves problems in the domain. This enables comparison with the student's solutions and helps identify and point out which problems of understanding and/or skills mastery the student may have
- The **user interface** presents learning material to the student and generally enables student-system interaction

These functionalities can be realised in many different architectures and may vary hugely in sophistication.

Core Components of Spoken Dialogue Systems

A typical architecture for spoken natural language dialogue includes the following modules, compare Figure 1:

- **Speech recognition** transforms the speech signal into one or several text strings
- **Natural language understanding** extracts semantics from the recognised string(s)
- **Dialogue management** decides, based on input semantics and contextual information, which output to produce next
- **Natural language generation** prepares an output text string in accordance with the dialogue manager's decision
- **Speech synthesis** transforms the output text into a speech signal
- **Application data and business logic** provides backend information for the dialogue manager. Its contents depend on the task and domain addressed.

If interaction is text-based-only, speech recognition and synthesis are left out. If spoken

interaction is not dialogue but only, for example, un-interpreted single-word input/output as in the pronunciation trainer (the fifth section), natural language understanding and generation are left out, and spoken dialogue management reduced to more basic interaction management. Multimodal interaction requires additional input recognition and interpretation components and often also fusion of information received in different modalities and/or additional output generation and rendering components, possibly including modality fission.

Space does not allow detailed discussion of spoken dialogue system component technologies and their pros and cons (see McTear, 2004; Delgado & Araki, 2005). Briefly, instructional systems developers may use commercial or research *speech recognisers* depending on the recognisers available for the language(s) used, quality requirements, and whether commercial recognisers offer the particular features needed, for example, extraction of prosodic cues. In the large majority of practical systems, *natural language understanding* of spontaneous spoken or typed input is based on shallow (or robust) parsing which extracts key words, phrases, and possibly certain grammatical constructs from the input string for building a conceptual representation of the input, using analytical or statistical techniques, and typically being guided by transcribed corpora of the kind of dialogue the system should be able to engage

Figure 1. Conceptual architecture of a spoken multimodal instructional system

in. Deep parsing based on some comprehensive grammar fragment is generally not sufficiently robust versus recognition errors, tends to get lost in multiple input interpretations, and is not needed to obtain usable results. In most cases, *dialogue management* must be developed from scratch unless the instructional system developers are on their way to having a platform which allows partial re-use from other systems. *Natural language generation* is typically based on stored output templates which are completed at run-time based on user input details and possibly on system state properties as well. *Spoken output* may be pre-recorded human speech or—for increased flexibility—produced by free or commercial text-to-speech synthesisers which have achieved high levels of intelligibility and naturalness for several languages. Finally, application-specific data (teacher model, expert model) must be developed from scratch as must the student model unless the developers have partially reusable components from similar systems.

Summarising, the addition of spoken dialogue to instructional systems implies non-trivial investment in a family of technologies, most members of which are not simply off-the-shelf components. Even if one chooses off-the-shelf recognition and text-to-speech, and unless the application requires basic dialogue capabilities-only, one is into non-standardised software development of, and contents provision for, natural language understanding, dialogue management, and natural language generation.

Spoken Multimodal Instruction Architecture

Since ITSs are primarily characterised by the right-most backend components in Figure 1 while spoken multimodal systems are mainly characterised by the other components shown, combining the two parts produces an ITS with a spoken multimodal interface. Figure 1 simplifies input fusion which may be done at different

input processing stages, primarily at signal and semantics level. In output fission, the output decided upon by interaction management is split between output modalities, such as speech and graphics, making sure that proper temporal synchronisation is maintained (Martin, Buisine, Pitel, & Bernsen, 2006).

SYSTEM ANALYSIS AND REQUIREMENTS: A SIMPLE EXAMPLE

Instructional system development follows general software engineering principles (Sommerville, 2006), adapting these to the application at hand. Decision on whether to use speech and spoken dialogue should be made early in the lifecycle as sketched for a simple spoken multimodal training system. The example also illustrates basic student, teacher, expert, and user interface models in action. The system does not include spoken dialogue but might come to do so later.

Early lifecycle work focuses on analysing the target system and specifying requirements. For analysis and specification, consideration of a standard set of factors (Bernsen & Dybkjær, in press) which helps structure analysis and determine requirements is recommended:

1. Application type
2. User, that is, general user properties to be taken into account
3. User profile, that is, description of the target user group(s)
4. Use environment
5. Domain
6. Task or other activity
7. Interaction
8. Interaction device

Assuming that the target application is a pronunciation trainer, how those factors might influence its specification will be sketched.

Even the most cursory target application description typically carries implications with respect to several factors. A description (1), such as “a speech recognition-based system for training immigrants in Danish single-word pronunciation” (Bernsen, Hansen, Kiilerich, & Madsen, 2006) implies the goal of improving student *skills* rather than knowledge and understanding (2) in the Danish second-language *domain* (5). Training should be in some quiet *use environment* (4), the *user profile* (3) being, if feasible, that of immigrants-in-general. Within the domain, a corpus of words which covers all Danish phonetic variations is needed. Basically, the student’s *task* (6) is to pronounce the words one-by-one. Decision on which *input/output modalities* to add to spoken single-word input and in which interactive roles (7) is less straightforward, which carries over to the choice of *interaction devices* (8). An open issue is how each training word should be presented to the student, for example, via (a) typed text, (b) an audio file of a native speaker’s pronunciation, (c) an audio/video file, (d) a semi-transparent animated human head pronouncing the word and displaying the vocal tract in action, or some or all of these. Another issue is whether to use spoken dialogue for some interactive role or if, for example, a standard GUI environment is sufficient.

In the current pronunciation trainer version, the *expert model* includes the phonetically rich

training vocabulary presented to students and algorithms for evaluating student pronunciation. The expert output is simply a set of pre-recorded text, audio and video files. An animated head is planned (Hansen, 2006). In the *student model*, basic and generalised results are distinguished between. *Basic results* are the logfiles stored each time a student pronounces a word and the system rates pronunciation quality based on phonemic similarity with a native speaker’s pronunciation of the same word. *Generalised results* are computed over basic results, for example, an accumulated numerical score for consecutive pronunciations of different words or identification of a set of pronunciation problems for a particular student. The *teacher model* is relatively simple. Since Danish single-word pronunciation has no levels of difficulty (it’s all hard!), the teacher model essentially (i) gives feedback on each pronunciation and (ii) uses student model generalisations to present pronunciation problem diagnoses and suggest remedial training exercises. Finally, the relatively simple *user interface* requires user identification through id entry (ensuring that user modelling models the right user) and enables training word selection, optional word presentation(s), word pronunciation, pronunciation quality score presentations (individual and cumulative), diagnostic feedback, and (planned) audio or video replay of the pronunciation (Figure 2).

Figure 2. Pronunciation training system with max. score Smiley emoticon feedback

Interestingly, the hardest part of pronunciation trainer development is one that tends to challenge many instructional systems, that is, to produce optimal, pedagogically meaningful student model results and teacher model feedback on performance and progress. Simply put: it tends to be easier to *evaluate* student performance quality than to *diagnose* its deficiencies and propose tailored remedial action. This is where human teachers and trainers excel, partly because their perception of student performance details is keener, and partly because their reasoning about those details is sharper than what current systems can do.

A MODEL OF INSTRUCTIONAL INTERACTION

Spoken multimodal instruction is characterised by the fact that a particular modality, speech, is used in multimodal combination. To address the potential roles of speech and spoken dialogue in instructional systems, a model of instructional interaction is needed. This section sketches a general model of a (self-) teaching or training session illustrated through reference to rather different system examples: the pronunciation trainer, case-based teaching of medical patient interviews, math training, the negotiation trainer and the Andersen system (the third section), flight simulation, and systems for teaching models in physics and ecosystems.

Expert Knowledge

Large parts of system contents and behaviour can be fixed in advance because these are independent of the input users might produce.

The developers can fix (1) the *problem space*—the words to be pronounced, a set of medical interview cases or math problems, a set of negotiation goals or flight simulation targets, or a model that should be worked upon. These example

systems are all task-oriented: the problem space is a *task space* in which the student works. Only the Andersen system has no task space because it is not task-oriented but *domain-oriented*. What the developers can fix is the person's personality, physical appearance, domain knowledge, habits, and so forth. (2) For task-oriented systems, developers can fix the nature and number of *actual problems* to be solved, such as pronouncing each word, critiquing each interview case, solving each math problem, reaching negotiation goals or simulation targets, or solving particular ecosystem problems. This cannot be done for the famous-person system because it is very much an empirical question what the students would want to learn from the person. (3) For each problem, the developers can determine the *solutions* that will be accepted as being correct and to which extent. Correct solutions may be defined either in terms of following *correct procedure* or arriving at *correct results*, or both. The famous-person system has neither correct procedure nor correct results.

User Interface

The problem space should be presented using the modalities most appropriate for the purpose, such as text, speech, video and animated-face graphics for pronunciation training, static text for medical interview cases and static math notation for math problems, giving the student time to carefully study each problem, speech and animated conversational characters for negotiation and famous-person, a haptic-visual cockpit environment for flight simulation, possibly augmented with acoustic alarms and spoken controls, and some combination of static text and static/dynamic graphics for physics and ecosystem models. Some implications are that (i) *any* modality or modality combination might be useful for problem space representation in some particular instructional system, (ii) many, if not most, problem space representations are *inherently multimodal*, and (iii) only a fraction of problem space representations have *spoken dialogue* as

main interactive modality, as in the negotiation and famous-person examples.

Student and Teacher

Now let the student be added to the model. Typically, the system is a longer-term companion which the student (4) first needs to *learn how to use* and then uses for some period of time to improve knowledge or skills. Working with the system, the student must (5) *understand the problem space* as presented, (6) *understand the problems* to solve, and (7) try to *solve the problems and present solutions*. The system must (8) *evaluate each solution* and feed back evaluations of process and/or results, (9) *generalise evaluations* of performance in order to spot patterns of difficulty in the student's problem-solving, *and present its generalisations* together with suggested remedies for removing the observed patterns of difficulty. Remedies might include special sessions for solving problems of a certain kind or increasing the level of difficulty for successful students. (9) requires observation of the individual student online and building of a model of that student's performance based on the observations made. This process is, in principle, the same for all input modalities: (mouse or hand) pointing, spontaneous speech, free text, and so forth: The system evaluates inputs one-by-one, accumulates the evaluations, spots patterns, compares training/test results over time, updates the student model, and so forth, and uses the resulting information to guide learning based on recommendations from the teacher model.

Model Variations

Finally, some model variations shall be added. Some systems might (10) distinguish between (a) *training/learning sessions* and (b) *test sessions*, for example, making (a) more free-style with ample pedagogical feedback and (b) more formal with no pedagogical feedback but with performance

scoring that enables easy comparison between test sessions over time. Some might (11) *reverse the roles of student and teacher/trainer*, the student teaching the system how to, for example, solve equations or model an ecosystem, the system asking questions in the process (Biswas, Schwartz, Leelawong, & Vye, 2005). Another interesting perspective is (12) *multi-user* teaching/training systems where several students work together.

The model needs not be fully implemented for a system to be instructional. Flight simulators, for instance, are typically just that, mission presentation, system operation instructions, and process and result feedback evaluations being provided by human instructors. Rather, the model is an ideal model aimed to include all the functionality necessary for an instructional system to enable self-training unaided by human instruction.

WHEN (NOT) TO USE SPEECH IN INSTRUCTIONAL SYSTEMS

The fifth section listed factors to consider when specifying an instructional system. The sixth section described a model of the kinds of information to be exchanged at the user interface. This provides the background for asking when (not) to use speech and spoken dialogue in teaching and training systems, in which roles, and possibly combined with other input/output modalities. A *modality* is defined in modality theory as a *particular way* of representing information in some *physical medium*. Today, the three principal media used for interacting with computers, and the corresponding human senses, are: light/vision, acoustics/hearing, and haptics (mechanical contact)/touch (Bernsen, 2002).

Strengths and Weaknesses of the Speech Modality

Speech has several modality properties that make it well-suited as a main modality in instructional

interaction, which is why speech is being widely used by human instructors. Studies of speech in multimodal contexts show that these properties are, among others, as described in Bernsen (1997) and Bernsen and Dybkjær (1999):

- Speech is a natural human modality for (1) **situated discourse** in which situation- or context-dependent information is being exchanged rapidly and spontaneously between interlocutors, each of whom can take the initiative
- Speech, and language more generally, has (2) **very high expressive potential**, so that virtually any piece of information could, in principle, be expressed in speech
- Compared to written language that evolved for non-situated information exchange, speech is more expressive due to (3) the **richness of the acoustic signal** which conveys far more than linguistic content, including emphasis, emotion, attitude, urgency, and so forth
- An acoustic modality, and unlike graphics and haptics, speech is (4) **omni-directional**
- Cognitively, speech can be effectively understood and generated in most (5) **heads-up, hands-occupied** situations, such as in the flight simulator
- Speech has (6) **high saliency**, that is, is quite attention-catching

On the negative side, the high salience of speech (6) can become a source of distraction both for the student and others. Moreover:

- Speech, being (7) **temporal and transient**, does not offer the advantages of static modalities, such as static graphics or haptic text, of allowing students free perceptual inspection of the information conveyed. That is why we found that users prefer static typed text over speech when exchanging exact, high-complexity infor-

mation and discussion summaries, whereas their discussions were all spoken conversation (Bernsen & Dybkjær 2001)

- Speech is ill-suited for expressing (8) **highly specific and detailed spatial information** like the contents of images and spatial 3D scenes, or exact spatial locations. This is why many instructional systems use static and dynamic *output* graphics, such as images, data graphics, video, or virtual and augmented reality information presentation—to complement speech or otherwise. For *input*, this is why it is useful to combine pointing gesture and speech to enable users to point to objects and events instead of trying to explain their locations in speech. For similar reasons, speech input is mostly a poor replacement for (haptic) object manipulation by hand
- Speech input and/or output must be replaced by other modalities, for example, sign language or written text, if users are (9) **hard-of-hearing** or have **speech disabilities**

These speech modality properties contribute towards explaining why the problem space of instructional systems is often dominated by non-speech modalities. Among the benchmark systems, the pronunciation trainer combines speech input with “canned” output in a GUI environment; the medical patient interview and maths systems focus on static written text (property 7), the negotiation training and Andersen systems have spoken conversation at centre-stage together with animated interface agents as both systems explore situated human discourse and the latter explores combined speech/pointing gesture as well (properties 1, 3, 8), the flight simulator space is dominated by haptic input control and augmented-reality vision but has an auxiliary role for speech (4, 5, 6, 8), and the model teaching system spaces are dominated by various forms of text and output graphics (7, 8).

Increasingly, spoken dialogue applications include output *talking faces* or *embodied animated characters* (Cassell, Sullican, Prevost, & Churchill, 2000). From one point of view, this is natural because human speech forms part of comprehensive communicative acts which include facial expression, gaze, gesture, and more; from another, some argue that the animations contribute little to instructional interaction and waste screen real-estate better used for presenting instructional task-related information; in a third view, their presence adds to instructional interaction more of the personal and expressive aspects characterising human instruction. This is an ongoing debate (Ruttkay & Pelachaud, 2004). In some cases, the animated face or agent is key to the application, for example, the semi-transparent human head demonstrating vocal tract articulation for pronunciation training, when the embodied character acts as physical training instructor; or when students learn from conversation with a life-like person from another age.

Roles of Spoken Dialogue in Instructional Systems

What are the most important roles of spoken dialogue or conversation in problem-solving-oriented instructional contexts? Given the enormous diversity of potential applications, target user populations, and so forth, and the limited number of spoken multimodal instructional systems developed so far, the best approach may be to learn from the roles of spoken dialogue in human instruction.

The question may be refined by considering a limiting case. When a human instructor is present and speech is not replaced by alternative options for situated discourse, for example, sign language, spoken teacher-student dialogue becomes possible. Given the expressivity of spoken dialogue, teacher and student will almost unavoidably talk from time to time, asking, discussing, clarifying, helping, and so forth. However, a limiting case

in which spoken dialogue is unnecessary can be defined, that is, when the instructional task is completely *self-explanatory* to the target users. A system that comes close is the Baldi language tutor which uses Baldi's talking face to improve the vocabulary of autistic and hard-of-hearing children (Massaro, 2005). Roughly, Baldi shows a screenful of, say, vegetables in static graphics, names them, asks the child to click on, for example, the zucchini, praises or gives another try, asks about another static image, and so forth, and moves on to a new screen. Baldi actually speaks to the kids and so might a human instructor, but the point is that everything is so straightforward that spoken *dialogue* is rarely needed.

Taking self-explanatory instruction as a limiting case, it is proposed that spoken dialogue may be added to instructional interaction for three main purposes, that is:

- **Task-oriented dialogue** about the core teaching or training tasks, that is, when the student solves a problem in dialogue with the system, including system feedback on the problem-solving process or solution
- **Non-task-oriented conversation**, primarily when the problem space itself is one of complex spoken dialogue or conversation but also when, for example, other tasks and solutions are less clear-cut and require discussion
- **Meta-communication** about the interaction, including handling of miscommunication, help dialogue, introductory dialogue about instruction purpose, problem space, how to use the system, and so forth

SPOKEN DIALOGUE IN MULTIMODAL INSTRUCTIONAL SYSTEMS

The seventh section identified three main roles for spoken instructional dialogue. Based on these, how far we are in exploiting spoken dialogue for multi-

modal instruction is now illustrated and discussed. Task-oriented dialogue and task-transcending conversation, meta-communication, and spoken interaction and learning gain are discussed in the eighth section.

Spoken Dialogue in Task-Solving and for Conversation

Today, nearly all instructional systems that include spoken dialogue are task-oriented and use limited *mixed-initiative* dialogue. Fully *user-directed* dialogue (no system initiative) seems unsuited for instruction while purely *system-directed* dialogue prohibits any kind of spoken intervention by the student. Limited mixed-initiative is typically obtained by carefully crafting the system's dialogue as illustrated in Figures 3 through 8. An obvious question is why these systems do not allow free mixed-initiative like in human instruction. Some reasons are:

- Speech recognition errors
- Vocabulary and (semantic) grammar
- Task and domain delimitation

Spontaneous speech recognition is error-prone, for several reasons. One is lengthy input: the longer the input the more likely misrecognition becomes. Since free initiative may encourage long input, ways must be found to reduce input length to keep misrecognition tolerably low. This can be done by carefully crafting the system's output in order to control initiative and limit input length. The alternative is to impose use of fixed spoken keywords and phrases but this increases student learning overhead and is infeasible for all but quite small-vocabulary input.

Systems allowing spontaneous speech input are often challenged as regards the sufficiency of their vocabulary and grammar. The solution is to continuously collect user input data and bootstrap the system on this data until it performs satisfactorily. This may require considerable effort. The

Figure 3. Example from (Rickle et al. 2002)

Paco: So, we succeeded in stopping engine two.
Student: Ok.
Paco: You take it from here.
Student opens fuel valve one on engine one.
Paco: Good.
Student opens the bleed valve on engine one.
Paco: That was a correct action, but I wasn't expecting you to do it now.
Paco: Let's go back to opening the fuel valves on engine one.
Student opens fuel valve two on engine one.
Paco: Great.
Student presses the engage button on engine one.
Paco: Whoops, you can't do that yet.
Student: What next?
Paco (Pointing): Press the on button on engine one.
Student presses the on button on engine one.
Paco: Good.
Student: I think I should set the throttle speed.
Paco: Right.
Student: What should the speed be?
Paco: The speed should be stop.

Figure 4. Example from (Peters et al. 2004)

Tutor: Since you had some difficulty ordering boundaries around compartments, let's work through some drills.
Tutor: I will pick a couple compartments, and you answer the questions about boundaries for each one.
Tutor: Let's start some drills with primary boundaries, and then move on to the secondary boundaries.
Tutor: Let's assume there is a fire here, in 3-220-2-Q.
Tutor: What are the primary bulkheads you should use for setting boundaries on compartment 3-220-2-Q?
Student: Primary forward two two zero primary aft two five four.
Tutor: Great job. Those are both right.

Figure 5. Example from (Litman and Silliman, 2004)

ITSPOKE: I didn't understand. What force acts on all objects within close proximity to earth?
 Student: uh the force of gravity
 ITSPOKE: Fine. Besides the Earth's gravitational force, are there any other forces acting on the person, keys, and elevator after the release?
 Student: no
 ITSPOKE: Yep. Thus, keep in mind that after the release, the only force on the person, keys, and elevator is the force of gravity. If gravity is the only force acting on an object, will it be moving or staying still?
 Student: it will be moving

Figure 6. Example from (Forbes-Riley and Litman, 2006); hand annotated emotions in square brackets

Tutor: So, when you add forces together, besides the magnitudes of the forces, what must you also consider?
 Student: direct- direction (ASR: the truck in direction) [correct, uncertain, non-frustrated/angry]
 Tutor: Yes. [...] The vector sum of the forces acting on the body is also equal to the mass of the body multiplied by its acceleration. What is another term for the vector sum of forces acting on a body?
 Student: net force (ASR: net force) [correct, neutral, non-frustrated/angry]
 Tutor: That's super. Another term for the resultant force is the net force. In this relationship, what is the direction of the net force applied to a body and the direction of the body's acceleration?
 Student: same same same (ASR: seems same type seems) [correct, certain, frustrated/angry]

Figure 7. Example from (Traum et al. 2005)

C(aptain): Hello Doctor Perez.
 D(octor): Hello.
 C: I have orders to move this clinic to another location.
 D: You want to move the clinic?
 C: Yes
 DECREASES SOLIDARITY: captain endorses undesired act 'run-clinic-there'
 D: Look at these people!
 D: we need to help them.
 C: It is not safe here, we can't protect
 DECREASES CREDIBILITY: captain asserted unbelieved (but possible) state 'patients-unsafe-here' 'patients-unsafe-here' could be established by captain's act of 'planned-attack'
 D: Protect me? Protect me from what?
 D: Are you going to attack?
 C: Yes
 DECREASES SOLIDARITY: captain committed to perform undesired act 'planned-attack'

Figure 8. Example from (Bernsen and Dybkjær, 2005)

Child: what is your favourite fairytale?
 HCA: I like several of my fairytales very much. One of my favourites is the ugly duckling. The ugly duckling is not accepted by the other ducks and animals because it looks different. It has a hard time of suffering and troubles. Eventually it wishes only to die till it discovers that it is in fact a beautiful swan. The point is that if you are different then you will get bullied.
 Child: can you dance?
 HCA: Sorry
 Child: can you do the moonwalk?
 HCA: I am sorry but i still don't understand. Maybe you are talking about one of the many things i still don't know about
 Child: what games do you like to play?
 HCA: My favourite childhood game was to play theatre...

more open the domain is the more data is needed. Clear and clearly communicated task and domain delimitation is crucial, so that the student knows exactly what the system can and cannot conduct dialogue about. Inappropriate delimitation runs a high risk that users address out-of-domain issues, creating recognition and grammar problems (Bernsen et al., 1998). The system's last defence is meta-communication which is difficult to engineer and always disturbs dialogue smoothness (the eighth section).

Figures 3 through 8 show instructional dialogue engineering aimed at minimising interaction problems. System questions are typically closed either through explicitly listing the answers to choose among (e.g., last tutor output in Figure 5) or by inviting short specific answers (e.g., first tutor questions in Figures 4 and 5, second in Figure 6). If the output invites student *initiative*, the tacit assumption is that the system will remain in control. Thus, in Figure 3, Paco offers initiative with little risk because the answer involves haptic screen graphics action rather than complex oral explanation. The Figure 7 dialogue is higher-risk because it opens up towards conversation. There is still a task to solve, however, that is, to convince the doctor that he must move. Figure 8 goes further by showing real conversation with the fairytale author. Since there is no instructional task, the developers can only control student input by making the character try to gently constrain the domains and topics of conversation.

Smooth and cooperative dialogues are major goals in most task-oriented applications, instructional or otherwise. Student cooperativity can be taken for granted as long as the student wishes to learn and manages to find out what (not) to talk to the system about. However, good human instructors are not merely cooperative in an extended Gricean sense of being to-the-point, taking into account student's background knowledge, and so forth (Grice, 1975; Bernsen et al., 1996) but re-phrase and re-explain when needed, never leave the student behind, tune the level of diffi-

culty to the individual, and motivate and encourage even if the student has not got it yet. This is non-trivial pedagogical art even for human tutors. Evaluative feedback may be given in many different ways. It may be simple like the smiling or sad emoticon face for pronunciation training (Figure 2) which only reflects the quality of the most recent pronunciation, comment nicely on the most recent student action (Figure 3), or be general as in Figure 4 where the system explains why the student gets the next task. The Figure 7 system gives no explicit feedback on student performance. Rather, the performance measure is how willing to cooperate the doctor becomes.

Good instruction draws on many information sources, including awareness of students' cognitive and emotional states. Still in its infancy, multimodal emotion recognition and generation is a popular research area today. In the speech modality, prosody delivers cues to the speaker's emotional, cognitive, and volitional states, potentially informing the tutor that the student is uncertain, lost, frustrated, or saddened by repeated failure, compare the hand-annotations in Figure 6. Vocal expression of emotional state has been investigated for decades (Scherer, 2003). Among the problems in recognising emotions from speech is that emotions rarely come in a pure full-blown form (Batliner, Fischer, Huber, Spilker, & Nöth, 2003) but must be recognised through cues expressed not only prosodically but also linguistically. These cues may contribute to detecting trouble in human-computer dialogue (Batliner et al., 2003). Also in instructional systems, emotion detection is considered important and is actively being researched. For instance, studies indicate that student emotions of frustration and anger correlate with system performance, in particular speech recognition problems (Rotaru & Litman, 2006), and ongoing work addresses how student emotion can be automatically detected and used in tutoring dialogue (Ai, Litman, Forbes-Riley, Rotaru, Tetreault, & Purandare, 2006).

Cognitive modelling is another source of good instruction which manages to select the striking example, or the successful analogy, based on detailed understanding of the student's background knowledge and interests. Training of the social skill of seeing things from the other person's perspective and acting accordingly during negotiation is illustrated in Figure 7 which shows part of a dialogue-turning-bad between a military officer and a virtual doctor. The doctor includes substantial cognitive modelling based on negotiation theory. Regarding the cognitive aspects of student certainty and correctness which are particularly important to instructional systems, studies show that tutors respond differently to student certainty and uncertainty, respectively (Liscombe, Hirschberg, & Venditti, 2005), and that there is a correlation between uncertainty/incorrectness and recognition problems (Rotaru & Litman, 2006), which indicates the importance of asking questions at the right level of difficulty.

The factors mentioned are just some of those that will continue to challenge developers of spoken multimodal instructional systems and their components for a long time to come.

Spoken Dialogue for Meta-Communication

The third role for spoken dialogue is for meta-communication, or communication about the communication (interaction) itself, which may be required throughout an instructional session. Under meta-communication repetition, correction, clarification, help dialogue and everything to do with introducing the system, its instructional purpose and use are included. Some types of meta-communication are hard to cope with in today's spoken dialogue systems and better error recovery strategies are very much in demand (Bohus & Rudnicky, 2008).

User-requested repetition signals failure to hear or understand what the system said and can usually be handled with a vocabulary that covers

the ways in which users might phrase the request. However, understanding failure cannot always be remedied by verbatim repetition. This problem is better avoided through careful output design than resolved on-line. *System-requested repetition* is easy to do and may work if the request is due to simple recognition failure of words and concepts known to the system. However, verbatim user repetition will not work if the input is out-of-vocabulary, grammar, or domain. It remains hard for systems to make these distinctions, which is probably why, as remarked by McTear (2008), much spoken dialogue miscommunication research has focused on speech recognition rather than other error sources. For these other sources, more active strategies are needed, such as asking the user to re-phrase, asking a new question (first system turn, Figure 6) or, like in Figure 8, stepwise nudging the user to change topic or relinquish initiative.

In general, it is worse for the system to misunderstand the user than to fail to understand and ask for repetition or re-phrasing. The former often makes the system appear silly and the user may initiate correction dialogue which can be difficult to handle. Linguistically and conceptually, *correction input* is more diverse than repetition requests, and the system may have to relate the input to what was said several turns back. Moreover, as systems aspire to interpret new types of input information, such as student emotion, new sources of misunderstanding must be dealt with. *System-initiated correction* is ubiquitous in instructional discourse, compare Paco's turns 4 and 7 (Figure 3), and its non-meta-communication complement, confirmation, is well illustrated in Figures 3 through 6. In fact, constructive and motivating correction and confirmation design is a major part of instructional systems development. Figure 4 illustrates careful generalised corrective feedback design. Arguably, the main problem is to flexibly handle student input which is not quite right and not quite wrong either.

Clarification is typically a difficult kind of meta-communication dialogue. Clarification requests may require explanation of virtually anything mentioned during dialogue. The best strategy is to try to prevent user clarification requests by design, that is, by sticking to core-task, core-domain terminology, and explaining everything necessary before the student asks. However, this is easier said than done even when the system is being designed for students having well-defined prior knowledge and skills. Everybody can forget the meaning of some technical term but the system can easily make a nuisance of itself by explaining all technical terms as it goes along. Unless the user's potential clarification needs are obvious, this problem has no easy solution and becomes harder the less task-oriented the system is, the wider the domains it covers, and the less is known about the student population. Somehow, future systems must be aware of their own ignorance as illustrated in Figure 8. System requests for clarification are part-and-parcel of instructional discourse but remain hard to do. It is symptomatic that there are no examples in Figures 3 through 8.

Student *requests for help* may concern how to solve a task or operate a device or the system itself. General context-*independent* help is fairly easy to design and may be compared to what is found in GUI help menus. Context-*dependent* help is often more difficult because the task- or discourse context must be taken into account. In Figure 3, having been corrected, the student requests context-dependent help on how to continue from the present state. Since the task context is well-defined, all the system has to do is inform about the next correct action in the context. While help dialogue is generally useful, there is more hesitation in recommending spoken dialogue for introducing the system, its instructional purpose, and use. Speech is sub-optimal for lengthy and complex explanation and, since students typically use the system for a while, an electronic manual is often preferable.

Spoken Interaction and Learning Gain

Instruction is all about learning gain. One-to-one human tutoring seems to be very effective compared to classroom sessions. Although sophisticated instructional systems do not achieve the same learning gain as good human tutors, they seem to do better than classroom teaching (Graesser, Person, Lu, Jeon, & McDaniel, 2005).

Regarding the speech modality, it has been explored if speech recognition problems affect learning gain. Empirical studies have not been able to show negative effects on learning (Pon-Barry, Clark, Bratt, Schultz, & Peters, 2004; Litman & Forbes-Riley, 2005), although recognition problems may cause frustration and affect perceived usability and motivation to use the system.

The impact on learning gain of spoken output quality, including pre-recorded human speech versus synthetic speech, has been investigated by Forbes-Riley, Litman, Silliman, and Tetreault (2006) in the context of ITSPOKE (the third section). Learning gain was not influenced by voice quality but this may be due to the fact that the spoken text was also displayed on-screen. This question seems to require more investigation. However, as synthetic voices improve, any negative effects are likely to disappear anyway.

Also the comparative question of learning gain with spoken versus typed text interaction remains an open one (Pon-Barry et al., 2004). A study by Litman et al. (2006) suggests higher learning gain for spoken human-human tutoring compared to written interaction whereas results for human-computer tutoring are less clear.

Learning gain is probably also strongly related to teaching strategy. Aiming at instructional systems, various studies of human tutoring address what makes a good teacher and which factors influence learning gain. Nevertheless, it remains an open question whether instructional systems should behave in the same ways as human teachers do. Thus, du Boulay and Luckin (2001) review

comparisons of human and computer tutors and of teaching strategies, such as the Socratic approach, and including, for example, how to deal with errors and how to provide feedback. Some examples of what has been investigated are: Jackson, Person, and Graesser (2004) examined the relationship between dialogue moves and student learning using AutoTutor (the third section). In line with previous research, they found that students who received more pumps and hints and played the active part in knowledge construction learned more than those who received more prompts and assertions from a tutor who controlled knowledge construction. Core, Moore, and Zinn (2003) looked at initiative using two different teaching strategies and, somewhat surprisingly, found that there is no direct relationship between initiative and learning.

CONCLUSION

Commercial spoken multimodal instructional systems are still rather few, and systems using spoken dialogue in some role or other are fewer still. This no doubt reflects the more general fact that *spontaneous speech* dialogue systems have entered the market only recently, where they are being used to help solve limited tasks of various (non-instructional) kinds. Arguably, most instructional systems which include spoken dialogue, will have to handle spontaneous spoken input because it is unrealistic to demand that students learn and remember lengthy sets of fixed keywords and phrases whilst engaged in learning or training things that are difficult enough in themselves. However, with spontaneous speech dialogue systems having entered the market, the technology would seem likely to spread across a wide range of application areas, including instructional systems.

The research systems that have been seen provide a useful indication of how far we are. With the technologies illustrated in Figures 3 through 8, it is possible, today, to build useful spontaneous speech, mixed-initiative, multimodal or unimodal

teaching, and training systems for many different purposes. Today's research systems are typically sufficiently rich in content to allow realistic training or teaching but rarely have the robustness required of commercial systems.

However, several factors seem likely to slow down the proliferation of spontaneous spoken multimodal instructional systems in the near future.

One such factor is speech recognition technology. Recognisers sometimes misrecognise and, although this may not influence learning gain, it is known to cause frustration. Thus, companies might be cautious launching applications which include spontaneous speech dialogue. The first computer games with spoken input have not received unanimous acclaim partly because of recognition errors, and the car industry keeps launching spoken keyword-based navigation and other systems rather than spontaneous speech technology. Another factor which was elaborated in in the fourth section is that adding spontaneous spoken dialogue to instructional systems has relatively high entry costs for researchers and industrial developers alike. The family of technologies required include several components which are poorly standardised as well as being rich in application-specific contents, both of which factors contribute to making development expensive and risky. Thirdly, the market is not necessarily willing to pay a lot for the great opportunity to improve everyone's skills and knowledge through self-training and self-teaching supported by the kinds of spoken dialogue which are ubiquitous in human instruction.

FUTURE RESEARCH DIRECTIONS

It has been argued that the technologies already exist for including spoken dialogue in a wide range of multimodal instructional systems. To see why the research challenges ahead remain massive, five main reasons why there is still a way to go

before system instructors can replace good human instructors have been pointed out.

1. Most current spoken dialogue instructional systems address knowledge and skills for which it is relatively easy to determine if the student's problem solving process and/or result is correct. The demands on the system's spoken dialogue capabilities are likely to increase strongly with more open-ended systems where there is no single correct answer and discussion and argumentation is key.
2. Large-domain "real" conversation, as opposed to more or less tightly constrained and primarily system-directed, task-oriented spoken dialogue, is challenged but not conquered by the Andersen system (Figure 8). Human-human conversation follows a multitude of often subtle and sub-consciously practiced principles many of which still have to be demonstrated in running applications.
3. The negotiation trainer (Figure 7) illustrates the tip of another iceberg, that is, that of emulating human communicative cognition, emotion, and volition as it works as an integrated whole, often sub-consciously, during dialogue and conversation.
4. To a larger or smaller extent, human instructors rely on *vision* for watching student task performance, facial expression, gaze, and so forth. The problems still facing machine vision research imply that most instructional systems must manage without emulating most aspects of human vision for some time to come.
5. Even if it may appear simple to enable natural multimodal student input using, for example, speech and 2D (surface) or 3D pointing gesture, this is not the case. The complexity of the multimodal fusion tasks that humans effortlessly accomplish are only now being discovered (Martin et al., 2006).

Chapter 3.5

Applying the ADDIE Model to Online Instruction

Kaye Shelton

Dallas Baptist University, USA

George Saltsman

Abilene Christian University, USA

ABSTRACT

This chapter assembles best ideas and practices from successful online instructors and recent literature. Suggestions include strategies for online class design, syllabus development, and online class facilitation, which provide successful tips for both new and experienced online instructors. This chapter also incorporates additional ideas, tips, and tricks gathered since the paper was originally published in the October 2004 issues of the *International Journal of Instructional Technology and Distance Learning* as “Tips and Tricks for Teaching Online: How to Teach Like a Pro!”

DOI: 10.4018/978-1-60960-503-2.ch305

INTRODUCTION

Online education has quickly become a widespread and accepted mode of instruction among higher education institutions throughout the world. Although many faculty who teach traditional courses now embrace some teaching methods popularized by online education such as incorporating online quizzes and discussion boards, some instructors may still feel intimidated when asked to develop a course offered entirely online. Even the best lecturers may find that teaching online leads to feelings of inadequacy and being ill-prepared. While providing training, offering tools for ePedagogy, and sharing success stories are good ways to build faculty confidence, solid

instructional course design is still a necessary process for quality online instruction.

The ADDIE model, described by Molenda (2003) as “a colloquial term used to describe a systematic approach to instructional development, virtually synonymous with instructional systems development” (p. 34), is a generic instructional design model that provides an organized process for developing instructional materials. This systematic model is a five-step process that can be used for both traditional and online instruction. The five steps, analysis, design, develop, implement, and evaluate, provide an ideal framework to discuss solid instructional design techniques for online education. In addition to this discussion, this manuscript offers tips and tricks for designing and teaching an online course, gathered from conversations and interviews with online instructors, current literature, conference presentations, and the authors’ personal experiences as distance educators.

ANALYSIS

The analysis phase, though one of the most essential in the ADDIE model, is often overlooked. Like any significant project, excitement to get started often overtakes methodical planning, and the eagerness to see the finished results can put relevancy and quality at risk. Undertaking something as involved as developing an online course demands careful analysis. For the purpose of this book, we divided the phase into three segments: analysis of the learners, analysis of the course (including its goals and learning objectives), and analysis of the online delivery medium.

Analysis of the Learners

In this part of the analysis phase, the course designer or design team should perform an audience analysis to provide focus on the learners, their needs, and their learning preferences. In

Figure 1. The ADDIE model

fact, Olgren (1998) reminds us that “if learning is the goal of education, then knowledge about how people learn should be a central ingredient in course design” (p. 77). The course developer should examine ways in which online learners are similar to learners in traditionally offered courses and how they are different as this also leads to an understanding of audience needs within the course. As far as demographics, Gilbert (2001) describes a typical online student as being over 25, employed, a caregiver, and already with some amount of higher education experience (p. 74). However, the demographics are changing at many institutions as more online courses are being offered and traditional full-time students are electing to take online courses as part of their regular course load. Therefore, both andragogical (adult learning theory) and pedagogical methods of course design as well as some mix of experiential, problem-based, and constructivist approaches to learning should be considered.

Students enrolled in online courses often have different expectations than when enrolled in traditional courses. These expectations, described by Lansdell (2001), include increased levels of feedback, increased attention, and additional resources to help them learn (as cited by VanSickle, 2003). In response to meeting these expectations, alternative methods of instruction and class facilitation have evolved to support student cohesiveness and

encourage learning. To successfully challenge the online student, increased communication is required between instructor and student (White, 2000). While much of that communication is created in the later phases of the ADDIE model, a careful analysis of the required communication elements will ensure that the intended communication is on target and appropriate for the audience at hand.

Analysis of the Course

In most cases, online courses are not new to the institutional curriculum but existing courses which are being created for a new medium. Therefore, course goals and learning objectives already exist and may not need modification. However, since the course developer will be, in essence, recreating the course from the ground up, the course developer should review the learning objectives for the course and how that relates to other courses and the overall program curriculum. A working knowledge of the goals and objectives is a must as these will be the guiding principles for all content creation.

The course developer should seek answers to the following questions: Why does this course exist? What does it seek to accomplish? Who is the course for? What are the learning objectives? In what ways does this course fulfill degree requirements? The answers to these questions provide the proper perspective in the following instructional design phases as well as provide a working set of priorities to be used in course design and development.

Analysis of the Online Delivery Medium

Online courses, being a relatively new medium of instruction, have yet to achieve a universally understood definition. It is helpful for the course developer and others involved in formulating a working definition of online delivery. For example,

for the authors, online delivery is assumed to have the following characteristics:

- The course is held online during a regularly defined class semester or quarter or an established amount of weeks.
- The course is broken up into separate learning modules.
- Student participation is required within a set time period—each content module is presented with a given start and end time.
- Learning takes place as students synthesize the prepared material and interact in class discussions with peers and the instructor(s) within the required time period described above.

Online course delivery offers exciting possibilities, as well as frustrating limitations. Without an analysis of the delivery medium, the online course can result in what Fraser (1998) calls “shovelware”—content that is simply moved from one medium to another without regard for the capabilities of that medium. To fully understand the concept, consider Fraser’s (1999) analogy: “When the motion picture was invented, early practitioners saw it primarily as a means of distributing existing material, such as stage performances. It was some time before movies were recognized as a new medium with expressive possibilities, which while overlapping existing media, went far beyond anything previously attainable” (p. B8). Could you imagine Star Wars as a stage performance? Just as film transformed storytelling, online education is reshaping education.

DESIGN

The design phase begins to organize strategies and goals that were formulated in the analysis phase. It also provides details which enhance the course delivery process. Brewer, DeJonge, and Stout (2001) found that course planning and prepara-

tion directly influences course effectiveness and really hinder student learning.

Before designing an online course, it is helpful for instructors to view existing courses already offered online. Not only does this familiarize the course developer with the basic components of an online course, it usually inspires ideas that generate excitement about the design process. A Web search can find open examples, but may be limited since most courses are located within password protected courseware management systems. However, there are two open initiatives which can be readily accessed: the MIT's Open Courseware (ocw.mit.edu) and Carnegie Mellon's Open Learning Initiative (www.cmu.edu/oli); both Websites offer many courses in various disciplines that can help instructors with their own course design. A third, The University of California Berkeley, provides online material in the form of Webcasts and enhanced podcasts (<http://Webcast.berkeley.edu/courses>).

The design phase is most analogous to that of the creation of a blueprint, a plan for construction that helps guide all involved toward the intended outcome. For online instruction, that blueprint is the course syllabus. The syllabus is the heart of the design phase; careful preparation of the syllabus prepares the learning environment and discourages confusion and miscommunication. For this phase, the major components are examined within the framework of a typical online course syllabus.

Ko and Rossen (2004) relate the syllabus to a course contract and observe that new online instructors do not usually include enough information. McIsaac and Craft (2003) term the syllabus as the roadmap for the course and remind us that students will be frustrated if they try to work ahead only to find out the syllabus has changed within the course. They suggest having a structured syllabus available before the course starts so students can be prepared for course expectations.

Within the syllabus, student expectations should be clearly defined along with well-written directions relating to course activities. These

expectations should be stated in the opening orientation material as well as in the course syllabus. Preparation includes clear definitions of the following within the syllabus: contact information, course objectives, attendance requirements, a late work policy, the course schedule, orientation aids, grading scales and rubrics, communication practices, technology policies and overall course design.

Contact Information

The syllabus should include administrative information such as available office times, phone number and e-mail address, and preferred mode(s) of contacts. However, unlike a traditional course, instructors should be very clear about "online office hours," or hours of unavailability. Boettcher and Conrad (1999) suggest an online instructor not be available 24 hours a day to students, but establish a framework for turnaround response. This framework should offer recommendations for how long a student should expect to wait before repeating an e-mail request that has gone unanswered and as Jarmon (1999) suggests, how quickly students should expect a response.

If there is a specific time when the instructor will be online, he or she should include a "fastback" time, or online office hours. A fastback time is a time period when students can expect a quicker than normal e-mail response, usually within the hour or soon after the message is received. Many instructors offer online office hours where they enter the class chatroom and wait for questions. It is often reported by instructors that students under-utilize this time of interaction, choosing to send e-mail as their questions arise, rather than waiting until a prescribed time in the future.

An alternative to using the virtual office hour for questions is to use the chatroom for social conversation. A virtual social experience helps create a closer bond with instructor and classmates, and strengthens the learning community. This is a form of a "cyber sandbox" as described

by Palloff and Pratt (1999). The cyber sandbox is defined as a generic discussion area for students to just hang out and talk about movies, jobs or other interests. The creation of a social outlet not only helps keep regular class discussions on topic, but Palloff and Pratt (1999) found that the social connection promotes group cohesion.

Course Objectives

Well-defined course objectives, derived from the analysis phase, are an important element to be published in any course syllabus. However, clearly stated objectives are even more imperative as students do not have the opportunity to participate in “first day of class syllabus discussions” so common in many traditional courses (Jarmon, 1999). The communication of course objectives is also important because in an online course, much of the responsibility for learning is placed upon the student. Failure to properly inform the student of the objectives leaves them feeling confused and puzzled about assignments, and moreover, where the entire course is headed.

Attendance Requirements

Attendance requirements should be clearly stated, as attendance is necessary for successful online learning communities. Palloff and Pratt (2001) advise, “If clear guidelines are not presented, students can become confused and disorganized and the learning process will suffer” (p. 28). The online learning community requires students to take active roles in helping each other learn (Boettcher & Conrad, 1999). Students who do not participate not only cheat themselves, but also those in the learning community.

If instructors expect good participation, then the requirements must be clearly defined. Ko and Rossen (2004) observed that when students were not graded, their participation was less than adequate. In fact, some students may think that if they take an online course, they can take a vaca-

tion and still catch up with their coursework upon their return or do a few modules ahead of time before they leave. While online courses do allow for flexibility, students must participate regularly with their instructor and classmates. Students may ask if they can post ahead of the other students or take the course on a self-paced schedule. Because of the prevalence of this question, online instructors should have a policy regarding early posting and state it clearly in the syllabus.

Participation in online courses is inherently different from traditional courses. Students do not automatically understand how to participate in online courses. Course participation requirements should be defined in the syllabus and with each assignment. Where possible, assignments should be grouped into familiar categories such as class discussion, Web searches, quizzes, reading assignments, and so forth. Creating a sample discussion, or model, may increase students’ understanding of the participation requirement and how credit is assigned.

Late Work Policy

A policy for late assignment submissions and missed exams should be created. Students who are not actively participating in the learning community are not supporting other students. Because of this interdependence, some instructors have a “no late work accepted policy,” while others assign reduced credit. Another option is to create alternative assignments or exams for past due work. To facilitate course management, these alternative assignments could be offered at the end of the course for those who missed assignments during the normal time period.

Course Schedule

One of the most important elements of an online syllabus is the course schedule. The course schedule defines each learning module with beginning dates and due dates, assigned read-

ing, assessment, and other activities. The course schedule becomes the course map for the student and should be included with the course syllabus and placed redundantly throughout the course. In fact, Ko and Rossen (2004) assert that “in an online environment, redundancy is often better than elegant succinctness” (p.76). If the Website or course management system allows linking from the syllabus, then link each course content module to the schedule making it readily available to the student. Students should be encouraged to print out and carefully follow their course schedules. Similarly, Johnson (2003) suggests that instructors should also “keep a schedule of activities for themselves: when to interact with students, when to respond to questions, when to grade assignments, and when to give feedback on performance” (p. 112).

The instructor should allow for flexibility and revisions of the schedule based on the progress and needs of the class but should avoid adding additional assignments not covered in the course syllabus. Careful consideration of course assignments should be given before the course starts to be sure that students meet the required learning objectives (Table 1).

Orientation Aids

Orientation notes for success in the class should be available for the student (Jarmon, 1999). This may include hints for time management and

good study practice. Frequently asked questions (FAQ) support self-help in answering questions (Jarmon, 1999) as it allows students to look for information before e-mailing the instructor. In fact, McCormack and Jones (1998) suggest an FAQ can significantly reduce questions. One doesn’t need all the questions or answers up front, as over time as questions arise and answers are provided, a comprehensive FAQ will emerge that can be utilized in future semesters.

Grading Scales/Rubrics

Grading scales and rubrics should be defined for each assignment. If the courseware management system allows, each assignment could be linked to the rubric for clarity. When group assignments are utilized, instructors should use a grading rubric for the students to grade each other as well as the entire group. This motivates students to participate and provides for equity in group work grading. It is also helpful if the instructor assigns groups or teams the first time as the class should get to know each other before self-selection is allowed.

Communication Practices

An inbox consistently full of e-mail will be overwhelming to most instructors. Therefore, it is important to include in the syllabus, guidelines for class behavior and posting to the discussion boards, e-mail protocols, and assignment submis-

Table 1. Sample online course schedule

Sample Online Course Schedule				
Session	Date Begins	Content	Assignments	Due Date
1	January 15	Chapter 1 of text	Post Introductions to Class Discussion	January 21
2	January 22	Chapters 2-3 of text	Class Discussion	January 28
3	January 29	Chapter 4 of text	Class Discussion	February 4
			Outside Reading Summary	
			Review for Exam	
4	February 5	Exam I over Chapters 1-4	Exam I open 3 days only Feb 11-13	February 13

sion procedures. Establishing e-mail protocols and communication guidelines will assist the instructor in classroom management. Many instructors require the course session number or identifier in the subject line so that the e-mail related to the course can be filtered to a separate mailbox. If students need immediate attention, the word “Help” should be placed into the subject line so the instructor knows to open that e-mail first, assuring prompt instructor response.

Many instructors create individual e-mail sub-folders for each online student. E-mail that has been answered or graded can be filed away, providing for a record of all course correspondence. Another tip for instructors is to read their mail backwards from newest received to oldest. In many cases, students have solved their problems so that earlier questions become irrelevant. Students may also be asked to use their institutional e-mail address so that instructors are not confused by address changes mid-term or are forced to deal with bounced mail from full inboxes.

Technology Policies

Technology policies should be stated in the syllabus directing students to a helpdesk or resource other than the instructor for technology difficulties. Additionally, instructors should encourage students to create draft postings of assignments in a word processor and save them before posting to the class. This will minimize spelling and grammar mistakes and provide a backup copy for the student in case of technical problems. Students should also be reminded to save all work on a computer hard drive and to a removable device, such as a floppy disk or USB flash drive. Saving work to a USB drive allows the student portability between home, office, and campus systems, and a chance of recovery if systems go down. Finally, students should be instructed to monitor spam filters that may prohibit them from receiving their online course e-mail.

Course Design

The online course design should provide an intuitive navigation path for the student. Students should be able to locate the syllabus, calendar, assignments, and other required activities quickly. Individual content items can be easily identified for the student by adding a consistent icon each time it is used. For example, each time a reading assignment is presented, an icon of a book could be used. Using the same colors and design for similar items will aid the student as well. As a final suggestion, each module of content should have an overview page for organizing the unit of material (Hirumi, 2003).

DEVELOPMENT

Development is a rewarding phase in that the results are concrete and visible. The development stage will include a review of the course objectives, an analysis of the textbook, content module development and content chunking, the creation of content, the development of learning objects, student assessment and additional resources. As a side note, development is also a stage where faculty members may be the most dependent upon outside assistance due to the skilled creation of graphical and multimedia elements commonly found in online courses. In every other stage, even though coaching and mentoring are highly recommended, faculty are usually capable of completing the requirements alone and with skills that are already within their repertoire.

Course Objectives

The online course objectives should be clearly identified within the analysis phase and built into the syllabus in the design phase, and now robustly used to guide the course developer during the development stage. Each lesson unit should be designed with the overall course objectives

in mind and the objectives should be stated at the beginning of each lesson unit informing the student of the content to be covered. The learning outcomes of the lesson unit should also match the course objectives and appropriate degree objectives, where applicable. Methodologies for assessing these objectives can be altered for the online classroom. If any activities such as the use of online group collaboration or asynchronous class discussion will be needed to meet course objectives, they should be identified in this phase.

Textbook

The textbook is an important asset for an online course. The instructor should examine the text from the perspective of online delivery and understand that in most cases, the text will be a primary source for content delivery. The text should be a strong, stand-alone resource for the course and ideally offer ancillary support for the student such as Website links and review quizzes. In many cases, textbooks will provide additional resources for both faculty and students. Textbooks that offer the instructor assistance in the form of a CD-ROM, test bank, lecture outlines, PowerPoint slides, or Website material give added support in creating an online course. Some textbooks published by Prentice Hall, Irwin-McGraw Hill, and others, offer these licensed resources free-of-charge should the instructor adopt the text. Other textbooks offer course cartridges of content that import directly into courseware management systems like Blackboard or WebCT.

Instructors are sometimes reluctant, when transitioning a course from traditional to online, to adopt a new textbook, but if the result is easier course conversion, they usually concur. The course text book should be chosen early enough in the process for the instructor to become familiar with the contents of the textbook, and, of course, should support the core objectives of the course. Changes in the text may require extensive changes in the supporting course content. Additionally, if

the instructor should decide to change textbooks, all of the publishers' licensed or copyrighted material must be removed from the course and replaced with content from the new text or from other sources. It is advisable to clearly document each resource with its original source so that it can be easily found should it need to be removed down the line.

Lesson or Module Unit

When designing the course schedule, the course should be broken into lesson units. These are often one-week periods, but can be shorter or longer, depending upon the course. Ideally, a good lesson unit has many parts such as introduction, session objectives, reading assignments, instructional content, handouts, class discussion, written assignments, quizzes and exams, and a unit summary.

The flow of the course should be intuitive, transitioning from week-to-week, or session-to-session without the student feeling lost or isolated in the process. The total number of sessions in the course has a great impact on the course design. Just adding or eliminating as few as two sessions can lead to total course redesign. If the number of course sessions changes often, consider using smaller content chunks (see "Content Chunking") that can be combined into a single unit. Redundancy of key course information is important.

Each learning module should contain a checklist to facilitate student completion. This should be "print ready" so that students can print and read them offline. Course content that presents an easy-to-find and understandable checklist will save numerous e-mails later from students inquiring about due dates and pleading for deadline extensions.

Content Chunking

Content chunking is more of an instructional design process, rather than a theory. It uses modular design in the delivery of online content. Each

“chunk” of material is broken into small, understandable lessons or vignettes for the students to absorb. An example of chunking would be to break apart a lecture (that would amount to five written pages for example) covering several topics into smaller pieces (perhaps one or two pages each). The entire lecture, if left un-chunked, would be a tedious Webpage to scroll through, and more importantly, too much information to absorb in one session. Instead, the concept of content chunking would break the lecture into perhaps five or six smaller concepts. When a lecture is broken into topics or ideas and put on separate pages, research shows the student is more likely to understand the content. In the online format, students can navigate through the session exercising personal preferences; for example, to skip the lecture and take the quiz first. It is to their best benefit if the content is organized and easy to move through logically.

Quality course content should be a constant concern for the institution. Course content contributes highly to the success of students and the online education program. Course content can be obtained from several methods such as purchasing from peer institutions or for-profit entities. However, most of the pioneering institutions in online education use internal sources for content creation.

Content Creation

Using rich media such as online graphical models and video can be impressive but is time consuming and expensive. Text-based content is easy to create, but cumbersome for the student to read, especially if it cannot be printed. Often, online students will print out the lectures and highlight or mark the text as they read; therefore, text-based lectures should be designed with this in mind.

Some institutions have created a style guide for the development of online courses. A style guide recommends colors, font styles, icon usage, and the placement of certain institutional information

in each of the courses. This consistency throughout the program conveys institutional ownership and endorsement of the courses and the materials in these courses. More importantly, it allows students to find the material they are looking for quickly and without unnecessary inquiries to the course instructor.

Along with the guidelines for a consistent look and feel, the style guide may also suggest the format in which the course material is presented. The institution often recommends an instructional design theory for the creation of course materials and publishes this in the style guide along with examples. When students are presented with a familiar learning unit layout, they are more able to focus on the content and learning objectives, which should increase student learning.

Learning Objects

In regard to online learning objects and interactive learning elements, there are three options: buy, borrow, or build with the latter consuming the most of this section. Should a faculty member elect to buy or borrow an element, module or course, there are many choices now readily available. While they may not be *exactly* what the faculty member had in mind from the analysis and Design stages, textbook publishers and online content brokers offer many choices, although some disciplines may be better represented than others. In the borrow category, learning object repositories such as MERLOT and Wisc-Online provide the course designer with peer-reviewed modules and most are free.

So what exactly are learning objects? According to the IEEE Learning Standards Committee (2001), a learning object is “any entity, digital or non-digital, which can be used, re-used or referenced during technology-supported learning.” Many free resources for learning objects are available online, or learning objects can be developed specifically for each course. The following is a list of repositories:

- Apple Learning Interchange: <http://ali.apple.com/ali/resources.shtml>
- Campus Alberta Repository of Educational Objects: <http://www.careo.ca/>
- The Connexions Project at Rice University: <http://cnx.rice.edu>
- Multimedia Educational Resource for Learning and Online Teaching (MERLOT): <http://www.merlot.org>
- Wisc-Online Learning Object Project: <http://www.wisconline.org>

For many faculty, the choice to build from scratch is the option they elect to exercise frequently. The creation is often team-based, where one or more instructors partner with one or more instructional designers and/or graphical designers. Team-based approaches help alleviate the need for support by spreading the burden across multiple individuals with multiple talents. Team-based courses can also allow for improved course content and more complete materials due to the broader range of expertise and experiences from multiple individuals.

Assessment

The distance element of online education adds a unique twist to assessment of student learning. The online platform and ubiquity of technology among students affords the course developer a host of electronic tools. Online assessment tools are usually provided with a courseware management system as well as commercial vendors such as:

- **Questionmark:** Questionmark Perception (<http://www.questionmark.com>)
- **Respondus:** Respondus (<http://www.respondus.com/>)
- **Software Secure:** Securexam (<http://www.softwaresecure.com/>)

These vendors support high stakes testing with products that do not allow students to print exams

or open additional browser windows; however, there are many ways around these safeguards such as secondary computers, digital cameras, and countless other ways to beat the system.

Obviously, the proctored testing environment provided by having all the students in a single location under the direct supervision of the course instructor is difficult to duplicate online. Some institutions, especially those with local audiences, still require on-campus proctoring of exams or work with institutions within testing consortia to provide such services. While this is an option, it does not really fit within the ideal of a completely online and time-flexible course. Therefore, many course developers have looked for alternative assessments and opportunities to examine student learning with alternatives to traditional testing methodologies. One suggested method is called authentic assessment which is defined as “a form of assessment in which students are asked to perform real-world tasks that demonstrate meaningful application of essential knowledge and skills” (Mueller, 2006). This method works exceptionally well in online environments and should be considered whenever possible. A good resource can be found at jonathan.mueller.faculty.noctrl.edu/toolbox/Index.htm.

Provision of the grading rubrics used for scoring assessments within the course material is also highly recommended. Students should be aware of grading criteria and allowed to self-evaluate wherever possible. One commendable practice is to have student pre-score their work and submit their assessment along with their work at the time of submission. This allows the faculty member to focus discussion on points of disagreement, helping guide students to better critical evaluation and awareness of their own work.

Additional Resources

In the connected world of the Internet, outside resources are easily built-in to the course. Linking to Websites and online resources is obvious. Other

resources, such as library resources, online reserve materials, and institutional support resources such as a writing center and tutoring centers provide students with just-in-time resources and referrals. Even referrals and links to technical support and helpdesk resources may be provided to the students where course developers anticipate certain technical tasks might prove challenging to students.

IMPLEMENTATION

The next phase, implementation, includes opening the course and initiating instruction. An enthusiastic and engaging opening week of class is a great way to start the course. This time period is fragile; disruptions or unnecessary interferences may set a tone that stifles learning for the remainder of the course. It is important to create an initial impression that will stimulate the development of the learning community and nurture the students to maturity. Hirumi (2003) suggests the following goals for students in the first week of the course:

- Have a good understanding of course requirements and expectations,
- Can locate and interpret relevant policies and procedures,
- Are confident in their ability to use various tools and course features, and
- Can identify challenges associated with and discuss strategies for facilitating virtual teamwork” (p. 87).

The course should begin with a welcoming e-mail and announcement, instructions for class-wide introductions, emphasis on the syllabus, a tone of excellence established, and nurturing the learning community.

Welcome E-Mail and Announcement

Moore, Winograd and Lange (2001) offer several tips for the first session of class: send a welcome

e-mail that invites the students to join the class, telephone students who do not appear the first week, and duplicate your welcome e-mail in a class announcement if the course management system allows. The announcement should also encourage students to regularly check their e-mail. The first week should have fewer assignments to allow students to post introductions and get to know each other. Technical issues should be resolved immediately.

Introductions

The instructor should spend time getting to know the students individually during the first week of class and encourage students to do the same. An introductory discussion inviting the participants to share something in particular with the group is a successful strategy for building learning community. The instructor should participate heavily in this discussion (being careful not to dominate) and should respond to one or two comments in each student’s introductory posting. Ko and Rossen (2004) suggest the “initial postings in the discussion forum, your first messages sent to all by e-mail or listserv, or the greeting you post on your course home page will do much to set the tone and expectations for your course. These ‘first words’ can also provide models of online communication for your students” (p. 189). To assist with personal connection, the instructor should print out the introductory discussion and keep it near the computer for reference. When responding to a student’s question, the instructor should occasionally refer to the discussion and reference a personal note to the student such as “How is your son who plays college baseball doing this season?” The discussion following the question, leads the student to feel as though he or she is talking one-on-one with the instructor.

Offering an icebreaker in the first session, such as “share your silliest moment in college” or “name the animal you most identify with,” helps to alleviate nervousness and provides insights to

the fellow students' personalities. Several good icebreakers that also provide an instructor with student information include the VARK learning styles (<http://www.vark-learn.com/english/index.asp>) and the Keirsey temperament sorter (<http://www.keirsey.com>). The Kingdomality profiler (<http://www.kingdomality.com>) provides not only a medieval vocational assessment, but is fun and generates discussion. Each of these Websites offers instant feedback, and the students can post their results and a short paragraph whether they agree or disagree. Many other Websites allow students to discover their commonalities and similarities and can be found with a simple Internet search.

Emphasize the Syllabus

A great tip for the first class session is to create a syllabus quiz or scavenger hunt that “teaches students how to navigate your course” (Schweizer, 1999, p. 11). Next, offering bonus points to assess syllabus comprehension is a successful way of engaging the student in the first class session. Encouraging students to review the syllabus more thoroughly can alleviate confusion later in the course as they familiarize themselves with the course requirements. For example, an art appreciation course requires outside visits to an art museum. This requirement is clearly listed in the syllabus; however, students sometimes want to visit a Web museum instead. This is type of question should be clarified with a syllabus quiz to alleviate any disappointment, confusion, or scheduling conflicts.

Establish a Tone of Excellence

The first several weeks also set the tone for academic participation. Instructors should grade discussions/assignments stringently in the first few assignment cycles. Establish a tone of excellence early and encourage students to do their best. “Students want to receive timely and personal feedback” (Boettcher & Conrad, 1999, p. 97) early

in the course because they may not be able to assess their progress as easily online (Boaz, 1999).

Nurturing the Learning Community.

As the course progresses, the learning community will still require nurturing from the instructor. A learning community becomes self-sufficient when an instructor provides ample communication, facilitates the discussion board, treats each student as an individual, adds emotion and belonging, responds quickly to questions, models required behavior, creates appropriately sized groups, and clearly outlines expectations for group activities.

Provide Ample Communication

Online students are eager for communication as it is “the foundation of successful distance learning courses” (Johnson, 2003, p. 113). In fact, Johnson (2003) also suggests that communication throughout the course “must be ongoing, regular, continuous, and easy” (Johnson, 2003, p. 113). Lack of instructor-student communication early on will create a negative learning community, thus debilitating the learning process. Instructors should use class-wide announcements, group e-mails, and chat archives to facilitate accessible, public communication in the online course. As the course continues, students should be encouraged to facilitate the discussion and assume some of the roles previously controlled by the instructor.

Communication must be both reflective and proactive. Many courses use class-wide journals or summaries to bring closure to modules. Sending out class-wide summation, introduction, and transitional e-mails at the end of each module, wrapping up the previous content, and introducing the next module provides for a sense of transition. Reminding the students of requirements for the current module, such as projects or exam dates, is helpful to the students and it only takes about 10 minutes a week for either of these tasks. Proactive communication yields fewer questions,

saving dozens of hours answering the questions individually. Johnson (2003) recommends that students should be taught to communicate early any questions or confusion they may have due to the lack of body language available in the online environment. Instructors cannot see looks of confusion or frustration.

Instructors should keep their interaction with the class as accessible as possible. Using the “Course Announcement” area frequently for reminders and duplicating important information in e-mails will increase open communication and provide the entire class access to the information. It is also important to communicate to students each time grades are posted. This creates a “don’t call me, I’ll call you” communication pattern for grade information and alleviates individual e-mails from students requesting grades on their assignments. Students will quickly realize the instructor will post a notification when grades are posted, so requests are unnecessary. Within that communication, students should be reminded to contact the instructor if they notice a missing grade. This places the responsibility back with the student for finding and submitting any missing work.

Facilitate the Discussion Board

Bischoff (2000) reminds us that “the key to online education’s effectiveness lies in large part with the facilitator” (p. 58). Likewise, for class discussion to be successful, the instructor should become a facilitator and review discussions without controlling them. Many online instructors have found that too much activity can be as harmful as none at all. This particular role of the facilitator in the online classroom can be difficult for a traditional instructor. A traditional instructor may be accustomed to dominating or controlling the discussion through lecture; however, in an online class, all students have equal opportunity to participate in the discussion and may outside of the instructor’s influence. It takes a good deal of time for some instructors to feel truly comfortable in allowing

the discussion to take place without their intervention; experience will eventually guide them.

For good discussion board facilitation, the instructor should randomly reply to students and provide prompt explanations or further comments regarding the topic of discussion. Johnson (2003) found that “when a professor shows interest in discussions by commenting on students’ ideas and insights, students feel valued and encouraged to participate more” (p. 113). The instructor should provide feedback in the discussion even if it is merely a “cheerleading” comment, redirection, or guideline submission. The instructor should intervene when the discussion seems to be struggling or headed the wrong way (Palloff & Pratt, 2001), but should not over-participate in the discussion, as this will be considered stifling and restrictive. Some instructors prompt absentee or “lurker” students with a gentle reminder e-mail or telephone call. According to Bischoff, (2000), “A phone call may prove more timely and effective” (p. 70) in helping a student engage in the discussion.

Many instructors assign assistant facilitators and summarizers for each discussion session, providing opportunities for different kinds of student involvement. Other instructors use “coaching teams” made up of students or tutors as the first line of support, then invite the students to ask the instructor for clarification or further assistance. Under favorable circumstances, the “discussion will end in acceptance of different opinions, respect for well-supported beliefs, and improved problem-solving skills” (Brewer et al., 2001, p. 109). McIsaac and Craft (2003) remind us that class discussions should take place after the reading assignments; students may also need to be reminded of this before they participate.

Treat Each Student as an Individual

Instructors should value individual contributions and “treat their students as unique” (White, 2000, p. 11). A simple technique is to use the students’ preferred names or nicknames in all correspon-

dence. It is also important to add positive emotion and visual cues. The online environment can be limiting when the communication is mostly text-based. Typing the cues in an e-mail can serve the same purpose as nodding a head in agreement or offering a welcoming smile as would occur in a traditional course.

Add Emotion and Belonging

When online learning is facilitated incorrectly, students can feel isolated and cheated. This could lead to feelings of separation and disappointment that negatively impact learning. White (2000) advises that “a positive emotional climate can serve as a frame of reference for online students activities and will therefore shape individual expectancies, attitudes, feelings, and behaviors throughout a program” (p. 7). Since there are no visual clues in the online classroom, one suggestion for communication is to type out the emotion expressed in parentheses (*smile*) or to include emoticons, such as:-) for happiness or:-0 for surprise or dismay. It is also possible to describe body language in e-mail. Salmon (2002) offers this example: “When I read your message, I jumped for joy” (p. 150). This descriptive effort shows the students the instructor’s personality and positively stimulates the online community. It is also beneficial, as Hiss (2000) suggests, for online instructors to remember to keep their sense of humor.

Respond Quickly

Time delays in a threaded discussion can be frustrating for students. This is especially true if a response was misunderstood and students have attempted to clarify. Instructors should try to post daily or on a regular schedule that has been communicated to the students. Some instructors create homework discussion threads for content support, which provides a forum for students to help each other.

Model Behavior

Instructors who engage students in collaborative groups should facilitate development of social skills. This begins at the onset of the course when the learning community is formed and students recognize the online classroom as a safe place to interact. Group skills should be modeled by the instructor and outlined in the course syllabus. For example, if a two paragraph introduction is expected, the instructor should model that in their own introduction to the class.

Create Appropriately Sized Groups

Most students enjoy the online social interaction and find that it encourages their learning experience. Independently minded students discover that the asynchronous nature of the course enables them to participate more readily than in the face-to-face classroom. In creating groups, Ko and Rossen (2004) recommend that instructors divide students into groups instead of allowing students to pick their own. Students may find it difficult to meet online and form groups quickly. Many instructors search the introductory material to find common elements among students to hasten group cohesion.

Groups should not be too large or too small. The most effective group size appears to be four students per group. Utilizing these suggestions, groupwork should begin early to promote a positive learning experience in the classroom. The actual process for completing the project should be outlined by the instructor, but the final outcome should be the group’s responsibility.

EVALUATION

The final stage of online instruction is for evaluation and assessment. Evaluation is a rewarding experience where one can observe learning occurring in the minds of students and reminds many

instructors why they choose this as their career. Evaluation is a time of reflection and satisfaction for a job well done. At this stage, instructors should assess each student's performance against course objectives, including what worked well and what should be improved. This is often accomplished by evaluating the course with a "best practices" online course rubric, keeping a journal and by soliciting feedback on instruction and course content.

Online Course Rubrics

With faculty teaching online for over a decade, online course rubrics have been developed to help evaluate quality in online courses. These rubrics examine best practices for design, requirements for interaction, and attempt to measure the overall quality of the course. Currently, there are several excellent rubrics but we can thoroughly recommend the following: California State University Chico's Rubric for Online Instruction (www.csuchico.edu/celt/roi/index.html), Blackboard's Exemplary Course Rubric (www.connections.blackboard.com/), and Quality Matters (www.qualitymatters.org).

Keep a Journal

Self-examination with contemplative thought is a successful approach for course improvement. A recommended practice is to keep a journal that records items that should be redesigned or altered the next time the course is taught. The instructor should make notes of assignments that worked well and those that were difficult, and critically evaluate the effectiveness of content and instruction.

Solicit Student Feedback on Instruction

Student feedback improves instruction. A good place to gather the feedback is inside the course management system. It is helpful to survey for student feedback during the course, not just at the

end with course evaluations. The instructor can develop a discussion thread for students to post feedback about the course anonymously, including possible suggestions for improvement. If a student does offer feedback, the instructor should acknowledge the feedback and be appreciative for the remarks.

Feedback instruments should provide the students with a way to communicate what they like the best or least about the course instruction. Schwartz and White (2000) suggest a mid-course feedback process by enlisting a student volunteer to send an e-mail message to the class soliciting feedback. They also suggest the following questions be used, encouraging honesty and participation:

- List three areas that are working well in this course
- List three ways to improve the class. (p. 175)

The student volunteer would gather the messages, remove names, and send them to the instructor. If possible, course changes in response to students' comments will allow students to feel empowered through taking an active role in their education. The feedback should also be used to change subsequent courses taught.

Solicit Student Feedback on Course Content

All online instructors should look for possible course revisions. Course content should never remain static. Moore et al. (2001) propose that "because online course design and teaching are so new, evaluating the effectiveness of your course and then refining it based on the results of that evaluation become imperative" (p. 12.3). If using end-of-course summary feedback, the instructor must receive this feedback in time to reevaluate the course for the next semester and modify, if necessary. Another possibility is an end-of-session discussion regarding the focus of the next session,

thus allowing for minor course revisions even as the course continues to be taught.

CONCLUSION

Online teaching has brought a new modality to education. It has also brought frustration and anxiety to instructors attempting this new method of instructing students. Moore et al. (2001) shared that “one faculty member who had only just finished her course online said it was like diving into a great chasm, blindfolded” (p. 11.3). Instructors who are comfortable with the traditional methods for teaching in the classroom may still struggle to engage students over the Internet. While many of the same techniques apply, teaching online requires additional techniques for success. The ADDIE instructional model provides a basic path for developing and teaching an online course: analyze the course objectives and audience; design and develop the materials and activities; implement the course materials and encourage learning, and finally, evaluate the effectiveness. In the online classroom, the environment is prepared with a carefully designed syllabus and policies and the learning community is nurtured to grow and become self-sufficient. By utilizing these strategies for teaching online effectively, an instructor will engage the online learner, nurture a successful learning community, and alleviate the frustration and fear that goes along with teaching online.

ABSTRACT

This chapter explores how social software tools can offer support for innovative learning methods and instructional design in general and those related to self-organized learning in an academic context in particular. In the first section the theoretical basis for the integration of wikis, discussion forums and weblogs in the context of learning are discussed. The second part presents the results of an empirical survey conducted by the authors and explores the usage of typical social software tools which support learning from a student's perspective. The chapter concludes that social software tools have the potential to be a fitting technology in a teaching and learning environment.

INTRODUCTION

One major task of higher education is to train students for the requirements of their future work in order to apply and adapt their knowledge to specific workplace-related requirements and settings. Due to the ongoing pressure on enterprises to cut costs, the periods of vocational adjustment in a company will become shorter and shorter.

On the one hand the rising pressure of innovation and the fast-paced development in the economy results in increased demand for continuous employee training. On the other, growing global competition forces enterprises to use available resources very economically, so that employee training is considered to be necessary and desired even though it is conducted under considerable time and cost pressure (Köllinger, 2002).

According to these goals, the settings of the education must be changed adequately. "While most of higher education still ascribes to traditional models of instruction and learning, the workplace is characterized by rapid changes and emergent demands that require individuals to learn and adapt in situ and on the job without the guidance of educational authorities" (Sharma & Fiedler, 2004, p. 543).

In the field of higher education, it has become an important goal to develop "digital literacy" and educate learners as competent users and participants in a knowledge based society (Kerres, 2007), but it can be assumed that there is a new generation of students, the "digital natives", who are accustomed to the digital and internet technology (Prenksy, 2001).

Oblinger and Oblinger (2005) characterise next generation students (called "n-gen", for Net-Generation) as digitally literate, highly internet savvy, connected via networked media, used to immediate responses, preferring experiential learning, highly social, preferring to work in teams, craving interactivity in image rich environments and having a preference for structure rather than ambiguity.

According to a study conducted by Lenhart and Madden (2005), half of all teens in the USA may be considered as "content creators" by using applications that provide easy-to-use templates to create personal web spaces.

Classical face-to-face learning is seen as rigid and synchronous and it promotes one-way (teacher-to-student) communication. Thus it is not surprising that more and more students are opting for web-based education, as a more flexible and asynchronous mode (Aggarwal & Legon, 2006).

The higher education system should provide answers to this new generation of students who enter the system with different background and skills. They are highly influenced by social networking experiences and able to create and publish on the internet (Resnick, 2002).

Educators and teachers therefore have to consider the implications of these developments for the future design of their courses and lectures.

In 2002 a new term, "Social Software", entered the stage to refer to a new generation of internet applications. One focus of this new generation is the collaboration of people in sharing information in new ways such as social networking sites, wikis, communication tools and folksonomies (Richter & Koch, 2007).

Wikis, weblogs and discussion forums will play a central role in the new context so the areas of application and possibilities will enlarge enormously. It can be assumed that this will also have considerable influence on learning and the usage of these instruments as learning tools.

The paper presents the results of an empirical survey in order to highlight the benefits of the above mentioned web-based social software tools from the student's point of view. 268 first-semester students, all in the first term of their studies) at Austrian Universities from different study programs took part in this survey. The students were asked to use one or more of these tools as a learning tool. The participation in this survey was voluntary.

The presentation of the results of this survey is divided into three parts: first the usage of the tools by the students (before they started with their studies), secondly the experiences the students had made with the tools during the study and, thirdly, the potential future usage.

The paper concludes with a discussion of the results of this survey in contrast with other empirical studies already published. Also the limitations of this survey and ideas for further research are pointed out.

THEORETICAL FRAMEWORK

This part refers to the necessary theoretical background required for the following empirical

study. Especially the areas of “Social Software” and “Learning” are addressed.

Social Software

The term „social software” emerged and came into use in 2002 and is generally attributed to Clay Shirky. Shirky, a writer and teacher on the social implications of internet technology, defines social software simply as “software that supports group interaction” (Shirky, 2003).

Another definition of social software can be found in Coates (Coates, 2005) who refers to social software as “Software that supports, extends, or derives added value from human social behaviour”.

Users are no longer mere readers, audiences or consumers. They have the ability to become active producers of content. Users can act in user and producer positions and they can rapidly change the position.

Nowadays the term “Social Software” is closely related to the “Web 2.0”. The term “Web 2.0” was introduced by Tim O’Reilly, who suggested the following definition: “Web 2.0 is the network as platform, spanning all connected devices; Web 2.0 applications are those that make the most of the intrinsic advantages of that platform: delivering software as a continually updated service that gets better the more people use it, consuming and remixing data from multiple sources, including individual users, while providing their own data and services in a form that allows remixing by others, creating network effects through an ‘architecture of participation,’ and going beyond the page metaphor of Web 1.0 to deliver rich user experiences” (O’Reilly, 2005).

Web 2.0 technologies such as blogs, wikis, podcasts, and RSS feeds or discussion forums have been dubbed “Social Software” because they are perceived as being especially connected and allowing users to develop Web content collaboratively and publicly (Alexander, 2006).

Until now the internet (Web 1.0) has one big disadvantage: it is easy to get information in it, but it is quite complicated and inconvenient to act as an author and take part in the development of contents. Web 2.0 should enable all internet users to actively take part in the further development of the internet. Everyone should be able to contribute easily. The focus of Web 2.0 is on the behaviour of the user. It should empower people to communicate and collaborate and contribute and participate.

This growing phenomenon is very interesting and ought to be examined carefully, in order to understand how the web is evolving and how this continuously regenerative cycle of performance and technological innovation empowers “learning by sharing” (Thijssen & Vernooij, 2002).

Based on the key principle of “architecture of participation”, social software can be seen as part of the Web 2.0. Wikis, weblogs and discussion forums are tools that are seen as social software applications and were selected for further research and the empirical study presented below.

Related Empirical Research

Institutions in the field of higher education have made efforts to introduce various IT-supported learning tools in the daily routine of students and lecturers (Evans & Sadler-Smith 2006; Aggarwal & Legon, 2006; McGill, Nicol, Littlejohn, Grier-son, Juster & Ion, 2005; Dooley & Wickersham, 2007; Duffy & Bruns, 2006).

Published results of the usage of weblogs in the prolearn-project (www.prolearn-project.org) have shown that a large majority of respondents considers personalization and adaptation of the learning environment as important and crucial factors. Learning should be individualized to become more effective and efficient. Personalization is a key element of the learning process, and specific problems need specific solutions, as students differ greatly in their backgrounds and capabilities.

Learning materials are typically too general in order to cover a very wide range of purposes and personal learning needs. Compared to classical learning personalization can be the most important added value that e-learning can offer. With it, education can be optimised and adjusted to various working conditions and needs, because students have different goals, interests, motivation levels, learning skills and endurance (Klamma, Chatti, Duval, Fiedler, Hummel & Hvannberg et al., 2006).

Chao (2007) explored the potential uses of wikis in the field of software engineering (38 participants), especially for software project team collaboration and communication. Overall, twenty-five students agreed and one student disagreed (two neutral) that wiki is a good tool for project collaboration. Concerning the applications of wikis, more than twenty-three students found that a wiki is a good tool for maintaining a group diary, managing user stories (project requirements), and project tracking and reporting. While a majority of students found that a wiki is a good tool for updating a project plan, managing acceptance tests, defect tracking, and developing user document, there was also a significant number of students who disagreed (Chao, 2007).

First results using wikis for collaborative writing (about 40 participants) also reported similar results. In this study students used wikis to write articles partly together with the lecturer.

After early problems with software usage software and writing contributions in the wiki, students were able to write articles by themselves or in teams. The motivation among students was on different levels, so the lecturer had to increase it during lessons. Other students, however, were highly motivated and were creating the contents and added them to the wikis (Bendel, 2007).

Constructivism and Learning - Presentation of the Learning Model

From a constructivist point of view learning focuses on the learning process by looking at the

construction of knowledge by an individual. As a consequence there is a recommendation to align (Holmes, Tangney, FitzGibbon, Savage & Mehan, 2001; Du S. & Wagner, 2005; Jonassen, Mayes T. & McAleese R., 1993) learning environments, especially in the academic context, with associate complex learning objectives to constructivist learning principles. Learning is not seen as a transmission of content and knowledge to a passive learner. Constructivism views learning as an active and constructive process which is based on the current understanding of the learner. Learning is embedded in a social context and a certain situation (Schulmeister, 2005).

The constructivist approach shifts learning from instruction-design-centered to a learner-centered learning and teaching mode. The role of the educator changes from directing the learner towards supporting and coaching him/her.

Baumgartner et al. (2004) have suggested three different prototypical modes of learning and teaching. These three different modes of learning and teaching are neutral to specific so they can be applied across all subject domains. Therefore, each teaching model can be used to teach e.g. sociology subjects as well as for teaching e.g. technical sciences. Learning can be portrayed as an iterative process that can subsequently be subdivided into different phases which are summarized in Figure 1:

In particular, these three different prototypical modes for learning encompass the following:

Learning/Teaching I: Transferring Knowledge

At the starting point the learner needs to be provided with abstract knowledge to lay the theoretical foundations and to understand relevant signposts, road markings and orientation points. This kind of factual knowledge is static and has little value by itself in real and complex situations. It merely serves as a shortcut to prevent pitfalls and to help to organize his/her learning experiences.

Figure 1. Prototypical modes of learning and teaching (Baumgartner, 2004)

The knowledge of the student is based on knowledge possessed by the teacher. Students have to learn what teachers ask them to learn. The teacher has the responsibility to make the knowledge transfer as easy as possible.

Learning/Teaching II: Acquiring, Compiling, Gathering Knowledge

In this section of the individual learning career, the student actually applies the abstract knowledge and gathers own experiences. In order to limit the action and reflection possibilities, the learner interacts within a somewhat restricted, artificial environment, which is reduced in complexity and easy to control by the teacher. To provide feedback, the learning environment is designed to include relevant devices where students can deposit their interim products and teachers can inspect it.

The emphasis in this model lies on the learning process of the student. Teachers try to help the students overcome wrong assumptions, wrong learning attitudes and assist in the reflection process of the subject domain.

Teaching III: Developing, Inventing, Constructing Knowledge

Teacher and learner work together to master problems. This model includes problem generation and/or invention. The environment is constructed in such a way that it represents, at least in certain aspects, reality or reality in a constrained form. This model includes two-way communication on equal terms, using either linguistic representations or other adequate kinds of language.

Teaching III has strong links to constructivism. From a constructivist point of view learning is considered as an active process in which people construct their knowledge by relating it to their previous experiences in complex and real situations in life. In their practical lives people are confronted with unique, unpredictable situations whose inherent problems are not readily observable (Baumgartner, 2004).

Constructivism does not represent a distinct theoretical position in the field of education. There exist some different approaches, thus constructivism can be understood as a continuum. For learning the two streams "communal constructivism" and "social constructivism" are essential (Pountney, Parr & Whittaker, 2002).

The social constructivism regards learning as a social process. Reality cannot be discovered, it does not exist prior to its social invention. Thus knowledge is also a human product, and is socially and culturally constructed. This means that knowledge is socially co-constructed, which is a negotiation process by the individuals with other individuals and with their environment. Social constructivists accept the existence of an “inter subjectivity” as a shared understanding about a knowledge object among individuals. Social constructivism stresses the importance of feedback and reinforcement.

On the basis of the upcoming technologies for learning and education Holmes et al. (2001) have suggested a new educational theory that goes beyond the existing social constructivism. According to their theory learners are not only constructing their own knowledge but they also produce knowledge for other students and learners. They consider that peer tutoring and project-based learning are obvious techniques. Furthermore they advocate the ideas of cognitive apprenticeship, the publishing of information, flexibility in the time table, a radical look at the way in which assessment is done.

Siemens (2005; 2006) coined the term “connectivism” due to the fact that by using the web learning and knowledge management have changed dramatically. He understands learning as creating networks. In order to deal with the increasing plethora of information he suggests the outsourcing of explicit knowledge to the network of the respective community. Having knowledge is not in the center, but rather knowing who can provide the necessary information to generate the knowledge needed

Students should be enabled to invent new things, produce or generate new knowledge. Consequently, learning and teaching at universities in most cases can be assigned to the requirements presented in Learning/Teaching II and III with respect to theories concerning the digital learning

support. In order to achieve this goal, a special learning environment must be provided.

Consequences for IT-Supported Learning and Teaching

Computer software can be used for all three models ranging from programmed instruction (Learning/Teaching I) to problem solving software (Learning/Teaching II) to complex simulations and/or so-called micro worlds (Learning/Teaching III). It is said that the inherent nature of the internet brings the real world into the classrooms and with its hyperlink structure it clearly advocates the model Teaching III (Hsu, 2008; Baumgartner, 2004).

The use of the internet, and especially through its social software, gains in importance because it can contribute to exceed the limits of classical teaching models. By adapting learning and teaching models to the new technical possibilities, the roles of learner and teacher are becoming more indistinct, because the learner can take a central part in the design and arrangement of the learning process (Kerres, 2006).

Systems that support learners with respect to the learning model III are called Personal Learning Environments (PLEs). PLEs are mostly web-based applications and are based on learning management systems (Seufert, 2007).

PLEs are personal and open learning environments and they are suitable for cross-linking contents and people. Learners can use PLEs to manage individual learning progress. They are ideally available for life-long-learning and are supported by the following processes:

Reflexive writing: Besides easy reading access to contributions it is the simple and efficient and rather robust encoding standard usually used in social software that allows the explicit modeling of content flows, feedback loops, and monitoring procedures of various kinds. Thus supporting these systems support an ongoing reiterative process of explication and reflection (Fiedler,

2003). PLEs should support the development of the ability to learn (“learning to learn”): Through the publication of one’s thoughts and reflections, content is made available for assessment as well as for further development, thereby improving self-observation and self-reflection skills. The way the learner can learn and acquire will be improved (Baumgartner, 2005).

As already discussed new learning theories for digital learning support have been developed, for example “social and communal constructivism” that considers learning as a social process or “connectivism” that understands learning as creating networks.

Communication and discussion: The integration supports the exchange of ideas as well as finding like-minded people. Furthermore, social software tools simplify the process of establishing connections between people of the same interests. They also simplify the construction of connections between people with similar interests. Simultaneously its open and expandable philosophy supports going beyond the thinking in groups (of a common interest) by supporting diversity and bringing together different perspectives and backgrounds (Efimova & Fiedler, 2004; Schulmeister, 2004). This supports learning from different perspectives.

Community building: PLE-tools have to provide a personal learning area for their authors. However, this does not force a general learning flow or learning style. Nevertheless, learners are not alone and can profit from the feedback of a community in order to examine and enhance the development of own ideas (Efimova & Fiedler, 2004; Fiedler, 2003; Böttger & Roll, 2004). Achieving synergies of self-organized and joint learning should be enabled by those tools. Through reading in other learning environments, especially beginners are enabled to learn from experts. At the same time they can actively participate in discussions beyond geographic or thematic borders (Efimova & Fiedler, 2004; Fiedler, 2003).

Life-long-learning: Life-long learning is a key issue for knowledge society for today and tomorrow. In order to cope with the fast change of knowledge future knowledge workers have to thus be prepared to react fast and manage their further education and training at the workplace. In addition, they have to take responsibility for their own employability (Klamma, Chatti, Duval, Hummel, Hvannberg & Kravcik et al., 2007). Life-long learning is seen as multi episodic, with individuals spending occasional periods of formal education and training throughout their working life (Attwell, 2007b). Life-long learners need tools that can be used for all learning activities no matter what subject they learn or which educational institution they attend.

Quality of contents: The quality of contents is a key factor that determines the sustainable usage of a knowledge management system. (Maier, 2004, p. 247)

Pleasure: Besides the activities that should be supported by social software tools the usage of the tools must give pleasure to the users. If knowledge management should be fostered, playful behavior needs to be supported rather than strict norms (Schneider, 2004; Landry, 2000).

Unlike a Learning Management System (LMS) that is usually related to one special institution or to one special course, a PLE is focused on the individual learner. A PLE should combine a broad mixture of different resources and sub-systems in a “personally-managed space” (Attwell, 2006).

In the previous decade, Learning Management Systems were developed that moved toward enterprise-level applications. “But the wealth of new, user-friendly, tools in the Web 2.0 environment suggests that the all-in-one monolithic e-learning systems may be entering a phase of obsolescence by the ongoing development of the web” (Craig, 2007).

Social software applications have the potential to cope with these requirements (Brahm, 2007).

DESCRIPTION AND CLASSIFICATION OF SOCIAL SOFTWARE TOOLS

In the following section three social software tools, weblogs, discussion-forums and wikis, are described more in detail and the tools are compared. Students were able to select these tools during the empirical study.

Weblog

A weblog, a compound of “web” and “logbook”, usually just called “blog”, is a website that contains new articles or contributions in a primarily chronological order, listing the latest entry on top.

Primarily, a weblog is a discussion-oriented instrument especially emphasizing two functions, RSS-feed and trackback. RSS-feeds, also called RSS-files can be read and processed for further use by other programs. The most common programs are RSS-readers or RSS-Aggregators that check RSS-enabled websites on behalf of the user to read or display any updated contribution that can be found. The user can subscribe to several RSS-feeds. Thus, information of different websites can be retrieved and combined. Preferably, news or other weblogs are subscribed to.

Trackback is a service function that notifies an entry in a weblog if a reference to this contribution has been made in another weblog. By this mechanism a blogger (person who writes contributions in a weblog) is immediately informed of any reactions to his contribution on other weblogs (Hammond, Hannay & Lund, 2004).

Weblogs are often interrelated with other weblogs, the blogosphere, and discussion forums are rather concentrated on one specific topic. The interrelations between discussion forums are not as intensive as in the blogosphere.

Discussion Forum

A discussion forum or web forum is a service function providing discussion possibilities on the internet. Usually, web forums are designed for the discussion of special topics. The forum is furthermore subdivided into sub-forums or sub-topics. Contributions to the discussion can be made and other people may read and/or respond to them. Several contributions to a single topic are called a thread.

The application areas of the two instruments weblogs and forums are quite similar. The most essential differences between weblogs and discussion forums can be described as follows:

- A forum is usually located on one platform while many bloggers develop their own, individual environment. They connect their weblogs via RSS-feed and trackback functions.
- Through the integration of RSS-files and trackback functions a discussion process can be initiated and continued crossing the boundaries of the bloggers' own weblogs without having to observe other weblogs.
- Weblogs tend to be more people-centered whereas forums are more topic-focused. Through the use of weblogs, learner-specific learning environments can be constructed without interfering with the learning environments of others (Baumgartner, 2004).

Wiki

A WikiWikiWeb, shortly called Wiki, is a hypertext system for storing and processing information. Every single site of this collection of linked web pages can be viewed through a web browser. Furthermore, every site can also be edited by any person. The separation between authors and readers who write their own text, change and delete

them is obsolete as also third parties can carry out these functions (Augar, Raitman & Zhou, 2004).

The most essential differences between weblogs, wikis and discussion forums can be described as follows (Wagner & Bolloju, 2005, p. 5):

Learning Activities Supported by Social Software

The integration of different Social Software Tools offers support in the following learning activities:

- Learning from different perspectives: The integration supports the exchange of ideas

as well as finding like-minded people. Furthermore, social software tools simplify the process of establishing connections between people of the same interests. They also simplify the construction of connections between people with similar interests. Simultaneously its open and expandable philosophy supports going beyond the thinking in groups (of a common interest) by supporting diversity and bringing together different perspectives and backgrounds (Efimova & Fiedler, 2004; Schulmeister, 2004).

Figure 2. Comparison of weblogs, wikis and discussion forums

	BLOG	WIKI	DISCUSSION FORUM
Speed of publication	Single-click publication possible with many implementations. Results reflected instantaneously on the server ("web speed")		
Ease of publication	Single-click publication possible with many implementations, indexing and formatting large handled by software. Users may have access to a simplified mark-up language		
Elementary information unit	Comment-on-topic-at-time	Comment-on-topic	Comment-by-participant-on-topic-at-time
Knowledge representation and organization	Chronological organization less useful than topical organization. Workaround through indices and access to archives.	Topical organization as well as bi-directional indexing, as well as chronology of changes.	Chronological organization less useful than topical organization, workaround "sticky" messages.
Content indexing	Time-indexed (topic-based exist too)	Topic-based	Time-indexed (topic-based exist too)
Team support	Meant for individual publishing; most tools offer team support as well.	Inherently open to public for contributions editing; most tools facilitate restricting wikis to a closed group of users.	Provided in the form of open or closed set of members; some of the members may be designated as moderators.
Mode of conversation	Broadcasting; one-to-many communication tool	Dialog; many-to-many communication tool	Dialog; many-to-many communication tool
Version management	Not provided; although blog posts may be edited by the contributor(s)	Versions and history of changes are provided; facilities are available for rollback	Not provided; messages posted are not expected to be modified (exceptions)
Community of practice fit	Innovation	Best practice	Help
Security	Security measures such as access rights, administrative permissions are normally provided.		

- Synergies of self-organized and joint learning: Social Software tools provide a personal learning area for their authors. However, this does not force a general learning flow or learning style. Nevertheless, learners are not alone and can profit from the feedback of a community in order to examine and enhance the development of own ideas (Efimova & Fiedler, 2004; Fiedler, 2004; Böttger & Röll, 2004).
- Digital apprenticeship: Through reading other wikis, forums or weblogs regularly, beginners are enabled to learn from experts. At the same time they can actively participate in discussions beyond geographic or thematic borders (Efimova & Fiedler, 2004; Fiedler, 2004).
- Weblogs and comparable tools support the development of the ability to learn (“learning to learn”): Through the publication of ones own thoughts and reflections, content is made available for assessment as well as for further development, thereby improving self-observation and self-reflection skills. The knowledge change of the learner will be improved (Baumgartner, 2005).
- Social Software supports reflexive writing: The simple, but efficient and rather robust encoding standard usually used in Social Software allows for the explicit model-

ling of content flows, feedback loops, and monitoring procedures of various kinds, thus supporting an ongoing reiterative process of explication and reflection (Fiedler, 2004).

Integration of Social Software Tools and the Learning/Teaching Modes

Baumgartner (2004) has integrated different types of Content Management Systems in relation to the most suitable learning/teaching mode. He clearly states that the boundaries are overlapping and that every tool – in one way or the other – could be used for every teaching model. The following Figure 3 presents the integration of the Social Software tools and the learning/teaching modes:

Weblogs and forums can be defined as “discussion-oriented” tools because the discourse and exchange of ideas related to a certain topic is the pre-eminent aim. Weblogs offer the possibility to support all three phases of the learning process. However, the main focus can be assigned to the modes “Teaching II” and “Teaching III”.

Based on the multitude of interaction possibilities, wikis can be attached to “Teaching III” (Baumgartner, 2004). Additional functions were added to weblog-tools that go beyond the scope of the central use of weblogs, e.g. longer articles can also be stored. Through the creation

Figure 3. Prototypical Modes and Social Software Tool

of directories, a structured collection of links can be implemented.

Through the additional linking of weblogs, wikis and forums, there is the possibility to develop a personal knowledge collection (Kantel, 2003).

EMPIRICAL SURVEY

The purpose of this survey was to determine if the integration of web-based social software tools (wikis, discussion forums and weblogs) are suitable to foster learning from the student's point of view.

Aim of the Survey and Methodology

Scrutinizing the possibilities and constraints of social software tools (wikis, discussion forums and weblogs) as a personal learning environment, students at Austrian universities were asked to use one or more of the offered tools for their research, home work and documentation purposes. In most cases collaboration of students was required to perform the assigned tasks.

The students were asked to use the tools for one course only during Winter Term 2006. Furthermore, there was no obligation for the students to use a tool at all, they were just encouraged to do so. Students were also offered the possibility using two or three tools - their selection was up to the students.

The courses were organized as blended-learning courses, so they included on-campus lessons and off-campus work in which the students could work face-to-face or using the social software tools.

More than 90% of the students attending the courses took part in this survey. In order to give the participants an impression of the functionality and usage of the tools short presentations of the tools were made by an instructor before the students made their choice.

At the end of the testing phase - after four weeks of using the tools - selected student reported their experiences with the tools used. Thereby students who had decided not to use the tools in the first place got an impression about the usage, advantages and disadvantages of the tools by their fellow students. Following these short presentations a questionnaire was completed that provided the basic findings for further inspections and research.

A total of 268 first-semester students of different Austrian universities in five selected courses took part in this survey. The majority of the participants were between 18 and 20 years old. The portion of female students was about 17%.

According to a survey conducted by Seybert (2007) concerning gender differences in computer and internet usages for young people (aged between 16 and 24), there is no gap between men and women in Austria. The proportion of women and men (in the relevant age class) that used a computer (almost) once a day is with 72% the same. A study by Otto et. al. (Otto, Kutscher, Klein & Iske, 2005) indicates that there is a positive correlation between a formal educational background and the usage of the internet in Germany.

"Beside socio-cultural resources like family background, peer structures and social support in general, the formal educational background turns out to be the main factor for explaining differences in internet usage" (Kutscher, Klein & Iske, 2005, p. 219).

As a consequence for the analysis of the results of this survey, no distinction between male and female students was made.

Table 1 presents the distribution of the participants concerning the degree program the students are attending:

For the further analysis of the results no distinction according to the degree programs will be made.

This questionnaire asked each participant questions about her or his subjective impression of the application of the tools. It included five-

Table 1. Distribution of students regarding the degree program

	Distribution
Management & Law	17%
Management & IT	31%
Management & Industrial Engineering	22%
Mechanical Engineering, Electronics	30%

point Likert scales for rating constructs such as eligibility, perceived quality or enjoyment.

The study was conducted to find answers about the

- usage of social software before the study started
- selection of the offered tools
- perceived quality of the contributions and the support for learning
- applicability of the instruments to support communication and community-building
- the correlation of the usage for private and educational purposes of the tools
- fun factor using the instruments
- potential future usage

The results of the study are presented in three parts:

- Part 1: Analysis of the usage of wikis, discussion forums and weblogs of the students before the study was started
- Part 2: Experiences made with the tools during the study
- Part 3: Potential future usage of the tools

Part 1: Tool-Selection and Pre-Study Usage

Due to the fact that the students could select the tools on their own, Table 2 shows the results of this selection process.

Table 2. Tools selected by the students

	Per Cent	Number
Only one tool selected		
Wikis only	23,1%	62
Discussion forums only	22,4%	60
Weblogs only	0,4%	1
More than one tool selected		
Wikis and discussion forums	42,9%	115
Wikis and weblogs	1,9%	5
Discussion forums and weblogs	0,7%	2
Wikis, discussion forums and weblogs	6,7%	18
No tool selected		
No tool selected	1,9%	5

According to the above table the combination of wikis and discussion forums is the most selected combination of tools (42,9%), followed by wikis only (23,1%) and discussion forums only (22,4%). In the end only five students (1,9%) did not take part in the study; they did not select a tool, although they first had had the intention to do so. Only one student used weblogs only. Generally, weblogs were not used very intensively by the participants.

Table 3 shows the usage of the tools by the participants before they took part in the study. It indicates that wikis (76%) and discussion forums (78%) are currently the most widely used tools. Weblogs are only used by 11% of the asked students.

The results clearly show that the weblog hype had not yet reached the surveyed students. Due to the fact that only about 11% of the students are currently using weblogs, the results for this instrument are not published for the first part of the

Table 3. Students already using the tools

	Wiki	Forum	Weblog
Yes	76%	78%	11%
No	24%	22%	89%

analysis. When it comes to the potential future usage of the instruments, weblogs are taken into consideration again.

The following section presents the results for questions analyzing the usage in more detail.

Tables 4 and 5 present the current usage of the tools for private and educational purposes. The question: “I often use (wikis, forums) for private purposes” was asked.

Table 5 shows the results for the corresponding question “I often use (wikis, forums) for educational purposes” are presented.

A huge majority (90%) stated that they use wikis for educational purposes and about two thirds (68%) used wikis for private purposes. Wikis are therefore more intensively used for educational purposes than for private purposes, whereas the usage of forums is exactly the opposite, they are more used for private purposes than for education.

The answers of the students concerning this question were that wikis are foremost considered as a source of serious information, whereas forums are ideal for getting hints or clues to problems related to their privacy. Questions about computer

problems, computer games, leisure activities, etc. were mentioned. A repetition of this image can be identified when the disagreement with the question is analyzed. 29% of the students do not or rarely use forums for private purposes, compared to 36% in their education.

Part 2: Experiences Made During the Study

This section presents the results of the study concerning experiences with the usage of the tools during the study.

Quality and Support for Learning

The next section refers to questions concerning the quality of contributions of wikis and discussion forums and their support for learning.

The results of the question “The quality of contributions in (wikis, forums) is in general good” regarding the quality of contribution are presented in Table 6. The contributions of wikis are evaluated to be much better than those of forums.

The surveyed pupils had the possibility to give reasons for their assessment concerning the quality of contributions via additional qualitative answers. The following summarizes the addressed reasons:

One reason for this excellent grade for the quality of wikis is the “Wikipedian Community”. The term “wiki” is often seen as synonym for the free online encyclopaedia Wikipedia (www.wikipedia.org). Wikipedia is widely used for a great variety

Table 4. Usage for Private Purposes

of tasks, so for research on all topics needed for educational and private purposes.

In contrast to the good evaluation of contributions of wikis, the open architecture of wikis was also mentioned. In most cases this open architecture allows everyone to edit entries which results in the uncertainty of whether the knowledge presented is correct or not. The quality of contributions in discussion forums was rated rather mediocre. Forums are primarily used for technical problems, especially computer related problems, and to get in contact with an expert of a certain topic and to get information on online-games.

The next question “The usage of (wikis, forums) leads to misunderstandings and confusion” is about the clarity of the contributions (Table 7).

Only a minority think that the contributions are not clear and may lead to misunderstandings. In this case wikis are also rated better than forums.

The next questions addressed the support of these instruments for learning. Table 8 summarizes the results for the question “When reading contributions in (wikis, forums) it is easier for me to acquire the learning contents”:

More than half of the students express that reading contributions in wikis is helpful for learning, whereas only about 8% think that it is not helpful. Compared to forums, wikis were again much better evaluated especially considering the big difference with the negative evaluations of forums.

Table 9 presents the learning support achieved by writing contributions (“When writing contributions in (wikis, forums) it is easier for me to acquire the learning contents”):

A different picture emerges in the statistics when comparing the evaluation of how writing an article or post supports the learning process. Here forums take the lead when it comes to positive assessment. In both cases there were a large number stating that writing is neither positive nor negative. The majority of the students rather read than wrote, whereas more students wrote in forums than in wikis.

Table 7. Clarity of Contributions

I slightly disagree	14%	22%
I disagree	19%	17%

Applicability for Communication and Community-Building

The question was formulated as follows: “(wikis, forums) are appropriate to support communication” (Table 10)

The results clearly demonstrate that discussion forums are “made for communication” whereas wikis are rather seen as a kind of reference book or encyclopedia, as already mentioned above.

The results of the next question, “(wikis, forums) support the set up of communities”, can be seen in Table 11.

Table 10. Applicability for Communication

	Wiki	Forum
I totally agree	9%	39%
I generally agree	33%	37%
neither ... nor (neutral)	29%	17%
I slightly disagree	15%	4%
I disagree	15%	3%

Table 11. Support for Community-Building

	Wiki	Forum
I totally agree	10%	28%
I generally agree	25%	32%
neither ... nor (neutral)	39%	23%
I slightly disagree	15%	11%
I disagree	10%	6%

Opinions about the applicability of wikis to establish a community is split. About 35% say that wikis are supportive of building a community, compared to 25% who said that wikis do not support community-building. The support of forums to build a community is rated much better – 50% indicated that forums are well suited to build a community. These results were to be expected because they confirm the nature of the instruments.

Fun Factor when Using the Instruments

In surveying whether students gain pleasure (“I enjoy using (wikis, forums)”), wikis again came back on top (Table 12).

A majority of 62% enjoy using wikis and forums (56%). Considering the answers that there is no (I disagree) or little (I slightly disagree) fun when using these instruments wikis (6%) are much better rated than forums (18%).

Part 3: Potential Future Usage of the Tools

The third section of the empirical study deals with the potential usage by students who had not used one of the instruments before the study. Students gained knowledge and experiences by using the tools during the study by themselves or on the basis of the reported experiences made by their fellow students.

The first question “I will use (wikis, forums, weblogs) for educational purposes in the future” yielded the results shown in Table 13.

According to this study wikis will then have a bright future and will be used often for educational purposes, whereas forums will be used less often. About 54% of the surveyed students had the intention of using wikis more or less often in the future. About 16% did not think that they will use wikis often in the future and 30% are not yet sure if they will use this instrument or not.

The results for forums and weblogs indicate no clear trend, but forums were rated slightly higher than weblogs. 39% of the students stated that they

can image to use forums (36% for weblogs) in the future for their education. At the other end of the scale, 45% did not have the intention to use forums (40% for weblogs).

The equivalent question “I will use (wikis, forums, weblogs) for private purposes in the future” leads to similar results (Table 14).

From this point of view, wikis are again the leading instrument, followed by forums and weblogs.

It must be said that the answers to this set of questions represented feelings, attitudes and opinions about instruments that had not yet been used by the asked participants. The purpose of posing these questions was to gain insight into the mindset in regard to these instruments.

DISCUSSION

The results clearly show that wikis are currently the most often used instrument and furthermore have the greatest potential as a tool for learning and knowledge management in the field of learning – and these findings are in line with other empirical studies (Bendel, 2007; Chao, J. 2007).

Other studies (Nicol and Macleod, 2004; McGill, Nicol, Littlejohn, Grierson, Juster and Ion, 2005) report that a shared workspace helped to support collaborative learning. Especially the possibility of being able to access and contribute to the development of resources at any time and from any location was appreciated by the students.

Table 14. Future Usage in Private Context (current non-users)

neither ... nor (neutral)	30%	25%	24%
I slightly disagree	14%	7%	16%
I disagree	9%	32%	28%

In an empirical study conducted by Wheeler, Yeomans and Wheeler (2008) 35 undergraduate students (1st-, 2nd- and 3rd-year) of a teacher training (Bachelor of Education) have been using open-content wiki software for one year as an integral part of their studies. Ages ranged from 18 to 25 years, and there were two mature students. Each participated in this evaluative study voluntarily. Students used the wikis regularly during their classroom sessions as a space to store and edit the work from their research exercises, and as a forum for discussion. During teaching sessions students were invited via the integrated discussion board to post their views on their use of the wiki. They were also invited to complete a post-module questionnaire via email.

The authors conclude that “wikis have the potential to transform the learning experiences of students worldwide. The benefits appear to outweigh the limitations.” (Wheeler, Yeomans & Wheeler, 2008, 994) Collaboration, rather than competition, should be emphasised as a key aim of any wiki-based activity.

A study conducted by Solvie (2008) took place during a three week period of a semester long reading methods course for preservice teachers. Eighteen preservice teachers participated in the study. A combination of quantitative and qualitative methods was used.

One major purpose of this study was to get insights into the usage of a wiki in combination with individual learning styles thereby the cognitive learning style model by Kolb was used. Generally the results show that the used wiki provided a space for effective collaborative work. The furthermore found out that there is a correlation between the individual learning style and the specific usage of the wiki.

Participants who believed the wiki was helpful in constructing knowledge of reading contents in this environment said seeing all the information together was helpful. Learning more about and looking in depth at their particular work was helpful, and researching their approach was

enjoyable. The participants had some problems using the technology but these problems were associated with their own level of confidence in use of technology.

The survey at hand made a distinction between reading and writing contributions with wikis and discussion forums. The results show that reading contributions in wikis is helpful (with the answers “I totally agree” and “I generally agree”) for learning (59%) compared to 21% who stated that writing in wikis is helpful for learning. Reading contributions in forums helped 29% of the participants whereas writing in forums is helpful to 26%. This survey supports the general statement that a shared workspace that supports a constructivist and learner-centered approach is helpful for learning.

An empirical study on an eLearning module on an MSc in Information Technologies and Management was conducted by Gilbert, Morton and Rowley (2007). Nineteen students located across the globe where enrolled on the module. All students were graduates, but most of their prior learning experiences had been in standard face-to-face delivery mode. A discussion forum was integrated in the learning environment that was used by all students more or less frequently. Most of them were very or quite comfortable about posting contributions to the discussion threads, although some students were not confident to make contributions. Compared to email, chat, telephone or face to face the discussion forum was the most widely used communication channel among the students.

Concerning the impact on learning students responded that they learnt from other students. The support from other students with discussion forums were the most frequently cited aspects of the learning process whereas some were reluctant to be the first contributor.

The pedagogical value in the context of learning is described in several publications (Babcock, 2007; Hurst, 2005). Weblogs can foster the estab-

lishment of a learning and teaching environment in which students and teachers can experience a greater degree of equality and engagement. Du & Wagner (2007) published results of a study of an Information Systems undergraduate course (31 participants). This study indicated that the performance of students' weblogs was a significant predictor for learning outcomes, while traditional coursework was not. Moreover, individuals' cognitive construction efforts to build their own mental models and social construction efforts to further enrich and expand knowledge resources appeared to be two key aspects of the constructivist learning with weblogs. According to this study there is a potential benefit of using weblogs as a knowledge construction tool and a social learning medium (Du & Wagner, 2007).

In this survey at hand weblogs were not yet widely used and their potential seems to be limited. It can be assumed that these limited prospects will change, when the penetration of weblogs into the daily routine of the students will increase – for private as well as for educational purposes. These results are confirmed by Reinmann (2008) who states that blogging in an educational context (“edublogs”) is obvious when the possibilities are taken into consideration whereas the usage of these tools is not widely spread in the daily routine. There are already projects and there is a lot of information about using weblogs in educational settings (Scheloske, 2008; Reinmann & Bianco, 2008).

The results about the potential future usage of wikis, weblogs and discussion forums show that these tools have the potential to be used for life-long learning. According to this study, wikis will have a bright future and will be used often for educational and private purposes. The results for discussion forums and weblogs indicate no clear trend, but forums were rated slightly higher than weblogs. Other studies (Klamma, Chatti, Duval, Hummel, Hvannberg & Kravcik et al., 2007; Attwell, 2007a) confirm these results, whereas

weblogs are considered to be more powerful for personal knowledge and learning management (Williams, 2004; Böttger & Roll, 2004; Fiedler, 2003).

The contribution of this thesis to the discussion that can be found in Oblinger and Oblinger (2005), Lenhart and Madden (2005), Aggarwal and Legon (2006) or Prensky (2001) about the already available “digital literacy” of young people indicates that wikis and discussion forums are currently the most widely used tools. More than 75% are already using these tools, whereas weblogs are only used by 11% of the asked participants. From these results it can be concluded that there is some form of digital literacy among young students.

Critics of the net-generation and the derived consequences for learning and teaching state that there is “a sense of impending crisis pervades this debate. However, the actual situation is far from clear. [...] Our analysis of the digital native literature demonstrates a clear mismatch between the confidence with which claims are made and the evidence for such claims” (Kennedy, Judd, Churchward, Gray & Krause, 2008)

Schulmeister (2008) points out that the term “generation” has often been used in the past by attributing some specific characteristics or qualities to people living in a certain period of time. In the USA, for example, earlier generations have been classified by researchers as the “matures” (1900-1946), the “baby boomers” (1946-1964), “Generation X” (1965-1982) or the “net generation” (1983-1991). In many cases these attributes are only valid for a minority of this generation but by establishing a classificatory system this minority is used to represent a whole generation.

In other publications (Media Awareness Network, 2004) it is reported that for young people it is normal to grow up with new technologies. Computers and other new technologies like mobile phones are not new for them, they just exist and they use new technologies to manage and organize their daily life (Tully & Zerle, 2005). A Canadian

study summarizes its results as follows: “The Internet, for young people, is part of the pattern of their day and integrated into their sense of place and time. The Internet just is.” (Media Awareness Network, 2004, p. 8)

With respect to the individual learning styles of young people Bennett et al. (2008) come to the conclusion that “young people’s relationships with technology is much more complex than the digital native characterization suggests. While technology is embedded in their lives, young people’s use and skills are not uniform. There is no evidence of widespread and universal disaffection, or of a distinctly different learning style the like of which has never been seen before. We may live in a highly technologized world, but it is conceivable that it has become so through evolution, rather than revolution.”

Thus it is important to provide systems that offer all possibilities of setting up a personal learning environment in order to enable people to work and learn according to their individual learning style.

To avoid possible pitfalls about the application of these instruments in the context of learning, some social and psychological issues must be taken into consideration (Kreijns, Kirschner & Jochems, 2003). Social interaction is essential for members of a team to get to know each other, commit to social relationships, develop trust and develop a sense of belonging, in developing a learning community. The size and the composition of the learning communities seem to be an important factor how interaction and communication within the learning community will take place (Dooley & Wickersham, 2007). There are also many unresolved issues, like provision of the technology and the services, intellectual property rights and digital rights management, security of data, access restrictions to the contents or questions in the field of information ethics (McGill, Nicol, Littlejohn, Grierson, Juster & Ion, 2005; Attwell, 2006; Sharma & Maleyeff, 2003).

FINAL REMARKS

The aim of this contribution was to investigate the experiences of students using social software tools in the context of learning. Wikis, weblogs and discussion forums are typical social software tools and were used for this survey.

The results clearly show that wikis and discussion forums can support learning and collaboration. The usage of weblogs in this study was limited and hence no statements about their applicability can be made. In order to assure a successful implementation of these tools social and psychological issues must be taken into consideration as well.

The results of this study are the basis for the introduction of social software into education to help students to set up their individual learning environment. These learning environments should support life-long-learning and the structuring of a personal learning environment.

In the “Hype Cycle for Emerging Technologies” report of 2008 describes microblogging and social social computing platforms as technologies and trends that are around the peak of the Hype Cycle in 2008 with the prospect that they will mature in two to five years (Fenn & Raskino, 2008)

Microblogging is a relatively new addition to the world of social networking, in which contributors post a stream of very short messages (normally fewer than 160 characters) providing information via various information channels.

There are likely to be other unplanned consequences of the intensive use of the internet in general and social software especially. Further research is needed to explore possible problems along with hinting at solutions.

The results of the empirical survey indicate that a long-term study in combination with the further development of social software tools may be promising.

Chapter 3.7

Integrating Blogs in Teacher Education

Yungwei Hao

National Taiwan Normal University, Taiwan

ABSTRACT

This chapter demonstrates some of the educational merits of blogs; including how blogs can be integrated in teacher education and proposing a methodology for evaluating blogs to meet the goals of reflection and technology literacy in teacher education. An undergraduate-level course was integrated with blog technology to help readers better understand the inquiry-oriented nature of the blog medium. This exemplar course modeled Web 2.0 technology to teacher educators and pre-service teachers who intend to integrate the technology into their future teaching. Surveys and interviews were used to investigate participant attitude toward blogs. The researcher proposes Zeichner and Liston's (1987) Reflective Index

as a potential framework for evaluating the quality of reflection in blogs. It is expected that this instructional model of blogs will help educators, in particular teacher educators and instructional designers, to design courses to more effectively meet the goals of higher-order thinking required in 21st century teacher education.

INTRODUCTION

Some people do not regard teaching as a profession and think that teaching requires little training. According to this belief, anyone who has the content knowledge would be able to teach. These are misconceptions. As Darling-Hammond (2006) indicated, teachers have a list of things they should know and should be able to do, including knowing how people learn, teaching

DOI: 10.4018/978-1-60960-503-2.ch307

effectively, meeting individual learner's needs, communicating and managing their classrooms well, and the like. One of the competencies, teaching effectively, often contributes to students' learning (Darling-Hammond, 2006). Especially in the digital era, teaching effectively requires more than content knowledge. To teach effectively, one needs knowledge of content, pedagogy, and technology integration, and the interplay of these three bodies of knowledge known as technological pedagogical content knowledge (TPCK) (Mishra & Koehler, 2006).

Mishra and Koehler (2006) defined technological pedagogical content knowledge:

This knowledge is different from knowledge of a disciplinary or technology expert and also from the general pedagogical knowledge shared by teachers across disciplines. TPCK is the basis of good teaching with technology and requires an understanding of the representation of concepts using technologies; pedagogical techniques that use technologies in constructive ways to teach content; knowledge of what makes concepts difficult or easy to learn and how technology can help redress some of the problems that students face; knowledge of students' prior knowledge and theories of epistemology; and knowledge of how technologies can be used to build on existing knowledge and to develop new epistemologies or strengthen old ones. (Mishra & Koehler, 2006, p. 1028-1029).
