Teacher education programs usually provide pre-service teachers with separate courses in which content, pedagogy, and technology literacy skills are introduced to learners. The interplay between the three components tends to be neglected. This chapter is not about developing technology nor content knowledge, but rather about solidifying technological pedagogical content knowledge by using blogs to meet the tremendous academic needs of teacher education in ways that have never before been available. The final goal of this chapter is to identify the importance of blog technology for pre-service teacher education.

BACKGROUND

The use of Internet technologies has been changing human interaction, communication, and relationships. By including Internet technologies in education, the technology revolution makes the learning environment diverse and complicated, and the role of teachers in students' learning is transformed into facilitating. Can teacher education keep updated with these changes and meet pre-service teachers' needs for their future teaching careers? The answer is far from certain, because the new skill sets required by the new century classrooms differ from skills developed by current teacher educators. The 21st century students are growing up in the time when Internet access has become widespread. Youngsters send/receive e-mails, use instant messaging, search for information online, play online games, and make online friends. Widespread access to information and resources is bringing young people the pros and cons of the digital age. To deal with the complexity of this environment, students need up-to-date skills to compete in the 21st century working environment. According to the report *enGauge 21st Century Skills: Literacy in the Digital Age* (2003) by the North Central Regional Educational Laboratory (NCREL), four groups of skills analyzed through literature reviews, surveys and interviews, represent the 21st century skills needed by students, citizens, and workers in the Digital Age. The skills are 1). Digital-age literacy: including basic, scientific, economic, and technological literacy, visual and information literacy, and multicultural literacy and global awareness, 2). Inventive thinking: including adaptability and managing complexity, self-direction, curiosity, creativity, and risk taking, and higher-order thinking and sound reasoning, 3). Effective communication: teamwork, collaboration, and interpersonal skills, personal, social, and civic responsibility, and interactive communication, and 4). High productivity: prioritizing, planning, and managing for results, effective use of real-world tools, and ability to produce relevant,

high-quality products. In the 21st century, we will need to go beyond textbooks and define literacy to include the ability to exercise thinking skills and to utilize Internet technologies.

While standards for learning and demands on teachers have been increasing, there are changed expectations for teachers and growing concerns about teacher educators. Research studies evidenced that teachers' school experience influenced their belief about teaching and influenced the way they teach (Carter & Doyle, 1996). How teacher educators teach pre-service teachers significantly influences the way pre-service teachers teach. Most of the current teacher educators were educated at the time when Internet access was not available or rarely available, and the information-communication technologies (ICT) were not as user-friendly as they are now. Presently, teacher educators lack sufficient knowledge of the value of the current technologies and hardly think of innovating teaching through the technologies. Teacher educators may continue to educate their students, namely, pre-service teachers, in the way they themselves were educated. Pre-service teachers may either imitate the way their teacher educators taught or adopt their intuition to teach (Gardner & Williamson, 2007). These outdated ways may directly or indirectly result in the inability of pre-service teachers to thrive as teachers. To equip young teachers with 21st century skills, teacher educators have to reshape teaching and learning using technology.

The Blog Technology

Internet technologies and software applications have become more intuitive, and computer technologies and Internet communication tools are being applied to the education field and integrated into classrooms. One of these tools is the weblog (often called blog), which is emerging rapidly in the context of education, providing an uncomplicated but powerful organizational form supporting online expression (Oravec, 2002). Especially

during the last few years, blogging has become a popular online activity across all ages, races, and countries. Many people either blog or read blogs every day. Blogging is a method of journal keeping, except that blogging can share and disseminate information and emotions around the world. In the blog environment, people ask questions, think about thinking (meta-cognition), and write to the public. The environment is culturally rich and educational. Because of its educational value, blogs deserve a high profile in teacher education.

Essentially, blogs are a reflective tool. When people blog, they reflect, and express thoughts through writing. Blog technology provides a premium platform for reflection. Usually bloggers *turn to prior experience, attend to their feelings and emotions, and re-evaluate their experience*; these three components are exactly what Boud, Keogh, and Walker (1985) once defined as reflection. Schon (1987) distinguished between *reflection on action* (reflection after practice has been completed) and *reflection in action* (thinking that takes place during practice). This distinction highlights the fact that there are cycles to thought, and their links, and their impacts on practice. Boud, et al. (1985) pointed out, "Reflection does not have to be a solitary activity" (p. 16). People can keep blogs in the form of groups and/or keep their own blogs. If blogging in groups, pre-service teachers can collaborate with their peers and get familiar with the ethics of working in groups. Through collaboration, pre-service teachers experience the process of knowledge construction in groups and develop collaboration and interpersonal skills. After all, schools often need teachers to work together to accomplish projects. Therefore, it is essential to develop pre-service teachers' effective communication skills during the period of teacher preparation. Another reason why blogs are recommended in teacher education is that blogs can help pre-service teachers become aware. Most learners are not aware of how they construct or attribute meanings to what they see. Learners often do things habitually. Learners can

become prisoners of rigid competencies (Candy, Harri-Augstein, & Thomas, 1985). Blogging can help pre-service teachers get out of the shackle of habit and develop reflective practice in teaching.

In addition to facilitating the skill development of higher-order thinking, keeping blogs can help pre-service teachers cultivate technology literacy. For the last five years, information-communication technology (ICT) has become more and more used as a tool to enhance the delivery of curriculum and instruction. Blogs, a type of Web 2.0 technology, can be regarded as information-communication technology (ICT). When blogging is integrated into teacher education, pre-service teachers can observe teacher educators modeling technology integration in an instructional setting. Pre-service teachers get familiar with the virtual learning environment, and are indirectly enabled, equipped with the pedagogical knowledge, technical skills and interplays required for their future teaching.

Taking advantage of their accessibility and the potential for accountability, blogs can be utilized as e-portfolios. Blogs record both the process and products of learning. Blog portfolios can encourage pre-service teachers to think creatively while considering what content to collect and how to use media to display their content. There have been numerous research studies investigating the significant relationships of individual differences and media modes (eg, Ford, 1985; Ford & Chen, 2001; Jonassen & Grabowski, 1993; Liu & Reed, 1994). Diverse media, including text and non-text, can complement individual differences in learning and can be easily placed in blogs to communicate pre-service teachers' thoughts, display their artifacts, and demonstrate learning outcomes.

Furthermore, the process of blogging helps to develop pre-service teachers' meta-cognitive skills, further generating educational value. To blog well, pre-service teachers monitor their own learning and learn when to ask for help or search for additional information. This type of meta-cognition, thinking about one's own thoughts, can empower pre-service teachers to

learn independently and help them become lifelong learners (Bransford, Brown, & Cocking, 2002). Once developing meta-cognition becomes a reality for pre-service teachers, then expecting K-12 students to be equipped with 21st century skills will be more realistic.

How to Integrate Blogs in Teacher Education

All over the world, we hear cries for the improvement of teacher education. If pre-service teachers get accustomed to recording their own performance through portfolios as early as when they are in teacher education programs, they may be less resistant to evaluation when they start their teaching profession. Thanks to the transparency of blog technology, there is little technical barrier to keeping a blog portfolio. Making blogs is as easy as writing e-mails. Training pre-service teachers to keep their blog portfolios not only prepares them for evaluation but also encourages them to reflect on their own work while promoting their technology literacy. The merits of blogs in education are multi-dimensional.

This section will describe how blogs can be integrated into teacher education programs. The process of teacher preparation is divided into two parts: course-work period and teaching practicum (including a practicum with and without direct supervision). It is crucial that teaching practice is supported by a theoretical foundation (Grossman, 1990). This chapter applies Cognitive Apprenticeship (Collins, Brown, Newman, 1989) to the context of the teacher education programs. Cognitive Apprenticeship is an instructional model in which teachers try to make thinking visible. The model combines elements of apprenticeship and schooling. To transition from a traditional apprenticeship to a cognitive apprenticeship approach, teachers should conduct the following tasks. 1). Identify the task process and make it visible to students. 2). Situate abstract tasks in authentic contexts, so that students understand the

relevance of the task. 3). Adjust the diversity of situations and articulate the commonality of tasks, helping students' transition from what they know to brave the new and unknown (Collins, Brown, Newman, 1991). Cognitive Apprenticeship (Collins, et al., 1989, 1991) identifies five approaches to making the blog-integrated activity an integral aspect of instruction. They are *modeling*, *coaching*, *articulation*, *reflection*, and *exploration*. Details are as follows.

During the first two years of pre-service teacher training, teacher educators should *model* innovative use of technology in their classroom. During that time, teacher educators should create opportunities for pre-service teachers to experience and observe innovative uses of blogs. Teacher educators should make their own teaching journals available in a blog, and demonstrate how to make teaching portfolios. This makes the process of teacher preparation active and develops pre-service teachers' pedagogical literacy. Teaching portfolios should include everything from how to set up a classroom, to how to deal with unexpected behaviors of students. In that way, pre-service teachers can observe and build a conceptual model of the processes that are required to design, develop, and teach a course; they will be better able to solve classroom problems and reflect on their teaching practice. While observing modeling, pre-service teachers can start building their own portfolios by placing their artifacts in their own blogs. Teacher educators will *coach* pre-service teachers by observing pre-service reflection through blogs. During coaching, teacher educators should offer hints, feedback, reminders, and assistance. They should offer these types of scaffolding, while giving the reins to pre-service teachers. Moreover, teacher educators need to clearly convey their expectations as pre-service teachers may want to work hard to meet the requirements of quality work. (Gathercoal, Crowe, Karayan, McCambridge, Maliski, Love, & McKean, 2007).

After pre-service teachers finish their course work and begin their teaching practicum, they can continue to blog, either in groups or individually. When blogging, pre-service teachers are required to *articulate* their thoughts, *reflect* on their reasoning processes, explain or compare their own problem-solving processes with those of an expert or another participant from their practicum. And it is crucial to require pre-service teachers to *explore* how to frame questions and problems (Collins, et al., 1989). Pre-service teachers should be assigned groups, where they can post questions and problems, respond to each other, collaborate and reflect together on their approaches to teaching and learning in their practicum. Pre-service teachers may sometimes get static with their blogging. Teacher educators need to regularly log in to their students' blog sites to provide feedback to group and individual blogs, and initiate discussions. In addition to functioning as a e-portfolio and reflective tool, blogs can be used as another form of class interaction. Through Cognitive Apprenticeship, the course work combined with blog integration, can address the theory-practice divide. And a teaching practicum based on the innovative use of technology will maximize the benefits of the students' in-school field experience. In the process of blogging, pre-service teachers create their own e-portfolios, observe how teacher educators respond and moderate the asynchronous online discussion, learn to reflect on their own practice, and get familiar with the Web 2.0 technology.

Google offers a free blog site "Blogger." Without any technical threshold, users do not need any special skills, teacher educators can go to <http://www.blogger.com> to apply for a free account. Then pre-service teachers can open their own accounts. Teacher educators maintain the class blog site for class discussion. Teacher educators can post diverse types of media (text, graphics, photos, video, MP3 and other media) as course supplementation. In addition, teacher educators should require pre-service teachers to post reflect-

tions on course content, express emotions and ideas that differ from in-class discussions by being more personal. Teacher educators do not need to restrict pre-service teachers about which part of the curriculum content to explore, and should model the way to reflect on the learning experience. The product, a blog, will give pre-service teachers a sense of ownership of their explorations.

When pre-service teachers post reflections on course content and their prior experiences, they are practicing higher-order thinking skills and making deeper connections to the material. For some people, learning is often dull. With blogs, learning becomes reflective and personal. And learning is supposed to be personal, since one has multiple intelligences, as Gardner (1993) advocates. Maintaining blogs in class activities, pre-service teachers actively participate in thinking and knowledge construction. Therefore, teacher educators should encourage pre-service teachers to explore the curriculum content, that way pre-service teachers have abundant choice to decide what to reflect on and how to reflect. By creating blogs, pre-service teachers learn autonomy, and develop into self-directed learners.

Findings

There have been research studies indicating the importance of opportunities for pre-service teachers to share reflection with each other in an environment of trust and respect (Gardner & Williamson, 2007). Creating opportunities for teacher educators to model innovative use of technology and reflection of their pedagogy to pre-service teachers is a necessity in today's teacher education programs. Based on the guidelines for implementation suggested in the previous section, a teacher education course, *Principles of Instruction* was integrated with blogs as a class assignment. The participants were 155 pre-service teachers in a national Taiwan university during the spring of 2006. The course was integrated with

blogs throughout the semester. The course blog was located at <http://spring06p1.blogspot.com/>.

The students were heterogeneous, sophomores to seniors, from a variety of disciplines. The course was a requirement for all pre-service teachers. Surveys and interviews were used for the investigation of the participants' attitudes toward blogs. Overall, the participants' positive attitudes toward blogs were above-average. The descriptive data of a few sample questions on attitude toward blogs are provided in the following paragraphs. More than 70% of participants agreed or strongly agreed that writing blogs helped them reflect on the course, and around 7% of participants disagreed or strongly disagreed with the statement. More details are displayed in Figure 1.

More than 75% of participants agreed or strongly agreed that writing blogs helped participants exchange ideas and thoughts with their fellows, and less than 10% of participants disagreed or strongly disagreed the statement. See Figure 2.

More than 80% of participants agreed or strongly agreed that writing blogs helped participants express emotions, and less than 6% of participants disagreed or strongly disagreed with the statement. More details are in Figure 3.

Figure 1. The distribution of participant agreement on the statement *Writing blogs helped me reflect on the course contents*.

Figure 2. The distribution of participant agreement on the statement Writing blogs helped me exchange ideas and thoughts with fellows.

Regarding the question: *How did writing blogs about the class help you learn the course content*, there are several types of learning that occurred during the course. Details analyzed from interviews are illustrated in Table 1.

Figure 3. The Distribution of participant agreement on the statement Writing blogs helped me express emotions.

The participants reported several types of feelings emerging when they read their fellows' blogs. Details of feelings brought up are in Table 2.

Table 1. How many types of learning took place in the learning context.

Type of learning	Participant Response
Attentive	"Writing blogs after class made me have to review and digest course content, and forced me to pay more attention to what the instructor said in class." "I have no idea what to write in blogs. But if I pay attention to the lectures, I get more inspiration of what to blog about."
Reflective	"Writing blogs helps me be aware of how much I learned in class." "Before going online, I need to make sure if my understanding of the course contents is correct. I usually evaluate it by reading the textbook again or reading others' blogs." "Blogging made me think more logically. Because before I blogged, I needed to think it through and make sure I didn't write something which I would feel ashamed with."
Meta-cognitive	"I often needed to evaluate and think about my own thoughts before writing blogs. Blogging made me do a lot of thinking." "Each week after class, I wrote blogs, and blogs became a tool for me to understand my learning progress. I can more regulate my own learning."
Communicative	"Writing blogs creates opportunity for me to exchange ideas with fellows." "Conversing" with fellows through blogs stimulates my thoughts and makes me feel a member of a learning community."
Connective	"Writing blogs reminds me of the theories I learned in class and connects with my learning experience."
Digital literacy	"The blog activity forced me to learn how to use blogs. At first I felt resistant to learning the tool. After using blogs, I'm glad I got chance exploring the tool. It's cool."
Collective	"Our personal blogs keep our own work" very well. When I had exams, the blogs collected my review notes so well that my life got much easier."
Resourceful	"There was a lot of useful information on other people's blogs. Sometimes I can find a lot of goodies there. For example, web site links to YouTube videos or to podcasts."

Table 2. Feelings brought up when participants read other fellows' blogs.

Feelings	Participant Response
Interest	"I was impressed with some other fellows' opinions. They looked at the things in the way I never thought of." "Reading others' blogs is like listening to people singing the same song; you got different interpretation of the song." "When I read different thoughts expressed in blogs, I feel they broadened my views."
Competition	"I'd like to read other people's blogs and contrast my opinions with theirs." "When I read blogs that are written well, I anticipate some day I could reach the level."
Relaxation	"When I read someone has the same opinions with me, I feel good about that." "I'd like we shared thoughts with each other. Sharing makes me feel relaxed".
Lurking	"Reading other people's blogs let me understand them more. I feel I am peeking their privacy."
Unpleasant feelings	"I feel pressured when I read blogs written with good insights and analyses. It makes me feel uncomfortable." "I'm disgusted with some people who just copied the words from textbook. It wasted my time to read their blogs." "Some blog web sites with messy interface pissed me off!"

The participants disclosed they experienced significant emotional response when they read their own blogs. Details of feelings for reading their own blogs are in Table 2.

Implications

The findings demonstrated the pre-service teachers' attitude towards blogs and the potential educational values of blogs. The evidence showed that pre-service teachers can use blogs to learn course content, to foster reflection, to monitor and assess their learning process. These are the basic elements

of the required 21st century skills (NCREL, 2003; Partnership for 21st Century Skills, 2007).

Reflection in teacher education is not a new concept, but using blogs to facilitate reflection is a new area of inquiry that deserves deep exploration. Based on these research findings of blog integration in a teacher education course, there are a few qualitative implications to address. First, group blogs and individual blogs function in different ways and should exist together in a learning community. Group blogs provide participants with a platform for interaction, communication, and discussion, and individual

Table 3. Feelings when participants read their own blogs.

Emotions	Participant Response
Motivation	"When I read my own blogs, I felt impressed with my work. Those blogs were written week by week and accumulated to such amount. I felt I learned something. I got great sense of achievement!" "Reading my own blogs helped me monitor my own learning progress and motivated me to write more." "I felt proud of myself that I can express myself."
Self-criticism	"Sometimes I felt stupid with my words. I wished I had not written such stupid ideas." "Sometimes when I read blogs, I felt I was making progress, because they were thought-provoking. But sometimes my thoughts were empty and full of ignorance."
Pleasant	"I felt great that I can express my emotions freely." "It's pleasant I can recall what happened in class by reading blogs."
Expectations	"I looked forward to people's responding to my ideas or discussing with me." "I'd like to get more feedback from my teacher."
Critical of the process or of others	"I felt childish with blogs. Blogging is like keeping a diary; a diary is supposed to be private." "People were so superficial in blogs, showing off ideas or stuff. I'm not going to play the stupid game."

blogs provide participants with personal space to keep learning notes, record learning progress, reflect thoughts and actions, and make personal e-portfolios. Through group blogging, pre-service teachers learned that collaborative interaction can create a positive learning experience, and they took the opportunity to share problems, and to offer suggestions or support each other. In the process of blogging, pre-service teachers addressed each other's concerns, and learned to search for solutions collaboratively, different perspectives were shared and ideas sparkled, resulting in more positive attitudes toward learning and teaching. Through individual blogging, pre-service teachers learned to reflect and construct their knowledge of teaching, become more aware of their thoughts and action, and make their e-portfolios for future career.

Second, participants need scaffolding for reflection. Atkins and Murphy (1993) indicated that the following components are necessary for reflection: self-awareness, description, critical analysis, synthesis, and evaluation. And Pater-son (1995) indicated the following factors affect reflection: 1) developmental levels of reflection; 2) perception of trustworthiness of the teacher; 3) clarity of expectations related to journal writing tasks; 4) quantity and quality of teacher feedback. Teacher educators need to recognize these factors and support pre-service teachers' progres-sion through those different skills of reflection. Starting with personal performance at a practical level, pre-service teachers learn to justify their teaching practice, and finally to reflect on values and thought-provoking issues (Furlong, 2000).

If necessary, teacher educators can post topics or raise questions, to stimulate pre-service teach-ers' thinking. Questions can be used as prompts. This chapter suggests a framework for reflection and prompts. Prompts vary, depending on the time frame of the learning context. Schon (1987) dis-tinguished the time frame of occurrence of reflec-tion, as mentioned earlier. Postholm (2008) added another segment, reflection before action, thinking about prior experiences and theories before tak-ing action. Reflection before action, reflection in action, and reflection on action constitute the complete process of reflection. Regarding what questions to ask during reflection, Smyth (1989) suggested four questions that can stimulate reflec-tion: What do I do? What does this mean? How did I come to be this way? How might I do things differently? With the four stimulating questions, a framework of reflection and questions to guide reflection in learning contexts is recommended in Figure 4. Notice that asking open-ended questions rather than closed ones is a must.

Third, to build a successful blogging com-munity, teacher educators need to participate in the blogs. The participants in this study emphasized that they looked forward to feedback from their instructor and peers. To meet the need, teacher educators should join blog reflection on a regular basis and leave comments on pre-service teachers' blogs. On the other hand, teacher educators can diversify feedback by assigning pre-service teach-ers into groups and requiring them to reply to each other. By doing so, pre-service teachers can acquire feedback from their peers and a learning com-munity is gradually built up. Considering the

Figure 4. Questions to stimulate reflection in the blog context.

limited time teacher educators can commit to a class, it is necessary to make effective use of the learning community and re-direct learners' reliance on the instructor to the learning community. But the instructor must be a part of the community! To encourage active participation in the blog community, teacher educators need to take responsibility for moderating online discussions.

Salmon developed a five-stage framework for moderating groups and suggestions for consideration (Salmon, 2000). Contextualized in the blog environment, the five stages of moderation are: 1) Stage of access and motivation: Teacher educators post welcoming and encouraging blogs to invite pre-service teachers to join the blogging; and construct the atmosphere in which pre-service teachers feel secure and can talk openly and honestly about their feelings. 2). Stage of socialization: Teacher educators introduce themselves to the class, demonstrate respect for differences among class members, and bridge differences of opinion in a non-judgmental manner. 3). Stage of information exchange: Teacher educators encourage pre-service teachers to share information and learning materials by, for example, providing web site links on blogs. 4). Stage of knowledge construction: When blogging, pre-service teachers post reflection on course content or post questions they have. Teacher educators participate in online discussions with pre-service teachers and facilitate the process of knowledge construction. For teacher educators, the priority is to maintain a flexible environment for knowledge construction. 5). Development: It is at this stage that teacher educators respond to questions and monitor the discussion process. As pre-service teachers reflect on their experiences in schools and their learning, it is necessary to interrogate, test, and challenge pre-service teachers' experiences to avoid unconscious assumptions, because assumptions may reduce creativity in trying to understand or resolve a problem. Incidentally, teacher educators should always take pre-service teachers' learning styles

into consideration to handle ideas or thoughts in blogs (Salmon, 2002).

Finally, the quality of the blogs will influence their effect. Some participants complained when they saw fellows not reflecting their thoughts but only copying the words from textbooks, they felt that reading the blogs was wasting their time. In light of the problem, it is essential that teacher educators emphasize and evaluate the quality of blog contents. Blogs provide users with an interactive platform for reflection. Thus, to evaluate blogs, reflection is a key. There are several frameworks for evaluating reflection (Boud, et al., 1985; LaBoskey, 1993; Sparks-Langer, Simmons, Pasch, Colton, & Starko, 1991; Valli, 1990). For example, Boud et al. (1985) categorized critical analysis into four elements: association (connecting new data with what is already known), integration (searching for relationships among data), validation (determining the authenticity of ideas, feelings and emotions that have resulted), and appropriation (making knowledge one's own). Regarding how to evaluate reflection, Zeichner and Liston (1987) designed the Reflective Index to identify student teachers' reflection in meetings with their supervisor. The Reflective Index consists of four categories ranked from lowest to highest in importance. The four levels can be used to measure the reflection that occurs in a blog context. Details are explained with examples as follows.

1. Factual level: When blogging, pre-service teachers recall some students' behavior that occurred in classrooms; the reflection is at the factual level.
2. Prudential level: When blogging, pre-service teachers evaluate the effectiveness of conducting objective assessments or e-portfolios; the reflection is at the prudential level.
3. Justificatory level: When blogging, pre-service teachers focus on the reasons why collaborative learning activities occurred, or

why some individual learning activities are suitable; the reflection is at the justificatory level.

4. Critical level: When blogging, pre-service teachers explore teacher educators' perception that underlies the reasons why teacher educators integrate blogs in the learning process; the reflection is at the critical level.

CONCLUSION

This chapter suggested the implementation how-to and rubrics for assessing reflection in an online blogging environment. To successfully implement blogs in teacher education, the administrative authorities in teacher education programs may have to require that teacher educators implement blogs throughout the period of teacher preparation and provide professional development for teacher educators whenever necessary. Requiring teacher educators to use blogs creates opportunities for pre-service teachers to update their technology literacy, to make personal e-portfolios by collecting artifacts from different courses into blogs, and to prepare for carrying out reflective practice in their future careers teaching in K-12 settings.

Effective technology integration in classrooms does not require expensive hardware and software. People tend to have the misconception that adopting technology integration in schools needs to be expensive. Quite a few web sites provide blog services for free. Teacher educators should learn how to make good use of free online resources and model the practice to pre-service teachers. After all, not all pre-service teachers can teach at schools with sufficient funding. Finally, teacher educators can take Cognitive Apprenticeship as the approach to develop pre-service teachers' pedagogical literacy and reflective practice. This instructional model combines aspects of traditional apprenticeship with formal schooling. Following the principles of Cognitive Apprenticeship, teacher educators will be able to help pre-service teachers

develop higher-level skills, such as decision making and problem solving in classrooms.

During the last decade, while new Internet technologies have been continuously emerging, the popular blog technology has made a significant impact on the dissemination of information and knowledge. Blogs are "transforming publishing and traditional media into more personal and interactive experiences" in which users become active participants, not just passive consumers (Kennedy, 2004, p. 249). Recognizing the potential and popularity of blogs in education, teacher educators in teacher education programs must update their traditional educational practice and connect theory with practice to help would-be teachers gain sufficient competence and confidence to thrive in the 21st century classrooms.

ABSTRACT

In recent years, educators across the globe have begun to employ portable, digital media players, especially iPods, as educational platforms. Unfortunately, while the iPod grows in favor as a mobile multimedia learning environment, relatively little is empirically known about its educational impact. This chapter explores the use of the iPod as an educational platform and reports on a study designed to examine individual differences in iPod

use as a mobile multimedia learning environment. This exploration into applied and basic research involving the iPod reveals that iPods are being used across a variety of content areas, educational levels and geographic locations, involving a variety of pedagogies. However, very little research has been conducted to establish the efficacy of the iPod for fostering learning. To address this need, the authors conducted a study that examined the effects of working memory capacity (WMC) on learning within an iPod-based mobile multimedia learning environment.

DOI: 10.4018/978-1-60960-503-2.ch308

INTRODUCTION

Mobile learning, or m-learning, is typically defined as learning with mobile technologies (see Laouris & Eteokleous, 2005). This type of definition generally emphasizes the ability to move beyond place-bound teaching and learning environments (Goh & Kinshuk, 2006; Seppala & Alamaki, 2003) based on the application of wireless educational technologies (e.g., mobile phones, personal digital assistants, laptop computers, portable digital media players). Educational research into the efficacy of mobile learning and mobile technologies tends to focus on “their use embedded in classroom practice, or as part of a learning experience outside the classroom” (Naismith, Lonsdale, Vavoula, & Sharples, 2006, p. 11). One arena in which this is especially the case is the use of portable digital media players (e.g., iPods, Zunes, MP3 players). In recent years, educators across the globe have begun to employ portable digital media players, especially iPods, as educational platforms (see Belanger, 2005; Cebeci & Tekdal, 2006; Trelease, 2006).

The use of the iPod for educational purposes has included lecture capture at Duke University (USA), podcasting at Auckland University of Technology (New Zealand), foreign language instruction at Astley Community High School (U.K.), math instruction at Apollo Parkways Primary School (Australia), and an entire degree at Sligo Institute of Technology (Ireland), to name only a few. Unfortunately, while the iPod grows in favor as a mobile multimedia learning environment, relatively little is known about its educational impact. How well do students learn from podcasts? How are students using iPods to view or re-view lectures? Does listening to native speakers on the iPod affect learners’ foreign language listening, writing, or speaking skills? This chapter explores the use of the iPod as an educational platform and reports on a study designed to examine individual differences in iPod use as a mobile multimedia learning environment.

IPOD RESEARCH

Over the past several years, research addressing the use of the iPod as a mobile multimedia learning environment has included both applied research, which is designed to solve problems, produce products, or fulfill a specific need; and, basic research, which is designed to expand the current knowledge base regarding learning in iPod-based mobile multimedia learning environments. There is, however, a disparity between the depth of applied and basic research, with there being much more applied research than basic research.

Applied Research: iPods in the Classroom

Mobile multimedia learning environments can take on many forms as technological advancements abound and are being used to supplement and even replace some forms of formal classroom education. The use of iPods and podcasts for educational purposes is a growing trend in the realm of education from primary school through college. Even the military has incorporated these educational tools for learning.

The Navy College Program for Afloat College Education (NCPACE) teamed with Dallas Tele-College to institute educational programs using the iPod for deployed sailors, thereby reducing the number of computers needed on board ships while still allowing the sailors the opportunity to learn (Jay, 2007). In addition, the National Defense University’s Information Resources Management (IRM) College not only uses video iPods to deliver education but also to allow students to create assignments for their courses, such as recording interviews with officers.

New Mexico State University (NMSU) offers educational programs to the airmen on Holloman Air Force Base so that they can continue to pursue their education while on deployment (Venegas, 2007). Their iPod program begins with “sociology in a sack” in which the iPod is loaded with sociol-

ogy lectures and includes support materials such as a syllabus, sample quizzes, and instructions for the program. Upon the end of their offsite operation, the airmen return the iPods to the school and take their exams for course completion. Considering distance education courses often utilize the Internet for most of their materials and lectures, this program can meet the needs of those airmen who are deployed in places where Internet connections are scarce and therefore limit the opportunities to continue their education.

In addition to military use, Apple has reported that there are a plethora of elementary schools, secondary schools, and universities that have reported success with the use of their iPod devices for educational delivery and production. For example, Bob Sprinkle, a teacher at Wells Elementary School in Maine, has been using iPods and podcasts with his third and fourth-grade students to teach research, writing, and presentation skills as well as the embedded technology expertise that inevitably accompanies projects such as these (Apple Education, 2007a).

Vanderbilt University (2007) has partnered with Sheridan School District in rural Arkansas to transform students' use of a lengthy bus ride into educational time. This project, the Aspinaut Initiative, was formed as a way to elevate the mathematics and science achievement of the rural community base and one aspect of this project includes the use of iPod podcasts for the students (Clark, 2007; Vanderbilt University, 2007). This three-year project includes iPods programmed with lessons that focus on science and math and as a bonus the students get to keep the iPods if they complete the full study. The school district's superintendent states that beyond the focus of the current project, the students may actually receive course credit for the time they spend learning while commuting to and from school (Paul, 2007).

High school students preparing for college admissions are also a targeted audience for iPod use. Kaplan, a college-preparation company, recently began to offer customizable iPod programs

to students via Apple's iTunes store (Man, 2007). This innovative SAT preparatory program allows students to purchase materials for viewing and practice with timed and untimed tests and the student can even vary the level of difficulty of the programs they choose. Kristen Campbell, the national director of SAT and ACT programs for Kaplan Test Prep, thinks that students will embrace these types of programs because they allow students to study in a medium in which they are familiar and comfortable. Currently, Kaplan is the only test-prep company offering these types of study programs via the iPod iTunes store.

The University of Minnesota's School of Public Health (SPH) features podcasts for many different uses for students and the general public (University of Minnesota School of Public Health, 2007b). They feature weekly health segments (Public Health Moment) and public lectures sponsored by SPH (Public Lectures). Their "Public Health Matters" section contains student and faculty-created podcasts that cover a wide variety of topics related to current research within the department and other public health issues (University of Minnesota School of Public Health, 2007a).

The University of Utah (UU) uses podcasts for a wide variety of information-sharing endeavors. They present podcasts of lectures, interviews, speeches, performances, and have developed several series of lectures for download (University of Utah, 2007). UU features five major categories for podcast feeds including humanities, politics and society, health and wellness, science and technology, and arts and culture. They also have several other podcast program offerings to include the Genetic Science Learning Center, Hinckley Institute of Politics, Humanities Happy Hour, and Sci-Fi Fridays.

The University of Wisconsin-Madison began their podcasting integration with iPods in 2005 to assist students with language acquisition in a German language class (Apple Education, 2007b). Their goals included incorporating class content (language instruction) into the daily lives of their

students outside of the traditional classroom models and making homework more fun for the student. Instructors report that their project actually helps students learn the German language more easily and increases student motivation because they format some of their podcasts in a fun radio show style with fictional callers; thus decreasing straight lecture format and time for the students.

iPod initiatives at Georgia College and State University (GCSU) began in 2002 and have evolved into more than lectures and music to enhance the classroom education of its students (Georgia College and State University, 2006). By the 2006-2007 academic year, there were nearly 50 iPod-based projects designed to reduce in-class lecture time and increase time for students and faculty members to collaborate on experiences and discuss the most important course content areas. These innovative iPod projects have spawned other technological advancements for the university as well, such as their iColony project, a virtual learning community for students with similar interests; and iDreamers, a group of faculty and staff members interested in further developing plans for iPod usage in the future.

The University of Virginia's (UVA) Web site boasts an enormous amount of iPod-based information available for their students as well as the general public. They list 20 categories of information to choose from ranging from academic lectures to science and research (University of Virginia, 2007). The available podcasts also include recurring series, such as *Engaging the Mind*, *Technology in World History*, and others. In addition, each school at UVA is represented with links for individual podcasts related to topics of interest for that particular area of expertise and interest.

While many higher education institutions are employing iPod technology, there are few who are formally evaluating their iPod and/or podcasting programs. Duke University was one of the first higher education institutions in the United States to implement an iPod program. In August

of 2004, more than 1,600 entering first-year students were given iPods (Duke University, 2005). Approximately 48 courses implemented iPod content during the first year of the program. These courses included music, foreign languages social science, and humanities (Duke University, 2005). Additionally, first-year engineering students used their iPods in the engineering programs' required computational methods course.

As part of the program evaluation conducted by Duke's Center for Instructional Technology, data were gathered via several methods: student and faculty focus groups; a survey of first-year students and faculty; course feedback; and conversations with staff, administrators, and campus stakeholder groups. As part of the evaluation, the Center for Instructional Technology wanted to discover how iPods were instructionally used. They found five categories of academic use for the iPod: disseminating course content, recording classroom activities, recording field notes, supporting study of the content, and storing and transferring files (Duke University, 2005). The evaluation also revealed several benefits in utilizing the iPods. The overall benefits reported after the first year of the program included the convenience of portability, easy digital recording, flexible location, increased student interest and engagement, and enhanced support for individual learning differences.

Despite the benefits of using the iPod in the classroom, Duke students and faculty reported several problems (Duke University, 2005). One problem concerned the challenges of integrating multiple systems for storing, accessing, sharing, and distributing content. Another issue was the limited pre-existing documentation and training resources regarding academic uses. Furthermore, integrating the iPods with Duke's existing technology infrastructure was difficult. PC users were also affected by the limited documentation and training. The inadequacy of documentation and training may have contributed to another problem: a lack of awareness and accurate knowledge among

students and faculty regarding how iPods function and their academic applications. A final set of difficulties with the iPods was bulk purchasing and licensing issues.

At the institutional level, Duke University reported several benefits from incorporating iPods into the classroom. The evaluators found four major institutional impacts (Duke University, 2005). The first was increased collaboration and communication between campus technology groups, which resulted in wider planning and improvement of Duke's infrastructure and technology services. The second impact was the widespread attention resulting from the program. Duke gained new contacts, partnerships, and collaborations with other institutions of higher education, publishers, and technology vendors. Third, the program sparked conversations between faculty, administrators, students, and staff about how to best implement technology in the classroom. Consequently, the 2005-2006 Duke Digital Initiative was created with continued iPod use and further incorporation of other technologies. Finally, the iPod program increased overall awareness of Duke's commitment to technology.

However, there were some problems with the evaluation, especially regarding the survey response rate. Only 28 percent of first-year students involved in the program responded to the survey, while only 13 percent of first-year student faculty responded (Duke University, 2005). The low numbers suggest that perhaps not all benefits or problems were accounted for. The program also began with no formal objectives, a limitation remedied in the 2005-2006 Duke Digital Initiative. Finally, cost was not addressed in the evaluation. While the implementation program cost \$500,000, there were no data included regarding how much money the university would have to spend to continue such a program.

Cost was addressed, however, in the 2005-2006 program evaluation report (Duke University, 2006). One of the main challenges mentioned in the report was the difficulty of acquiring mul-

timedia course content in a cost-effective and timely manner. Additionally, cost was alluded to in other challenges. Ongoing planning, training, and support is an expensive challenge due to how rapidly technology changes. Furthermore, the university lacked the classroom capabilities to meet the demand for video recording of classroom presentations. Upgrading classroom infrastructure to meet this demand would be an expensive endeavor, although as part of the 2007-2008 Initiative infrastructure development is planned.

Cost was not the only challenge. The evaluators again found that faculty and students need more training on how to use the iPod and to transition classroom pedagogy into the multimedia environment (Duke University, 2006). Improvements slated for the 2007-2008 year include more development and utilization of support services and teaching strategies in addition to further research of technology in learning and instruction.

Besides Duke University, many other American colleges and universities have implemented iPod programs and podcasting as a means to advance instruction. The University of Michigan's School of Dentistry started a podcasting program in response to first-year dental students' anxiety regarding the quantity of information presented in their courses (Brittain, Glowacki, Van Ittersum, & Johnson, 2006). Originally, the students asked for video recordings, so the School of Dentistry asked an advisory group to study the situation and recommend solutions. In the first pilot study, the focus was on what type of media format was best for lecture review. The results revealed that students preferred an audio-only format over video or audio-synced PowerPoint. The preference was due largely to the mobility of the audio files.

Two more pilot studies were conducted to fully examine the issue (Brittain et al., 2006). The second pilot study focused on the costs involved with recording lectures. Recording via the computer, although more expensive than recording with the iPod, was deemed more suitable by students and faculty due to its superiority in audio recording

quality. The School of Dentistry decided to use a computer and automated recording, processing, and posting tools to reduce staff time, thus decreasing the overall costs involved with the project.

Finally, the third pilot study looked at the dissemination of recordings, in particular the file format students preferred most (Brittain et al., 2006). MP3 and AAC files were both found to be equally well-liked, so the school decided to post both file types to a centrally located Web site for downloads. Due to convenient access, students' usage of the recordings rose from 28 percent to 57 percent.

In addition to the many American higher education institutions using iPods and podcasting, international institutions are also bringing iPod technology into their classrooms. One such institution is Charles Stuart University in Australia. Researchers investigated and evaluated the use of podcasting in an undergraduate and postgraduate class by studying the listeners, producers, and educators involved in podcasting the course (Chan, Lee, & McLoughlin, 2006). Some of the students were part of the production team, which created podcasts targeted towards other students in the class, who served as the listeners.

To evaluate the "listeners" students, an online survey was employed to gather data concerning students' podcast use, the educational value of the podcasts, and the knowledge and skills gained through listening to the podcasts (Chan et al., 2006). The researchers had a 42 percent response rate to their survey. The majority of students used the available podcasts frequently, felt they were useful, and helped with assignments.

To evaluate the "producers," the researchers used a focus group interview (Chan et al., 2006). The focus group questioned participants about motivation, benefits related to involvement, skills developed, lessons learned, and suggestions for improvement. After coding the transcripts, the researchers found that the main area the producing students elaborated on was the skills they developed from participating in the production of

the podcasts, especially with regard to teamwork, communication, and critiquing others.

A study at another international institution looked at an undergraduate course in communication (Edirisingha, Rizzi, Nie, & Rothwell, 2007). At Kingston University in London, students enrolled in the Introduction to Intercultural Communication course served as participants. Students were surveyed and interviewed as part of the study. The survey revealed that 50 percent of the students had not listened to any of the podcasts available to them via the virtual learning environment (VLE). The main reason given for not listening to the podcasts was a lack of time. Other reasons included; they did not know the podcasts were available, they had technical difficulties accessing the materials, and they did not view the podcasts as relevant for learning. Additionally, of those who did listen to the podcasts, many did not download the podcasts because they could access the material any time they wanted. Furthermore, 31 percent noted that they preferred their MP3 player to be dedicated to music listening only, indicating they did not want the podcasts residing on their portable players.

Students were also surveyed regarding their activities while listening to podcasts (Edirisingha et al., 2007). The majority of respondents (47%) reported they only listened and did not participate in other activities, while 33 percent noted that they took notes while listening. Only seven percent reported doing other activities while listening to the podcasts. These findings suggest that the students, for the most part, engaged with the podcasts.

In addition to the previous findings, the researchers asked students about the key learning objectives related to the podcasts (Edirisingha et al., 2007). Students rated the following statements favorably: (a) Podcasts were useful for me to know more about the assessed work, (b) Podcasts were useful in preparation for workshops/seminars, and (c) Podcasts provided a good supplement to the other learning material for this module. Other statements regarding motivational aspects

were rated highly as well. The students, however, did not believe that the podcasts were helpful in organizing weekly activities or made good use of their time. A study by Edirisingha, Salmon, and Fothergill (2007), looking at learners' attitudes, found similar results.

Although students may remark that the podcasts are useful and aid their learning, there is little empirical evidence to support these claims. While many institutions are now using podcasts and iPod technology, more information about how humans learn from mobile technology is needed before such programs are implemented in the curriculum.

Basic Research: iPods as Mobile Multimedia Instructional Environments

Part of the allure of iPod-based mobile technology is the mobility (being able to use the technology in multiple and mobile environments). Unfortunately, while there is substantial applied research involving the use of iPods in education, there is very little basic research examining how students learn from iPods. Due to the paucity of educationally related basic empirical literature on the use of the iPod, the following studies are taken from a wide array of disciplines.

Salvucci, Markley, Zuber, and Brumby (2007) examined participants' ability to drive under the distraction of iPod usage. Participants were asked to search for and play music, podcasts, and videos while using a driving simulator. Salvucci et al. (2007) found that searching for and the selection of all three media types had a significant detrimental effect on driver performance, measured by lateral deviation (drivers ability to maintain a central lane position) and speed change (drivers ability to maintain a constant speed). Overall, Salvucci et al. (2007) discovered that simply listening to songs or podcasts had no significant effect on driving performance, but that searching for and selecting

media led to an increase in driver distraction and a decrease in driver performance.

O'Hara, Mitchell, and Vorbau (2007) also found distraction during mobile technology use in a study addressing individuals' daily use of mobile technologies, including iPods. O'Hara et al. (2007) studied the behaviors of established users of mobile technologies and found that the technology was being consumed in a variety of places and times such as at home, work, cafes, gyms, and airport lounges, as well as while driving to work, eating lunch, and going to bed. Reasons for using these mobile technologies included avoiding others, blocking out the surrounding environment, sharing videos, using time more effectively, and managing solitude. During the study, O'Hara et al. also found that the use of mobile technologies could lead to divided attention; that is, users often needed to divide their attention between watching a video using the mobile technology and monitoring others around them or being aware of events such as the arrival of a desired bus (2007).

While Salvucci et al. (2007) and O'Hara et al. (2007) found that iPod-based mobile technology is used in a variety of locations, for a variety of reasons, and that iPod use may be distracting, Hürst, Lauer, and Nold (2007) focused on screen size or the presentation modality effect on learning. Hürst et al. (2007) had participants view an animation on algorithm application using either an iPod, with a 2.5" screen, or a laptop computer. In addition Hurst et al. (2007) had participants view either an animation with on-screen text explanations or animation with audio narration. Hürst et al. (2007) deduced that there was no difference in student learning based on screen size (i.e., iPod versus laptop), but that students who viewed the animation with audio narration presentation learned more than students who viewed the animation with on-screen text presentation. Hurst et al.'s (2007) findings that learning was improved through the use of animation with audio narration, as compared to animation with on-screen text, is in agreement with previous research (Ginns, 2005;

Mayer & Moreno, 1998). Also, when asked which of the devices participants preferred for learning, half expressed no preference and the other half preferred the device they had used to engage the material with audio narration presentation. Ultimately, Hürst et al. (2007) concluded, “maybe the most important observation from our experiment is that people actually were able to learn something by using mobile devices” (p. 164).

The findings of Hürst et al. (2007) have demonstrated that iPods may be used effectively to foster learning and the findings of Salvucci et al. (2007) and O’Hara et al. (2007) lead credence to the question of whether or not attention, or distractibility, is a variable of interest in the use of iPods in education. With the issues of learning and attention in iPod-based mobile multimedia instruction environments in mind, a study was conducted.

IPODS AND INDIVIDUAL DIFFERENCES: A STUDY OF WORKING MEMORY

iPods are currently being used in many primary and secondary schools, as well as colleges and universities, as an educational platform. As the previous discussion of basic research into iPod use demonstrates, however, little is known regarding how the iPod-based educational environment interacts with the learner. One aspect of the learner that may bear on the use of the iPod as an educational platform is the learner’s attention. Attention has previously been demonstrated to be an essential component of learning in desktop multimedia instructional environments (Mayer, 2005b; Mayer & Moreno, 1998; Moreno & Mayer, 2000). This previous research has demonstrated that when attention is split between two sets of stimuli, such as an animation with on-screen narrative text (Mayer & Moreno, 1998); or when attention is diverted from instructional content to non-instructional content, such as when an animation is accompanied by

non-essential sounds, music, or videos (Moreno & Mayer, 2000); learning suffers. In addition, Mautone and Mayer (2001) have indicated that when attention is guided *toward* instructional content, learning improves.

Given the iPods’ mobility and its 2.5” screen, it is reasonable to question whether attention plays a special and important role in learning complex mental tasks in an iPod-based multimedia learning environment. In general, learning complex mental tasks has been sensitive to individual differences in attention; specifically, in individual differences in the ability to control attention (Daneman & Carpenter, 1980; Oberauer, Süb, Schulze et al., 2007; Wilhelm, & Wittmann, 2000). The ability to control attention is a central component of *working memory capacity* (WMC; Kane, Bleckley, Conway, & Engle, 2001; Kane & Engle, 2003), where WMC is defined as the ability to (a) maintain the current cognitive task in working memory, (b) maintain task relevant information in working memory, and (c) retrieve task relevant information from long-term memory (Feldman Barrett, Tugade, & Engle, 2004). A study was completed to assess the importance of attentional control, low WMC versus high WMC, in stationary and mobile multimedia learning environments using the iPod.

Working Memory Capacity

Working memory capacity (WMC) represents the ability of an individual to control his or her attentional resources relative to working memory, especially in the presence of distraction (Feldman Barrett et al., 2004; Unsworth & Engle, 2007). That is, WMC moves beyond working memory storage capacity (see Miller, 1956) to include both storage *and* processing capacity (see Daneman & Carpenter, 1980; Kane & Engle, 2003). Thus, ultimately, WMC is a measure of control: the ability to control the maintenance of information in working memory (storage) and the retrieval from long-term memory of information relevant to a

current problem or situation (processing). This control is most evident when there are distractions, internal (e.g., thoughts, drives, feelings) or external (e.g., talking, music, motion), challenging the attentional system (Unsworth & Engle, 2007).

Is this type of attentional control important? Previous research has indicated that individuals with high WMC outperform individuals with low WMC on measures of general fluid intelligence (Conway, Cowan, Bunting et al., 2002; Kane et al., 2004), long-term memory activation (Cantor & Engle, 1993), attentional control (Kane et al., 2001; Rosen & Engle, 1997), resistance to proactive interference (Kane & Engle, 2000; Lustig, May, & Hasher, 2001), primary memory maintenance and secondary memory search (Unsworth & Engle, 2007), and resistance to goal neglect (Kane & Engle, 2003; Roberts, Hager, & Heron, 1994). While these studies have indicated a positive effect for WMC on memory attributes, there is also extensive literature indicating that high WMC positively affects more academic pursuits, such as reading comprehension (Daneman & Carpenter, 1980), language comprehension (Just & Carpenter, 1992), vocabulary learning (Daneman & Green, 1986), reasoning (Conway et al., 2002; Kyllonen & Christal, 1990; cf. Buehner, Krumm, & Pick, 2005), computer language learning (Shute, 1991), lecture note taking (Kiewra & Benton, 1988), Scholastic Aptitude Test performance (Turner & Engle, 1989), mnemonic strategy effectiveness (Gaultney, Kipp, & Kirk, 2005), and story telling (Pratt, Boyes, Robins, & Manchester, 1989). This research has demonstrated a strong, positive relationship between variations in WMC and variations in complex cognitive task performance.

A Study of iPods and Individual Differences

To investigate the effects of high and low WMC students' learning in stationary and mobile iPod-based multimedia learning environments, 76 undergraduate students (52 males and 24 females)

were taken from a larger population of 294 students who were administered the OSPAN working memory span test. The OSPAN test measures working memory capacity and requires students to solve math sentences aloud (e.g., is $(2 + 6) - 2 = 4$?) while also maintaining a list of unrelated words in working memory (La Point & Engle, 1990; Turner & Engle, 1989). Using the OSPAN test scores, the upper and lower quartiles of the original 294 students were designated as high ($n = 38$) and low ($n = 38$) WMC, respectively. These 76 students were then randomly assigned to either the stationary instruction group ($n = 38$) or the mobile instruction group ($n = 38$).

All students, regardless of WMC (high or low) or instructional group (stationary or mobile) engaged in a multimedia tutorial designed to address the workings of a car brake. The multimedia tutorial consisted of a narrated Flash® animation explaining how a car brake works (see Mayer & Anderson, 1992). This explanation included drawings of a foot pressing a brake pedal, a piston moving inside a master cylinder, brake fluid moving out of the master cylinder, brake fluid expanding smaller pistons in the wheel cylinder, and these smaller pistons pushing the brake shoes against the brake drum (see Figure 1). The animation from the foot stepping on the brake pedal to the brake shoes pressing against the brake drum lasted 30 seconds; however, this 30 second animation was played three times in order to accommodate the narration. Thus, each multimedia instructional episode lasted 90 seconds. Finally, this car brake multimedia tutorial was presented on a 5th generation iPod (i.e., video iPod) with a 2.5" screen and Altec Lansing® headphones.

Students in the stationary instruction group viewed the multimedia tutorial on an iPod while sitting in a chair at a desk in a computer lab. Students in the mobile instructional group were first provided with a random number from 1 to 3 and then asked to walk 25 yards down a hallway, and back, repeatedly, until the multimedia tutorial came to an end. Every five yards along this

Figure 1. Sample animation screens and accompanying verbal content from the brake tutorial (animations adapted from and text quoted from Mayer & Anderson, 1992, p. 446)

walk was a two-sided sign on the floor that included the numbers 1, 2 and 3, and above each number an arrow pointing left or right (see Figure 2). Participants were instructed to walk to the side of the sign indicated by the arrow above the number to which they were assigned. This walking and navigating, while engaging in the multimedia tutorial, simulated the type of mobile environment one might encounter while trying to walk across a college campus.

After students finished engaging in the multimedia tutorial, whether in the stationary or mobile

instructional group, they were seated and asked to answer both recall questions assessing students' ability to remember the essential knowledge to which they were exposed and their ability to

Figure 2. Directional signs used in the mobile learning environment

express this knowledge, and transfer questions assessing students' ability to apply the knowledge recalled to new, yet similar situations (i.e., near transfer). Students' recall of the car brake tutorial was assessed using a single open-ended question: "Please provide an explanation of how a car brake works." Two trained raters evaluated each student's recall response ($r = .90$) and provided one point for the inclusion of each of the following idea units, regardless of wording: "(a) driver steps on brake pedal, (b) piston moves forward inside master cylinder, (c) piston forces brake fluid out to the wheel cylinders, (d) fluid pressure increase in wheel cylinders, (e) small pistons move, (f) small pistons activate brake shoes, (g) brake shoes press against drum, and (h) drum and wheel stop or slow down" (Mayer & Anderson, 1992, p. 450).

Students' ability to transfer knowledge from the car brake tutorial was assessed using four questions (see Mayer & Anderson, 1992, p. 449): (a) "Why do brakes get hot?"; (b) "What could be done to make brakes more reliable, that is, to make sure they would not fail?"; (c) "What could be done to make brakes more effective, that is, to reduce the distance needed to bring a car to a stop?"; and (d) "Suppose you press on the brake pedal in your car but the brakes do not work. What could have gone wrong?" Two trained raters evaluated each student's responses ($r = .83$) based on acceptable answers established by Mayer and Anderson (1992). Acceptable answers to the first transfer question, "Why do brakes get hot?" included friction causes brakes to get hot; acceptable answers to the second transfer question, "What could be done to make brakes more reliable, that is, to make sure they would not fail?" included maintain a back up system or use a system to cool the brakes; acceptable answers to the third transfer question, "What could be done to make brakes more effective, that is, to reduce the distance needed to bring a car to a stop?" included using a brake shoe that is more sensitive to friction or providing a smaller gap between the brake shoe

and brake drum; and finally, acceptable answers to the fourth transfer question, "Suppose you press on the brake pedal in your car but the brakes do not work. What could have gone wrong?" included that there may be a leak in the brake fluid line or that the brake pads are worn.

Results and Discussion

The results of the study addressed high and low WMC students' cognitive performance in stationary and mobile multimedia learning environments. Overall, there was a significant difference in cognitive performance between participants who learned in a stationary learning environment as compared to participants who learned in a mobile learning environment. Specifically, participants in the stationary learning environment recalled more idea units ($M = 5.74$, $SD = 1.75$) from the car brake multimedia tutorial than participants in the mobile learning environment ($M = 4.92$, $SD = 2.96$), $F(1,72) = 4.72$, $MSE = 25.94$, Cohen's $d = 0.33$, $p = .03$. In addition, participants in the stationary learning environment transferred more car brake knowledge ($M = 5.58$, $SD = 0.59$) than participants in the mobile learning environment ($M = 4.97$, $SD = 1.21$), $F(1,72) = 19.02$, $MSE = 12.36$, Cohen's $d = 0.69$, $p = .00$. These results indicated that participants recalled and transferred more information when learning in a stationary versus a mobile learning environment. Specifically, it was found that students who learned about car brakes using a portable digital media player (i.e., iPod), while navigating a walking course that required attention to the path taken, performed significantly more poorly on measures of recall and transfer than students who learned while simply sitting at a desk.

In addition to the stationary/mobile learning results, an analysis of the WMC data indicated that high WMC students recalled more idea units ($M = 5.92$, $SD = 2.67$) than low WMC students ($M = 4.74$, $SD = 2.07$), $F(1,72) = 7.27$, $MSE = 39.94$, Cohen's $d = 0.49$, $p = .00$. Similarly, for

transfer, high WMC students generated more valid transfer responses ($M = 5.61$, $SD = 0.67$) than low WMC students ($M = 4.95$, $SD = 1.16$), $F(1,72) = 29.96$, $MSE = 13.63$, Cohen's $d = .69$, $p = .00$. These results are consistent with previous findings regarding a general WMC effect (Doolittle, 2007; Unsworth & Engle, 2007), that high WMC students outperform low WMC students on recall and transfer after engaging in a multimedia tutorial.

The preceding results demonstrate that students learn more from a short cause-and-effect multimedia tutorial when stationary, as opposed to when mobile, and that high WMC students learn more than low WMC students. However, a significant question yet to be answered is whether or not there are individual differences in stationary/mobile learning when WMC is taken into account. The answer is mixed. Specifically, there was no interaction between instructional group (stationary, mobile) and WMC (high, low) for recall of the car brake tutorial. There was, however, a significant interaction for transfer (see Table 1), $F(1,72) = 11.98$, $MSE = 7.79$, $p = .00$. An examination of the means indicates that mobile learning environments are less advantageous to low WMC students than high WMC students. This examination was confirmed using a contrast analysis comparing the mobile-low WMC group to the remaining three groups (i.e., mobile-high WMC, stationary-low WMC, stationary-high WMC), $F(1,72) = 27.53$, $MSE = 0.65$, Cohen's $d = 1.33$, $p = .00$. These interaction results indicate

that if deep learning, as measured by transfer, is the goal of instruction, mobile multimedia learning environments significantly disadvantage students with low WMC. Namely, students with the least attentional control and the most susceptibility to distraction (low WMC students) performed the poorest under conditions that required significant attentional control: learning while mobile.

IPODS AS MOBILE MULTIMEDIA LEARNING ENVIRONMENTS

The preceding discussion and research has indicated that (a) iPods are currently being used as educational platforms; (b) podcasting is the typical, although not the only, pedagogy of choice; and (c) students can and do learn from engaging with the iPod. However, previous research also indicates that (d) little basic empirical research is being conducted on the efficacy of the iPod as a learning platform; but (e) recent empirical research has demonstrated that students with low working memory capacity perform less well in mobile learning environments than students with high working memory capacity. These findings begin to bring into focus the landscape of iPod-based instruction, although a crisp and clear picture is still distant.

At the most basic level, it is important to note that Hürst et al. (2007) and the study reported within this chapter both found that students learn

Table 1. Means and standard deviations of recall and transfer from engaging in a car brake multimedia tutorial for instructional groups (stationary, mobile) and WMC groups (low, high)

	Instructional Environment									
	Stationary					Mobile				
	Recall		Transfer			Recall		Transfer		
	M	SD	M	SD		M	SD	M	SD	
Low WMC	5.33	1.68	5.50	0.51		3.71	2.33	4.00	1.35	
High WMC	6.43	1.69	5.71	.072		5.63	3.10	5.54	0.65	

Note: Maximum score for recall was 8. Maximum score for application was 7.

as the result of engaging in an iPod-based instructional episode. In the case of Hürst et al., students learned strategic knowledge, a search algorithm, while students in the current study learned procedural knowledge, how a car brake works. These foundational findings provide support for the use of the iPod as an instructional platform.

The research of Salvucci et al. (2007) and the current study, however, also demonstrate that the iPod must be used with caution and that all students may not benefit equally from the instructional use of the iPod. Salvucci et al. found that, generally, using the iPod can require significant attentional resources in conditions of distraction, for example, using the iPod while driving. Further, the present study revealed that students with considerable attentional resources—high working memory capacity—were unaffected by distractions when using the iPod; however, students with fewer attentional resources—low working memory capacity—were negatively affected by distractions while using the iPod. These findings demonstrate that students' attentional control has a significant impact on the efficacy of the iPod as an instructional platform.

As mobile learning opportunities have become ubiquitous with the advent of portable, lightweight devices (e.g., mp3 players, mobile phones, PDAs) it is imperative that educators, instructional designers and instructional technologists maintain a 360° view of the educational playing field. At this nexus of pedagogy, design and technology “there is a tension... that comes from the fact that most mobile devices in current use are not designed specifically for education or training but rather for personal information management or personal communication” (Kukulska-Hume & Taxler, 2005, p. 3). Kukulska-Hume and Taxler goes on to state that “future projects ought to address learning gains more directly, to gather evidence of what can be learnt using these [mobile] devices” (p. 189). These comments emphasize that for mobile learning to be educationally successful

there is a need to focus on the development of educationally appropriate technology, individually appropriate pedagogy, and the interaction between the technology and the individual.

FUTURE RESEARCH DIRECTIONS

Research and explorations involving mobile multimedia learning environments utilizing portable digital media players is just beginning. While the initial findings are promising, much is still unknown. What specific types of pedagogies work best with specific types of mobile technologies based on specific areas of instructional content? What individual difference variables (e.g., spatial ability, reading ability, prior knowledge, working memory capacity) affect students' success when learning in mobile multimedia learning environments? How can mobile multimedia learning environments be made more accessible to students with special needs? How can, or should, the use of mobile multimedia learning environments be integrated into the daily educational environments of students?

Currently, educators are forced to create mobile multimedia learning environments within mobile devices that were not originally designed to foster learning; cell phones, MP3 players, and PDAs were designed more as communication tools than educational tools. Given that these communication tools are being adapted for educational purposes, it is essential that educators share their adaptations so that others may benefit from and expand these initial efforts. In addition, however, these case studies of adaptation must include rigorous evaluation and assessment so that there is evidence from which to make educated decisions. Without rigorous evaluation and assessment the field of mobile learning runs the risk of devolving into a faddish application of technological flash without substance.

Chapter 3.9

Telementoring and Project– Based Learning: An Integrated Model for 21st Century Skills

Joyce Yukawa
St. Catherine University, USA

ABSTRACT

While common models of telementoring (ask-an-expert services, tutoring, and academic and career telementoring) can serve a variety of learning objectives, these models are limited with respect to sustained inquiry learning such as project-based learning (PBL). To reach the full potential of PBL with telementoring, this chapter proposes a telementoring model that integrates inquiry learning, information literacy, and digital media literacy and is implemented by a team of experts – subject matter experts as telementors, classroom teachers, school librarians, and instructional technology specialists. The model provides for multifaceted learning experiences for students that involve disciplinary knowledge and habits of mind, critical thinking, collaborative problem solving,

and information, media, and technology skills. Brief overviews of inquiry learning approaches, information literacy, and digital media literacy are described in relation to telementoring. Design considerations, the benefits and challenges of the model, and broader implications for educational change are also discussed. Using the integrated telementoring model, the PBL team exemplifies the interdisciplinary collaboration and new literacy skills that students need in today's workplaces and communities.

INTRODUCTION

Often associated with apprenticeships in a community of practice, mentoring is the age-old process of wiser, more experienced persons taking younger protégés under their wing. As role models, mentors guide their young initiates into

DOI: 10.4018/978-1-60960-503-2.ch309

the art, craft, ways of thinking, and values of their community, helping to shape not only knowledge and skills but also the identity and personal and professional maturity of their protégés. Mentoring is rewarding for both the mentee and the mentor. The mentee has a deepening relationship with a special person in his/her life - not a parent, teacher, or friend, but a wise guide who listens, cares, encourages, and gives advice. For the mentor, this is a unique opportunity to make a difference in a young person's life and give back to one's profession and community.

Since the rise of the World Wide Web in the 1990s, a variety of online tools has been available to support mentoring beyond the barriers of time and place. Telementoring, also known as online mentoring and e-mentoring, can be defined as:

... using telecommunications technology (including e-mail, conferencing systems, or telephones) to develop and sustain mentoring relationships where face-to-face ones would be impractical. In the field of education, telementoring often involves linking students up with knowledgeable adult volunteers who have an interest in fostering their development. This sort of arrangement allows the participants to take part in intellectual partnerships that would not otherwise take place. (O'Neill, 2000, p. iii)

While communicating online makes telementoring different from traditional face-to-face mentoring, telementoring offers some distinct benefits. Mentors are not limited to the local community and can be drawn from any profession, organization, or geographic location around the world where adults are willing to help a young person develop. And mentors and mentees can communicate at any time, using a wide range of online tools.

Telementoring uses various mentor group configurations to provide different kinds of expert support to students seeking help. MENTOR/ National Mentoring Partnership's "Elements of

Effective Practice" (http://www.mentoring.org/find_resources/elements_of_effective_practice/) identifies these five types of contemporary group mentoring: (1) traditional mentoring (one adult to one young person); (2) group mentoring (one adult to up to four young people); (3) team mentoring (several adults working with small groups of young people, in which the adult to youth ratio is not greater than 1:4); (4) peer mentoring (caring youth mentoring other youth); and (5) e-mentoring (mentoring via e-mail and the internet).

Expert support online comes in many forms – ask-an-expert services for one-time, discipline-based questions; tutoring for supplementary or remedial study; telementoring for career guidance and academic advice; and telementoring for inquiry learning. Examples of each of these types, as well as their strengths and limitations, will be discussed later in the chapter.

This chapter's main focus is on telementoring for sustained inquiry in the classroom through project-based learning (i.e., project-based telementoring). It is written at a time of extraordinary economic and technological changes and associated challenges to the U.S. educational system. The Partnership for 21st Century Skills, a group of leading education, business, community, and government organizations, has identified essential skills beyond reading, mathematics, and science that students need to "increase their marketability, employability and readiness for citizenship" (Partnership, 2008, p. 10):

- Thinking critically and making judgments about the barrage of information that comes their way every day – on the Web, in the media, in homes, workplaces and everywhere else.
- Solving complex, multidisciplinary, open-ended problems that all workers, in every kind of workplace, encounter routinely.
- Creativity and entrepreneurial thinking – a skill set highly associated with job creation (Pink 2005; Robinson 2006; Sternberg,

1996). Many of the fastest-growing jobs and emerging industries rely on workers' creative capacity – the ability to think unconventionally, question the herd, imagine new scenarios and produce astonishing work.

- Communicating and collaborating with teams of people across cultural, geographic and language boundaries – a necessity in diverse and multinational workplaces and communities.
- Making innovative use of knowledge, information and opportunities to create new services, processes and products. The global marketplace rewards organizations that rapidly and routinely find better ways of doing things. Companies want workers who can contribute in this environment.

Project-based telementoring has the potential to address many of these important skills. Due to the widespread use of the internet and the plethora of free or low-cost technologies for online communication and collaboration, the possibilities for innovative telementoring programs are unprecedented.

Providing the environment and structural support for new types of telementoring is a significant challenge. The New Media Consortium (NMC), a community of hundreds of leading universities, colleges, museums, and research centers, sees the following as the most critical challenges schools will face as they integrate new technologies and reshape the educational experience in the next five years: (1) There is a need for formal instruction in key new skills. (2) Educational practice and materials are changing too slowly to support current student needs. (3) Learning that incorporates real life experiences is not occurring enough and is undervalued when it does take place. (4) New technologies must be adopted and used as an everyday part of classroom activities, but effecting this change is difficult. (5) The fundamental structure of the K-12 education establishment

is resistant to any profound change in practice (Johnson, Levine, Smith, & Smythe, 2009, p. 7-8). These trends indicate not only the challenges that schools face, but also the potential of project-based telementoring to contribute to needed changes in structure, teaching practice, and a more relevant educational experience for students.

The next sections of this chapter provide brief overviews of inquiry learning approaches, information literacy (including mastery of information technology), and digital media literacy (particularly with communication and collaboration technologies), as they relate to telementoring. This is followed by an assessment of strengths and weaknesses of common models of telementoring. To reach the full potential of project-based learning, I propose a telementoring model that integrates inquiry learning, information literacy, and digital media literacy and involves a team of specialists – subject matter experts as telementors, classroom teachers, school librarians, and instructional technology specialists. Because of the diverse expertise of this project-based learning (PBL) team, the model provides for multifaceted learning experiences for students that involve disciplinary knowledge and habits of mind, critical thinking, collaborative problem solving, and information, media, and technology skills. Design considerations, the benefits and challenges of the model, and broader implications for educational change are also discussed. Using the integrated telementoring model, the PBL team exemplifies for students the interdisciplinary collaboration and new literacy skills that are increasingly valued in today's workplaces and communities.

INQUIRY LEARNING APPROACHES AND TELEMENTORING

Other chapters in this book explore in depth the use of telementoring in inquiry, problem-based, and project-based learning. The goal of this section is to provide an overview of these approaches

as the foundation for a discussion of how well different models of telementoring can meet the learning challenges and address the new media literacy skills needed today.

Scientific inquiry in the classroom is often simplified to a linear process of asking a question, formulating a hypothesis, performing an experiment, collecting data, and drawing conclusions. The University of California Museum of Paleontology's website, *Understanding Science* (<http://www.understandingscience.org>), aims to accurately communicate "the real process of science" – not only a process of exploration, discovery, and testing ideas, but also of scientific growth based on community analysis and feedback that is shaped by the benefits and outcomes for individuals and society. Science is a process that is dynamic and intensely human:

[S]cientists often begin an investigation by plain old poking around: tinkering, brainstorming, trying to make some new observations, chatting with colleagues about an idea, or doing some reading. Scientific testing is at the heart of the process. In science, all ideas are tested with evidence from the natural world. ... You can't move through the process of science without examining how that evidence reflects on your ideas about how the world works — even if that means giving up a favorite hypothesis. The scientific community helps ensure science's accuracy. Members of the scientific community ... play many roles in the process of science, but are especially important in generating ideas, scrutinizing ideas, and weighing the evidence for and against them. Through the action of this community, science is self-correcting. ... The process of science is intertwined with society. The process of science both influences society ... and is influenced by society. ("A blueprint for scientific investigations," http://undsci.berkeley.edu/article/0_0_0/howscienceworks_03)

Scientific inquiry is clearly a social process as well as a rigorous procedure for testing hypotheses.

Identifying a scientific problem and testing one's ideas through communication, collaboration, and peer review are critical aspects of inquiry often missing from the student's classroom experience. Through the partnerships and collaboration enabled through telementoring, a subject matter expert can be one of the most valuable members of the classroom's community of inquiry.

The Telementor's Guidebook (O'Neill, 2000) describes and analyzes a number of telementoring relationships with project groups from a 9th grade class that illustrate the types of guidance subject matter experts can provide. For example, two students doing a research project on earthquakes were matched with a geology graduate student who provided both intellectual and emotional support to help them reach their project goals. Other examples of telementoring by community experts can be found in the project summaries provided on The Electronic Emissary K-12 Telementoring website (http://emissary.wm.edu/project_public.php).

Inquiry learning approaches such as problem-based learning and project-based learning extend the problem beyond a single lesson or two and bring to the classroom some of the complexity, curiosity, creativity, serendipity, and communal effort that more accurately reflect the nature of scientific inquiry. The Illinois Mathematics and Science Academy's PBLNetwork (<http://pbln.imsa.edu/model/intro/index.html>) provides this definition of problem-based learning:

Problem-based learning (PBL) is focused experiential learning organized around the investigation and resolution of messy, real-world problems. PBL engages students as stakeholders immersed in a messy, ill-structured, problematic situation. PBL organizes curriculum around this holistic problem, enabling student learning in relevant and connected ways. PBL creates a learning environment in which teachers coach student thinking and guide student inquiry, facilitating

learning toward deeper levels of understanding while entering the inquiry as a co-investigator.

A challenging issue in problem-based learning is ascertaining problem difficulty in ill-structured problems, with respect to learners' ability to solve such problems. Jonassen (2000; Jonassen & Hung, 2008) identifies a number of factors that contribute to problem difficulty. Factors related to the learner are level of domain knowledge, experience in solving problems, and reasoning skills. Factors inherent in the problem are level of abstraction, stability of problem attributes over time, complexity, and how well- or ill-structured the problem is. Jonassen and Hung (2008, p. 16) recommend that problems should be open ended, moderately ill structured, and with a degree of complexity that is challenging and motivating to students. Appropriate ill-structured problems should "provide opportunities for students to examine the problem from multiple perspectives or disciplines; [be] adapted to students' prior knowledge; [and be] adapted to students' cognitive development and readiness" (p. 16).

An example of a problem statement for elementary students who role play being entomologists shows how problem-based learning can be approached (Goodnough & Hung, 2008, p. 90):

Every summer, Mrs. Bartlett likes to sit in a chair and enjoy her beautiful garden where she has lots of plants and flowers with butterflies flying from one to another. However, before Mrs. Bartlett can enjoy her peaceful summers, she always has to fight with hungry caterpillars who love to eat the leaves of her plants in the spring. ... You and your teammate are entomologists (bug experts) in training. ... What can your team tell Mrs. Bartlett about caterpillars? What can your team do to help Mrs. Bartlett with her problem without destroying her garden? Mrs. Bartlett will choose the best solution to her problem from all the proposals. In order to produce an effective and trustworthy solution proposal, your team should use scientific

methods, such as continuous, consistent observation and keep a journal of your research plan, how the plan has been carried out, and whether any revisions to your research plan are needed after a period of doing your research.

Similarly, project-based learning attempts to infuse authenticity, complexity, and community into the learning process. The Buck Institute for Education (BIE, n.d., p. 4) defines project-based learning as "a systematic teaching method that engages students in learning knowledge and skills through an extended inquiry process structured around complex, authentic questions and carefully designed products and tasks." BIE (p. 4-5) criteria for exemplary PBL projects include:

- Recognize students' inherent drive to learn, their capability to do important work, and their need to be taken seriously by putting them at the center of the learning process.
- Engage students in the central concepts and principles of a discipline.
- Highlight provocative issues or questions that lead students to in-depth exploration of authentic and important topics.
- Require the use of essential tools and skills, including technology, for learning, self-management, and project management.
- Specify products that solve problems, explain dilemmas, or present information generated through investigation, research, or reasoning.
- Include multiple products that permit frequent feedback and consistent opportunities for students to learn from experience.
- Use performance-based assessments that communicate high expectations, present rigorous challenges, and require a range of skills and knowledge.
- Encourage collaboration in some form, either through small groups, student-led presentations, or whole-class evaluations of project results.

What does project-based learning look like in the classroom? Planning any educational effort begins with the desired outcomes in mind, known as “backward mapping” (Wiggins & McTighe, 1998). A PBL project begins with developing a project idea, deciding the scope of the project, selecting curriculum standards, working from project design criteria, and creating the optimal learning environment (BIE & Boise State University, 2005). Most projects last several weeks but some can last much longer. Information/data collection that involves library research or active research in the field, such as interviews and community inquiry, can extend the length of the projects. Successful projects usually involve adults, either experts or community representatives, as partners or mentors in a project, necessitating more time. Some projects address broad, open-ended questions with many different solutions, resembling problem-based learning. Complex projects need sufficient time for preparation and student research. Student autonomy is one of the characteristics of PBL, and students can be involved in the project design.

Examples of successful PBL projects at the high school level can be found on the website of High Tech High in San Diego, California (<http://www.hightechhigh.org/pbl/index.html>). The descriptions of such projects as how drugs affect your body, how human habitation affects the environment, and how math and science affect artistic expression generally include a project overview, standards addressed, a timeline and narrative of activities, lesson plans, assessment rubrics, and teacher and student reflections. Other examples of PBL projects are found in the additional resources listed in Additional Reading.

PBL projects center on driving questions that are “open-ended, go to the heart of a discipline or topic, are challenging, can arise from real world dilemmas that students find interesting, and are consistent with curricular standards and frameworks” (BIE & Boise State University, 2005). While the subject matter specialist may have deeper and more

extensive content knowledge than the teacher, the teacher has a unique knowledge base needed for PBL: pedagogical knowledge, knowledge of the students, and pedagogical content knowledge – “the blending of content and pedagogy into an understanding of how particular topics, problems, or issues are organized, represented, and adapted to the diverse interests and abilities of learner, and presented for instruction” (Shulman, 2004, p. 227). PBL projects require teachers to be learning facilitators, drawing on their pedagogical content knowledge. O’Neill (2000, p. 37) provides an example of how the teacher’s unique knowledge helps ensure telementoring success:

While teachers may not participate directly in telementoring relationships, they can do a number of other things indirectly, to help them flourish. To begin with, Mr. Wagner [the teacher] set requirements for the students’ investigation that gave Dan [the telementor] an appropriate role to play. If the students’ assignment had been a more traditional book report, or an investigation of much shorter duration, Dan may have had very little opportunity to become richly involved. Mr. Wagner didn’t simply match his students with their mentor and let them go, either: he was there to make decisions about whether or not the students’ research proposal was solid enough to go forward, so that Dan was not forced to do this on his own. While Dan had ideas about what the students might be capable of doing, and to what level of perfection, only the teacher had intimate enough knowledge of the students to make a confident decision about this. Finally, during Andy, Cori and Bill’s [the students] correspondence with Dan, Mr. Wagner offered the students a substantial amount of behind-the-scenes guidance and support himself. This included helping the students to interpret some of Dan’s messages, which they weren’t always able to understand easily. Even the very best telementor sometimes talks over mentees’ heads unintentionally.

In PBL, teachers are also project managers who structure and guide a project to a successful conclusion while supporting students as they move through an open-ended process of discovery and reflection.

A key consideration is student readiness. Do students have sufficient content knowledge and skills to handle the project successfully? Can they take independent initiative and work collaboratively? Do they have the necessary skills with technology and access to the required tools? Technological resources can be powerful and engaging for students, but they must also be essential tools for learning. Teachers also need fluency with these resources so that the learning can focus on the central content and investigation rather than managing and troubleshooting the technology. While there is no evidence that tools such as virtual learning environments, social software, and other information and communication technologies are being extensively used for project-based learning (Dede, 2007, p. 21), new guides are appearing for how to implement PBL with digital tools, the internet, and Web 2.0 (Boss, Krauss, & Conery, 2008).

Problem-based learning and project-based learning are similar in their emphasis on student autonomy, a shared goal, authentic problems, evidence-based investigations and solutions, collaborative learning, and reflection (Savery, 2006). The primary differences are the goals and the structuring of the activity. Problem-based learning focuses on solving ill-structured problems that require learners to set their own parameters. Project-based learning focuses on an end product. Clear design criteria are essential, with teachers and other adults serving as instructors, coaches, mentors, or project collaborators who provide expert feedback in a timely manner. Ravitz (2009, p. 6) notes that although there are differences among problem-based, project-based, inquiry-based, design-based, and challenge-based learning, “the similarities are more significant, allowing them to be viewed as ‘close cousins’ with many similar characteristics.”

In addition to teachers and subject matter experts, other experts contribute to inquiry learning – helping students think critically and creatively, access and evaluate information, investigate complex problems, and effectively express their ideas. The school librarian and the instructional technology specialist are two of these experts.

INFORMATION LITERACY AND TELEMENTORING

While school librarians are often viewed mainly as the managers of the school library resources, they are much more than that. With credentials and experience in library and information science as well as teaching, school librarians are experts in information literacy and knowing how people seek information. As the complexity of information resources and technologies increases, they are called upon to use their unique skills as learning specialists to help students develop 21st century skills (Zmuda & Harada, 2008). Their roles in PBL are as an instructional partner, a connector with a holistic view of the curriculum who facilitates integration across content areas, and an integrator who links disciplinary concepts with information resources and helps incorporate information literacy skills at various phases of the project (Harada, Kirio, & Yamamoto, 2008b).

The American Association of School Librarians (AASL) has developed new standards that address many of the much-needed skills identified by the Partnership for 21st Century Skills and the New Media Consortium discussed in this chapter’s introduction. The *Standards for the 21st-Century Learner* are based on a set of fundamental beliefs (AASL, 2007):

- Reading is a window to the world.
- Inquiry provides a framework for learning.
- Ethical behavior in the use of information must be taught.

- Technology skills are crucial for future employment needs.
- Equitable access is a key component for education.
- The definition of information literacy has become more complex as resources and technologies have changed.
- The continuing expansion of information demands that all individuals acquire the thinking skills that will enable them to learn on their own.
- Learning has a social context.
- School libraries are essential to the development of learning skills.

Within the inquiry learning framework, school librarians aim to assist students with the following skills, dispositions, responsibilities, and self-assessment strategies (AASL, 2007).

Skills:

- Develop and refine a range of questions to frame the search for new understanding.
- Find, evaluate, and select appropriate sources to answer questions.
- Evaluate information on the basis of accuracy, validity, appropriateness for needs, importance, and social and cultural context.
- Make sense of information gathered from diverse sources (e.g., textual, visual, media, digital) by identifying misconceptions, main and supporting ideas, conflicting information, and point of view or bias.
- Apply critical-thinking skills to information and knowledge in order to construct new understandings, draw conclusions, and create new knowledge.
- Use technology tools to access, analyze, and organize information in the pursuit of inquiry.

Dispositions:

- Display initiative and engagement by posing questions and investigating the answers beyond the collection of superficial facts.

- Demonstrate confidence and self-direction by making independent choices in the selection of resources and information.
- Demonstrate creativity by using multiple resources and formats.
- Maintain a critical stance by questioning the validity and accuracy of all information.
- Demonstrate adaptability by changing the inquiry focus, questions, resources, or strategies when necessary to achieve success.
- Display emotional resilience by persisting in information searching despite challenges.
- Use both divergent and convergent thinking to formulate alternative conclusions and test them against the evidence.

Responsibilities:

- Respect copyright/intellectual property rights of creators and producers.
- Seek divergent perspectives during information gathering and assessment.
- Follow ethical and legal guidelines in gathering and using information.
- Use information technology responsibly.
- Connect understanding to the real world.
- Consider diverse and global perspectives in drawing conclusions.
- Use valid information and reasoned conclusions to make ethical decisions.

Self-Assessment Strategies:

- Monitor own information-seeking processes for effectiveness and progress, and adapt as necessary.
- Monitor gathered information, and assess for gaps or weaknesses.
- Seek appropriate help when it is needed.
- Determine how to act on information (accept, reject, modify).
- Reflect on systematic process, and assess for completeness of investigation.
- Recognize new knowledge and understanding.
- Develop directions for future investigations.

Guided by these standards and the imperative to connect learning to student needs, school librarians are taking a larger role in curriculum planning and instructional design. They are partnering with teachers to support inquiry learning (Harada & Yoshina, 2004) and project-based learning (Harada, Kirio, & Yamamoto, 2008a). In the school context, the need for these collaborations is not always self-evident, and the development of partnerships is a challenge under the heavy constraints on time and budget. Two of the bases for successful librarian-teacher partnerships are professional development support and the creation of communities of practice over time (Yukawa, Harada, & Suthers, 2007). When teachers and school librarians participate jointly in sustained, practice-based professional development, significant improvements can occur in the design of inquiry-focused learning and student performance (Yukawa & Harada, 2009).

School and public librarians are increasingly offering chat reference services to students that generally provide factual answers, information resources, and limited research help, much like ask-an-expert services. Among the few studies of librarians as telementors, Yukawa (2005) examined two library and information science graduate students who telementored two high school students doing yearlong senior projects and found that building rapport and relationships were critical for sustaining telementoring.

In published examples and research, it is rare to find PBL projects that are collaboratively designed and implemented with school librarians, despite the fact that the information and technology resources of the library are often essential for background knowledge, research, and the development of final products. For example, High Tech High's San Diego Field Guide project (<http://www.hightechhigh.org/pbl/sd-field-guide/>) is a 16-week project in which 11th grade students "conduct an environmental assessment of the fauna along the intertidal zone of San Diego Bay. They publish a comprehensive Field Guide including scientific

studies, creative writing, photographs, and histories of human development, industry, environmental measures, mapping and other changes to Bay." The interdisciplinary project (biology, humanities, mathematics) is implemented by a subject matter specialist and two high school teachers, but school librarians do not appear to have a role in guiding the information seeking and research processes.

School librarians have a deep understanding of the guidance and instruction that students need to become information literate, a holistic perspective on the school and curriculum, and extensive knowledge of information resources and information technology. In collaboration with other experts on the PBL team, they can provide students with essential project-based learning experiences and resources.

DIGITAL MEDIA LITERACY AND TELEMENTORING

While there is increased use of new technologies for classroom learning (e.g., Moller, Huett, & Harvey, 2008), distance education (e.g., Huett et al., 2008), and library services (e.g., Burger, 2007; Casey & Savastinuk, 2006), there is little evidence that information and communication technologies are being used for project-based learning or telementoring. Email has been the dominant mode of telementoring communication since the 1990s. The selected K-12 telementoring programs listed in Appendix B indicate that most of these programs use email or discussion lists. Newer forms of online communication such as web-based synchronous communication (instant messaging, text messaging, online chat, and videoconferencing) and asynchronous communication (e.g., using wikis and blogs) have the potential to expand telementoring and help reshape learning to meet 21st century educational challenges (Dede, 2007). The instructional technology specialist is the member of the PBL team with the best understanding of how to use and manage

these technologies for learning, communication, productivity, and creativity.

As noted in the introduction, The Partnership for 21st Century Skills has implicated information, communication, and collaboration technologies in the innovative, entrepreneurial thinking that students will need for future success. Attaining literacy with these technologies is thus essential. The New Media Consortium defines 21st century literacy as “the set of abilities and skills where aural, visual and digital literacy overlap. These include the ability to understand the power of images and sounds, to recognize and use that power, to manipulate and transform digital media, to distribute them pervasively, and to easily adapt them to new forms” (NMC, 2005, p. 2). Technology is implicated in all of the top trends the NMC has identified as likely to affect teaching, learning, and creativity in the next five years: (1) Technology continues to profoundly affect the way we work, collaborate, communicate, and succeed. (2) Technology is increasingly a means for empowering students, a method for communication and socializing, and a ubiquitous, transparent part of their lives. (3) The web is an increasingly personal experience. (4) Learning environments are increasingly virtual rather than physical spaces. (5) The perceived value of innovation and creativity is increasing (Johnson et al., 2009, p. 6).

Among the technologies likely to have a significant impact on schools within the next five years are collaborative environments, online communication tools, mobile devices, and the personal web (Johnson et al., 2009, p. 6). While research on the learning impact of newer technologies is still emerging, a number of guides for classroom use are available (e.g., Pitler, Hubbell, Kuhn, & Malenoski, 2007; Richardson, 2008; Solomon & Schrum, 2007). These technologies have the potential to be powerful tools for inquiry-, problem-, and project-based learning in the hands of technologically fluent telementors and motivated, tech savvy, creative students.

Collaborative environments are virtual workplaces where students, teachers, telementors, and others can communicate, share information, and work together. Collaborative online spaces come in many forms, from online office suites for document sharing (for examples of these and other tools, see Table 1), online document collaboration, personal publishing, social networking tools to connect people and collect resources, flexible learning management systems, personal web portals, to classrooms in virtual environments. As well as enabling collaboration, the online spaces leave persistent conversations that remain for self reflection and peer critique. These spaces can be used synchronously or asynchronously at a distance, or to support and document collaborative work done in class.

Full-featured wikis such as PBworks (<http://pbworks.com>) and WetPaint (<http://www.wetpaint.com>) are powerful tools for telementoring. In addition to supporting the collaborative creation of web pages, these wikis also provide productivity and communication plug-ins such as calendars, spreadsheets, Google gadgets, chat rooms, photo and video integration, and page level discussion threads. Students working on problems or projects can gather resources, post plans, exchange ideas, and write drafts of papers and presentations on wiki pages. Telementors can monitor student progress as it evolves and provide feedback on these wiki pages. Studies have shown that wikis promote collaboration, encourage negotiation, and familiarize students with new technology tools (Elgort, Smith, & Toland, 2008; Hazari, North, & Moreland, 2009). They are also an effective tool for collaborative project planning and documentation (Parker & Chao, 2007), information or data gathering and organization, and organizing a personal or team research library (Walsh & Hollister, 2009).

Online communication tools such as instant messaging and online chats via desktop video conferencing are a popular way for students to interact with family and friends online. These

Table 1. Technologies for telementoring

Examples	Collaborative Environments	Communication Tools	Mobile Devices	Personal Web	Telementoring Software
	Wikis (PBworks, Wetpaint), blogs (WordPress, Blogger, LiveJournal), office suites (Google Docs, Zoho), flexible learning management systems (Moodle, Sakai), personal web portals (NetVibes, Pageflakes, iGoogle), social networking tools (Flickr, SlideShare, YouTube), virtual environments (Second Life)	Instant messaging (AIM, Meebo, Google Talk), online chat (AIM, Google Talk, Skype), desktop video conferencing (Skype), blogging, micro-blogging (Twitter), voice-over-IP (AIM, Google Talk, Skype), combination voice-video-text messaging (YackPack)	iPhone, BlackBerry	Tagging (Delicious, Diigo), RSS feed aggregators (Bloglines, FeedDemon, Google Reader, Netvibes, Pageflakes), simple, all around personal web tools (Tumblr, Posterous)	Telementoring Orchestrator
Uses	Project planning, document sharing, collaborative writing, personal publishing, social networking, resource collections, portfolios, online classrooms, feedback from teachers, experts, and peers.	One-to-one, one-to-many, and many-to-many communication; archiving messages and conversations; multimedia journals; voice, video, and text communication.	Range of communication options: telephone, email, text messaging, internet faxing, web browsing, multimedia. Third-party applications to support learning and research.	Resource collections, keeping updated on student work, enhanced email communication in a telementoring relationship, portfolios.	Building and describing a mentor pool, matching mentors and mentees, providing opportunities for just-in-time learning, limiting administrative overhead, and preventing mentor overload.

familiar tools can also be used to extend learning through telementoring. Desktop videoconferencing, instant messaging services, personal publishing like blogging and micro-blogging, and voice-over-IP enable one-to-one, one-to-many, or many-to-many synchronous communication. As one example, YackPack (<http://www.yackpack.com>) utilizes voice, video, and text messaging that can also be recorded. This enables one-to-one or one-to-many communication that allows students and telementors to see and hear each other in real time or via archived messages. Students can use blogging tools to set up multimedia journals to share their opinions, ideas, and research. Telementors, teachers, and peers can provide feedback using the comments feature.

Mobiles devices such as the iPhone and the BlackBerry are increasingly being used by young people (Johnson et al., 2009, p. 16). These provide a range of communication options: mobile telephone, email, text messaging, internet faxing, and web browsing. They support multimedia, with a camera and the ability to play music and video. They also incorporate productivity tools such as an address book, calendar, and calculator. Mobile devices have strong potential for educational uses because of the ability to run third-party applications such as GPS and collaborative document software. As of early June 2009, there were approximately 50,000 third-party applications of all types available for the iPhone. It is easy to imagine a wide range of applications being developed for fieldwork, data capture, information organization and analysis, visualization, data sharing, and other research and productivity aids that could support inquiry learning and result in products shared with telementors.

The personal web refers to how we manage the way we view and use the internet, based on “a growing set of free and simple tools and applications that let us create customized, personal web-based environments that explicitly support our social, professional, learning, and other activities” (Johnson et al., 2009, p. 25). The internet has

been a major contributor to information overload. Finding, organizing, and evaluating online content are critical for research and learning. Just as researchers and librarians are doing, students can tag and organize web links by subject. Another valuable personal web tool is the feed aggregator, a web application that gathers syndicated web content in one place for easy viewing. News sites, blogs, podcasts, wikis, social networking sites, library websites, and many others provide RSS feeds that automatically appear in personal aggregator content. With the tools of the personal web, teachers, students, and telementors can tag, categorize, annotate, publish, and review work online and build resource collections using web feeds and resources tagged by others. Teachers, students, and mentors can keep track of student work using RSS feeds to import updates of student publishing on the web.

One example of a free, very easy to use personal web tool that can serve a variety of communication and learning functions in telementoring is Posterous (<http://www.posterous.com>). By simply sending email with attachments to Posterous or grabbing content from the web, one can create a blog with text, video, photos, and music. Posterous provides for privacy, group sites, and email subscriptions to inform each group member of new postings. Posterous could be an effortless way to conduct one-to-one or one-to-many telementoring communication via email, with text enhanced by multimedia in a chronological, open record of the exchanges.

Specialized software may be needed for those who wish to launch their own large-scale telementoring projects and services. One of the best developed is the Telementoring Orchestrator (TMO) from Simon Fraser University's On-line Learning Relationships Lab (<http://www.learningrelationships.org/>). TMO streamlines the tasks of building and describing a mentor pool, matching mentors and mentees, and providing opportunities for just-in-time learning, as well as reducing administrative overhead and preventing mentor

overload (O'Neill, Weiler, & Sha, 2005, p. 114-115). TMO supports these roles and functions:

Telementoring Orchestrator assumes three roles: (1) mentors, who volunteer by filling out a recruiting form; (2) coordinators, who solicit the assistance of one or more mentors from the volunteer pool, assign them to mentees, and provide oversight for the relationships until they are closed; and (3) an administrator, who configures the TMO software for a particular program or initiative, and creates accounts for coordinators. ... At a minimum, configuring the installation involves: (1) Setting up an e-mail routing account that can be used by mentors and mentees to exchange messages. (2) Specifying a Knowledge Forum 'database' (workspace) in which mentors and their mentees can work together. (3) Defining the varieties of expertise or interests that volunteers might share with their mentees. (O'Neill et al., 2005, p. 115-117)

Freely available, this software currently works only on Mac OS X.

To make effective use of these technologies, schools and classrooms need a reliable technology infrastructure, as well as high-speed internet access. Instructional technology specialists understand how and why technology can be used effectively for learning, communication, and productivity. In collaboration with other experts on the PBL team, they guide students toward achieving better digital media literacy and provide tools for creative expression and the development of innovative, personally meaningful products.

As discussed in this chapter's introduction, schools also face more fundamental and far-reaching challenges as they integrate new information and communication technologies (ICT) and reshape the educational experience. As Dede (2007, p. 35) notes:

At this point in history, the primary barriers to altering curricular, pedagogical, and assessment

practices toward the transformative vision of ICT in education ... are not conceptual, technical, or economic, but instead psychological, political, and cultural. We now have all the means necessary to implement alternative models of education that truly prepare all students for a future very different from the immediate past. Whether we have the professional commitment and societal will to actualize such a vision remains to be seen.

TELEMENTORING MODELS

This chapter began with a brief mention of the types of expert advice being provided online—ask-an-expert services for one-time, discipline-based questions; tutoring for supplementary or remedial study; and telementoring for career guidance, academic advice, or sustained inquiry learning in the classroom. With the exception of the last, these types of advice address three learning needs: the need for disciplinary knowledge, the need for academic advice, and the need for career guidance. Our exploration of inquiry learning, information literacy, and digital media literacy provides a backdrop for assessing the strengths and limitations of these types of online expert advice.

Disciplinary Knowledge

Ask-an-expert services provide answers to one-time, discipline-based questions such as “What are simple, complex, and compound fractions?” or “What is the Pythagorean theorem?” Examples of these services are Drexel University’s Ask Dr. Math (<http://mathforum.org/dr.math/>), U.S. Geological Survey’s Ask A Geologist (<http://walrus.wr.usgs.gov/ask-a-geologist/>), and NASA’s Ask an Astrophysicist (http://imagine.gsfc.nasa.gov/docs/ask_astro/ask_an_astronomer.html). Students can ask experts questions that they could not ask of others, and receive answers in a timely manner. However, these services can only provide answers to factual questions that are isolated from

the learning context. Factual information does not in itself help students develop critical and creative thinking skills. Moreover, the one-time nature of the process does not help them develop disciplinary knowledge over time.

Online tutoring and homework help services provide supplementary or remedial study that supports well-focused learning needs and guides the student in solving well-structured problems. Often these services are a combination of self-paced tutorials and 24/7 help from live tutors, such as the fee-based services, Tutor.com (<http://www.tutor.com/>) and Homeworkhelp.com (<http://www.homeworkhelp.com/>). Free homework help sites are also available, many of them developed or sponsored by school and public libraries. The Internet Public Library’s Homework Help page (<http://www.ipl.org/kidspace/browse/ref8000>) lists a number of free sites. The disadvantage of online tutoring is that the questions and problems are provided mostly by the service, not driven by student inquiry. Online tutoring does not help students develop critical and creative thinking skills by solving authentic, ill-structured problems relevant to their own lives and interests.

Academic Advice and Career Guidance

Academic advice and career guidance are often combined in programs that are aimed at vulnerable and at-risk students. This type of mentoring resembles the traditional mentor model of wise counselor to a young protégé. For example, icouldbe.org (http://www.icouldbe.org/standard/public/lm_index.asp) targets at-risk students from low-income communities. Connecting to Success (<http://ici.umn.edu/ementoring/default.html>) aims “to promote successful transition of youth with disabilities to adult life.” In these types of telementoring programs, mentors encourage students to stay in school and work toward career goals and further education. They provide care and concern, helping with homework and study skills, plans for

college, and how to seek and keep jobs. They also help youth improve their communication skills, raise their self-esteem, and change negative and damaging behaviors.

Other telementoring programs are aimed at closing the gender gap in science, technology, engineering, and mathematics (STEM) professions. Programs such as Zoey's Room (<http://www.zoeyroom.com/>), an online community for middle school girls that fosters interest in STEM subjects, feature chat rooms where girls can interact with professional women with careers in STEM fields.

These programs provide valuable mentoring to specially targeted sectors of students but are not focused on inquiry learning for the development of critical and creative thinking skills. (For those interested in selected programs of these types, Appendix B provides further information).

Integrated Telementoring Model for Project-Based Learning

While ask-an-expert services and academic and career telementoring address important student needs such as the need for factual knowledge, general study skills, career information, and guidance for at-risk students, they are each limited with respect to sustained inquiry learning focused on authentic problems. To reach the full potential of project-based learning, I propose an integrated telementoring model that involves a team of specialists – teachers, subject matter experts, school librarians, and instructional technology specialists.

- *Classroom teachers* manage PBL projects and facilitate learning on many levels – the process of project-based learning, the team process, community building, individual learning, and the achievement of the learning outcomes.
- *Subject matter experts as telementors* encourage, guide, instruct, and model disciplinary practices and ways of thinking.

- *School librarians* guide students to become information literate and help them navigate the increasingly complex terrain of information resources.
- *Instructional technology specialists* help students achieve better digital media literacy and provide opportunities for creative expression using a wide array of technological tools.

Table 2 summarizes the complementary sets of skills and expertise the team brings to PBL. The model provides a framework for rich learning experiences for students and supports scaffolding of disciplinary knowledge and ways of thinking, project-based learning, information literacy, and digital media literacy. This model is further discussed in the next section.

DESIGN CONSIDERATIONS FOR AN INTEGRATED TELEMENTORING MODEL

For the development of 21st century skills, I have proposed that an integrated model of telementoring implemented by a PBL team has the potential to be more effective than current forms of telementoring. This section discusses how the model could be implemented, based on findings from previous studies of telementoring and/or problem-based learning. The main studies referred to are: (1) an examination of the Portals project, funded by the National Science Foundation to support telementoring relationships in project-based computational sciences classes, involving 40 high school students, five teachers, and 12 mentors (Tsikalas, McMillan-Culp, Friedman, & Honey, 2000); (2) Abbott's (2005) study of eight teachers whose students participated in online learning projects hosted by five established online PBL programs (The Electronic Emissary, iEARN, KidLink, ThinkQuest, and ThinkQuest Jr.); (3) a study by Hmelo-Silver and Barrows (2006) that

Table 2. Integrated telementoring model for project-based learning (PBL)

PBL Team	Teacher	Telementor	School Librarian	Instructional Technology Specialist
Primary Role	Pedagogy, Project Management • Pedagogical content knowledge • Knowledge of learners • PBL coordination & facilitation • Project design • Project planning • Project management • Fostering community building	Disciplinary Inquiry • Exploration & discovery • Testing ideas – Gathering data • Testing ideas – Interpreting data • Community analysis & feedback • Broader perspectives on the benefits of inquiry to society	Information Literacy • Accessing information • Evaluating information • Critical thinking to analyze, organize & use information for decision making • Information ethics • Reflecting on the information seeking process	Digital Media Literacy • Technology tools • Uses of tools for learning • Uses of tools for communication • Uses of tools for productivity • Uses of tools for creative expression

analyzed the facilitation of a student-centered problem-based learning group in higher education; and (4) Project INSITE, a four-year professional development program to prepare teachers to use problem-centered, inquiry-based science (Lehman, George, Buchanan, & Rush, 2006).

As discussed previously, several components of this model – project-based learning, teacher-librarian collaboration, and the use of information and communications technologies for learning – are in themselves challenging to implement. As an integration of these components, this model is even more challenging, as it involves collaboration among all of the PBL team members and the potential use of a variety of online tools. The model requires careful planning, coordination, ongoing collaboration, and negotiation of roles and responsibilities among members of the PBL team.

The planning is done by the school-based members of the team. During the implementation of the project, the teacher's role is both project manager and learning facilitator. Important factors to consider when designing a project using the integrated telementoring model are commitment to the project, learning goals, roles and functions of participants, the online learning environment, and participant readiness for project-based learning.

Commitment

Project-based learning takes much time to plan and sustained effort to complete (Abbott, 2005). The first and most important factor to consider is the desire and willingness of the school-based team members to tackle project-based learning using this model. Another important factor is the school climate and readiness – whether school administrators and peers welcome innovative uses of technology or not. Access to and funding for new technology may also be key considerations.

Learning Goals

These are some of the typical goals teachers set for project-based learning with telementoring (Abbott, 2005; BIE, n.d.; Hmelo-Silver & Barrows, 2006; Lehman et al., 2006; Tsikalas et al., 2000):

- Students engage in the central concepts and principles of a discipline and develop reasoning skills appropriate to the discipline.
- Students do in-depth exploration of authentic and important topics.
- Students solve complex, multidisciplinary, open-ended problems.
- Students create products that solve problems, explain dilemmas, or present infor-

mation generated through investigation, research, or reasoning.

- Students engage in self-directed learning.
- Students acquire, evaluate, and use information effectively.
- Students use essential tools and skills, including technology, for learning, self-management, and project management.
- Students effectively communicate and collaborate with each other in teams, and online with adult experts.
- Students reflect on their own work and provide effective feedback to peers.

During planning, the school-based team members align learning goals with various content standards, technology standards, and life skills standards (e.g., McCREL, 2009), as well as information literacy standards (AASL, 2007). These learning goals are also associated with the 21st century student outcomes outlined by Partnership for 21st Century Skills (2008), namely, knowledge in core subjects; learning and innovation skills; information, media and technology skills; and life and career skills.

Roles and Functions

The complex, interdisciplinary, and open-ended nature of project-based learning requires a clear view of general functions and roles, as these may be taken on flexibly by different members of the team over time. Functions generally fall into four areas: (1) structure, (2) process, (3) facilitation, and (4) community building (Tsikalas et al., 2000). Strategies and functions related to each of these areas may be assumed by any member of the PBL team or by the students themselves, depending on their readiness for PBL.

Structural strategies and functions refer to how activities, communication, and the process of project development are structured. What tasks and activities will be done, when, and by whom? Who will communicate with whom, about what,

and when? In their study of the Portals project, Tsikalas et al. (2000) found that structural strategies and functions are generally set by the teachers and mentors. Teachers specify student roles and also set the activity structure in which the telementoring occurs, tied to a set of project deliverables. Mentors often structure the process of project development, advising students on what steps need to be taken to complete the deliverables by the deadline. In the integrated telementoring model, school-based PBL team members would collaborate on these activities and make decisions about how to integrate information literacy and digital media literacy skills in a timely manner.

Process strategies and functions refer to expectations related to the learning conversations over time. Tsikalas et al. (2000) found that these are often set by students, who decide on what role the mentor will take, set expectations, ask good questions, build personal relationships with the mentor, and manage the communication (such as selecting the type of media to use to communicate about certain topics). Mentors also perform process functions – assessing and anticipating student needs, providing information, stimulating students through questioning, directing action, extending students' vision of their projects, and exercising quality control.

Facilitation strategies and functions refer to the means of guiding, supervising, and supporting the learning and communication processes. Facilitation strategies can be considered a form of modeling done by the PBL team. Such strategies include pushing for explanations; restatement; summarizing; encouraging students to generate hypotheses; mediating content by reviewing, digesting, and re-teaching; and redirecting communication from impasses (Hmelo-Silver & Barrows, 2006; Tsikalas et al., 2000). Teachers are critical facilitators in the mentoring groups (Lehman et al., 2006; Tsikalas et al., 2000). They create structures to facilitate mentoring, mediate students' interactions with others, and build community. Some help students rehearse important conversations

and provide opportunities for students to teach or mentor. When teachers are involved, student communication with mentors is often richer with ideas, opinions, and emotions (Harris & Jones, 1999). In some cases, teachers take on the role of co-mentor (Tsikalas & McMillan-Culp, 2000).

Community building strategies and functions refer to sharing materials, activities, or messages to promote a shared sense of purpose and benefit from participation in the online community. Tsikalas et al. (2000) found that these are undertaken by students, teachers, and mentors alike. For students, this means primarily collaboration within their team. Teachers help build community by fostering a climate of collaboration in their classrooms. Mentors support community building by helping students to socialize into particular cultures; treating students as colleagues; providing acceptance and encouragement; and referring students to other people for assistance.

The work of teachers as facilitators and project managers is often unknown to mentors. Making this work visible to telementors can provide them with valuable insights into students' knowledge, skills, learning styles, and communication styles. When relevant PBL team communication and collaborative work are conducted or documented in the online spaces, these four types of strategies and functions can be better coordinated and duplication of efforts avoided.

Online Learning Environment

The use of online tools should be carefully planned to meet learning goals, ensure ease of use, and accommodate potentially differing levels of technological fluency among the participants. Factors to consider in structuring the online learning environment include whether online communication will be synchronous, asynchronous, or a combination of both (and which tools to use); whether communication between participants will be private or open to other project teams

and mentors; and how to organize resources and individual and group spaces.

Choices about modes of communication and technology tools should be integrated into the regular project planning process – determination of the learning goals, how the learning will be assessed, the skills and understandings expected as outcomes, and the activities that will enable students to achieve those outcomes. For example, if a learning goal is that students understand the structure of a subject, students can organize information in databases (Jonassen, Carr, & Yueh, 1998) or online repositories in wikis and tag each item. Students can then discuss and develop their understanding of conceptual relationships among the tags using a concept map and receive feedback from the PBL team.

In general, the use of separate online tools can be confusing for new users of technology, so the use of a single comprehensive tool (e.g., a full-featured wiki or flexible learning management system) as the main communication center is advisable. The advantage of a wiki over a learning management system is that it can be edited and new pages can be added by any member of a private wiki. At the start of a project, it is important to post goals, project criteria, selected resources, and templates that are accessible to all members of the PBL team, students, and telementors. During the project, wikis are an effective tool for collaborative project planning and documentation (Parker & Chao, 2007). They are also effective for information or data gathering and organization, as well as organizing a personal or team research library that tracks the research process and showcases final products (Walsh & Hollister, 2009). Here, the school librarian plays the major role.

Wiki pages are designed primarily for collaborative writing. Asynchronous discussion and feedback about wiki pages can be done through the page comments or page discussion features available on most wikis. Synchronous discussions may be preferable for brainstorming and other activities that require immediate response. For

these, chat plug-ins are available on most wikis. The recorded communication can be used for further collaborative writing, self-assessment, and critique by peers and the PBL team. At the completion of the project, wiki pages and other online spaces can be used for presentations and portfolios.

Telementor-student communication can be done privately and asynchronously via email or synchronously via instant messaging. For group mentoring, O'Neill (2004, p. 182) argues for the importance of "mentoring in the open," where telementoring conversations are visible to other groups and experiences are shared. This provides an opportunity for students to see exemplary telementoring relationships at work and learn from such vicarious, peripheral participation (Lave & Wenger, 1991). Public mentoring discussions can take place asynchronously via discussion forums and synchronously via chat plug-ins in the wiki. These open conversations allow telementors to use the experiences of other groups to guide and scaffold learning, as well as to initiate peer support. When members of the school-based team also participate online or post summaries of face-to-face work in the online spaces, collaboration is strengthened.

Issues and challenges related to mentoring in an online environment are: (1) miscommunication, due in part to the lack of nonverbal cues; (2) slower development of relationships online than face-to-face; (3) the need for competency in written communication and technical skills; (4) a reliable technology infrastructure; and (5) protection of privacy (McLoughlin, Brady, Lee, & Russell, 2007, p. 4).

Participant Readiness

The importance of student readiness cannot be overemphasized. Do students have sufficient content knowledge and skills to handle the project successfully? Do they have the necessary skills with technology and access to the required technol-

ogy both within school and without? Can they take independent initiative and work collaboratively? Tsikalas et al. (2000) found that students who could communicate and collaborate well with each other tended to do this more effectively with telementors. They also found that mentoring relationships were more successful when students were aware of their needs and proactive about seeking specific assistance. The PBL team can prepare students for the telementoring experience by: (1) encouraging them to be open and honest with their mentors about what they do not understand; (2) providing opportunities to practice describing what they do and do not understand; (3) providing peer and teacher feedback about their communication; and (4) educating them about the various roles and functions mentors may take (Tsikalas et al., 2000, p. 10).

The school-based members of the PBL team need a common understanding of the philosophy, principles, and practice of PBL and preferably some experience either as facilitators or learners. Because implementing PBL online adds complexity, experience with implementing it first face-to-face is beneficial (Savin-Baden, 2007, p. 39). Collaboration requires significant time and effort but also brings rewards in personal learning, professional development, and student achievement. In a study of a yearlong professional development course involving teacher-librarian partners who collaborated on curriculum, Yukawa and Harada (2009, p. 13-14) found that:

Participants characterized the relationship as a partnership of equals, with teachers providing subject expertise and intimate knowledge of their students and librarians providing information literacy expertise, knowledge of resources, technology expertise, and guidance to students through the conceptual and emotional challenges of the research process. Participants appreciated using each other as sounding boards in deepening conversations about unit and lesson planning, standards, essential questions, assessment tools,

and information literacy instruction. A key change in roles was the degree to which librarians were integral to the entire process of planning, implementation, and assessment, with joint responsibility and accountability. A valuable theme was the way the partnerships extended to other faculty at the school.

Telementors who join the PBL team from private and public sector organizations outside of the education sector often find it a challenge to understand how telementoring works in the school culture, which may be quite different from their organizational cultures (O'Neill et al., 2005, p. 111). The role of the telementors can be diverse and encompassing. They encourage, offer advice, coach, help students clarify their values or goals, provide information, act as role models, help students socialize into particular cultures, and stimulate students to acquire new knowledge (Tsikalas et al., 2000, p. 10-11). The most likely mentor group configuration for PBL is one telementor to a small group of students, although a telementor may work with a single student or an entire class. At the start of a project, telementors may need an orientation to inquiry learning, project goals and expectations, student learning needs, their role as consultants, the roles of the other members of the team, the school context, technology and software to be used, and tips on how to communicate with the students online (Bennett, Heinze, Hupert, & Meade, n.d.). Advice to telementors should continue as needed throughout the telementoring relationship.

Using the integrated telementoring model, the PBL team serves as a model for students of the interdisciplinary teamwork that is increasingly valued in today's workplaces and communities. As the PBL team members plan, implement, manage, and facilitate project-based learning for students, they model the skills in collaborative problem solving, information literacy, technological fluency, innovation, and leadership that they

expect students to demonstrate as a result of their PBL experiences.

BENEFITS AND CHALLENGES OF PROJECT-BASED TELEMENTORING

Although PBL with telementoring is time consuming, many teachers feel it is worthwhile because of the benefits to their students. Student benefits include: (1) increased student engagement and motivation, (2) improved writing and speaking skills, (3) improved information gathering skills, (4), improved reasoning and problem-solving skills, (5) learning science and scientific processes, (6) learning about technology, (7) the transfer of learning into student performance, (8) self-directed learning skills, (9) improved collaboration and cooperative learning skills, (10) opportunities to teach their peers, and (11), self-evaluation techniques (Abbott, 2005; Lehman et al., 2006; Ravitz, 2009).

Interviews with volunteer telementors indicate the self-perceived benefits of telementoring: (1) doing outreach for their employers, (2) cultivating interest in their field, (3) increasing the representation of women and minorities in their field, (4) engaging in the pursuit of challenging inquiry, (5) learning more about teaching and about themselves, (6) giving back, and (7) realizing the potential of the internet (O'Neill, 2000, p. 11-15).

PBL with telementoring also brings benefits to teachers, who value: (1) learning new teaching methods and strategies to increase student motivation, (2) learning more about a discipline, (3) learning new technologies and gaining increased technological competence, (4) becoming less directive and more facilitative to promote student-centered learning, (5) seeing students' success, (6) collaboration with others, (7) increased satisfaction from teaching, and (8) improved personal confidence (Abbott, 2005; Friedman, Zibit, & Coote, 2005; Lehman et al., 2006).

The disadvantages of PBL with telementoring include: (1) heavy demands of time and effort, (2) problems with technology and access to technology, (3) disparity in student technology access or skills, (4) classroom management problems, (5) lack of sufficient materials and supplies, (6) difficulties with group dynamics, (7) problems covering content when PBL interferes with the regular curriculum, and (8) poor collaboration and lack of support from team members (Garcia & Rose, 2007; Lehman et al., 2006).

Another significant challenge is effective facilitation. Although facilitation is generally seen as one of the most important dimensions of PBL, Savin-Baden (2007) points out that “there has still been relatively little discussion about what is being facilitated – whether it is students’ understanding and enactment of problem-based learning, the team process, the process of learning, individual learning, or the achievement of the learning outcomes, and to what extent the tutor’s ability to facilitate affects all these” (p. 41).

While the process of planning, implementation, and assessment of a telementoring project is an important type of professional development in itself, more structured educational opportunities for learning about PBL may also be necessary. One of the best ways to understand PBL and telementoring is for educators to experience these processes for themselves (Gareis & Nussbaum-Beach, 2007; Hitchcock & Mylona, 2000; Weizman et al. 2008). Experience with telementoring, project-based and problem-based learning, and technology integration should begin with pre-service teacher education (Garcia & Rose, 2007; McLoughlin et al., 2007; Price & Chen, 2003) and be extended with in-service professional development (Dede, 2006; Yukawa & Harada, 2009; Weizman et al., 2008).

CONCLUSION

The purpose of this chapter has been two-fold: (1) to explore the rich potential of telementoring

for project-based learning in the context of the urgent need to help students develop new skills and literacies, and (2) to provide the framework for an integrated telementoring model to be tested by new telementoring projects. Using this model, an interdisciplinary PBL team of experts – the subject matter expert serving as telementor, the classroom teacher, the school librarian, and the instructional technology specialist – can provide students with new opportunities for holistic, authentic, personally meaningful learning using emerging technology.

Subject matter experts as telementors encourage, guide, instruct, and model disciplinary practices and ways of thinking. Teachers manage PBL projects and facilitate learning on many levels – the process of project-based learning, the team process, community building, individual learning, and the achievement of the learning outcomes. School librarians guide students to become information literate and help them navigate the increasingly complex terrain of information resources. Instructional technology specialists help students achieve better digital media literacy and provide opportunities for creative expression using a wide array of technological tools. As a team, these experts model the skills in collaborative problem solving, information literacy, technological fluency, innovation, and leadership that are needed in the workplaces and communities of today and tomorrow.

This model requires careful planning, coordination, ongoing collaboration, and a clear view of general roles and functions with flexibility in assuming them. Important factors to consider when designing a project using the integrated telementoring model are commitment to the project, learning goals, roles and functions of participants, the online learning environment, and participant readiness for project-based learning. While collaboration requires significant time and effort, the rewards in personal learning, professional development, and student achievement can be great.

Implementation of the model cannot be divorced from broader educational issues and challenges – the need for formal instruction in new literacy skills for students and educators, professional development on learner-centered approaches like PBL, developing and sustaining school-wide and community-based communities of practice, learning environments that incorporate new technologies, and fundamental changes in the structure of the educational environment. These challenges are also opportunities for project-based telementoring to contribute to needed changes in educational structure, transformations of teaching practice, and more relevant learning experiences for students.

Chapter 3.10

Developing Educational Screencasts: A Practitioner's Perspective

Damien Raftery
Institute of Technology Carlow, Ireland

ABSTRACT

YouTube to iTunes, company to college websites, there is a seemingly exponential explosion in creating screencasts. A screencast is a digital recording of computer screen activity, often with an audio commentary. Short and engaging, screencasts have the *potential* to enable learning in new and exciting ways. They are becoming easier to create and, as a teacher in higher education, I have gradually increased my use of screencasts, learning with experience and from the generally positive feedback from students.

Drawing on existing research and personal experience, this chapter will introduce screencasts and discuss their potential. The importance of integrating screencasts thoughtfully and carefully into the teaching and learning process will be ex-

amined, including pedagogical and instructional design issues. Next a four-step process for creating a screencast will be presented: prepare, capture, produce and publish. Prior to conclusions and final reflections, future research directions will be examined.

INTRODUCTION

The other day I wanted to embed a YouTube video into a PowerPoint presentation: to link and view directly a video on YouTube, rather than hyperlink out to an internet browser or embed the downloaded video file. I didn't know how to do this, so I searched YouTube and *hey presto* a series of videos appeared. Selecting the first video, I watched a screencast showing how to do the task I wanted to do myself. I was able to watch it, pausing at places and switching to my

DOI: 10.4018/978-1-60960-503-2.ch310

presentation to embed the video I wanted. As well as the basic process, the screencast gave a number of tips. Less than ten minutes later I had completed my task.

A screencast is often used to capture *how-to-do-something*, for example how to use particular software. In the vignette above, I learnt and practiced a new skill: I had an immediate need, I found help in a form that was immediate, understandable and engaging, and I used that help to complete my task.

Increasingly educators are blending more online elements with traditional face-to-face teaching, often by simply using a virtual learning environment (VLE) to provide notes and other documentation as well as to communicate with students. As part of a multimedia approach (combinations of video, animations, images, text and sound) to blended learning, screencasts offer a multimedia-rich option to support student learning in particular contexts (such as learning a new skill as above). Thus a screencast can be a standalone multimedia learning object or can be part of a series that together comprise a fuller learning resource, or indeed be part of a learning object that integrates a screencast(s) with other hypermedia elements. Screencasts are becoming easier to create: a computer, some software and a microphone is enough. At the simplest, it could be adding a voiceover to a presentation, perhaps by using the narration feature within Microsoft PowerPoint. A little more complicated is recording on-screen activity with explanatory labels or a voiceover. With more effort, a screencast can integrate some interactivity, including clickable zones and quizzes. The time, resources and expertise required increases with the complexity of the screencast.

So what exactly is a screencast? How does one go about creating a screencast? What are the pedagogical and instructional design, technical and practical issues involved? And, of course, why do it? What are the benefits for learners? The rest of the chapter will explore these questions, starting

with examining in more detail what a screencast is and sharing some personal experiences of using screencasts with students.

EDUCATIONAL SCREENCASTS

A screencast is a digital recording of computer screen activity, often containing audio narration. It is sometimes referred to as a video podcast or simply a video, and also as a *scrast* (verbally shortening the word screencast to one syllable).¹ A screencast gives a *look over my shoulder effect* similar to one-on-one instruction and can be accessed whenever and wherever it is convenient (Educause, 2006). Students particularly value this, flexibly using screencasts to support their learning and thereby allowing for greater learner independence. A screencast usually has control buttons, enabling it to be paused and particular sections to be replayed: this level of learner control over pace is important (Oud, 2009, p. 169). The combination of video and audio appeals to different learning styles (as an alternative to predominantly text-based learning materials) and, as it is produced locally, it may be more approachable than glitzy packaged instructional videos (Kanter, 2008).

Short, sharply focused screencasts can be very useful in supporting students, working at their own pace, to achieve learning outcomes. Screencasts are particularly useful for teaching software applications and showing how to use online tools such as websites and library catalogues, having the following benefits over reading step-by-step instructions, as identified by Mount and Chambers (2008): ‘improving student cognition through improved information integration, reduced information redundancy and an improved representation of the dynamics of software operation’ (p. 49). They can provide engaging revision materials and, like other learning materials, are particularly valued by students if focused on preparing for assessments. Screencasts can be used to give short presentations (mini-lectures of voiceovers over

images or PowerPoint slides). These short teaching episodes are best used for topic overviews, difficult concepts and guidelines for the module, projects and assessments as well as for just-in-time support for project- or problem-based approaches. Other potential uses include explaining model solutions, correcting and giving feedback, answering frequently asked questions (FAQs) and website testing. Using a tablet and wireless pen together with software for writing on the screen, *mathcasts* (screencasts where the solution to a maths problem is hand-written to an accompanying voiceover explanation (see Budgett, Cumming, & Miller, 2007; Bonnington, Oates, Parnell, Paterson, & Stratton, 2007; Fahlberg, Fahlberg-Stojanovska, & MacNeil, 2007) and other screencasts incorporating writing, drawings and highlighting can be created.

Personal Experiences

A number of years ago, as part of a quantitative techniques module, I introduced first-year students to spreadsheets and then looked at their applications to financial mathematics and statistics. In a computer lab, students first worked through some generic introductory exercises focused on basic skills and then progressed to applying these skills and learning new ones by tackling subject-specific exercises. I would often explain new spreadsheet features using a digital projector, requiring the entire class to stop and watch, irrespective of their progress. The disadvantage of these *helpful* interruptions was that the timing did not suit all the students and thus some would fail to get the full benefit of these explanations.

Changing to an alternative approach, I created a series of short screencasts (using the four-step process explained later in this chapter) that introduced the basic features of spreadsheets as needed by the introductory exercises (each exercise listed the relevant screencasts). Students were now free to work through the exercises, watching the relevant screencast(s) as required. This allowed

a student to watch the screencast exactly when needed, as often as they wanted with full control to pause and replay particular sections. Thus students could spend more time on task, as well as freeing more time for me to assist individual students. Together with a number of screencasts showing how to do a sample assessment, this series of screencasts formed a reference bank that students could draw upon as and when needed, including when revising.

Screencasts showing a suggested approach to completing the tasks of a sample assessment are, like everything explicitly linked to assessment, very popular with students. Useful also are screencasts of solutions to assessments, especially if released prior to results: they provide valuable feedback (and also can be used in future iterations of the module as further sample assessments). Moreover, a reference bank of screencasts introducing a topic, such as the ‘introduction to spreadsheets’ screencasts as described in the vignette above, can subsequently be used in more advanced courses as a quick revision for students to go through prior to classes; this has the benefit of encouraging students to engage prior to the first class as well as establishing a minimum starting level. Groups of screencasts can also be used as a first point of reference for former students who make contact asking for help on using software applications, which usually enables them to resolve their difficulties by themselves.

Initial feedback from students has been very positive (similar to Bush, 2008; Peterson, 2007; Winterbottom, 2007). Consistently for the past five years, in end-of-module evaluations for computer lab-based subjects, most students indicate that the available screencasts have been very useful and, that for future iterations of the module, more should be produced. Accessed through the college’s virtual learning environment, the screencasts provide students with rich, multimedia online content to complement face-to-face classes. The VLE also provides a platform for the integration of scre-

encasts into the module, so that they naturally support other activities and materials.

Recently, one week prior to a test, I uploaded to the VLE a series of four mathcasts (two to three minutes each) showing the handwritten development of the solution to a number of mathematics problems. The screencasts were presented with the questions, so that prior to viewing the screencast the student could read and indeed was encouraged to attempt the question. In the week prior to the test, over half the students in the class accessed the resource and nearly a quarter on two or three different days. A small number of students watched the screencasts over the weekend, with the heaviest use in the day before and the morning of the exam. The screencasts were viewed both during the day and into the late evening. Feedback from students a week after the exam (via a short anonymous in-class survey) showed a positive and enthusiastic attitude, indicating that almost all students would like to see more of this type of support and that using it helps to get a higher grade, with about three quarters of students thinking that this type of online solution is very useful for them personally. Students used the online solutions in a variety of ways, from just quickly watching them, through thinking carefully about the question before watching, to trying the question and then watching the solution (or fast-forwarding to the end to check their answer). Some students study together in groups, only resorting to the mathcasts if the group cannot solve the problem. A reservation that surfaced among a substantial minority, particularly from those who did not use the mathcasts, was the inability to print the solutions.

This vignette illustrates the potential of screencasts: students engaging with revision materials prior to an assessment. They did not all use the online solution, and those that did used the mathcasts in a variety of ways, a way that suited them. It raises the importance of being aware of individual differences and preferences for different ways of engaging with the materials. How screencasts are presented to students is important.

Screencasts need to be integrated into the teaching and learning process, with attention to their design and use so as to avoid passivity and encourage engagement: students doing tasks, thinking and solving problems.

The profusion of screencasts on the internet, on YouTube and on specific websites such as www.teachertrainingvideos.com (a collection of screencasts for teachers to help them to incorporate technology into their teaching) and www.demogirl.com (a blog with short screencasts explaining new internet applications and services), links to a dilemma that faces a teacher considering using screencasts: should you just link to useful screencasts you find on the internet, or create your own? Creating screencasts involves time, pedagogy and technology, with an important trade-off between final screencast quality and sophistication, and the time taken to develop it. Getting the balance right can be difficult, but may be answered by keeping the benefits to students clearly in mind: sometimes it's better to link to a screencast produced elsewhere, other times preferable to create your own. Prior to presenting a four-step process for creating a screencast, the next section will consider some pedagogical and instructional design issues.

Integrating Screencasts into the Teaching and Learning Process

All teaching starts with a learner's need. Screencasts are created by teachers to assist the learning process of students, to help students achieve learning outcomes. As the goal is to support student learning, it should always first be asked whether a screencast approach is the most appropriate and effective way to accomplish this. Only after reflecting on this should screencasts be created. Thus screencasts should be *pedagogically led* rather than *technology led*: in short, when creating a screencast, think about the learner. It is advisable, like with other teaching innovations, to start

small and build on initial successes, learning what works best for your students.

Create bite-sized screencasts: it is better for students to choose from a series of short, clearly focused screencasts than to have to navigate a smaller number of longer ones: two to four minutes, definitely less than ten minutes (see Cann, 2007). Shorter screencasts are more flexible for reusing with other learners and can be updated more easily. Each screencast should have a specific, clear purpose (ideally focused on one learning outcome), such as

- introducing a module
- providing guidelines or giving an overview
- reviewing a difficult concept
- previewing a forthcoming lecture, reviewing or summarising a previous lecture
- illustrating the steps to solve a problem
- explaining a technical diagram or picture
- demonstrating a software or website feature (particularly useful for software that students have limited access to)
- supporting an activity or project
- revising for a test
- answering frequently asked questions
- correcting or giving feedback

Combined together, a series of screencasts can form a reference bank (as discussed earlier) that can be used as a comprehensive resource for independent study and revision, a support for project work and a starting point for more advanced modules. Note that for students viewing on campus, particularly in computer labs, consideration of whether to use audio is required: Will all students have headsets or should an alternative no-audio screencast with captions also be produced? Veronikas and Maushak (2005) concluded, from a small research study, that students learning software applications prefer audio and text, rather than text only despite no statistically significant evidence that audio improves test scores (p. 204).

Careful preparation is crucial to the creation of high quality educational screencasts of high value to students. When creating a screencast, balance the time and effort involved against the potential benefits for learners. Also consider whether the screencast is to be of limited use, by a small number of students for a short period of time? Or should you expend more time and effort to create a screencast of higher quality that can be productively used by a variety of learners over a longer time-span across different modules and contexts? This extra effort may be rewarded if screencasts can be shared, either internally within a college or externally via YouTube or a national repository of learning objects.

A potential and real criticism of screencasts is that they can have a teacher focus rather than student focus and can lack interactivity (Educause, 2006), and thus may encourage passivity in learners, an attitude of *just sit back and watch*. To counteract this, think carefully how students can be encouraged to be active when using screencasts (a criticism and response that was also considered by Franciszkowicz (2008) when using screencasts to teach problem-solving skills and conceptual understanding in a general chemistry module). If possible, add some interactions. These could be some quiz elements, such as answering multiple-choice questions or dragging and dropping. It could be the addition of clickable zones, for example where a student must click on the correct button to get a software demonstration to continue. At the most basic, it could simply be a requirement to click a button to continue, paired with an instruction or exhortation to think or do something before continuing. For example, if illustrating how to solve a question, such as an accounting or engineering problem, the screencast could display the question and then pause, instructing the student to read it carefully and consider how to proceed. The student could then click to view how to approach the question, with an audio explanation linked to underlining or highlighting on screen the key terms and numbers. Then the

student might be requested to attempt the question, only viewing when having completed their solution as best they can. As the learner can forward and rewind, they can focus on specific areas of difficulty, watching these sections a number of times. The solution could be partitioned into stages, with pauses at each transition.

There is an element of ‘watch what I do’ in a screencast: this can be useful, enabling the student to watch an expert at work, thereby offering a scaffold for undertaking the activity herself/himself. Some interactivity giving feedback may be incorporated into the screencast itself, as discussed above. This increases the complexity of the screencast, requiring greater time and expertise to create it; indeed many screen capture softwares may not support this, or it may be easier to create a simple screencast and build the other elements separately. This latter approach is where screencasts may bring audio-visually rich media to an online learning activity, a form of reusable learning object (RLO). Alternatively, it may be better to create simple screencasts and then carefully consider how these can support learning in conjunction with activities designed for students to undertake.

Oud (2009) presents a useful summary of the implications stemming from the limited capacity of short-term or working memory and how this limits learners’ capacities for information processing. When too much information is presented, learners’ ‘working memory is overloaded and they cannot process anything well, which leads to poor understanding, retention and learning’ (p. 166). Thus when creating a screencast, it is important to minimise the cognitive load. This leads to practical recommendations (see below in the Capture section). Of particular importance is chunking, the splitting of longer or more complex content into small sections (p. 167).

Instructional design approaches are valuable for informing the screencast development process. An instructional design approach to the

development of educational multimedia, specifically screencasts, is based upon the application of appropriate research, such as the psychology research on cognitive load theory summarised above. Instructional design is the use of systematic design procedures, thereby making, according to Gustafson and Branch (2002), ‘instruction more effective, efficient and relevant than less rigorous approaches to planning instruction’ (p. 18). Fundamental to all systematic design approaches are the following elements: analysis, design, development, implementation and evaluation (often referred to by their acronym ADDIE). (Readers interested in instructional design are directed to the References and Additional Reading sections.) In the next section, the four-step model proposed for creating a screencast broadly corresponds to the middle three elements of the ADDIE model.

Creating a Screencast

The motivation for creating a screencast is to support learning. The process builds naturally on existing teaching expertise, often using low threshold applications (i.e. technology with a relatively short learning curve, Gilbert 2002). As shown in Figure 1 the process to create a screencast can be envisioned in four steps:

The process starts with preparation, careful consideration of a teaching activity and learning opportunity. With a computer, screen capture software and a microphone, educational screencasts can quickly be created that are of immediate use and value. Voiceovers can be captured when recording the screencast or added later during the production process. The production process can be elaborate, including the addition of captions and other visual cues, additional voiceovers and interactive elements such as quiz questions. Alternatively, given usual time pressures, this pre-deployment step can be minimised to simply publishing the screencast in the required technical format (Costello, 2008). Then the screencast can

Figure 1. Four-step screen capture process (with a summary of each step)

be deployed via a virtual learning environment, a blog, an intranet or the Internet. Although Figure 1 presents the four steps as a linear process, the boundaries are fuzzy and, similar to the AD-DIE model, there may be jumps back and forth and reiterations.

For capturing a screencast, there are both hardware and software requirements. The computer needs to be sufficiently powerful to run the capture software plus any target applications that you are recording. The same general issues apply to sound quality as when producing a podcast and an inexpensive microphone headset usually suffices. For capturing handwriting on the screen, such as for mathcasts, a tablet laptop is likely to result in much clearer handwriting than an external USB tablet and it is easier to use for annotations as you are writing on the actual screen. Software that is useful here includes Microsoft OneNote, PDF Annotator and Microsoft PowerPoint, as well as drawing tools such as Microsoft Paint.

There are many capture software options available, from sophisticated packages with powerful capture and editing features such as Adobe Captivate and Camtasia to simple, free options that simply publish what you capture without any editing such as Jing and Screenr.com.² These four software options all include screencasts showing how to use the particular software to create screencasts (see links in Additional Reading). Your choice of software should be dictated by the extent to which you wish to edit your screencasts,

as well as the importance of particular features, such as being able to add quiz elements, modify menu options, accessibility features and publishing format options.

In the following four sections, each of the four steps will be discussed in terms of instructions and tips for creating educational screencasts.

Prepare

Plan your recording carefully. Know what you want to show, to do and what you want to say. Be aware of what your students already know. It may be useful to create a storyboard, a ‘visual representation which illustrates the content, navigation and structure of the learning materials’ (Clarke, 2001, p. 173). Use the storyboard to help the chunking of complex sections into simpler pieces. For short, simple screencasts, the storyboard can be an overview of the major elements. For longer screencasts, the storyboard may be more elaborate, detailing each major element or screen display. If the storyboard indicates a long screencast, consider whether it is possible to break it into a series of two or more shorter screencasts. Remember at this stage to think carefully how students are likely to use the screencast and what cues you can incorporate to encourage them to be active when using the screencast.

Decide when to record the audio. For short simple screencasts you may decide to record narration as you capture the screen activity. For

longer screencasts, it may be easier to record the audio separately after capturing the screen activity. For example, if demonstrating how to use a website, it may be better to first edit out any time waiting for pages to load and any glitches before adding the voiceover. Also recording the audio afterwards allows you when screen capturing to focus on doing clear screen actions. Consider using a script: the trade-off is between spontaneity and naturalness versus a professional, confident narration mostly free of ums and ahs. An added benefit of a script is that it can be used as a transcript or for closed captions.

To summarise, a teacher creates screencasts to help learning happen. Creating good screencasts depends on ‘planning a session with an eye toward its being recorded and on thoughtful editing afterwards’ (Educause, 2006). Careful planning and thoughtful reflection can assist in translating teaching activities into useful screencasts: indeed this preparation is key to the *capture* stage in the creation of educational screencasts.

Capture

After your planning, you should know exactly what you are going to record. If recording audio, use a quiet room with telephones turned off. Ensure that any other applications will not interfere with the recording, for example an email application beeping or otherwise alerting that a new email has arrived. Indeed you should close any unneeded applications. A tip when recording is to record only the application window or a defined area, and to consider recording at low screen resolution (such as 800x600). It is important to be aware of any quirks of your screen capture software that may result in glitches in your recording. For software demonstrations, make clear mouse movements at a pace that is suitable for learners to follow.

Be conscious of instructional design principles. In particular use strategies to minimise cognitive load such as the following guidelines suggested by Oud (2009, pp. 176–177): start with an outline

and end with a summary; split content into small segments/chunks; sequence content logically; use words (text or audio, not both) with graphics; provide clear interface, navigation and instructions; remove unnecessary graphics, text and audio; and, focus attention on important areas with visual or verbal cues.

A pragmatic approach is to record a rough run-through, review it and then record the main version. For a short screencast, if you make a mistake you could just restart recording rather than having to edit. For longer screencasts, errors can be edited out during the *produce* stage.

Produce

The *produce* stage may be extensive, short or omitted entirely (especially in the case of screencasts that are not to be used extensively). Start with editing the video, removing glitches and unneeded elements such as video showing the loading of webpages. Edit the audio, removing ums and ahs (or record the narration at this point). Make the modifications decided upon in the *prepare* stage: add captions as appropriate (or edit captions that have been automatically created by your screen capture software), whilst remembering not to overburden the viewer with too many simultaneous elements; use text animation, highlighting and zoom effects to focus attention and reinforce important points; and, add interactivity such as clickable zones and buttons, quiz elements or simply pauses with exhortations to think.

If your screen software capture allows, modify the default menu (player) options to your desired configuration, ensuring to allow learners substantial control. Now the screencast should be ready to *publish*.

Publish

The *publish* stage of the screencast creation process involves creating the final screencast file(s) in a technical format suitable for use by learners.

Depending on the software used to capture and process the screencast, there may be a variety of options, such as Macromedia Flash (swf), Windows Media Video (wmv), Audio Video Interleave (AVI) or executable (exe). Screencasts can be delivered on a variety of platforms, primarily streamed via the internet for watching via a browser with suitable media player, but also downloadable for later viewing on a computer or portable device capable of playing video (although note that the small display size of some portable devices may be insufficient to display certain screencasts in sufficient detail). For example, Adobe Captivate creates Flash files to be viewed via a browser, also creating the HTML code for launching the screencast.³ It can also create Windows executable files (not requiring any other software) and AVI (which can be further processed for uploading to YouTube).

It is straightforward to upload these files to a VLE, a blog, an intranet or the Internet. Decide whether to only allow the screencasts to be viewed online, or to permit downloading for offline viewing. Some issues may arise regarding file size and server space if uploading a large number of screencasts (particularly within a VLE where each file must be uploaded separately to different courses). A solution is to host separately and to post links to the VLE. For students viewing screencasts from home, large file sizes necessitate having broadband. A separate issue is how students should be notified of new screencasts. Within a VLE, they may be uploaded to the relevant section, possibly accompanied by an announcement or email notification.

FUTURE RESEARCH DIRECTIONS

Screencasts are very popular with students and many teachers in higher education are exploring their use. Although most practitioner-reported experience views screencasts positively, there may

be questions as to the effectiveness of screencasts in improving learning for students; for example Lee, Pradhan, and Dalgarno, (2008) report on a research project in which screencasts were used to support the teaching of programming, finding ‘no significant effect of the provision of screencasts during learning’ (p. 75). The level of complexity of the task or subject matter for the screencast is important, with Bhowmick, Khasawneh, Bowling, Gramopadhyea, and Melloya (2007) finding that for complex procedural tasks ‘a combination of audio, video and synchronized text yields the best results both in terms of learning performance and process efficiency’ (p. 615). Given the development of national repositories for reusable learning objects (RLOs) such as the National Digital Learning Repository Project (NDLR) in Ireland, Jorum in the United Kingdom and MERLOT in the USA, it is appropriate to consider the development of quality screencasts that are reusable by students on a variety of programmes, in different ways and contexts.

A potential criticism of the four-step screen capture process presented above is that, unlike the ADDIE model, it does not explicitly include an evaluation stage. There is a need for the evaluation of the use and effectiveness of screencasts in a variety of intents and contexts. These evaluations and related research should inform the development of evidence-based recommendations for good practice in the creation and use of educational screencasts.

It is incumbent on teachers who develop screencasts to become proficient with the technology. However those who create screencasts also need to become familiar and draw upon research in areas such as instructional design, pedagogy, educational psychology and accessibility. This should be viewed within the context of major change in higher education underpinned by technology and the attending change in the role of the academic (see Davidson-Shivers, 2002).

CONCLUSION AND REFLECTIONS

Simple, short screencasts are quick and easy to produce, popular with students and can help learning happen. The combination of text, audio and video is engaging. Screencasts can be used for many purposes, for instance to introduce a module, give an overview or review a difficult concept, illustrate how to solve a problem, explain a technical diagram or picture, show how to use software or a website, and give feedback. Students can flexibly use short, sharply focused screencasts how, when and where they want.

To create a screencast, you need a computer, some software and a microphone. There are many software choices, with more powerful options having a steeper learning curve. Time is often the major issue, whether to capture a simple screencast and publish with little editing or to expend greater effort in creating a screencast together with interactive elements that is of use by a greater number of students in a wider context.

When introducing screencasts into a module, there are some personal considerations. Screencasts, like full digital recordings of lectures, are a more public form of teaching. This combined with the possibility of the digital recording of mistakes (Do *you* want to appear on YouTube? See Young, 2009) may enable possible misuse by students and criticism of presentation style by colleagues (see Budgett et al., 2007). This openness is broadly positive, but requires a certain level of confidence. Another issue may arise: if recording mini-lectures, software demonstrations and explanations for model solutions of questions, will students stop coming to class? No, I would tentatively suggest; it is likely that screencast use and class attendance are positively correlated, consistent with the findings of Grabe and Christopherson (2007) who found that the use of online lecture resources, lecture attendance and examination performance were positively related. Screencasts do need to be thoughtfully integrated and their introduction may provide an opportunity

to rethink the use of classroom time, to create space for implementing more active learning strategies.

Screencasts indeed have the *potential* to enable learning in new and exciting ways. Screencasts can be used to support greater learner independence and may allow for a change in how lectures, tutorials and lab sessions are used, with less time spent presenting and more time spent on students doing things. It is important to reflect on the strengths and weaknesses of screencasts to be able to harness their potential, as well as to draw upon pedagogical and instructional design principles in their development. In particular, it is essential to carefully integrate screencasts into the teaching and learning process to support students' active engagement with their learning.

<http://www.jingproject.com>: website for Jing, where you can download Jing or upgrade to Jing Pro, read about Jing's features, watch screencasts demonstrating how to use Jing and visit the Help Center.

<http://www.lynda.com>: website of provider of educational materials on using technology. Many of their courses comprise of a series of screencasts and the site provides an opportunity to review some high quality screencasts.

<http://www.rlo-cetl.ac.uk>: website of the Centre for Excellence in the design, development and use of learning objects. They define an RLO as 'a web-based interactive chunk of e-learning designed to explain a stand-alone learning objective'. RLOs can contain screencasts and this website has many good examples.

ENDNOTES

- ¹ Note Educause's (2006) definition of a screencast as 'a screen capture of the actions on a user's computer screen, typically with accompanying audio, distributed through RSS' (p.1); thus a student will have subscribed to the teacher's RSS feed which will automatically highlight any new screencasts that have been added since the student last logged in (Educause, 2007).
- ² I have used a variety of software, starting with Viewletbuilder (www.qarbon.com), then switching to Adobe Captivate (www.adobe.com) and most recently testing Jing (www.jingproject.com). Another very popular screen capture software, particularly in higher education, is Camtasia (www.tech-smith.com). Note that there are many software options to choose from. The choice of software is a balance between sophistication of features, ease of use and financial cost. If you want to create a professional screencast, usable over time by many students and reusable by others, using a professional tool such as Captivate or Camtasia is advisable. Captivate, which I am more familiar with, has many features enabling full editing of your screencast (editing of recording and

sound, adding captions, clickable zones and buttons, highlighting and much more) as well as the development of e-learning objects with quizzes and branching scenarios. It is part of a suite of e-learning tools. Captivate incorporates a good text-to-speech converter and supports accessibility features like closed captioning. Like Camtasia, it has a presentation feature seamlessly enabling the narration of a PowerPoint presentation. The power of Captivate does come with a learning curve, especially for those less technically literate. Both Captivate and Camtasia have fully functioning trial versions that can be used for 30 days, with integrated screencasts demonstrating how to use the main features. A simpler option that can be used to quickly produce screencasts, especially throwaway (one-use) or limited-use ones, is Jing. Jing makes the capture very straightforward. The free version allows screen captures of up to five minutes to be recorded, with audio if desired. Jing, in conjunction with Screencast.com (www.screencast.com), makes it easy to upload your screencast to the internet, in the process generating a unique URL to link to and the HTML code to embed it within your VLE, blog or other webpages (similar to the options for linking to a YouTube video). Disadvantages however include, as well as the five minute limit, not being able to add captions, indeed not to edit the screencast at all nor to add audio after screen capture, as well as the commercial branding of Jing at the end of screencasts produced. These can be partly overcome by moving to the professional version (which allows removal of commercial branding as well as an easy upload to YouTube) or by bringing the SWF file generated by Jing into Camtasia for editing. At this early stage of my experience of working with Jing, it seems a promising option for colleagues who wish to produce the occasional screencast for use by their

own students and I can see myself increasingly using it for limited-use screencasts (or alternatively Screenr.com, a new web-based option offering similar features). However the editing power of Captivate means it likely that I will continue to use it or similarly powerful screen-capture software for producing screencasts that will be used more widely.

³ It is sometimes useful to create a simple webpage with links to a series of screencasts that students can open as full screen in a separate browser window. These files can be put into one zipped file and uploaded as a package file (for example, when uploading content in Blackboard choose 'Unpackage this file' to allow the online display of the zipped material, pointing to the index page from which the screencasts will be launched).

ABSTRACT

The development of learning communities has become an acknowledged goal of educators at all levels. As education continues to move into online environments, virtual learning communities develop for several reasons, including social networking, small group task completions, and authentic discussions for topics of mutual professional interest. The sense of presence and copresence with others is also found to be significant in developing Internet-based learning communities. This chapter illustrates the experiences

with current learning communities that form in a 3D immersive world designed for education. Faculty at Appalachian State University (ASU) have developed and taught the graduate instructional technology program in an award-winning 3D world setting for several years. Additional ASU faculty and program areas are currently transitioning into this environment. Further, colleagues from major universities in other countries are using this environment for their students to work and to collaborate across time and distance. Telecommunications technologies in education (exposing the graduate students to the breadth of IT experiences and knowledge required), hypermedia, and advanced Web design are examples

DOI: 10.4018/978-1-60960-503-2.ch311

of IT-related courses offered in the graduate program. The results of these experiences highlight the efficacy of this tool toward the formation of authentic communities within 3D Internet-based worlds as online distance education environments continue to evolve.

INTRODUCTION

New technologies for collaboration have generated increasing interest in the formation of various kinds of online learning communities for distance education. A wide range of distributed learning communities are currently involved in training, education, gaming, social networking, and other emerging online endeavors. These distributed learning communities are available in different forms and demonstrate underlying frameworks that include collaborative text-based environments, Web-based text and graphical multiuser domains, and the more sophisticated CAVEs (projection-based automatic virtual environments). Each of the above presents its own unique technologies and possibilities for online distributed collaboration and learning. Each presents opportunities for group interactions in different ways that bring a sense of community to the task. This chapter will focus on the findings and experiences of various communities of learners formed within a 3D immersive Internet-based virtual world developed for graduate education.

Descriptions of a 3D Internet-based learning environment—called Appalachian Educational Technology Zone (AET Zone)—used by the instructional technology program in the Department of Leadership and Educational Studies at Appalachian State University have been noted in other research (e.g., Bronack, Riedl, & Tashner, in press; Riedl, Bronack, & Tashner, 2005; Tashner, Bronack, & Riedl, 2005). An Active Worlds universe server (<http://www.activeworlds.com/>) serves as the current platform for AET Zone, and provides a means to build virtual worlds for

students, instructors, and other invited guests to meet and to work together in ways not found in other learning environments currently available. AET Zone may be characterized by significant components of space, movement, physical presence and copresence, conversational tools with small and large group shared workspaces, and metaphors and artifacts that assist with collaboration and learning online in unique and powerful ways. Students, faculty, and guests, graphically represented by avatars, move through the 3D world spaces interacting with each other and with artifacts within the worlds. These artifacts may be linked to different resources, Web pages, and tools necessary to provide content and support for various kinds of synchronous and asynchronous interactions. Small and large group shared workspace tools enable interactive conversations in text chats, threaded discussion boards, and audio chats. Group sharing of documents, Web pages, and other types of application software also are available within the virtual world.

Typical students in this graduate program are mid-career K-12 classroom teachers who want to learn more in-depth ways to integrate technology into their curriculum, or who want to become instructional technology specialists in their schools or chief technology officers (CTO) at the district level. Many of the students in the program teach within a 100-mile radius of the institution. However, recent initiatives have expanded opportunities to enroll K-12 teachers in a totally online experience. For example, several Mexican teachers from the D'Amicis School in Puebla, Mexico, and faculty and students in Griffith University in Brisbane, Australia, are working within AET Zone. Without the ability to depend on face-to-face contact, these international collaborations are challenging us to rethink the way we develop and enhance the sense of community in distance educational settings.

The instructional technology program at Appalachian State University uses a cohort model, where students enroll and move through

the program together through a specific sequence of courses. Students and faculty currently meet face-to-face regularly at the beginning of the program, with reduced numbers and frequency of meetings as the members of a cohort become more comfortable working within the virtual world and gain understanding of course structures and expectations. While the virtual world is used for each class, the number of face-to-face meetings rapidly decreases after the first several courses to only an orientation class at the beginning and a final class session for student presentations at the end. A handful of courses during the final phase of the program are conducted completely within the virtual world, with no concurrent face-to-face meetings.

A set of four cohorts, consisting of 80 students who had experienced at least 2 years in the program, were asked several questions concerning ways they would describe their experiences as learners in this immersive 3D world. An informal qualitative analysis was conducted for the common themes expressed through the aggregated responses. These are presented and discussed below.

BASIC TENET

Conceptual Framework

A conceptual framework (Reich College of Education, 2005), based upon social constructivism (Vygotsky, 1978), was developed by the College of Education and provides a clear foundation that guides teaching and learning within AET Zone. These basic concepts are:

- Learning occurs through participation in a community of practice
- Knowledge is socially constructed and learning is social in nature in a community of practice

- Learners proceed through stages of development from novice to expert under the guidance of more experienced and knowledgeable mentors in the community of practice
- An identifiable knowledge base that is both general in nature and also specific to specialties emerges from the community of practice
- All professional educators develop a set of dispositions reflecting attitudes, beliefs, and values common to the community of practice

AET Zone reflects these assumptions about teaching and learning, and provides a powerful space through which effective learning communities are formed and nurtured. Students know and can see when their colleagues are logged into the world. They can approach other students and talk to them about life, work, or the latest news. Through these interactions, both planned and serendipitous, students begin to create knowledge together. They talk about the work they are doing in class, they share ideas, processes, and resources with one another, and they contribute to the base of knowledge that exists in their field. Throughout this process, they move from novice to expert, both in terms of knowledge and skills, but also in terms of their abilities to work collaboratively within a virtual learning environment using tools previously unknown to them. Their beliefs about teaching and learning are challenged, refined, and shaped by the process of learning together in an authentic social world of dialogue and discovery (Sanders & McKeown, 2007).

Differences Between Conventional Classrooms, Traditional Distance Education and Emerging Environments

Table 1 describes the differences between conventional classrooms, traditional forms of distance

education, and emerging educational environments such as AET Zone. These characteristics are based on observations of what occurs in each environment. One key factor is the continuity and persistence of the AET Zone setting in which students and faculty run into each other during all times of the day and night regardless of physical location. While one can argue that similar persistence and continuity can and does occur on traditional campuses, it should be noted that there is a distinct *discontinuity* between the confines of the classroom setting and the rest of the campus setting. In AET Zone, the learning environment and the social environment are one and the same. Thus, the community of practice is more explicit and becomes a more obvious factor in the experiences of students and faculty.

Learning Communities

Learning communities have been characterized in many ways, and some division exists in current literature on the actual meaning of learning communities. “Communities of learners,” according

to some, are groups formed to increase their understandings or knowledge base in specific areas. Jonnasen (1997) cites the following necessary components for a learning community: active, constructive, collaborative, intentional, complex, contextual, conversational, and reflective. Others use the term “community of practice” which seems to indicate communities of similar practitioners who are currently exploring various aspects of their endeavors together. Wenger (1998) states that communities of practice include: “a *joint enterprise* as understood and continually renegotiated by its members..., *mutual engagement* that bind members together into a social entity.... and the *shared repertoire* of communal resources (routines, sensibilities, artifacts, vocabulary, styles, etc.) that members have developed over time.” Others use the terms “learning communities” and “communities of practice” interchangeably.

Developing Online Communities

In either case, the literature suggests several main themes that emerge as useful guides for developing

Table 1. Analysis of the principles of the RCOE conceptual framework

	Conventional Instruction ¹	Current Distance Education ²	AET Zone ³
Knowledge is socially constructed and learning is social in nature	Usually only within the context of each individual class	Rarely and if so within the context of an individual class	Within the entire virtual world community
Learning occurs through participation in a community of practice	Usually only within the context of each individual class	Rarely and if so within the context of an individual class	Regularly throughout the entire virtual world community
The development of educators proceeds through stages from novice to expert under the guidance of more experienced and knowledgeable mentors in the community of practice	Rarely; contact with mentors usually limited to the course instructor	Rarely; contact with mentors usually limited to the course instructor	Exposure to and interaction with a wide range of mentors throughout the virtual world community
An identifiable knowledge base emerges out of the community of practice that is both general for all educators and specific to specialties and content areas	Limited by lack of exposure to the broader community of practice	Limited by lack of exposure to the broader community of practice	Regular contact with the broader community of practice develops a full and shared knowledge base
All professional educators develop a set of dispositions reflecting attitudes, beliefs, and values common to the community of practice	Limited by lack of exposure to the broader community of practice	Limited by lack of exposure to the broader community of practice	Regular contact with the broader community of practice leads to sharing of beliefs and values leading to dispositions that are part of that community of practice

online virtual communities. An overview from a recent conference on building learning communities states that such communities:

Foster peer-to-peer collaboration, communication, interaction, resource sharing, negotiation and social construction of meaning, and expressions of support or encouragement among students. A blended or online learning community must have its own meeting or gathering space, as well as a defined set of members' roles and norms for resolving disputes. ("Academic Impressions," 2006)

A key element in the development of the community in AET Zone is that faculty members who teach in this environment stop thinking of students in one section of a class as "their" students but instead they interact with all students across sections and across classes. The "flattening" of their thinking is trickling down to students as well. Students are meeting each other online, learning what they have in common and how they differ, and then forming effective online partnerships and communities around real-world projects and activities (Sanders, Bronack, Cheney, Tashner, Reidl, & Gilman, 2007). Students just beginning in programs are interacting with students who are nearing graduation. Students in school administration, library science, higher education, and reading programs are interacting with each other and with instructional technology majors. Virtual worlds such as AET Zone are moving distance education efforts toward realizing the full potential of what distance learning might become. The virtual world serves as a catalyst for a learning community that reaches far beyond what normal classroom settings have been able to accomplish. Zhao and Kuh (2004) support this goal, asserting, "Learning communities are associated with enhanced academic performance, integration of academic and social experiences, gains in multiple areas of skill, competence, and knowledge, and overall satisfaction with the college experience" (p. 130).

The communities forming between and among students are beginning to resemble what Wilson and Ryder (2006) describe as "dynamic learning communities." Such communities are defined as "groups of people who form a learning community generally characterized by the following: distributed control; commitment to the generation and sharing of new knowledge; flexible and negotiated learning activities; autonomous community members; high levels of dialogue, interaction, and collaboration; a shared goal, problem, or project that brings a common focus and incentive to work together." These dynamic communities of learners are the ultimate goal in the process of applying social constructivist theory in the design and development of tools and spaces to support effective Internet-based communities for learning.

Common Themes in Learning Communities

Several common themes consistently emerge from these descriptions of learning communities. Communication, collaboration, and support are central to their development and maintenance. Other factors include shared resources and authentic reasons to join together. Recently emerging research and the emergence of 3D Internet-based environments for teaching and learning suggest the importance of the sense of presence and copresence in the development and evolution of online communities (Schroeder, Steed, Axelsson, Heldal, Abelin, Widstrom, et al., 2001). Using such characteristics as both a vision and a guide, the instructional technology graduate program has been studying ways to develop an environment that continues to foster and to support a wide variety of learning communities that may be identified with these characteristics.

Development and support of communities within 3D immersive worlds used for learning require consideration of how students will move through the course environments in collabora-

tive ways, how to provide means to enhance the communication between students, guests, and instructors, and how to ensure participants will interact with the various resources in the environment that contribute to building meaningful communities of learners.

Collaboration

Participants in courses and other activities within AET Zone express a strong sense of collaboration by those engaged in learning within the virtual world. This collaboration exists between students in a specific cohort as well as between students from different cohorts. In fact, students from one section of a course often collaborate on specific tasks with students from other cohorts enrolled in sections of the same course, thereby increasing their collaborative resources exponentially.

Additionally, students cite many instances of working with other students from different program areas who were also taking different courses within the virtual world. It was indicated that students felt a strong collaboration with instructors, who served as knowledge guides rather than sole sources of expertise, as well. Additionally, students

know that the course resources (including fellow students and faculty) will remain available to them through the AET Zone following completion of the course, and for graduates, even after completion of the degree program. They are free to visit other courses, to access various resources, and to engage students in other courses as resources in the learning process.

COMMUNICATION

Learning is a social process which reveals a conflict between what is already known and what is being observed (Brooks & Brooks, 1993). To resolve this conflict, an effective learning process requires interaction between learners and content, between learners and their peers, and between learners and those more expert than they (Levin & Ben-Jacob, 1998). Tools for communication, topics about which to communicate, and an authentic need to communicate are requisite factors for effective communication to be sustained within learning communities or communities of practice.

Figure 1. A community of learners collaborating in AET Zone

Figure 2.

Synchronous Communication

In 3D immersive worlds, several kinds of communication tools are found to be necessary to support ongoing tasks and community building. Synchronous tools such as text-based and audio chat capabilities are critical parts of the infrastructure necessary for creating learning communities. Such tools provide a means of working together at the same time in ways not otherwise possible. According to a recent analysis (Tashner et al., 2005), participants are able to develop and work together on authentic projects and topics because of the communication tools provided.

Asynchronous Communication

Asynchronous tools, however, also are important to the participants as ways of sharing ideas, research, and practice over time. For instance, a well-defined threaded discussion board provides opportunities for participants to share ideas, opinions, practices, and research. This communication tool also provides for the element of reflection that is not immediately available in synchronous environments. It is noted that the blend of these two communication tools within virtual worlds such as AET Zone enable a greater opportunity for interactions between and among participants.

Both formal and informal communication occurs in AET Zone and throughout the IT courses. Analysis further suggests that the informal communication is a powerful contributor to effective learning within 3D immersive worlds. Informal communication may spring up casually as faculty and students move around together in the world. Just as students on campus are thought to learn a great deal of content outside of structured classroom environments, so too, informal discussions in 3D immersive worlds may provide similar results. For example, students may join an audio chat room while simultaneously walking through the virtual world exploring together the artifacts that are present. Participants also may explore other topics of mutual interest that may or may not be part of their formal curriculum or agenda, but may still be tangentially relevant. This is an essential element of collaboration, communication, and community building.

SENSE OF PRESENCE AND COPRESENCE

Much contemporary Web-based instruction is characterized by “essentialists” view of teaching and learning. That is, certain “essential” things are to be learned as set forth by the instructor.

Information flows in one direction, from the instructor and auxiliary materials to the student. Interactions that occur in such environments generally are limited to those between a single student and the student's instructor or in limited cases, between students enrolled in the same class. The student then shows the instructor by summative assessments that learning has occurred. When done online such environments lack many of the interactions and social aspects of learning that characterize communications within 3D immersive worlds. Emerging constructivist paradigms as noted above can be used as guiding principles in designing environments in which students engage in discussions with others across sections of the same class, different classes, and even different programs to deal with and to solve problems of interest from different perspectives. Such interactions include different forms of student to student, groups of students, instructors, and other experts interacting in various configurations to develop perspectives, to solve tasks, or to explore issues of mutual interest.

As 3D multiplayer games emerged in the late 1990s, researchers became interested in exploring these types of richer participant interactions taking place within gaming environments. Research suggests that social networks are powerful components of online multiplayer games (Jakobsson & Taylor, 2003). Drawing from ethnographical and constructivist approaches, Manninen (2001) offers a taxonomy to conceptualize these forms of interactions based on components such as language-based communications, avatar appearance, body language (subconscious), and physical contact. Research has also focused on roles that presence and copresence may play in enhancing participant interactions within virtual worlds (Schroeder, 2002). While the term "virtual" has recently been applied to many different types of technologies and mediated environments, Schroeder's definition of "virtual reality" focuses on the common elements linking these technologies and environments together, specifically, "a computer-

generated display that allows or compels the user (or users) to have a feeling of being present in an environment other than the one they are actually in and to interact with that environment" (p. 2).

Presence

Schroeder (2002) argues that shared virtual environments "combine a high degree of presence with a high degree of co-presence because the sense of being in another place and of being there with another person reinforces each other" (p. 5). Furthermore, "presence and co-presence will be affected by the extent of experience with the medium" (Schroeder, 2006, p. 439). The more familiar and comfortable users are with the medium and the social norms of the virtual environment, the more their sense of presence and copresence will be heightened. However, regardless of the users' competence and proficiency working in a virtual environment, two users' "connected presence" in that environment will have an impact on the overall experience for both users, simply as a result of being in the environment together (in a similar way to how ethnographers have noted that the act of observing influences that which is being observed).

As an immersive 3D environment, AET Zone allows participants to "see" each other via representative avatars. Each participant moves his or her avatar through the virtual world using a keyboard or a mouse. As one moves, one's perspective changes; thus what the environment looks like changes. This change in perspective as one moves creates a sense of "presence." A participant has the perception of being somewhere else. In addition, as one observes others in the environment, one has a feeling of being somewhere else with someone else or "copresence." These concepts lead one to experience a connected presence or mutual awareness of others. As the mutual awareness increases, so does the desire for and feeling of heightened engagement in the world and in the activities conducted within the

world. Emerging from these feelings is a strong theme of the importance of both presence and copresence in developing learning communities. Students report that the feeling of isolation and working alone diminished as they become accustomed to working in the environment. This was of particular import to both retention and to the individual successes of students toward their educational goals (Tashner et al., 2005).

Interestingly, presence is evidenced in several ways. The foremost is sensing that you are actually somewhere different than your physical location. As you move through the world and you sense the movement, your perspective changes and you become “there” as well as “here.” Some students will desire to change their personas on a frequent basis by changing their avatar. When asked why, they state that they were “feeling different.[sic]” On the other hand, some students do not see “themselves” in the same way.

Copresence

Copresence is characterized as being “there” with “someone else,” though the “someone else” is represented by an avatar. We have noticed that adults take into the 3D world some parts of their personalities and cultural more that they exhibit in the outside world. For instance, if one avatar gets too close to another, the second one will move in order to preserve “personal space.” Novice students must learn to minimize windows so that they can “see” when others are trying to communicate with them. Some become disheartened when they speak to another avatar and the “other” ignores them. Yet, we have also seen a reluctance to meet “others” outside their class, to converse with “strangers” in the 3D world. Such issues are worked through by assignments to meet others, explore courses together with “persons” you do not know, and many other techniques as needed. However, these examples demonstrate the importance of understanding the concepts of presence and copresence in immersive worlds.

Role of Presence and Copresence in Online Communities

The sense of presence and copresence are critical factors in creating and maintaining deeply engaging online communities. As participants gain more of a sense of being somewhere and with somebody else, communication and collaboration are dramatically enhanced. According to Ahuna (2006), when constructs such as communication and collaboration combine to support the formation of community, “a semantic world of sharing knowledge, solving problems, working as a team, playing, building, quarreling, cooperating, planning and forming relationships develop.” The following screen shot illustrates an overview of the Network Basics building. Students move through the building, walking across the various components, clicking on components to access descriptions and resource information. For a slightly different perspective, students may choose to float above the floor. Various tools to enhance the cognitive awareness and understanding of the concepts and constructs are available to the learners. Group interaction is encouraged as an important piece of the learning process, in developing the learning communities, increasing collaboration, and to increase levels of content understanding. The combination of communication and small group shared collaboration tools with a sense of presence and copresence provides opportunities for developing authentic learning environments for Internet-based learning that goes far beyond attempts to replicate traditional classroom instruction using typical Web-based applications.

Our experiences with graduate students in the AET Zone suggest that many forms of communities evolve as needed. Some will develop for specific tasks and time periods and then dissolve. These include task oriented communities, for example, where students will form groups to read and to discuss specific books and to inform other larger groups of what they are learning in

various discussion formats. Hence, a group of four students may find themselves in discussions on ideas with eighty other students. Another example might be a task involving the development and implementation of certain projects that include ideas, knowledge and resources shared among a larger group who have similar interests. Others will remain intact for longer periods of time. For instance, different forms of social groups also have been noted in AET Zone that are more persistent. One group who met online each week to work on assignments decided to meet together at a different time for dinner. They cooked the same dinner, drank the same wine and met, not face-to-face, but connected inside the 3D world in an audio chat room to enjoy each other's company for a while.

Certainly, our experiences in thinking about the roles of presence and copresence in AET Zone help us understand the importance of these sensory inputs in Internet-based instruction. However, we are deeply aware that we are dealing with very complex variables. We are exploring new questions that emerge from our observations. How might we develop a deeper sense of belongingness to these communities? Are there pedagogical ways to provide social networking within a series of courses or is it even desirable?

Instead of information flow in one direction only from a source to a receiver, many other

possibilities emerge. The result is a vibrant, active, participatory, and engaging environment developed for community members to build new knowledge based upon the foundation presented by the group.

METAPHORICAL GRAPHICAL USER INTERFACES

One striking feature of AET Zone is its extensive use of metaphors in the design of the graphical user interface. As students move through the world, they find themselves in plazas, gardens, frontiers, and suburbia. Every space in the 3D world is built upon a metaphor or a series of metaphors to provide students with access to content, context, and tools for navigation. We have been very deliberate in our selection of metaphors in our designs and believe that thoughtful and reflective choices about the metaphors to use are important to the success our students have working within the virtual world.

Cates (1994) cites Lakoff and Johnson in defining a metaphor as "understanding and experiencing one kind of thing in terms of another." One thing, often familiar, is a figurative representation of the other, often abstract or unfamiliar. According to Nicholson and Sarker (2002), Aristotle understood the value of a metaphor when he said, "Ordinary

Figure 3.

words convey only what we know already; it is from metaphor that we can best get hold of something fresh.”

Some suggest that simply a virtual representation of a physical space or artifact is not metaphorical, but rather, the virtual representation must be different in its representation (e.g., Cates, 1996). According to Cates (1996), a graphical user interface (GUI) that is metaphorical must be based on either an explicit or implicit metaphor, but it makes little difference as to whether the metaphor is obvious to the user or not. The important aspect is that the metaphor works to provide some insight into or aid in understanding of that idea, concept, or thing it represents.

According to Black and later expanded upon by Cates (1994), there are two types of metaphors: *underlying* or *primary* and *auxiliary* or *secondary*. An underlying metaphor is the main metaphor used. For example, in one of the courses taught in the instructional technology program, the underlying metaphor of the Wild West was used as the main metaphor throughout the course space within the virtual world. An auxiliary metaphor is one that is consistent with the underlying metaphor and is used to support or enhance this main metaphor. In the case of the aforementioned course, examples of auxiliary metaphors might include a “saloon” for meeting and conversing, a “general store” for finding useful content, and a “haystack” that links to useful search engines.

Complimentary Metaphors

Complimentary metaphors are those that enhance the online teaching and learning environment. These are complementarily aligned with one another to assist learners in developing a “conceptual framework of understanding through which the learner can further enhance prior knowledge and conceptualize a higher level of understanding towards the knowledge being obtained” (Henry & Crawford, 2001, p. 3). Henry and Crawford

further suggest that through the utilization of these metaphorical graphical user interfaces (MGUI), “a sense of community is presented to the learner, and in turn, a collaborative e-learning environment is well on its way towards realization.” (p. 4) This community emerges out of an immersive environment in which students “collaborate on projects, work in teams, and create material and artifacts together... Students assume a variety of roles...and students must negotiate as they will have to negotiate in the adult world” (Marshall, 2000, p. 5). For this to occur, auxiliary metaphors selected must be complementary to the underlying metaphor employed.

The effective use of metaphors in an online learning environment can be valuable in offering students a model to assist in understanding more abstract concepts in more familiar, concrete terms and can help students understand a concept and content more quickly than without the use of the metaphor by helping students learn and understand how things should work (Bishop & Cates, 1996; Cates, 1994). Bishop and Cates (1996) note existing literature that supports the position that content can be better learned through the interaction with metaphorical graphical user interfaces by providing both “superficial and deep similarities between familiar and novel situations.” Ultimately, it is the finding of these and other studies that the use of metaphors helps students build knowledge, develop higher level thinking skills, build community, and gain a more universal understanding of the subject matter being taught (Bishop & Cates, 1996; Henry & Crawford, 2001).

The goal in the use of underlying metaphors is to enhance the students’ learning experience by providing a device that allows each to interact with the instruction and the content in ways more familiar, and, as a result, more accessible, to them. Well-crafted auxiliary metaphors complement the underlying metaphor and the overall learning experience.

Confounding Metaphors

It should be noted, however, that the ineffective use of metaphors can have a deleterious effect on even the most well-designed and well-intended learning environments. Some have suggested that gratuitous or fantastical metaphors can be in conflict with the tenets that ground effective meaning-making (e.g., Nicholson & Sarker, 2002). While this assertion is in stark contrast with the value of metaphor discussed above, it does provide an important reminder that problems can arise in the use of metaphors, especially those that are auxiliary to the underlying metaphor.

Form should follow function, and the selection of underlying and auxiliary metaphors (form) should enhance and complement the teaching and learning tools and activities (function) embedded in a virtual world. One challenge in the inclusion of metaphors is the overdependence on their use within the interface design (Cates, 1996; Nelson, 1990). There are times when the poor choice of metaphors overshadows the instructional design of the content and the virtual world in which the content is presented. When this happens, students must reconstruct what they think they know and understand about the content and virtual world with which they are working. Again, according to Cates (1994, p. 103), “When users are faced with such an auxiliary metaphor [confounding] they are required to reconstruct the environment radically, envisioning a book [for example] that is unlike any that the user has ever seen. Users seem unlikely to make such radical reconstructions.... When users come to this conclusion, the benefits of the underlying metaphor are greatly reduced.” It is even possible that students may reject and disengage from the virtual world completely if the cognitive dissonance created by the confounding metaphor is too great.

Multiple studies warn that metaphors used incorrectly or out of context can make it difficult for learners to engage effectively within environments

such as virtual worlds (e.g., Rosendahl-Kreitman, 1990; Semper, 1990; Vertelney, Arent, & Lieberman, 1990). Misalignment or inappropriate linkage between metaphors and expectations may result in a debilitating tension for learners (Burge & Carter, 1997). Barrie (1996) explains this tension as created out of a “pause in the cadence of the composition...producing a reaction of tension and anticipation” and notes an emotional reaction occurs when this pause or interruption occurs, often resulting in frustration or even feelings of incompetence. Rohrer (1995) offers a different twist, suggesting that there is also a tension taking place between the literal and figurative, or “magical,” qualities of the metaphors being used, and this tension extends to the a tension between the user and the computer itself, which is viewed as an “other—a sentient being with a consciousness of its own (and usually a malevolent consciousness at that).”

When it comes to metaphors, it seems, numbers count. Incorporating too few or too many metaphors can pose problems for users as well. Learners may not have enough to make sense of the interface nor to understand the content to be learned if there are too few metaphors employed. On the other hand, too many metaphors can be overwhelming to a learner and lead to cognitive overload (Cates, 1994). Regardless, any use of metaphor has the potential of requiring learners to translate not only the content and instruction being delivered into more familiar and understandable terms, but also to force them to work through another cognitive layer posed by the use of the metaphor. When the layers overload, the use of metaphors may hinder—rather than help—learners make sense of the information at hand (Lohr & Heng-Yu, 2003). As previously mentioned, the poor use of metaphors can ultimately cause learners to abandon the metaphor altogether (Rohrer, 1995).

What is the lesson for designers of user interfaces for virtual worlds, then? The lesson is clear.

To design an effective virtual world for learning, it is essential to use complementary metaphorical strategies that foster the development of community and to avoid becoming enamored with the metaphors themselves.

SUPPORT

An additional theme that has emerged from our work with virtual worlds for learning is that of “support.” Support is expressed in many forms but in this case, the concept is of peer and instructor support. It is often expressed as assistance that is usually available whenever one requested it. Whether the online library resources, an individual course, or even professional assistance is needed, there is an instructor or peer ready to offer support. In social constructivist learning communities, such as AET Zone, participants move along a developmental continuum from novice to expert. Indeed, in each course and throughout the program, students represent various aspects of this continuum at various points in each individual’s personal development. As each becomes more aware of others through planned and serendipitous interactions, and as each becomes increasingly comfortable with others, their collective working relationships weave a complex support network for and by all participants. Bender (2003) suggests that a feeling of belonging within a chosen community of practice is requisite for effective learning. Both feeling supported and feeling supportive play an integral role in this important construct of belonging.

LEADERSHIP

It is in these same 3D communities that participants find themselves alternately leading and being led and where some participants unexpectedly find

themselves becoming leaders and identifying with leadership roles. The leadership theme emerges as personal as well as organizational leadership.

Working collaboratively and communicating together in learning communities enhances the leadership skills and comfort levels of participants, with self-reported transfer to their own teaching and learning environments. Students who spend time in AET Zone, for example, report a heightened sense of awareness of their own expertise arising from interactions and participation in the various communities in which they work and learn. They express an increase in personal and professional self-confidence, which they indicate is transferred into their professional practices.

In addition to leadership dynamics that emerge naturally from participation in 3D immersive communities of learners, deliberate leadership-focused prompts, such as case studies, provide problem-based learning situations in cross-disciplinary contexts that foster deeper levels of development. In AET Zone, for example, participants are immersed in authentic circumstances requiring the development of leadership “voice” in the “safety” of the virtual community. Participants are given opportunities to “try out” various responses to situations in an effort to solve problems within organizational communities. In the virtual environment mistakes can be made, consequences examined, and corrections tried without fear of real consequence or penalty. This type of natural yet safe learning is necessary for developing better leaders. Thus, experimenting with shared leadership skills can become a natural consequence of learning within the 3D community and, as well, can be a result of responding to deliberately conceived situations requiring leadership thought and decisions (Angel, Sanders, & Tashner, 2005; Sanders & Angel, 2005). In short, the 3D environment is a rich context for learning personal leadership skills and, as well, for applying those skills in real work situations outside this environment.

FUTURE RESEARCH DIRECTIONS

The convergence of sophisticated gaming platforms, communications technologies, social networking trends, and educational needs provide rich opportunities for future research. In this time of global transition, we are changing paradigms of what it means to teach and to learn. Rather than trying to address old problems with new questions, we must begin to ask new questions about new problems.

Online educational environments started by attempting to recreate the four-wall classroom that had been successful in the past. Should online learning continue to try to be the same as its face-to-face counterpart? Can it be unique in its approach, using different methods and tools for teaching and learning? How might a newer generation of online learning platforms containing more immersive and engaging environments add value to learning? Furthermore, should we be asking additional questions about how specific technologies allow us to expand beyond the four walls of a traditional classroom and transcend borders, cultures, and perspectives to create active participatory groups of learners? The development of online pedagogies to create the teaching and learning models needed for a 21st century education is a field ripe for research.

Especially important in future research may be the applications of social constructivism pedagogies to online environments. Social constructivism is fundamentally about the social construction of knowledge through participation in communities of practice. Through interaction and communication, collaboration and mentoring, learners become a part of and contribute to this community of practice. Researchers have just begun to explore the effects of various kinds of online collaboration and communications between students, instructors, and colleagues in developing these communities of practice. Questions subsequently begin to emerge regarding the value that might be added

by the use of tools and processes whose purpose is to enhance synchronous and asynchronous collaborations and communications in the context of social constructivist learning environments.

Specific research questions to be asked include: What constitutes online learning communities and how might they be developed and expanded? To what extent do learning communities enhance online learning? What is the added value of the participants' sense of presence and copresence in online environments? What tools are needed to assist them in high level functioning? Additionally, one might ask: What kinds of skills and attitudes are needed by educational leaders to move and to support students and teachers as their organizations move into 21st century learning environments? How might current educational leaders develop such needed skills and attitudes?

Finally, the need for new assessment methods and tools is critical if we are serious about teaching toward higher levels of "critical thinking" and performance. The current testing movement in the United States is geared toward measuring lower level cognitive skills, thus creating a mismatch between what is measured and what is stated as goals for 21st century success. Teaching and learning in online environments, especially those that are built upon a foundation of social constructivism, will require new assessment tools and measures in order to know and understand the learning that takes place in these 21st century learning communities. Basic research must consider what an educated person looks like in the 21st century. What kinds of educational experiences are needed to develop 21st century individuals? In a world where the same knowledge base is accessible by everyone, what does "knowing," mean? What skills and knowledge are needed by individuals to be deemed "educated"? The answers to these questions will assist researchers in the development of valid and reliable assessment tools that are more consistent with a social constructivist approach to online teaching and learning.

CONCLUSION

Those who have learned and taught within AET Zone report a variety of positive experiences, advantages, and learning outcomes from their work in this environment and through the powerful learning communities that develop within. While participating in this social constructivist, immersive environment, students enrolled in these courses use a variety of tools and metaphors for communication and collaboration, fostering various forms of learning communities. These include the many virtual communities developing within AET Zone for social networking, small group task completions, and authentic discussions on topics of mutual professional interest. Feedback from multiple cohorts across time and distance suggests the strong sense of presence and copresence felt while in AET Zone is a critical factor that fosters the development of useful learning communities which, in turn, facilitate practical, useful learning.

The shared experience of AET Zone participants has a number of other outcomes as well. Students share a variety of resources both during and after their period of formal participation. They also report that the environment provides support for learning, both from instructors and peers. As a result, students' sense of leadership and vision is heightened.

Virtual worlds such as AET Zone are unique environments for teaching and learning. The tools, support, and constructivist pedagogies embedded within AET Zone lend themselves readily to the creation of learning communities. Clearly, there is a need for well-designed research studies to develop a body of literature that will guide educators as they continue to move into emerging online environments for teaching and learning.

ABSTRACT

This chapter states and explains that a learning design is the result of a knowledge engineering process where knowledge and competencies, learning design, media and delivery models are constructed in an integrated framework. Consequently, we present our MOT+ general graphical language and editor that help construct structured interrelated visual models. The MOT+LD editor is the newly added specialization of this editor for learning designs, producing IMS-LD compliant Units of Learning. The MOT+OWL editor is another specialization of the general visual language for knowledge and competency models based on the OWL specification. We situate both models

within our taxonomy of knowledge models respectively as a multi-actor collaborative process and a domain theory. The association between these “content” models and learning design components is seen as the essential task in an instructional design methodology, to guide the construction of high quality learning environments.

INTRODUCTION

Building high quality learning designs is a very important and demanding task. It is also a difficult task that we started to address already a decade ago by progressively building an instructional engineering method (Paquette et al., 1994, 2005a; Paquette, 2003), a delivery system (Paquette et

DOI: 10.4018/978-1-60960-503-2.ch312

al., 2005b) and a graphical knowledge modeling editor (Paquette, 1996, 2002).

In this on-going work and for the present discussion, the point of view is taken that a learning design is the result of a knowledge engineering process, where knowledge and competencies, learning design, media and delivery models are constructed in an integrated framework. In the first section of this chapter, we present the MISA¹ instructional design method based on these four models and their relationships to each other. The second section presents the MOT (modeling with object types) visual language and the specialized editing tools that have been used in numerous applications. We summarize the theoretical basis of the language, its syntax and semantic. Moreover examples within the MISA instructional design method will be presented.

The third and fourth sections address the standardization issues and how the MOT+ software is adapted to provide visual aid to designers building knowledge and/or pedagogical models. The third section focuses on the learning design models, the IMS-LD specification and the specialized MOT+LD editor that helps designers build IMS-LD compliant and interoperable units of learning. The fourth section presents the ontology web language (OWL) and the specialized MOT+OWL visual editor. We use it to represent domain knowledge models and target competency that can be used to plan, support staff roles and evaluate the quality of learning designs. In the fifth section we discuss the association between LD models and OWL models to support what we believe is the central task for knowledge-based instructional design aiming to support learning environments within the Semantic Web.

Finally, the concluding section will summarize the properties of representation languages that we have found most useful while designing and using the various specializations of the MOT+ software through its evolution from a general knowledge modeling tool to a standardized tool at the heart of the instructional design methodology.

INSTRUCTIONAL DESIGN BASED ON VISUAL MODELING

In this section, we present a synthesis of the MISA 4.0 instructional engineering method main components and concepts. A knowledge modeling approach using the MOT editor was used to define the instructional engineering method itself, its concepts, processes and principles. And thus, this method can also be seen as a visual modeling application.

This R&D initiative, started in 1992, has led to the MISA 4.0 version (Paquette, 2001a, 2002a) and to its support tool, called ADISA² (Paquette et al., 2001). The editor MOT+ is embedded in the ADISA system and accessible through a Web browser from workstations linked to the Internet. It can also be used without ADISA together with forms provided by the MISA documentation. Since 2001, the method has been adapted to the huge standardization work that has occurred in the e-learning sector; we will address this aspect in later sections of this chapter.

Overview of the Method

The MISA learning engineering process produces specifications of learning environment grouped in documents called documentation elements (DE). Table 1 presents these DEs.

Each DE results from tasks distributed into six phases. Within phase 2, 3, 4 and 6, these DE can also be viewed according to four axes or dimensions of an e-learning environment: knowledge, pedagogy, media and delivery. Presently, MISA 4.0 comprises 35 basic sub-tasks, each producing one DE, numbered, as shown in Table 1, from 100 to 640. The first digit denotes the phase, the second, the axis, and the third, the sequence number within the axis. A DE is either a visual model, identified in bold italic in Table 1, or a text-based form describing guidelines for a model or properties of objects in the model.

Table 1. MISA 4.0 documentation elements: Phases and axes

Phase 1: Definition	100 Organization's Training System 102 Training Objectives 104 Learners' properties 106 Present Situation 108 Reference Documents			
	Knowledge Axis	Pedagogy Axis	Media Axis	Delivery Axis
Phase 2: Initial solution	210 Knowledge Model Orientation Principles 212 Knowledge Model 214 Target Competencies	220 Instructional Principles 222 Learning Events Network 224 Learning Unit Properties	230 Media Principles	240 Delivery Principles 242 Cost-Benefit Analysis
Phase 3: LE architecture	310 Learning Unit Content	320 Learning Scenarios 322 Activity Properties	330 Development Infrastructure	340 Delivery Planning
Phase 4: LE detailed Design	410 Learning Resource Content	420 Learning Resource Properties	430 Learning Resource List 432 Learning Resource Models 434 Media Elements 436 Source Doc.	440 Delivery Models 442 Actors and their resources 444 Tools and Telecommunication 446 Delivery Services
Phase 5: Validation	540 Test Planning 542 Revision Decision Log			
Phase 6: Delivery Plan	610 Knowledge/Competency Management	620 Actors and Group Management	630 Learning System/Resource Management	640 Maintenance/Quality Management

MISA proposes a problem solving approach in 6 phases. Each MISA phase is subdivided into a number of steps where parts of a learning environment or system are constructed. These phases are sequential, but spiral, with frequent returns to modify the result or previous tasks:

- **Phase 1:** Designers build a description of the training problem, its context and constraints. The general goal that the solution must fulfill and the main characteristics of the target population are the most important aspects to address at this point.
- **Phase 2:** Designers define a preliminary training solution, centered on a knowledge model for the learning domain. Prerequisite and target competencies are associated to the most important knowledge entities in the model. In this phase, designers also build a first pedagogical visual model called “the learning event network” grouping the main modules or learning units, their sequencing and the resources need-

ed to perform them or to be produced by learners and facilitators.

- **Phase 3:** Designers construct a detailed learning design and specify the infrastructure necessary. Visual learning scenarios are built for each learning unit defined in phase 2, describing the learning and facilitating activities, the actors that perform them and the resources needed or produced by these actors. At the same time, a sub-model of the phase 2 knowledge model is associated with each learning unit thus defining “the learning unit content.” According to the evolution of the design, media and delivery principles are refined to prepare the next phase.
- **Phase 4:** Centered on the learning resources and delivery models and the properties of objects in these models several professionals may work on the initial design of a learning environment (LE). Another important concurrent task is the description of the properties of resources in learning scenarios and the association of a sub-

model of the knowledge model to provide a specification of the “learning resource content.”

- **Phase 5:** The project manager plans the validation of the learning environment and produces a list of possible revisions and decisions about how to improve the specifications created in the previous phases.
- **Phase 6:** Designers and project manager prepare elements necessary to the delivery of the learning environment. They produce a synthetic and global description of the learning environment for its maintenance and quality management by various actors.

A Visual Modeling Approach

In each of phases 2, 3, 4 and 6, MISA also proposes the development of the learning environment along four axes: knowledge and competency (content model), instructional, resources and delivery. The central product of each axis is one or more visual models.

The *knowledge model* centers on a graphical representation of the learning environment content domain. In this model, the domain’s facts, concepts, procedures and principles are displayed and interrelated with precise links. Then, target and prerequisite competencies are linked to knowledge elements in the model, thus identifying prerequisites and learning objectives for the pedagogical model. Subsequently, knowledge units and competencies are also associated to learning units and to the resources present in the learning units’ scenario models.

The *instructional model* is essentially a visual network of learning events and units, to which knowledge and target competencies are associated. Each learning unit is also described by a visual learning scenario specifying learning and support activities linked to resources in the environment. Resources holding content (as opposed to tools and services) are associated with a subset in the knowledge model.

The *learning resource models* are useful to describe materials (or learning objects) to be adapted and produced, their media components, source documents and presentation principles as well as other properties aimed at graphical designers and learning material producers.

Finally, *delivery models* are produced to show how and where actors use or provide learning materials and resources such as tools, communication means, services and locations, used in the learning environment. Each delivery model is a multi-user workflow, where actors use or produce resources, while assuming different roles. These processes address organizational issues, such as group organization, staff assignments, technical help, resource delivery, and so on, which must be prepared to ensure smooth deployment of a network-based or a distance learning environment.

Each and every one of these models is built using the MOT+ knowledge representation technique and tool (Paquette, 1999, 2002b). Graphical visual models are the basic DEs in each axis, the backbone of the MISA method. Most of the other tasks, in MISA, describe properties of objects in these models (e.g., competencies, learning units, resources, roles) as well as their relationships.

MOT+: A GENERIC VISUAL LANGUAGE AND TOOL

When designers start building a learning environment, two basic questions arise: “Which knowledge must be acquired, what are the target competencies or educational objectives for that knowledge?” and “How should the activities and the resources be organized to best achieve knowledge and competency acquisition?” To help designers solve this type of questions, we have developed a graphical knowledge modeling method and tools, which help visualizing activity sequences, actors and tools. In this section, we present the MOT modeling language that serves that purpose and the MOT+ visual modeling editor.

The graphic or visual representation formalism that we present here (Paquette, 1996; Paquette, 2002) has been tested for the past 10 years in a vast array of modeling applications and in many various contexts. It is used by trainers for corporate training, and designers or professors use it to prepare university courses or to propose modeling exercises to their students. It has served to model processes for the implementation of a computer-supported high school, or to model instructional methods or research projects processes.

Basis for a Graphical Knowledge Representation Language

It is often said that a picture is worth a thousand words. That is true of sketches, diagrams, and graphs used in various fields of knowledge. *Conceptual maps* are widely used in education to represent and clarify complex relationships between concepts. *Flowcharts* are graphical representations of procedural knowledge or algorithms. *Decision trees* are another form of representation used in various fields, particularly in decision-making expert systems.

All these representation methods are useful at an informal level, as thinking aids and tools for the communication of ideas, but they also have their limitations. One is the imprecise meaning of the links in a model. Another issue is the ambiguity around the type of entities or symbol system that is used. Objects, actions on objects and statements of properties about them are all mixed-up, which make graph interpretation a fuzzy and risky business. Another difficulty is to combine more than one representation in the same model. For example, concepts used in procedural flowcharts as entry, intermediate or terminal objects could be given a more precise meaning by developing them in conceptual sub-models of the procedure. The same is true of procedures present in conceptual models that could be developed as procedural sub-models described by flowcharts, combined or not with decision trees.

In software engineering, many graphic representation formalisms have been or are used such as entity-relationship models (Chen, 1976), conceptual graphs (Sowa, 1964), the object modeling technique (OMT) (Rumbaugh, Blaha, Premerlani, Eddy, & Lorensen, 1991), KADS (Schreiber, Wielinga, & Breuker, 1993) or the unified modeling language (UML) (Booch, Jacobson, & Rumbaugh, 1999). These representation systems have been built for the analysis and architectural design of complex information systems. The most recent ones require the use of up to eight different kinds of model, which rapidly become hard to follow without considerable expertise.

Our initial goals were different. We needed a graphic representation system that was both simple enough to be used by educational specialists, such as teachers, professors and tutors, who are not, in general, computer scientists, still general and powerful enough to represent the components and their relationships of computer-based educational environments.

There is a consensus in educational science to distinguish four basic types of knowledge entities (facts, concepts, procedure and principles), despite some diversity in terminology and definitions. See for example, the work of Merrill (1994), Romiszowski (1981), Tennyson and Rash (1988), and West, Farmer, and Wolf (1991). This categorization is retained as the basis for the MOT graphic representation language.

All four types of knowledge are also considered in the framework of schema theory. The concept of schema is the essential idea behind the shift from behaviourism to cognitivism, the now dominant theory in psychology and other cognitive sciences, based on the pioneering ideas of Inhelder and Piaget (1958) as well as Bruner (1973). In the early seventies, Newell and Simon (1972) developed, on the same basis, a rule-based representation of the human problem solving procedural activity, while Minski (1975) defined the concept of “frame” as the essential element to

understand perception, and also to reconcile the declarative and procedural views of knowledge.

Schemas play a central role in knowledge construction and learning (Holoyak, 1991; Anderson et al., 1995). They defined perception as an active, constructive and selective process. They support memorization skills seen as processes to search, retrieve or create appropriate schemas to store new knowledge. They describe understanding as a comparison of existing schema with new information. Globally, through all these processes, learning is seen as a schema transformation enacted by higher order processes, aiming at schema construction and reconstruction through interaction with the physical, personal or social world, instead of a simple transfer of information from one individual to another.

The distinction between conceptual and procedural schema has been accepted for a long time in cognitive science. More recently, a third category called “conditional or strategic schema” has been proposed (Paris, Lipson, & Wixson, 1983). These schemas have a component that specifies the context and the conditions to trigger a set of actions or procedures, or to assign values to the attributes of a concept. These categories map very well on the existing consensus in educational science.

The MOT Visual Modeling Language

We will now present briefly the syntax and semantic of the MOT visual modeling language, based on the notion of schema. Here, we could use graphs similar to UML object models to represent the attributes that describe a schema with different formats according to their type. In the MOT graphic language (Paquette, 1996, Paquette, 1999, Paquette, 2003), we have improved the readability and the user-friendliness of graphs by externalizing the internal attributes of a schema into other objects, with proper links to the original schema or object. For example, the link between the schemas “Triangle” and the “Rectangle Triangle” is shown explicitly on Figure 1 using a

specialization (S) link from the later to the former concept. Links between the “Triangle” concept and its sides or angles attributes is externalized using a composition (C) link. The links from an input concept to a procedure and from a procedure to one of its products are both shown by an input/product (IP) link. The sequencing between actions (procedures) and/or conditions (principles) in a procedure is represented by a precedence (P) link. Finally, the relation between a principle and a concept that it constrains, or between a principle and a procedure that it controls, are represented by a regulation link (R).

Using these links, the triangle concepts are arranged in the MOT model of Figure 1 where relations between knowledge entities are transparent, mixing the types of entities and links.

Concepts (or classes of objects), *procedures* (or classes of actions) and *principles* (or classes of statements, properties or rules) are the primitive objects of the MOT graphical language. The type of the objects are represented by geometrical figures as shown on Figure 2, where each class or individual is represented by a name within the Figure.

These objects are different types of schema whose attributes are all explicitly externalized and related to other schemas using six kinds of typed links constrained by the following grammar rules:

1. All abstract knowledge units (concepts, procedures, principles) can be related by an instantiation **I** link to a set of facts representing individuals called respectively examples, traces and statements.
2. All abstract knowledge units can be specialized or generalized to other abstract knowledge using specialization **S** links.
3. All abstract knowledge units can be decomposed, using **C** links into other entities, generally of the same type.
4. Procedures and principles can be sequenced together using **P** links.

Figure 1. A simple MOT model

Figure 2. Types of knowledge units in MOT

5. Concepts can be inputs to a procedure using an **IP** link to the procedure, or products of a procedure using an **IP** link from the procedure.
6. Principles can regulate, using **R** links, any procedure to provide an “external” control structure, to constrain a concept or a set of concepts by a relation between them, or to regulate a set of other principles, for example to decide on conditions of their application.

- **Concepts** can be object classes (countries, clothes, vehicles, etc.), types of documents (forms, booklets, images, etc.), tool categories: (text editors, televisions, etc.), groups

Figure 3 summarizes these grammar rules of the MOT graphic language in the form of an abstracted graph where the entities represent types of MOT objects.

There are various possible semantic interpretations of these graphic symbols.

Figure 3. The MOT metamodel

of the main MISA visual models constructed with the MOT editor.

Figure 4a presents an example of a knowledge model that describes part of the knowledge in the domain of artificial intelligence (AI) for an introductory Web-based course on that subject designed with MISA. Here ovals represent AI processes, rectangles represent AI concepts and hexagons represent AI principles.

Figure 4b presents an example of a *Pedagogical model* representing a learning scenario model for one of the course modules where learning activities are represented as procedures (ovals) and learning resources as concept/object (rectangles).

Figure 4c presents an example of a *Media model* representing the structure of a Web site for the course. Concepts represent Web pages or page elements, ovals or circles represent hyperlinks, as possible actions or procedures. Templates are represented by principles. Facts represent concrete objects such as page elements with their actual texts, pictures or other resources.

Figure 4d presents an example of a *Delivery model* representing the course delivery process where actors are represented as control principles, acting on tasks represented as procedures, each having input and output resources.

This first version of the MOT editor has been extended to the MOT+ editor, a mature editor with advanced graphic editing capabilities (fonts, color, disposition on a page, etc.). Sub-models can be embedded at any depth and knowledge objects in each one can be displayed in a multilayer mode. Models may be filtered in order to display only some types of knowledge objects or links. Sub-models from one model can be associated to objects in another model called a co-domain, which is very useful for example to assign knowledge to activities in a pedagogical model. Graphic objects can be associated to any type of document (using the OLE standard) such as a text document, slide presentation, Web page, spreadsheet or database file, which can be displayed by clicking on the graphic symbol. MOT+ has extensive export facilities to

XML, HTML, Excel and other commonly used formats. In particular, the “export to XML” command provides the possibility for graphic models to be processed by software agents respecting for example the IMS LD or OWL schemas.

REPRESENTING MULTI-ACTOR WORKFLOWS AND LEARNING DESIGNS

In the two following sections, we address the issues of the standardization of visual modeling languages, to promote the reusability of educational models and the interoperability between systems delivering learning environments. With the advent of an educational modeling standard specification like IMS-LD, we decided to develop a specialization of MOT+ to represent the IMS-LD concepts. During the eduSource and LORNET (www.lornet.org) projects, we found that this specification was closely related to the MISA pedagogical model including some aspects of the MISA delivery model. This R&D and the extension to a Web-based graphical editor are presented in the following sections.

The MOT+LD Special Visual Language

IMS-LD provides a representation of the components of a learning environment in a standardized XML schema that can be executed by any compliant e-Learning platform. IMS-LD does not provide a visual language to build a learning environment specification. Initially, these had to be built using an XML editor or a form-based editor like RELOAD (2005). Also, IMS-LD is not an instructional design method to build such representations. It needs to be accompanied by any instructional design method, and MISA is more closely related than many other methods. Unfortunately, the MOT+ pedagogical models built in MISA are not executable on a variety of

platforms because they are not standardized. In fact, in the projects where we have used MISA, the specification was translated by hand, into the platform's activity editor, with some loss of information.

To address these problems, we first developed a graphic modeling editor for the IMS-LD specification (level A) and made it available as a specialized editor in the MOT+ software. Many examples of learning designs have been produced by different groups using this editor. They can be found at the IDLD portal (www.idld.org). Figure 5 shows part of a unit of learning (UoL) on solar astronomy presented recently at a workshop (Paquette & Léonard, 2006).

It shows an act and its activity structure containing various learning and support activities, all represented as MOT procedures (ovals). Method, plays, and acts are also represented as procedures in other parts of the model. Each procedure type is indicated by a little label at the right lower corner of the ovals representing the procedures.

Similarly, roles are represented by different kinds of MOT principles (hexagons). Environments, learning objects, services and outcomes are

represented by different kinds of MOT concepts (rectangles). Standard MOT links are used between these objects. C (is composed of), P (precede), R (regulate or govern) and I/P (input / product) links are sufficient to cover all the components of a standard IMS-LD level A learning design.

The MOT+LD editor is presented with some detail in (Paquette, Léonard, Lundgren-Cayrol, Mihaila & Gareau, 2006). It enables a designer to build graphically a compliant IMS-LD model. Afterwards, the graph is automatically validated and exported as an instance of the IMS-LD XML schema. This XML file can be read in form-based IMS-LD editors such as RELOAD (2005), if level B conditions and/or level C notifications need to be specified. The XML can then be run by IMS-LD compliant players or platforms to deliver online learning sessions to their users.

Paquette and Marino (2005) briefly discuss the strengths and weaknesses of the IMS-LD educational modeling specification. One weakness is the absence of knowledge representation, which is central to learning and knowledge management that we seek to support by the TELOS³ system. We have proposed to improve that by the semantic

Figure 5. An example of a MOT+LD learning design

annotation of the activities, resources and roles included in a learning design. A *semantic annotation* is a mapping from a subject matter ontology to the learning design that associates knowledge elements to the components of the design. This aspect will be developed in the following sections.

Extending the MOT+LD Editor

Another aspect of IMS-LD we need to improve is the control structure of the workflow that is actually covered by level B and C specifications, where properties and conditions can be included in the design to alter the flow of activities, notify an actor or present a resource depending on previous actions or results stored in a user and group file or model. This aspect may not be that important in open learning environments where a total or large degree of liberty is left to the learner and facilitators, but for a business workflow in an organization, or to aggregate software components into larger resources, it is an important dimension.

To address that and provide a basis to build a function editor for the TELOS system, conceptual work on function maps has been defined as a central piece of the TELOS architecture (Rosca, 2005; Paquette, Rosca, Mihaila, & Masmoudi, 2006). Moreover, a comparative analysis has been made between business workflows, IMS-LD learning designs and function maps (Marino et al., 2006), leading to the identification of 21 control situations for workflows encountered in software engineering literature (Correal & Marino, 2006). It was found that IMS-LD covers only some of these control situations, but probably the most useful ones for pedagogical design.

Based on this work and the actual MOT+LD editor, we are in the process of designing a new visual editor. The *scenario Editor* aims both to generalize IMS-LD and to capture the main aspects of business workflows. The graphs produced by this editor will be executable, providing interfaces for concrete actors to enact the activities and use the resources during delivery. It will also serve to

orchestrate actors, activities and other resources, a fundamental principle built in to the TELOS system. A specialization of the scenario editor is being defined to cover all three levels of the IMS-LD specification.

The scenario editor uses four kinds of MOT objects with subtypes taken from the TELOS technical ontology (Magnan & Paquette, 2006). These are shown on Figure 6. *Concept* symbols represent all kinds of resources: documents, tools, semantic resources, environments, resource-actors, resource-activities and datatypes. *Procedure* symbols represent function models composed of activities and commonly used operation templates. Finally, *principles* are used both to represent different types of actors (as control agents) and control conditions. These two kinds of control entities are represented here by different symbols. The actor's symbols are active agents representing users, groups, roles or software agents that enact the activities using and producing resources as planned by the scenario model. Conditions are control element inserted within the basic flow to decide on the following activities that can be activated.

In Figure 7, we see a combination of some of these symbols where a coordinator writes the plan of a document in a first activity, after which the Figure shows a general split condition. After that, these activities are executed in parallel, controlled by the properties of the split condition object. Later on, the flow of activities merges through

Figure 6. Scenario editor symbols

Figure 7. A simple scenario model

the merge condition object the assemble activity takes control. This activity will wait for some or all of the incoming flows to be activated before it is executed, again based on the properties of the merge condition object.

Figure 8 shows another kind of condition that alters the flow of execution. In activity-2, if the time-event condition is met, the flow of control will change. Depending on the type of the condition, the activity-4 will be shown or hidden. Activity-3 is still available. If activity-4 is shown and completed, then activity-5 can be performed.

Properties of the event condition symbol will provide the details on the condition and action parts of the control principle to provide the execution engine with a clear formal definition of the processing to take place.

In the scenario editor, we see a combination of a control flow and a data flow. The control flow is modeled using the MOT basic P and R links. P links indicates the basic sequence or flow of activities. R linked conditions identify which activities an event will trigger, thus altering the basic flow.

IP links from MOT serve to model the data flow, either from resources to activities where they are consulted, used or processed, or from activities to the resources they help produce. This is why we need to distinguish between actors as active control entities and resource-actors that

will serve as data providers or be products of an activity (e.g. a new person or software agent added in a system). A similar distinction is made for resource-activities that can be seen as resources to be transformed, for example by other activities creating or modifying their description.

C links from MOT may also be used to show the composition of an entity into other entities. A new unification, U link, is also necessary to guide the execution engine, when components are aggregated and outputs from one need to be connected with the inputs of another.

In TELOS, the scenario editor will enable engineers to combine resources into larger aggregates, technologist to built platform workflows for designers of learning or knowledge management

Figure 8. Event-based control

environments, designers to build courses, work flows or learning /teaching scenarios.

MOT+OWL: A STANDARDIZED ONTOLOGY EDITOR

In the first section we identified the pedagogical and the knowledge models as the most important ones. We now proceed with a second standardization task, that of the knowledge model. Any type of knowledge representation, including text-based narratives or informal graphic models, can be used to describe a domain of study. At the initial stage of design, the informal nature of an ontology representation is useful. The user's mind must be free to choose any representation that seems best suited for the educational project to be considered. Still, this very freedom does not facilitate the software processing of the representation.

Semi-formal modeling languages like MOT go part of the way to address this. Unlike informal graphs built with any graphic editor, such as PowerPoint, the MOT graphic syntax is structured and has a general unambiguous semantic. Using the MOT editor, models can be exported in many formats, including a native XML schema. Using this schema, software agents can perform different kinds of processing. Still, some ambiguity remains. In instructional engineering applications, we had to constrain the MOT graphic language even more to enable the delivery of learning scenarios in a digitized platform like Explor@-2 (Paquette, 2001). Even then, part of the transfer of the design to the delivery platform had to be done manually, to prevent enforcing unnatural graphic representations on the designers.

The Ontology Web Language

To deliver computer-based learning environments, after a phase where informal graphic design has cleared up ideas, we need to move from informal or semi-formal graphs to formal computable

graphic representations. Knowledge in a subject domain can be represented in many ways: taxonomies, thesauri, topic maps, conceptual graphs and ontologies.

We have selected to use OWL-DL ontologies (see W3C, 2004) for a number of reasons. It is one of the three ontology Web languages that are part of the growing stack of World Wide Web consortium recommendations related to the Semantic Web. Of these three languages, OWL-DL has a wide expressivity and its foundation in descriptive logic guarantees its computational completeness and decidability. *Descriptive Logic* (Baader, Calvanese, Nardi, Patel-Schneider, 2003), is an important knowledge representation formalism unifying and giving a logical basis to the well known traditions of frame-based systems, semantic networks, object-oriented representations, semantic data models, and formal specification systems. It thus provides an interesting framework to represent knowledge for which a growing number of processing agents are built throughout the world.

OWL-DL provides a precise XML schema but no graphic representation per se. Some ontology editors like PROTÉGÉ (2006), provide some graphical views of the ontology, but the construction of an ontology is essentially form-based. Our goal was to provide a complete formal graphic representation of the OWL-DL that could combine the virtues of interactive construction with the computational capabilities of a formal graphic representation.

The MOT+OWL Visual Language

In the context of the MOT representation system, ontologies, in particular OWL-DL constructs, correspond to a category of models called theories. Ontologies can thus theoretically be modeled graphically using the MOT syntax. While doing this, we found out that while the MOT primitive objects and links were sufficient to represent ontologies expressed in OWL-DL, the graphs

Figure 9. OWL-DL equivalents

would become cumbersome unless new symbols were added. We have thus specialized the MOT language and graphic editor by adding sub-types for concepts, principles and facts and by adding new links.

Figure 9 gives a few examples of the MOT+OWL graphic elements with their interpretation in descriptive logic and their correspondence to standard OWL-DL XML schema fragments. See Paquette and Rogozan (2006) for a complete description of the MOT+OWL graphic language.

Three types of MOT entities are sufficient to represent OWL-DL models. Concepts represent classes, principles represent properties and facts represent individuals. On these graphic entities, icons are added corresponding to axioms or principles stating a property of the class. We also added some new special links to express things like equivalent “equi” or disjoint “disj” classes stating properties of two classes or two properties.

In the standard MOT syntax, these icons or special links would be expressed by principles with “R” links to classes or properties. For example, in the second and the two last examples of Figure 9, the following standard graphs (Figure 10) are equivalent, with the same precise OWL-DL interpretation as XML schema components. These would of course make the graphs more difficult to read.

Using a limited set of graphic symbols, we can formally describe any semi-formal MOT model that is amenable to a representation in descriptive logic. This is obviously the case for most conceptual models, laws and theory models. However, this is less evident in the case of procedural models, sometimes called task ontologies. Procedural and process/methods models are im-

portant for our purpose because learning environments are built around multi-actor processes.

Figure 11 presents a MOT+OWL visual graph that translates the conceptual structure of a learning design presented in the IMS-LD information model (2003). In the Figure, “C” properties (green hexagons) are an abbreviation for “is-composed-of” which has the same meaning as the C link in standard MOT models, or the aggregation link in UML models.

This example illustrates the fact that functional relations between components of multi-actor processes such as a learning design can be represented by ontologies. Such ontologies have been used to test, for example, the conformance of particular learning designs to the IMS-LD XML schema (Amorim, Lama, & Sanchez, 2006), and to execute them in the context of an ontology-driven system.

Associating Knowledge and Competencies to Learning Designs

We have pointed out earlier the importance of associating knowledge and competencies to the components of a learning design. This is a key element of the MISA method. Actually, in IMS-LD, the only way to describe the knowledge needed to achieve the activities or that is present in the resources is to assign optional educational objectives and prerequisites, to the unit of learning as a whole and/or to all or some of the learning activities. These can not be added to express the level of competency for a support activity carried out by a teacher or tutor. Objectives and prerequisites correspond to entry and target competencies as used in the

Figure 10. MOT standard equivalents

	Inverse properties $\forall x, \forall y: \text{Prop1}(x, y) \leftrightarrow \text{Prop2}(y, x)$	<code><owl:ObjectProperty rdf:ID="name_Property1"></code> <code><owl:inverseOf</code> <code> rdf:resource="#name_property2"/></code> <code></owl:ObjectProperty></code>

Figure 11. A simple task ontology for multi-actor scenarios⁴

MISA method. They are essentially unstructured pieces of text composed according to the IMS RDCEO specification (IMS 2002).

Unstructured texts are difficult to compare. Consistency checking between different levels of the LD structure cannot be supported computationally. Even at the same level of a learning design, for example within an act, no relations exist between the content of learning activities and of the input or outcome resources, and from these to the actors' competencies. In fact, in IMS-LD the knowledge represented in learning resources is not described at all, and the actor's knowledge and competencies are only indirectly defined by their participation in learning units or activities, if, and only if, educational objectives have been associated to the activities.

What we need first is a qualitative structural representation of knowledge and competencies associated to activities, resources and roles. This can be done using domain ontologies. As a first step, the MOT+ editor allows to show side by side a learning design, using the MOT+LD editor, and a domain knowledge ontology using the MOT+OWL editor. An example is shown in Figure 4. The left hand window is the learning design presented earlier in Figure 5. The right hand window presents part of domain ontology of the solar system (that was built before Pluto was declared a quasi-planet).

A *semantic annotation* is simply a mapping from the domain ontology to the learning design that associates knowledge elements (classes, properties and individuals of the ontology) to components of the learning design.

In Figure 12, we see that data on the orbital period of planets in the solar system has been associated to a learning object in the design, which is a PowerPoint presenting this data to team A. This resource is an input to learning activity 2.1.A, but it is not the only input to this activity. There is also another resource (clues A) that gives additional information to team A, plus the chat between team members that will bring other more information to each participant. As a result, the sub-model of the

ontology associated to activity 2.1A would logically correspond to the union of the sub-models of all input resources to the activity.

Finally, the Figure shows that most of the ontology model should be the subject of the discussion, since there is another team, team B that has more information to bring to the discussion using also information from input resources and in a team B chat. The larger sub-model is thus associated to the 2.0 activity structure.

This example shows how semantic annotation can help guide the construction of learning designs and to evaluate their coherence. By associating the right amount of knowledge to the different resources and activities, a designer can build a coherent design that will trigger collaboration between learners, or help a trainer decide on its intervention, or guide the actions of an intelligent tutoring system, and, in general support the evolution of the learners' competencies.

Desirable Properties in a Visual Educational Modeling Language

This chapter concludes with a discussion of the most important features and characteristics of a visual educational modeling language, which we think are the most useful and beneficial to the user.

Figure 12. An example of ontology annotation of a learning design

Visual

The benefits of graphical cognitive modeling have been eloquently summarized by Ausubel (1968), Dansereau (1978), Novak (1993) and Jonassen, Beissner and Yacci (1993). Graphs illustrate relationships among components of complex phenomena. They uncover the complexity of actors' interactions and make the most important parts stand out. They facilitate the communication about the reality studied. They favor the global comprehension of the phenomena under study. They help grasp the structure of related ideas by minimizing the use of ambiguous natural language texts. As an example, entity-relation graphs reduce ambiguity compared to a natural language description, but some remain on the interpretation of the terms written on the links or on the nodes. Ambiguity can be reduced further by the use of standardized typed objects and typed links.

User-Friendliness

Not all graphic modeling languages are user-friendly. A good counter-example is UML. The large number of models and symbols require considerable expertise and a steep learning time for the interpretation and for the construction of models. Furthermore, each type of model captures a different viewpoint of the information and it is impossible to mix them in the same graph to provide a global view of a subject domain. The representational system must be easy to use without technical or scientific mastery after a short period of initiation. Dansereau and Holley (1982), have studied experimentally the use of different sets of graphic symbols by learners. Their results show that typed links are preferred by the majority of learners, as long as there are not too few nor too many links and they express sufficiently different meanings.

Generality

Generality means that the representation language should have the capacity to represent, with a relatively small number of object and link categories, all knowledge in very different subject domains, at various levels of granularity and precision. It should enable, to represent simple models such as a multiplication table, up to complex models such as multi-actor workflows, rule-based knowledge systems, methods and theories. It should also embed equivalent representations to commonly used graphs such as conceptual maps, semantic networks, flowcharts, decision trees or cause/effect diagrams.

Formalizable

The graphic language should be upward compatible from informal graphs, up to semi-formal and totally unambiguous formal models. At the informal level, an integrated representation framework facilitates the organization of thought and communication between humans about the knowledge which is exchanged, all along the evolution of the graphic representation model. Here the process is more important than the result. On the other end, the graphic language makes it possible to use more constrained elements to produce totally unambiguous descriptions that can be exported to a set of symbols, such as an XML file, to be processed by computer agents. Here the model is more important than the process.

Declarative

Graphic language can be procedural or declarative. Procedural graphic languages have been built in the past; essentially extending flowcharts to promote graphical programming that would produce code directly. Our proposal is to use, as much as possible, a declarative graphic language, for a number of reasons. Firstly, it is easier for a person to declare the components of his/her

knowledge than to describe the way it should be processed. In expert systems for example, the executive instructions are not wired-in the program, but externalized and made visible in a knowledge base on which a general inference engine proceeds. Secondly, the same model can be used for many different applications, not necessarily the one for which the processing has been planned in a procedural program. This is done by querying the model using an inference engine, in a Prolog-like manner. Thirdly, the processing knowledge itself can be given declaratively, so that higher order meta-knowledge, also can be singled-out. This idea is similar to structural analysis as proposed by Scandura (1973) and it is exactly the way we should see the relation between generic skills and domain knowledge in a competency, as meta-knowledge given declaratively, applied to domain knowledge, for example, rules for diagnosing a component-based system applied to different models describing a car, a software or a learning environment.

Standardized

Standardization is an important property to support knowledge communication and use between persons or software agents. At the informal level, each model constructed by a person must be interpretable by another person. At the formal level, the communication capabilities extend to software agents. The move towards graphic versions of standards like IMS-LD for learning designs and OWL for ontologies adds wider communication capabilities between researchers and educators while at the same time adding formal non-ambiguous interpretation for machine processing.

Computability

Computability is a step beyond standardization. Not only can the graphic model receive a non-ambiguous formal representation that can be processed by computer agents, but this formal

representation is complete (all conclusions are guaranteed to be computable) and decidable (all computations will finish in finite time). These considerations have motivated the construction of the MOT+OWL graphic language that is equivalent to the OWL-DL XML schema based on descriptive logic.

CONCLUSION

This chapter has presented a 10-year effort to provide an educational visual language for applications that can span from informal support to idea generation, up to structured semi-formal graphs based on typed objects and links, and finally to graphic design on the formal conceptual and specification levels (MOT+LD, MOT+OWL).

In Botturi et al. (2006), the reader can find a classification of other visual languages, some of them being presented in other chapters of this handbook. According to this classification, MOT+ has the same properties as those of UML. It qualifies as a visual, layered, formal, conceptual and specification elaboration language, with multiple perspectives.

This corresponds to our initial goal of building a virtual language that is both user-friendly for designers (compared to UML) and still general and powerful enough to enable the design of the main components of a learning system, according to standard specifications. With the development of the new scenario editor based on MOT+ concepts, we can now go a step further and provide a visual scenario programming language that can be executed by an ontology-based engine to deliver usable learning environments to its users.

Chapter 3.13

poEML: A Separation of Concerns Proposal to Instructional Design

Manuel Caeiro-Rodríguez
University of Vigo, Spain

ABSTRACT

This chapter introduces a new visual educational modeling language (EML) based on a separation-of-concerns approach, poEML: perspective-oriented EML. EMLs were proposed to support the modeling of educational units. These languages are related to ID, as they are intended to represent models of educational units. This chapter introduces the poEML separation of concerns and its graphic constructs. The main idea underlying poEML is to break down the modeling of educational units into separate parts that can be specified independently. poEML is mainly focused on supporting the computational execution of educational unit models. In addition, the

separation of concerns allows us to approach the modeling of educational units in an incremental way, offering advantages in expressiveness, formality, adaptability and flexibility.

INTRODUCTION

As a design discipline, ID is devoted to produce effective educational units (e.g., a lesson, a course, a practice, a workshop). Botturi, Derntl, Boot and Figl (2006) show how modeling languages can contribute to ID by supporting the creation of visual models that facilitate the design, communication and execution of educational units. Specifically, some VIDLs are focused on supporting the creation of computational models of educational units that can be executed by customized LMSs. This is the

DOI: 10.4018/978-1-60960-503-2.ch313

main goal of the ID language described in this chapter, while other goals are secondary (e.g., to facilitate the design and the communication).

The achievement of a VIDL that allows us to create computational models of educational units is a complex endeavor. These are some of the problems involved:

- **Expressiveness:** One main problem is how the VIDL will support the creation of models representing the broad variety of static and behavioral issues involved in educational units. Depending on the learning goals, pedagogical approach (e.g., behaviorism, constructivism, social-collaborative) or learning context (e.g., face-to-face, blended, Web-based), teaching and training requires different resources and procedures. Here are some examples: in a traditional face-to-face course a teacher gives lectures and proposes tasks to learners; in a Web-based course a learner accesses a Web site to get documents and to perform tests; in a tennis lesson a player repeats the same movements several times under the supervision of an instructor; in a primary school, children play games to learn numbers and letters. There is a large variety of elements, resources, procedures, and behaviors present in educational units and a VIDL should allow us to express them in models.
- **Formality:** Formality is necessary to support the computational execution of the models in customized LMSs. To be executed, models need to include an appropriate level of detail, and need to be arranged in accordance with clear and unambiguous constructs. Therefore, the intended VIDL should allow us to create models with precision and consistency.
- **Adaptability and flexibility:** Another problem for VIDLs is that educational models are not fixed. Educational units rarely work perfectly in accordance with a

predefined plan. Usually, educational plans have to choose between several alternative paths, or they have to be changed to solve unexpected situations. Therefore, a VIDL should allow us to create adaptable and flexible models of educational units.

The proposed VIDL tries to solve these problems by following a *separation-of-concerns* approach. Separation of concerns is an important principle in other design domains (e.g., architecture and software design). For example, in architecture, building models or plans are divided into several parts. These include plans of the structure of the building, the layouts of floors, electrical installation, and plumbing installation. This separation of concerns facilitates the design task, as the designer's attention can be focused on one concern at a time. Similarly, the modeling of educational units can be approached from a separation-of-concerns approach as well. For example: the activity structure of educational units can be considered as one concern, and the order in which activities have to be performed as another. The proposed VIDL, developed with this separation-of-concerns principle, is called poEML: *perspective-oriented educational modeling language*.

The remainder of the chapter is organized as follows. The following section introduces the context of this proposal and its classification. The next section describes the main ideas of the language, together with the proposed separation of concerns. Then, the fourth section includes the description of the poEML elements and their graphical representations. This section only contains poEML elements that are most relevant to an ID point of view. Next the JPoEML graphical editor is introduced. In the sixth section, a simple course is modeled with poEML as a case study. The chapter ends with some conclusions.

BACKGROUND

The EML Context

poEML is introduced here as a VIDL, but it was developed as an EML: educational modeling language (Koper, 2001). EMLs have been proposed as modeling languages which “describe the content and process within a ‘unit-of-learning’ from a pedagogical perspective in order to support reuse and interoperability” (Rawlings et al., 2002). Several languages have been proposed as EMLs trying to satisfy this definition. IMS-LD (instructional management systems—learning design) (Koper *et al.*, 2003; Koper & Tattersall, 2005), issued by the IMS Global Consortium¹, is the principal attempt and the current *de-facto* EML standard. Since its publication, IMS-LD has become an important e-learning standard, and has promoted the development of active research and practitioner communities (see Chapter XV in this handbook). In any case, IMS-LD does not provide appropriate solutions to solve the problems identified in the introduction of this chapter (also described in Chapters XIII and XIV in this handbook). poEML is an attempt to develop a solution to some of these deficiencies.

Classification

This section introduces poEML in accordance with the classification framework proposed in Botturi, Derntl, Boot and Figl (2006) for ID languages. poEML features and classification is presented in Table 1.

THE SEPARATION OF CONCERNS

Separation-of-concerns is a long-standing idea that simply means that a large problem is easier to manage if it can be broken down into parts. It is an important design approach in other areas, such as software design, where it is used to facilitate the understanding, design and management of complex systems. Accordingly with the separation-of-concerns approach, programs are broken down into distinct parts that overlap in functionality as little as possible (Kazman, 2001). aspect-oriented programming (AOP) has further developed the separation-of-concerns approach to propose the concept of crosscutting concerns as concerns that cut across other concerns (Kiczales et al., 1997).

Table 1. poEML features and classification

Classification of features of poEML	
<i>Stratification</i>	Layered , poEML offers different representations to describe entities of different types, namely: roles, activities, learning materials, etc.
<i>Formalization</i>	Formal , poEML defines a closed set of concepts and rules for composition of concepts.
<i>Elaboration</i>	poEML is mainly an implementation language as it is able to provide a high level of detail of elements and strategies involved in educational units.
<i>Perspective</i>	Multiple , as it provides different views on the same entities. For example, it provides structural, order and temporal diagrams related to different static and behavioral issues about the parts of educational units.
<i>Notation system</i>	poEML has both a textual (XML) and a graphical notation.
Classification of application	
<i>Communication</i>	poEML is reflective and communicative . It is reflective as it is intended to support structuring and conceiving solutions. It is communicative as the graphical representations can be used to share and interchange design solutions.
<i>Creativity</i>	poEML is both generative and finalist . It is generative in the sense that it can be used to create and refine design solutions. It is finalist as its purpose is to formalize the design models that can be processed by computational systems.

poEML follows the separation-of-concerns approach to support the modeling of educational units. Similarly to AOP, poEML identifies two kinds of concerns to break down educational unit models, namely: *perspectives* and *aspects*. These two kinds of concerns can be represented in orthogonal axes (see Figure 1). On the one hand, the horizontal axis separates the elements involved in educational units in different *perspectives*. Static and behavioral elements are both taken into account in the perspectives. For example: the environments are considered in one perspective and the order between activities in another. On the other hand, the vertical axis separates models in accordance with different levels of control or *aspects*. Each *aspect* involves a certain level of control that can be used to determine changes in the structure or behavior of the elements in the perspectives. The basic level of control is *determined*, which does not allow any change in an educational unit model to be specified.

Perspectives

The *activity theory* is a meta-theory about activities and their constituent components (Engeström,

1987). Considering that any educational unit can be conceived as a set of hierarchical aggregated activities, the *expanded mediation model* provided by this theory provides an interesting framework to identify *perspectives* (see Figure 2). The core of this model is that any *activity* involves a *subject* playing a *role* acting on an *object* to achieve a certain *goal*. This connection is influenced by the *environment* and the *community* where the *activity* is performed. In other words, the *activity* depends on the *environment* and the *community*. The *environment* contains the tools and resources that can be used by the *subject* to act on the *object*. The *community* puts the emphasis in the social context where the *subject* operates, involving the influence of two new issues: *rules* and *division of labor*. The *rules* component highlights the fact that within a *community*, *subjects* are bound to rules and regulations that affect the way they interact in the *activity*, including also the interaction with the *environment* and its elements. The *division of labor* refers to the breaking down of the goal into sub-goals and the distribution of responsibilities among the available *subjects*. As a result new subsidiary activities (*sub-activities*) are produced.

The *expanded mediation model* has guided the identification of 13 *perspectives*:

Figure 1. Separation of concerns in poEML through Perspectives and Aspects

- **Structural:** The structural perspective is about the arrangement of the elements involved in educational units. The proposed structure is based on the activity concept. Educational units are conceived as a set of hierarchical activities grouping all the other elements: functional goals, actors, environments, sub-activities, and specifications. This structural perspective enables these elements to be grouped in an *activity hierarchical structure*. Each of the elements is further described in one of the following perspectives:
- **Functional:** This perspective is about the *functional goals* that have to be attained in an educational unit. Functional goals in-

Figure 2. Proposed perspectives in accordance with the activity theory expanded mediation model

cluded in an activity specify the work that has to be performed by participants on it. For example, a functional goal can be “to produce a basic transistor circuit” or “to evaluate the learners.” These functional goals are different from learning goals that refer to a desired knowledge, skill, or capability. This perspective involves the description of static and behavioral issues of functional goals. The static issues involve features and elements included in functional goals (e.g., input and output parameters). The behavioral issues involve relationships among functional goals (e.g., dependency and completion relationships). They can be used to create *functional flows* in educational units, indicating how goals included in an activity are related with goals included in its sub-activities.

- **Participants:** This perspective is about the participants involved in the educational unit. Participants in the models are not specific persons. Instead, the desired participants are represented by *roles*. This perspective involves the description of the static and behavioral issues of participants. The static issues involve the description of the roles and the structure of groups in-

cluded in each activity. The behavioral issues involve the *participants flow*, namely, how the participants performing a certain role in an activity have to be assigned to another role in a sub-activity.

- **Environments:** An environment is a place where the activity of an educational unit is performed. An environment is also made up of artifacts and tools that can be used by participants. For example, a lab environment is made up of several simulators as well as documentation about the simulators operation. This perspective involves the static description of the environments and the relationships among environments. It does not consider any behavior issues.
- **Data:** This perspective is about the data elements used in educational units. These data elements are included in the other elements: input and output parameters in functional goals; properties in roles; and artifacts in environments. This perspective involves the description of static and behavior issues of data elements. The static issues are about the features of data elements (e.g., type) and their structure. The behavior issues are about the transfer of

data between data elements, namely, the *data flow*.

- **Tools:** The tool concept is used to represent the applications and services that can be used in an educational unit (e.g., simulators, editors, communication, and collaboration services). To facilitate the reuse of the educational unit models, tools are not fixed during design, but are described in an abstract way. During the run-time, tools provided by different vendors that satisfy such description can be used (this differentiation is similar to the distinction between roles and participants).
- **Organizations:** This refers to the organizational structure required to carry out an educational unit. This information may be used to constrain the behavior of other perspectives. For example, the assignment of a teacher to an evaluation activity may depend on his position in the organizational structure.
- **Order:** This perspective is about the sequence in which activities have to be performed. It indicates whether activities have to be performed in sequence or in parallel to set synchronization points among several activities performed in parallel, etc. In other domains this order perspective is also known as *control flow*.
- **Temporal:** Temporal constraints can be used to indicate when an activity must or can be initiated and when it must be finished. An example of temporal constraints would be to indicate that a lab practice must be initiated by 14:00 and that it has to be finished in 2 hours.
- **Authorization:** Authorization involves participants' rights to access the environments' elements, mainly access to the artifacts' and tools' functionalities. For example, a simulator may provide two different permissions: "expert" and "novice." Teachers may be assigned the "expert"

permission while learners are assigned "novice."

- **Awareness:** Awareness refers to the processing of runtime information (events) and the notification of relevant situations. For example, in many educational units it is very important that teachers be aware of learners' actions. Nevertheless, as important as this is, it is not to overload the teacher with excessive information. Therefore, awareness involves giving the right participant the appropriate information and avoiding information overload. To accomplish this, awareness should be focused, customized, and temporally constrained (Baker *et al.*, 2002).
- **Interaction:** This perspective is about the performance of automatic operations in tools. Many of the controls required to support collaboration among a group of participants involve the invocation of operations in collaborative tools at certain time points or as a result of events. This perspective involves the mechanisms required to support the invocation of operations.
- **Causal:** This causal perspective involves the use of competencies (Cooper & Ostyn, 2002), metadata (Duval, 2002), learning objectives, and pre-requisites to inform participants about why they should perform an educational unit.

This chapter is mainly focused on the ID features of this proposal. Some of the perspectives specifically exist to support collaboration in educational practices (e.g., *authorization*, *awareness* and *interaction*). As such, these perspectives may not be very important from an ID point of view and will not be discussed further in this chapter.

Aspects

In addition to the breaking down of static and behavioral issues in *perspectives*, the vertical axis

distinguishes among different levels of control. They are introduced in order to support different kinds of control in educational unit models, from determined to decision-based. The *aspects* proposed in poEML are:

- **Determined:** This is the basic aspect. In accordance with this aspect, the structure and behavior of an educational unit is fixed in the model. During the run-time the educational unit is always carried out in the same way. A “determined” aspect does not introduce any element.
- **Data-based or conditioned:** This involves the use of conditions on data elements to control changes in the structure or behavior of educational unit elements. For example, the functional goals of a course may need to change from optional to mandatory depending on a data element of the learner profile.
- **Event-based:** Event-based aspects involve the use of events to control changes in the behavior of educational units. Events are used to signal situations that appear unexpectedly during the execution. For example, a lab activity has to be finished when a certain event is produced in a simulator.
- **Decision-based:** This involves the use of human decisions to control changes in the structure and behavior of educational units. Often, changes are not dependent on data or events, but on the judgment of responsible persons (one or several). For example, a teacher may decide the goals that should be optional or mandatory. This aspect is used to explicitly describe the human decisions that have to be taken during run-time.

POEML

This section introduces the poEML elements and graphical notations which are most relevant from

an ID point of view. poEML is arranged in several packages reflecting the separation-of-concerns explained in the previous section. The modeling of each perspective and aspect is supported with the elements of a specific package. Therefore, the structural, functional, participants, environment, data, order, and temporal packages are described. For each package, a UML diagram showing its elements and relations is included. (See Chapter IX of this handbook for a good UML primer.) In addition, the graphical representation of such elements and relations is also presented. First, we will explain some general issues about the language.

General Issues

This section describes some general issues about the poEML elements and their features.

Common Features

All poEML elements have two common properties: a name and a description. The name is used as an identifier and a reference. The description is used to inform designers during design-time as well as participants during run-time about the purpose of the element. For example, for a functional goal:

- The *Name* identifies the functional goal in the educational unit model: “To design a microprocessor.”
- A *Textual Description* informs participants about its purpose: “Design a microprocessor of eight bits that enables the performance...”

Abstract Elements

poEML includes several abstract elements. One of the most important is the *Choice Point* that belongs to the *Aspect* package. This element is an abstraction of a *Condition*, *Event*, or *Decision*. Conceptually it represents a point where a choice has to be performed during run-time. Obviously,

this choice can be established using any of the elements considered in these aspects.

Graphical Conventions

poEML elements are represented using different geometric figures. In addition, it includes several kinds of relations (association, aggregation, specialization and dependence) that are represented using arrows. These arrows are depicted in accordance with UML conventions (see Chapter IX in this handbook). As there are many different kinds of dependencies, dependency arrows are annotated with a label that indicates the type of dependency.

Run-time Instances

poEML enables to specify the number of run-time instances that need to be created out of the elements defined. This feature is required in order to support the computational execution of educational unit models. For example, usually *Goals* have to be accomplished only once, but certain *Goals* have to be executed several times (e.g., “a teacher has to assess an examination as many times as individual learners have performed the exam”). In this situation, the functional goal is specified once, but it has to be performed repeatedly for each individual. poEML allows us indicate the number of run-time instances by the specification of a number. This number can be set during design-time or determined during run-time in accordance with the value of a *Choice Point*. In addition, it is also possible that the number of instances take the value zero. In this case the element will not exist during the run-time. This feature enables the adaptation and modification of models.

The Structural Package

The structural package is used to arrange and organize all the elements involved in educational unit models. To support such an arrangement, an

activity-centered approach is followed, but instead of “activity,” the term *Educational Scenario (ES)* is used. From a conceptual point of view, an *ES* represents a complete piece of instruction with a specific educational purpose. It can be used to represent educational unit models at different levels of aggregation, from simple lessons to complete curricula. From a practical point of view, any educational unit model involves a hierarchical structure of aggregated *ESs*. In other words, an educational unit is represented by an *ES* (named as *root-ES*) that is composed by other *ESs* (named as *sub-ESs* or children *ESs*). These *sub-ESs* can also be made up of other *ESs*.

In addition, each *ES* involves a closed system of elements. The elements included in one *ES* can operate with elements included in the same *ES*, exclusively. The interactions with elements in other *ESs* have to be explicitly specified at certain perspectives as *functional flows*, *participant flows*, *data flows*, and *control flows*.

Elements Involved

Figure 3 illustrates the *ES* and its constituent elements. It represents an *ES* element involving an aggregated structure relating the elements considered in the 13 perspectives: (i) its own break down in *sub-ESs*; (ii) a *Goal* (or set of *Goals*) that need to be satisfied; (iii) a participant or set of participants (specified as *Roles*) that will work towards the goals achievement; (iv) one or several *Environments* where participants will work, composed by (v) *Data Elements* and (vi) *Tools* that represent applications and services; and optionally (vii) a particular *Organizational Structure* that situates participants in an organization scheme; (viii) *Order Specifications* to indicate the order in which the *sub-ESs* are intended to be performed; (ix) *Temporal Specifications* to indicate or constrain the moment at which each *sub-ES* has to be initiated and finished; (x) *Authorization Specifications* giving permissions to participants for the use of resources; (xi) *Awareness Specifica-*

tions indicating how events should be processed and notification submitted to participants; (xii) *Interaction Specifications* with constructs that permit the performance of automatic operations; and, (xiii) several *Records* containing descriptions of competencies, learning objectives and pre-requisites. Each one of these elements is modeled in a different package.

In addition to its constituent elements, an *ES* can involve the specification of multiple *instances*. Sometimes during execution several instances of the same *ES* must be created. For example, an *ES* involving a pair of learners performing a lab practice has to be created for as many pairs of learners there are in the class, because the same lab practice has to be performed by each pair.

Graphical Representation

The elements of this package can be graphically represented as a set of hierarchical aggregated elements. At this time this representation is a hierarchical tree (see Figure 4). The root and the branches of the tree are *ESs*. The leaves of the tree are the other poEML elements that are represented by appropriate symbols. The root *ES* is represented with an icon different from the icon used for the other *ESs* to show that it is the root *ES* that represents the educational unit.

The Functional Package

The *Functional* package involves the modeling of *Goals* (functional goals). Every *ES* needs to include a *Goal* or set of *Goals* indicating what to do. It involves the modeling of the static and behavioral issues of functional goals.

Figure 3. Main elements and relationships involved in the Educational Scenario element

Figure 4. Graphical representation of the elements of the Structural package

Elements Involved

Figure 5 represents in an UML diagram the elements and relationships of this package.

The next items describe the elements of this package:

- *Input Parameters* and *Output Parameters* indicating the data elements that have to be provided to perform the *Goal*, and the data elements that must be produced as a result of the performance of the goal, respectively. For example: “Specifications of the problem,” “The qualification obtained in an evaluation.” These parameters are characterized in accordance with the *Data Element* of the *Data* package (see Figure 5).
- *Input Constraints* and *Output Constraints*. The *Input Constraints* enable control of when a functional goal can be attempted. For example: “The software tool that supports the design of microprocessors must be available,” “The learner assigned to the corresponding *ES* has obtained a qualification greater than five in a previous ques-

Figure 5. Main elements and relationships of the Goals package

tionnaire.” Meanwhile, *Output Constraints* enable control of when a goal has been satisfied. For example: “The document containing the microprocessor design has been delivered.” These constraints are specified using a *Choice Point* of the aspect package or they can reference to other functional goals.

- The *Mandatory or Optional* character of a *Goal*. Many times, educational units include certain parts that are not required. They are included as a complement to satisfy learners’ curiosity or to get a better understanding. poEML recognizes this possibility and distinguishes between mandatory and optional goals. This aspect can be fixed during design-time or determined during run-time using a *Choice Point* of the aspect package.
- The *Instances* that have to be created of a *Goal*. In poEML, a *Goal* has to be performed as many times as instances are created from it. This construct permits us to indicate how many times a *Goal* has to be performed. The number of *Instances* of a *Goal* can be fixed to a value during design-time, be determined during run-time, or constrained in accordance with a *Choice Point*.
- The *Accesses* indication allows us to specify how many times a *Goal* can be accessed for performance. Some times *Goals* cannot be satisfied by an unlimited number of attempts, but have limits. For example: “A student airplane pilot has to learn to take off and land in less than a certain number of attempts.” Similarly to the *Instances* indication, this value can be fixed during design, determined during run-time or constrained.
- Relationships between *Goals*. Finally, poEML allows two different kinds of relationships to be indicated:

- *Aggregation Relationships* are used to indicate that a *Goal* (G1) can be decomposed into several *sub-Goals* (G1, G2, ... GN). To satisfy G1 it is necessary to satisfy the N *sub-Goals*. This allows complex goals to be broken down into more simple ones. For example, a practice has as a goal “to develop a software application.” This goal is broken down into the following sub-goals: “perform the analysis”; “design a solution”; “program the design”; and “perform tests.”
- *Specialization Relationships* are used to indicate that a *Goal* (G1) is detailed by several *sub-goals* (G2, G3, ... GN). To satisfy G1, some number of the N specialized *sub-goals* must be satisfied. This allows different paths to achieve the same purpose. For example, the goal “examine the learners” has the following possible specializations: “make a written examination;” “make an oral examination;” “make a portfolio examination;” etc.

Graphical Representation

Figure 6 shows the graphical representation of the elements of this package. Please note the following issues:

- *Goals* are represented with different colors depending on whether they are mandatory, optional or hidden. They include the name of the *ES* and the name of the *Goal*.
- The *Aggregation* and *Specialization* relationships connect *Goals* with other *Goals*.
- The *Mandatory or Optional* (MO), *Input* (I) and *Output* (O) dependencies connect *Goals* with *Choice Points*.

Figure 6. Graphical representation of the elements of the Goals package

- The *Number of Instances* (NI) and *Number of Accesses* (NA) connect *Goals* with *Data Elements*.

Dependencies with the Structural

Perspective

The *Goals* specification has strong implications for the execution of the educational unit models. The *structural* package permits us to compose the structure of the educational unit through the aggregation of *ESs*. Meanwhile, the *Goals* package let us indicate what has to be done in the educational unit. This enables the design of “goal maps” where different paths through the structural model can be conceived.

The Participants Package

The *Participants* package involves the modeling of *Roles*. Every *ES* may include a *Role* or set of *Roles* representing the expected participants.

Notice that each *ES* has to define its own *Roles*. They can be the same or different from the *Roles* in its *Parent ES*. During the execution, participants will be transferred from the *Roles* in the *Parent ES* to the *Roles* in the *Sub-ESs* ac-

cordingly to a *participant flow* specification. This kind of specification facilitates the reuse of *ESs*.

Elements Involved

Figure 7 represents in a UML diagram the main elements and relationships of this package.

The next items describe the main elements of this package include the following:

- *Properties* involving *Data Elements* about the *Role*. The value of the *Properties* during the execution will correspond with the particular participant assigned to the *Role*. Some examples of properties associated with a *Role*: personal data as name, surname, address; previous knowledge, etc.
- *Role Aggregations* enabling the specification of *Composed Roles* made up by other *Roles* (*sub-Roles*). This feature allows the modeling of groups. For example a project group is made up by the following roles: one leader, three developers, one tester and one supervisor.
- The *Instances* that have to be created of each *Role*. During the execution each instance of a *Role* has to be performed by a different participant. In this way it is pos-

Figure 7. Main elements and relationships of the Participants package

sible to indicate that a certain *ES* requires the participation of several persons in the same *Role*. For example: “A discussion *ES* needs to involve five learners.”

- The *participant flow* recognizes that participants can change their *Role* between activities during the run-time. For example: “A participant performs as learner in a theoretical *ES* and as project leader in a practical *ES*.” The *participant flow* can be modeled using two elements:
 - *Role Connectors*. These are operators that indicate how participants will be processed. Four types of connectors are supported: (i) *selection* connectors that permit us to take several participants from a larger set; (ii) *election* connectors that let us to take exactly one participant from a larger set; (iii) *relation* connectors that enable to constraint possible elections; and (iv) *assignment type* connectors distinguish between *forced assignment* and *voluntary assignment*.

- *Role Flow* elements. These are simple arrows connecting *Roles* and *Role Connectors*.

Graphical Representation

Figure 8 shows the graphical representation of the elements of this package. Note the following issues:

Figure 8. Graphical representation of the elements of the Participants package

- Three different kinds of *Roles* icons are provided: *Learner*, *Staff* and *Group*. They include the name of the *ES* where they are included and the name of the *Role*.
- The *Aggregation* association is used to model *Groups*.
- The *Parameter* (P) and *Number of Instances* (NI) dependencies are used to connect *Roles* with *Data Elements*.
- Each kind of *Role Connector* is represented with a different icon.
- The *Role Flow* dependency is used to connect *Roles* with *Role Connectors*.

The Environments Package

The *Environments* package involves the modeling of *Environments*. Every *ES* may include an *Environment* or set of *Environments* containing the resources that can be used. *Environments* contain *Tools* and *Artifacts* specified with *Data Elements*. Two different kinds of *Environments* are considered: virtual and physical.

Elements Involved

Figure 9 represents in a UML diagram the elements of this package.

The next items describe the elements of this package:

- *Artifacts* contained in the *Environment*. These *Artifacts* are characterized using *Data Elements*. Some examples: “A document explaining a concept,” “A variable indicating the grade obtained in a questionnaire.”
- *Tools* contained in the *Environment*. These *Tools* are characterized in accordance with the *Tool* element of the *Tools* perspective. Some examples: “A simulator,” “A text-editor,” “A chat service.”
- *Environment Aggregations* enabling the specification of *Composed Environments*

Figure 9. Main elements and relationships of the *Environments* package

made up by other *Environments* (*sub-Environments*). For example: “A laboratory room is made up by a working environment and a test environment.”

- The *Class* element is used to support the classification of the resources included in the *Environments* of an *ES*. Many times, the resources of an environment need to be classified. For example: “Resources for expert learners and resources for novice learners.” They are used in the specification of the *awareness*, *authorization*, and *interaction* perspectives.
- Finally, poEML considers that *Environments* will be characterized in an abstract way during design-time. Then, during run-time, a concrete environment containing the specified *Artifacts* and *Tools* will be provided. This is similar to the distinction between *Roles* and participants. Nevertheless, it is possible to specify the use of a concrete *Environment*. To do so, a *Reference* indication has to be specified to establish the concrete environment. In addition, this *Reference* can also be used to indicate that an *Environment* in an *ES* has

to be the same that other *Environment* in other *ES*.

Graphical Representation

Figure 10 shows the graphical representation of the elements of this package. Please note the following issues:

- Special icons are used to represent *Physical*, *Virtual*, and *Class* elements. They include the name of the *ES* where they are included and the name of the element.
- A *Contains* (C) dependency is used to indicate which *Artifacts* and *Tools* are included in each *Environment*.
- A *Belongs* (B) dependency is used to relate resources with *Classes*.
- A *Reference* (R) dependency is used to indicate the reference from an *Environment* to other *Environment*.

The Data Package

The *Data* package supports the modeling of *Data Elements* and the transfer of data values between *Data Elements*. *Data Elements* may be included in *Goals*, *Roles* and *Environments* to feature parameters, properties and artifacts respectively.

Elements Involved

poEML proposes the elements depicted in Figure 11 to support the representation of data needs in educational unit models:

- The *Data Element* is the main component. For each *Data Element*, the following properties can be specified: name, description, type, and default value.
- The *External File* element allows one to specify data elements contained in a file external to the educational unit model. This element can be used to transfer information to or from the external context.
- The *Data Flow* element enables the indication of how data values flow between *Data Elements*, *External Files*, and *Data Connectors*.
- The *Data Connector* involves several alternatives to transfer values between data elements. Three different connectors are available:
 - The *Reference* connector shows that a *Data Element* has the same value as other one
 - The *Copy* connector shows that a *Data Element* takes the value of other *Data Element*. The *Copy* can be synchronous (if it is produced when the sink *Data Element* is created) or

Figure 10. Graphical representation of the elements of the *Environments* package

Figure 11. Main elements and relationships of the Data package

asynchronous (if it is produced when a *Choice Point* is satisfied).

- The *Transformation* involves the performance of operations using the data contained in *Data Elements*. Some operation types are: Boolean (e.g., AND, OR), mathematical (e.g., +, -, *), string processing (e.g., sub-string, delete).

Graphical Representation

Figure 12 shows the graphical representation of the basic elements in the *Data* package. The different *Data* types have particular graphical representations.

Figure 12. Graphical representation for the elements of the Data package

The Order Package

The *Order* package allows us to indicate the order in which the *sub-ESs* of an *ES* will be performed. It is not possible to establish order specifications among *sub-ESs* that belong to different parent *ESs*. This constraint is introduced to help facilitate the reusability of *ESs*.

Elements Involved

The indication of the *Order* among *sub-ESs* is maintained in *Order Specifications*. For an *ES*, several *Order Specifications* can be included in the same model. During the execution one or zero in the *Order Specifications* may be activated in accordance with a *Choice Point*. Each *Order Specification* is composed by the elements depicted in Figure 13:

- The *Order Flow* element enables the specification of links between *ESs* and *Order Connectors*.
- The *Order Connector* element is used to indicate different order operations. The provided connectors are:
 - **Sequence:** The Sequence specification describes a point where an *ES*

Figure 13. Main elements and relationships of the Order package

can be initiated when the previous *ES* has finished.

- **Unordered Sequence:** The Unordered Sequence specification describes a situation where several *ESs* can be initiated in sequence, but with no predefined order in which they must be performed. The order is decided during the execution.
- **Parallel Split:** Parallel split specifies a point where several *ESs* can be initiated and performed in parallel.
- **Loop:** Loop specifies a point where a return to an already finished or completed *ES* may be required.
- **Merge:** Merge specifies a point where several *ESs* that were being performed in parallel converge. Each time one of the *ESs* finishes, a new instance of the next *ES* is created and initiated.
- **Synchronization:** To specify a point where several *ESs* that were being performed in parallel converge, the

synchronization specification is used. To initiate the next *ES*, all parallel *ESs* must finish. Using an association with a *Choice Point* it is possible to indicate that the synchronization has to be produced in a *Deferred* way, namely, when a condition, decision or event is satisfied.

Graphical Representation

Figure 14 shows the graphic representation of the elements of this package. Note the following issues:

- Two special figures are used to indicate the start and the finish of the order execution.
- Each *Order Connector* is represented by a different figure in accordance with its behavior.
- The *Order Flow* arrow is used to connect *ESs* with *Order Connectors*. Each *ES* and *Order Connector* has exactly one input *Order Flow* and one output *Order Flow*.

Figure 14. Graphical representation of the elements of the Process package

The Temporal Package

The *Temporal* package allows one to indicate and constrain the time at which an *ES* can/has to be initiated or finished.

During run-time, *Temporal Specifications* and *Order Specifications* may produce conflicting situations. For example: “Both the lab practice and the exam have to be performed in sequence. The exam has to be started at 16:00.” To know what to do in these cases *Temporal Specifications* are assigned as a priority factor.

Elements Involved

Temporal indications and constraints are specified in *Temporal Specifications*. For an *ES*, several *Temporal Specifications* can be included in the same model. During the execution one or none of the *Temporal Specifications* may be activated in accordance with a *Choice Point*.

Each *Temporal Specification* is composed by elements depicted in Figure 15:

- The *Temporal Flow* element enables the specification of links between *ESs* and *Temporal Connectors*.
- The *Temporal Connector* element is used to indicate different temporal relations. It can be associated with a *Choice Point* or a *Data Element*. If it is associated with a *Data Element*, that element represents an absolute time (e.g., February 14th, 2007). In the other case, when a *Temporal Connector* is associated with a *Choice Point* it acts as a temporal reference (i.e., the time at which an event is produced). In this case an *Offset* can be included to indicate a delay to the

Figure 15. Main elements and relationships of the Temporal package

relative time. These issues affect the four *Temporal Connectors*:

- **Equality:** To specify that action A has to be performed just when another action B is produced. For example: “The exam has to be initiated just when the lab practice has been finished,” “The course starts on September 19th.”
- **Hard-Before:** To specify that action A has to be performed before another action B is produced. If action B is produced and A has not yet been produced then action A is forced to be performed. For example: “The lab practice has to be finished *hard-before* the test activity is finished.”
- **Soft-Before:** To specify than action A can be performed before another action B is produced. If action B is produced and A has not been produced yet then action A cannot be performed. For example: “An optional activity can be initiated *soft-before* the examination has been initiated.”
- **After:** To specify that an action A can be performed after action B is produced. For example: “The video session can be initiated after the debate has been initiated.”

Graphical Representation

Figure 16 shows the graphic representation of the elements of this package. The dependencies are used in the following ways:

- The *Temporal Flow* connects an *ES Temporal Input* or *Temporal Output* with a *Temporal Connector*.
- A *Reference (R)* dependency is provided to link *Temporal Connectors* to *Choice Points* or *Data Elements* indicating relative or absolute temporal references, respectively.

Figure 16. Graphical representation of the elements of the Temporal package

- An *Offset (O)* dependency is provided to link *Temporal Connectors* to *Data Elements* to indicate an offset on the temporal specification.

THE JPOEML EDITOR

JPoEML is an authoring tool that enables the design of educational unit models in accordance with the poEML structure and organization (see Figure 17). It is available at <http://www.poeml.com>. This application permits us to approach the design of educational units by focusing on each *perspective* and on each *aspect* each time. In this way, it is an appropriate tool to test the ID capabilities of the language.

The JPoEML graphical interface is separated in two main areas:

Figure 17. JPoEML editor graphical interface with an *OrderSpecification* in edition

- The right side of the screen includes two panels to provide permanent information about model elements. It is composed of two panels:
 - The top panel is used to represent the structure of the educational unit model. It shows the hierarchical tree structure of *ESs* and contained elements. This panel provides a permanent and global view of the educational unit model.
 - The bottom panel is an area where the properties (e.g., name, description, type) of the active element are displayed. Depending on the active element (e.g., *ES*, *Goal*, *Role*) different data fields are provided.
- The central portion of the screen is the more important part of the JPoEML editor. It permits the graphical representation of each perspective and aspect. At a given moment only one perspective or aspect can be represented. Perspectives and aspects are indicated at tabs in the bottom side and left side of this panel respectively. In addition, a contextual panel with tools for each perspective and aspect is available on the left side.

AN EXAMPLE

This section describes an example of an educational unit model. Another example can be found in chapter XVI of this handbook. This educational unit is made up by a theoretical part and a practical part with separated examinations.

poEML enables the incremental design of educational units. The following sections show the models for the functional, structural, participants, environments and order perspectives.

The Goals Model

The *Goals* perspective is an appropriate starting point to initiate the design. The idea is to specify the goals that indicate what participants have to do. The *Goals* specification may be done incrementally, first indicating the main *Goals* and then refining these *Goals* into more detail by specifying aggregated goals, specialized goals and other features.

Figure 18 depicts the graphical representation of the case study functional goals' model. This representation is incomplete as some goals may be further subdivided, and additional elements at each goal may be included. The "root" *Goal* is "Perform the Course." It breaks down into two *sub-Goals*: "Perform the Theory" and "Perform the Practice." The first one includes an *Output Parameter* (a *Composed Data Element*) and the second one includes an *Input Parameter* and an *Output Parameter*. These goals are further divided. Some of the *sub-Goals* are depicted in a light brown color indicating that they are optional. The "Perform the Examination" *sub-Goal* of the theory has two specializations: "Perform an Oral Exam" and "Perform a Written Exam." During execution, only one is required.

The Structural Model

The *Structural* perspective may also be used to initiate the design of educational unit models. In this case, it has been performed after the *Goals* were available. This is how the previous *Goals* are assigned to the *ESs*.

Figure 19 shows the example structure. The course breaks down into four main *ESs*: two for the theoretical and practical parts and two for the examinations. In addition, these main *ESs* also break down into other *sub-ESs*. At this design stage these *ESs* only include the *Goals*. *Roles*, *Environments* and the rest of elements will be added to each *ES* in accordance with the perspectives.

Figure 18. Graphical representation of the simulation course Goals perspective

The Participants Model

Figure 20 shows the *Participants* model. The course *Roles* are represented in the top of the figure: a *Learner* and a *Teacher*. The *Learner* has two associations of type *Number Instances* with *Condition Elements*. They are included to indicate the minimum and maximum number of learners that may be involved. Similarly, the *Teacher* has an association of type *Number Instances* connected with an *Integer Data Element*, fixing the number required teachers (in this example two).

The *Roles* of other *ESs* also have associations of type *Number Instances*. Notice that the theoretical *ES* only includes a *Learner Role* with one instance. Obviously, all the learners have to perform the theoretical part of the course. To do it, the theoretical *ES* is assigned a number of instances equal to the eventual number of learners. In this way, each learner will work in a particular instance of the theoretical *ES*. The same is applied to the practical part *ES*, where two *Roles* are involved: a *Pair* of two *Learners* and a *Teacher*.

Notice that the *Pair* has an association *Number Instances* with an *Integer Data Element*. In the *Condition-based* aspect this element takes the value number of learners divided by 2 plus 1. This is the number of *Pairs* that have to be created.

The diagram also includes *Role Connectors* and *Role Flows* to indicate how participants are transferred from *Role* to *Role*. These connectors are of type *Election* and *Relation*. The *Election*

Figure 19. Graphical representation of the simulation course Structural perspective

Figure 20. Graphical representation of the simulation course Participants perspective

uses a “FIFO” (First-In-First-Out) algorithm establishing that learners are assigned in the order they are enrolled in the course. The *Selection* involves a “Difference” mode, establishing that the teacher assigned to the *Theoretical Exam* has to be different from the teacher assigned to the *Practical Part*.

The Environments Model

For this example, the instruction has been considered as a blended course where the theoretical part examination has to be performed face-to-face and the other parts are performed on the Web. Figure 21 shows the *Environments* for the main example *ESs*. In the “root” *ES* two *Environments* are specified: the “Course Env.” contains a file with general information about the course and the “Teacher Environments” provides information for teachers. This environment should be visible and accessible for teachers (this can be specified with the elements of the *Authorization* package). The rest of the *ESs* includes particular environments containing different artifacts and tools. Notice that the theo-

retical exam *ES* includes two environments: a *Physical Environment* named as “Aula Magna,” that is fixed using *Reference* association with *Data URI Element* to a particular room; and a *Virtual Environment* named as “Assessment” that contains a *Data Composed Element*. This last environment is also used in the practice examination *ES*. To do it, a *Virtual Environment* is specified in such *ES* and connected using a *Reference* to the previous one.

The Order Model

Figure 22 shows an *Order Specification* for the *ESs* under the “root” *ES*. It involves three types of *Order Connectors*: *Sequence*, *Parallel Split* and *Synchronization*. In accordance with this specification the course is initiated with the theoretical part *ES*. When it is complete, it is possible to initiate the practical part and to perform the theoretical exam. When the practical part is finished it is possible to perform the practical examination. The course ends when all the *ESs* are completed.

Figure 21. Graphical representation of the simulation course Environments perspective

Figure 22. Graphical representation of the simulation course Order perspective

CONCLUSION

This chapter introduces poEML focusing on its ID capabilities. poEML has been proposed to contribute to the modeling of educational units in the context of EMLs. This language is oriented towards several goals: expressive power, formality, flexibility and adaptability. The eventual achievement of all these goals is not an easy task. It is likely that a large improvement process involving several steps will be required to improve the poEML language. Currently, it is not clear in which direction and which steps should be taken to improve EML and poEML is an attempt to explore a particular direction: separation-of-concerns.

Following a separation-of-concerns approach poEML breaks down the modeling of educational units into a set of separated parts that can be specified step-by-step. In this way, the expressiveness of the language is enhanced as it is possible to notate more issues and behaviors of educational units at each part. The formality of the solution is also enhanced, to make it easier to support the computational processing of the models by considering each part independently. In addition, models are adaptable, to make it possible to include several alternatives and consider their activation during run-time using *Choice Points*; and flexible, so that the modeling of a perspective/aspect can be changed affecting other perspectives in a controlled way. Based on these assumptions, poEML and its graphical notation may be a valuable tool for ID.

ACKNOWLEDGMENT

I want to thank “*Conselleria de Innovación e Industria*” for its support to this work under grant “*E-BICS: E-learning—Bases de Integración e Coordinación sobre eEstándares*” (PGIDIT06PX-IB322270PR).

ABSTRACT

One of the crucial activities in the development of e-learning courses concerns the design phase. In this phase, instructional designers define the e-learning processes by specifying the activities students should carry out (knowledge objects, assessment, practice, etc.) and their temporal sequence. This phase is usually performed using an iterative process, with step-by-step refinements. Thus, it can greatly benefit of the availability of tools that assist instruction designers to carry out their work. In particular, a rapid prototyping approach could be effectively supported if the

tool is also able to automatically generate the courses starting from the supplied specification. Moreover, such a tool should also provide support for reuse. To fulfil these requirements, in this chapter we present a tool based on a suite of visual languages, which has been specifically conceived to support instructional designers in the definition and creation of learning processes. The use of visual languages is motivated by the success they have achieved in other contexts (e.g., software engineering) for the construction of suitable models that allows to focus only on the features of interest and to provide more effective descriptions and reasoning. The proposed suite of visual languages includes the learning activity diagram, which extends UML activity diagrams to make

DOI: 10.4018/978-1-60960-503-2.ch314

them suitable for modelling e-learning processes, the Self-Consistent Learning Object language used to define knowledge contents, and the Test Maker Language for specifying assessment and self-assessment tests. The visual languages have been then implemented in SEAMAN (System for E-Learning Activity MANagement), a system prototype conceived to support instructional designers in the design, the generation, and the deployment of e-learning processes.

INTRODUCTION

E-learning or electronic learning is a general term used to refer to computer-enhanced learning. The most notable advantages of e-learning are flexibility, convenience, and the ability to work at your own pace. In particular, groups of students participate and complete coursework enjoying e-learning activities in accordance with their daily commitments, thus making e-learning a viable alternative for learners with disabilities or those that have other commitments such as family or work.

One of the crucial activities in the development of e-learning courses concerns the design phase. In this phase, instructional designers define the e-learning processes by specifying the activities students should carry out (knowledge objects, assessment, practice, etc.) and their temporal sequence. The e-learning evolution proposes a good number of approaches and tools aimed at assisting instructional designers during the analysis, design, and delivery of instruction (Bruce & Sleeman, 2000; Campbell & Mahling, 1999; Designer's Edge, 2003; Goodyear, 1997; Schar & Kriger, 2000; Vrasidas, 2002). Many instruction design approaches proposed in the literature are based on traditional pedagogical learning approaches, or on the object-oriented paradigm. Indeed, existing models of instruction design have been influenced by linear or object-oriented software development processes. Nowadays, the new trend consists of

exploiting ideas and benefits of component-based approaches for implementing and delivering learning environments. In particular, the idea is to compose an e-learning process reusing learning components or activities, at different granularity levels (Rosenberg, 2001).

In this chapter we describe a visual language-based approach aimed at supporting the definition of e-learning processes assembling predefined didactic contents. The learning contents can be broken down and structured into a hierarchy from smaller, lower order blocks of material to higher, more complicated levels of learning. In particular, we have identified three different granularity levels referring to the size of knowledge contents. The use and assembling of these knowledge components provides the instruction designer with a modular paradigm to create distance courses, which resembles software development processes based on visual languages (Ferrucci et al., 2002; OMG Group, 1993). Hence, it has been defined a hierarchy of three visual languages to be employed during the different phases of the distance courses design process. Based on these languages we have constructed the System for E-Learning Activity MANagement (SEAMAN) to provide automated design support. The system and the underlying approach are particularly suitable for learning methodologies centred on didactic materials and assessment rules.

The first visual language we propose extends the activity diagrams of UML (unified modelling language) (OMG Group, 1993) to enable the specification of didactic contents, assessment activities, and their relationships. For that reason such diagrams are named learning activity diagrams (LAD). They provide an explicit way to represent complex relationships between structural and behavioural e-learning activities. Any activity specified in a LAD sentence can be further refined by reusing previously defined e-learning activities or using a visual sentence belonging to either the self-consistent learning object (SCLO) language or the test maker language (TML). SCLO

is a special case of state transition diagrams, and enables the instruction designer to define learning content objects. Instead, TML extends state diagrams to enable the design of assessment and self-assessment tests. It lets us describe tests that adapt themselves to student's answers. It is worth noting that tests play an important role in our approach, allowing us to define learning processes adapting themselves to student performance.

The chapter is organized as follows. The next section provides an overview of related work. Then the proposed visual languages are presented. The description of the SEAMAN system architecture, its facilities, and a sample application follows. Finally, a discussion on the achieved results and future work concludes the chapter.

RELATED WORK

Many activities regarding the e-learning process development are today accomplished by software tools that support instructional designers in their job (Bruce & Sleeman, 2000; Campbell & Mahling, 1999; Designer's Edge, 2003; Goodyear, 1997; Vrasidas, 2002). In particular, the e-learning evolution proposes a good number of tools assisting instructional designers during the analysis, design, implementation, and delivery of instruction via the Web (Bruce & Sleeman, 2000). If, on one side, an automated support should be provided by authoring tools (Campbell & Mahling, 1998; Chang et al., 1996; Kasowitz, 1997; Thomson & Cooke, 2000), on the other side these tools should implement suitable e-learning process design methodologies (Douglas, 2001; Goodyear, 1997; Muraida & Spector, 1997; Vrasidas, 2002).

Muraïda and Spector (1997), and Kasowitz (1997) review much of the work done in automated instruction design support tools. In particular, Muraida and Spector (1997) assert that there is "a lack of instructional designer expertise, pressure for increased productivity of designers, and the need to standardize products and ensure the

effectiveness of product." Thus, tools supporting instruction design during all the phases of the learning process definition are desirable. Goodyear views the instruction design as falling within four main approaches (Goodyear, 1997). These approaches allow the instruction designer to generate e-learning activities from given specifications by means of tools supporting the design of course structure, the selection of presentation templates, the reuse of design elements, and the coordination of activities accomplished by a design team. Moreover, Goodyear also proposes an approach for analyzing and designing distance courses that is divided into neat parts (Goodyear, 1999). The first part of Goodyear's approach resembles the work of other people (outside education) who are interested in the design of technology supporting the work of information systems designers, requirements engineers, human factors specialists, and so on. The second part is instead focused on the design of good learning tasks exploiting traditional analysis and design processes. Often, these tools are not able to compensate the lack of expertise of instruction designers. Jones et al. (2003) have presented an information systems design theory for the design of information systems to be used in Web-based education. Vrasidas (2002) presents and discusses a system to develop hypermedia approaches as part of courses and learning environments delivered on the World Wide Web. It details the structuring of information, branching and interactivity, user interface, and navigation through Web-based distance courses.

Opposed to these approaches, which are based on traditional models of instruction design, there are approaches and tools relying on object-oriented models. Douglas (2001) proposes an instruction design methodology based on the object-oriented paradigm. Designer's Edge (2003) provides another interesting approach and tool for instruction design based on the object-oriented paradigm.

Differently from the approaches we discussed above, AIMS (2004) Project describes a theoretical framework in which the knowledge domain edit-

ing and the course editing are distinguished. First the instructional designer constructs the domain model in terms of concepts and links. Finally, he/she defines the course structure starting from that description. Similarly, Thomson and Cooke (2000) propose the APHID method to support designers during the course creation by using instructional patterns. They also provide patterns describing teaching strategies known to be successful in particular situation. These patterns are used to design hypermedia applications.

New trends seek means to exploit ideas and benefits of component-based approaches for implementing and delivering learning environments. In particular, the idea is to reuse learning components, at different granularity levels. At the topmost level there are existing self-consistent learning contents that may be composed of learning objects, which in turn may be composed of raw contents (Rosenberg, 2001). It is worth noting that the self-consistent learning materials can be seen as a framework in which instruction designers insert learning contents and raw contents specifying their interrelations and dependencies. Therefore, it could be interesting to reuse a self-contained learning content and possibly also the associated learning objects.

Lin et al. (2002) suggest the use of workflow technology to define and manage the coordination of e-learning activities. In particular, the authors introduce an e-learning environment, called Flex-eL, which has been built upon workflow technology. The workflow functionality of Flex-eL manages the coordination of learning and assessment activities of the course process between students and teaching staff. In particular, this environment provides a unique environment for teachers to design and develop process-centric courses and to monitor student progress. A process-modelling tool called FlowMake is also proposed in order to define e-learning processes. A process model is defined as workflow graph containing tasks and workflow modelling structures. Tasks are associated with roles and applications. The

course activities and associated roles are identified and modelled using FlowMake. Personalization of the learning processes according to learners' diversities is not provided. Differently, Carchiolo et al. (2002) present a prototype of a Web-based e-learning environment through which students can follow dynamically adapted learning process. In particular, the environment provides students with all formative paths moving from an initial to a desired knowledge, and where paths are adapted according to the student needs and capabilities, and dynamically modified according to the learners' and teachers' feedbacks.

VISUAL LANGUAGES

Visual and diagrammatic representations play a central role in several application domains, since they provide important tools for describing and reasoning. As visual languages have been applied to new application domains, such as spatial databases, education, software engineering, and so on, many different types of visual notations have been devised. In particular, in the software engineering domain they are widely employed for supporting the phases of the development process, such as requirements specification, analysis, and design. The numerous analogies between the software development and the instruction design processes suggested us to exploit visual languages to support several tasks of the instruction design process. Thus, the three visual languages we propose extend or resemble languages that have been successfully and largely used in the software engineering field to design software systems.

The main language is the learning activity diagrams (LAD), which extends UML activity diagrams with means to model the workflows of learning processes (OMG Group, 1993). LAD can be used to model e-learning activities composed of distance modules, assessment, and self-assessment tests. States in LAD are activities, and most of the transitions are implicitly triggered

upon the completion of the actions associated to the e-learning activities. The second visual language we have defined is used to refine the learning content objects, whereas the third one is employed to design the assessment and self-assessment tests. These visual languages have been introduced to refine the basic objects used within learning activity diagrams. They are named self-consistent learning content objects (SCLO) and test maker language (TML). We describe them in the following subsections.

Learning Activity Diagrams

The purpose of the LAD language is to model workflows associated to distance educational processes. As consequence, it allows instruction designers to describe educational materials, dependences, and assessment rules. Material dependences allow the author to vary the degree of control over the order in which the students must explore the materials spread in SCLO objects. Moreover, using the results of assessment or self-assessment tests, the flow of the learning process is adapted to the learner performance. For example, before taking up a course the instruction designer can define a student test whose result may be used for assessing the knowledge, and to properly adapt the student learning process.

The visual language symbols are shown in Figure 1. The first symbol (Figure 1A) represents a SCLO object, or content object for short. The name of the object can be placed in the symbol. This symbol represents a state of a learning process that is left when the associated learning object is completely executed. Every learning object can in turn be separately analysed and refined by using another visual language (Figure 1B). When this happens the icon shows a nested structure. The arrow (Figure 1C) represents the transition symbol, and it can contain a label. When the transition is not labelled, the only result of interest is content object completion. In those cases where it is important to know which content object has been

completed, we associate different coloured coins to content objects execution. The synchronization symbol (Figure 1D) is a thick horizontal bar, and is used to coordinate content objects. The actions underlying content objects may be concurrently executed more than once. The number of concurrent invocations is determined at runtime by a concurrency expression. The synchronization bar provides a simple way to express concepts like waiting for concurrent content objects to finish before proceeding forward along the learning process (join), and the starting of several content objects in parallel (fork). It is worth noting that by removing the synchronization bar elements from the LAD language we derive a special case of flow diagram, but with a considerably reduced language power. In fact, we cannot describe activities without dependences; hence all the activities have to be consumed in a sequential fashion. In the definition of processes focused on flows, and driven by internal processing, like for example industrial, didactic and software processes, this type of behaviour is vital.

Let us now introduce two symbols describing assessment and self-assessment activities. The assessment test symbol (Figure 1F) is used to represent an activity aiming to evaluate the

Figure 1. LAD icons: A) SCLO object; B) refined self-consistent learning content object; C) transition element; D) synchronization bar element; E) self-assessment element; F) assessment element; G) merge element; H) start and stop marker

learner knowledge. The self-assessment activity (Figure 1E) is meant to be accomplished by the student to assess his/her knowledge. As a consequence, we differentiated the notations for these two symbols. Both symbols are used to represent decisions. As an alternative to guards on separate transitions leaving the same state, the aim of these objects is also to synchronize the incoming activities. These have one or more incoming arrows, and one or more outgoing arrows. The guard conditions are used to indicate different possible transitions that depend on test results. A decision may be shown by labelling multiple output transitions of an action with different guard conditions. These guard conditions may depend on self-consistent learning content objects that the instructor has to assess.

We have used a merge symbol (Figure 1G) to merge back decision branches. A merge has two or more incoming arrows and one outgoing arrow. As opposed to the synchronization bar, the incoming transitions are not synchronized.

Content experts, instruction designers, instruction technologists, media developers, and evaluation specialists are all professional figures that could be involved in the distance learning development process. For this reason, learning objects may be organized into swim lanes; the lanes can be used to organize learning objects with respect to these professional figures.

The last two symbols (Figure 1H) are the start and the stop markers. They are used to indicate the initial and final states of a diagram.

Figure 2 shows an example of LAD visual sentence, which represents a set of e-learning activities that have been structured into 4 swimlanes based on the learner knowledge. The student knowledge is assessed using the first test, so if the student has a score less than 60% then his/her knowledge is considered elementary. Thus, the learner has to study in depth the content presented in Material_1, and Material_2 before going on. Vice versa, when the test result is between 60% and 80% the contents presented to the learner will be those

of Material_4. Finally, Material_3 is presented to the learner with advanced knowledge. After that, there are two parallel e-learning activities, which do not depend on the student knowledge. Following Material_7 there is an assessment test, so if one student has a learning deficiency in that self-consistent e-learning activity then he/she must revise it and repeat the associated test. This means that the self-assessment element needs memory to remember the test result.

Self-Consistent Learning Object Language

The SCLO language is a kind of state transition language. Before defining it, we have investigated several languages used in multimedia software engineering (MSE). However, most of MSE languages have turned out to be complicated, requiring high expertise to be used. However, our aim was to formalize a visual language to be easily used by the target user within the visual environment implementing it. Thus, we have first

Figure 2. A LAD sentence

defined a graph language to describe multimedia contents of learning processes.

Four icons have been used to define this language. These are the multimedia node, multimedia link, start and stop marker node. Multimedia nodes (Figure 3A) represent the educational content that will be presented to the student. Typically they are composed by one or more multimedia raw contents. Thus, this node can be an atomic element or it may be composed aggregating atomic multimedia contents. The atomic content elements can be single Web page or simple multimedia objects, for example, short movies, songs, jokes, images, simulations, and so on. The multimedia object can have one or more incoming arrows, and one or more outgoing arrows (Figure 3B). Two multimedia nodes can be joined through a multimedia link. This represents the fact that students can browse multimedia contents by crossing links connecting objects. The last two symbols are the start and the stop markers (Figure 3C and 3D). These are used to indicate the initial and final state. The system prototype we present in the chapter implements this visual environment by presenting a predefined page layout to the lecturer that he/she can use for managing knowledge content objects.

Figure 4 shows a visual sentence example of the SCLO visual language.

Test Maker Language

Student assessment and self-assessment is a critical task in the knowledge process (Cynthia et al., 2000; Safoutin et al., 2000). The literature proposes a wide range of authoring tools to construct tests. Often, these tools do not have an associated visual environment to describe the test structure and its contents. In this chapter we introduce the test maker language (TML), a visual language supporting teachers during the design and implementation of tests. The language provides means to describe tests that adapt their contents to student answers. TML has five different symbols and three link types. The symbols are: question, aggregation symbol, multimedia object, and start and stop markers. The three link types define transitions between language symbols. Each of them has a different colour.

The instructor can use the question symbol to represent one question and its associated answers, or he/she may refine it by using symbol annota-

Figure 3. The visual language elements: A) multimedia node or knowledge fragment; B) multimedia link; C) start marker node; D) stop marker node

Figure 4. A visual sentence representing a learning content object

tions. Annotation is performed by using visual sentences from the same language.

Question symbols (Figure 5A) are grouped with respect to knowledge contents and swim lanes. These are also used to give an execution order to regrouped answers associated to knowledge contents; the swim lanes order is from left to right.

Links are used to model answers to questions. Thus, when a language sentence has an *any link* (Figure 5D) it means that the following question does not depend on the answer. Conversely, the false and true links (Figure 5E and 5F) modify the student test structure. The last symbol (Figure 5C) is recommended to motivate answers.

An example of visual sentence from the TML is depicted in Figure 6. It is worth noting that swimlane tags can be used to declare the score that the learner must achieve in order to pass the tests.

SYSTEM PROTOTYPE

In this section we present SEAMAN (system for e-learning activity management), a prototype based on the described visual language hierarchy. SEAMAN assists instructors during the specification and implementation of e-learning processes and their associated e-learning activities, supporting the delivery of instruction via the Web. The system integrates modules for several authoring activities, such as knowledge contents, assessment, and self-assessment tests. The system can be configured as a centralized application so that the instruction

designers can share and reuse content objects at different granularity levels.

To better understand the functionality of SEAMAN, let us consider the use case diagram in Figure 7 showing the relationships among use cases, instruction designer, and the framework used to deliver learning processes. In particular, two actors were identified, namely the instructional designer and the e-learning framework. The former actor can define the learning process flow of e-learning courses, the knowledge content objects, and the tests using SEAMAN tool. Once the definition of learning process flow and its e-learning activities is completed, the course can be generated. The generation process releases instruction contents to be deployed via Web, and will be available using an e-learning framework, as for example E-World (Casella et al., 2007).

Figure 8 shows the layered architecture of SEAMAN. It includes three visual editors, one for each presented visual language, an application logic layer, corresponding to the generation engine module, and a repository. The LAD editor allows the instructional designer to describe and model

Figure 5. TML elements: A) question node; B) start and stop marker C) multimedia symbol; D-E-F) joint lines

Figure 6. A visual sentence representing a student assessment process

Figure 7. A SEAMAN use case diagram

the learning process flow based on knowledge content objects, assessment, and self-assessment tests, and their dependences. The knowledge contents and the tests are defined by using the SCLO editor, and the TML editor, respectively. The generation engine module generates learning processes, knowledge contents, and the tests using the predefined generation rules stored within the repository of the system prototype. Furthermore, the generation engine module produces a zip file that contains didactic resources and configuration files. The didactic resources are composed of HTML files and SVG (scalable vector graphics, 2007) files, which are described by metadata files. Some configuration files to allow the e-learning framework to manage the learning process are also produced. The generated e-learning course and its activities are stored in the repository to enable the instructional designer to eventually successively deploy them in an e-learning framework, for example, E-World (Casella et al., 2007).

The SEAMAN tool is further described by the UML package diagram of Figure 9 and the UML class diagrams of Figure 10. In particular, Figure 9 shows the semantic dependencies among the packages: graphical user interface (GUI), graphic panel, graphic symbols, input & output, and properties. The GUI package is aimed at managing the graphical components, allowing the interaction between SEAMAN tool and the instructional designer. To insert and delete objects in the visual programming environments implemented in SEAMAN the classes in the graphic panel

package have been implemented, while the classes in the graphic symbol package are aimed at visualizing the language objects in SEAMAN visual environments. In particular, this package contains the interface that all the visual objects have to implement since they can be managed by SEAMAN visual environments. The classes implementing the proposed visual objects are in this package too. The input and output of the visual sentences are managed by the classes of input & output package. Finally, the property package is used to manage the users' preferences, and the multilingual menu of SEAMAN.

The class diagram in Figure 10 shows the relations between the classes implementing the three visual editors and the *generation engine*.

Figure 8. The SEAMAN architecture

Figure 9. SEAMAN package diagram

This class diagram highlights the extensibility and the flexibility of the proposed system prototype. It is worth noting that extensions or customizations of the proposed visual language hierarchy can be implemented by developers in SEAMAN with little effort. In such a way new types of e-learning activities can also be introduced to complete the formative offer.

As output of SEAMAN is an e-learning environment that is delivered on the Web, features

such as usability, colours, and graphical layout become crucial for student welfare and e-learning course success. For this reason we defined several predefined graphical layouts that instruction designer chooses for the Web pages implementing the e-learning activities of a given process. Moreover, the prototype allows us to define new layouts or to customize existing ones.

The e-learning activities generated by the prototype are iteratively navigable through a Web browser. Although the e-learning activities generated using the proposed approach are HTML pages, we need sophisticated technologies that only some browsers support. Thus, SEAMAN works for recent versions of Netscape and Internet Explorer.

Although the language aims to support the design and development of learning processes, it has also turned out to be a powerful tool for presenting e-learning activities, and for monitoring student progress. Thus, an animation of diagrams allows students to monitor their progresses. Moreover, thanks to SVG storage format of LAD visual sentences, the student learning process can be

Figure 10. SEAMAN high level class diagram overview

visualized by using a Web browser with a suitable plug-in. The animation is executed only when the activities of a given distance course are deployed in an e-learning platform, implementing the learning traceability through a special conceived software component, such as the SCORM Run Time Environment (ADL, 2003). Moreover, SEAMAN generates a server module interacting with the LMS. The server module is integrated in the platform when the course is delivered. Colouring the activities green when the student finishes them, we provide a high level representation of the learning traceability.

A SAMPLE APPLICATION

Several lecturers at University of Salerno have used SEAMAN to create e-learning courses. In particular, in this section we show its use for the design of the *Programming Language Technologies* course (PLT for short), belonging to the bachelor's degree in computer science at University of Salerno. The aim of the PLT lecturer was to design the e-learning process to provide students with knowledge and expertise in the design and implementation of compilers. After attending the course generated starting from the defined e-learning process, the student should be able to design and implement a language compiler. In particular, as a course project the student is required to implement a subset of functionality of the Java language compiler back-end.

The main steps to create a course with SEAMAN are:

1. Use the LAD environment to define the course structure in terms of contents and tests;
2. Use the SCLO environment to insert content for each SCLO object mentioned in the LAD sentence;

3. Use the TML environment to define assessment and self-assessment tests in the LAD sentence.

Figure 11 depicts the visual sentence describing the learning process of the PLT course within the SEAMAN visual environment. On the other hand, Figure 12 highlights how the same sentence is presented to the student by using a Web browser with SVG plug-in. The sentence does not provide traceability animation because no e-learning activity has been completed. The two figures show that the course is divided in two parts. The former deepens topics about compilers preliminary notions, and basic tools for developing them (such as Lex and Yacc). The second part is conceived for designing and implementing compilers. In particular, the main characteristics of the JAVA, C#, and C++ compilers are shown. There are no dependencies among these topics, so their content can be also completed simultaneously.

Starting from the objectives and the topics of the course the lecturer has introduced three tests,

Figure 11. LAD sentence describing PLT learning process in SEAMAN

Figure 12. LAD sentence describing PLT learning process displayed using Internet Explorer

two of which are self-assessment and one is assessment. The first self-assessment test, depicted in Figures 11 and 12, regards LEX and YACC tools. Since these tools are considered vital for the realization of the final course project, the lecturer has introduced a test and a feedback on them. Instead, the runtime environment and the

compiler of the Java language are evaluated by using the second self-assessment test depicted in Figures 11 and 12. The visual sentence describing this test is shown in Figure 13. In this picture we can also see an example of question with the associated answers. Finally, the lecturer has created a test for assessing the learners' knowledge on the whole course contents.

The visual sentence in Figure 14 shows the definition of the learning content object "Compilers/Interpreters" depicted in Figures 11 and 12. The main fragment describes the compilation and interpretation processes, whereas subsequent fragments show the detailed activities.

CONCLUSION

Academic and commercial e-learning authoring tools (Apple et al., 2002; Campbell & Mahling, 1998; Douglas, 2001; Goodyear, 1997; Muraida & Spector, 1997) use the basic concepts of the multimedia software engineering (MSE) (Christoffersen & Christoffersen, 1995). This is a new frontier for both software engineering (SE) and visual languages (VL) (Bell & Jackson, 1992; Campbell & Mahling, 1998). As it has happened

Figure 13. TML sentence describing the test on the runtime environment and compiler

Figure 14. A visual sentence representing the Compiler/Interpreter learning content object

for these fields, also the e-learning field can benefit from the use of visual languages to simplify the work of an instruction designer. To this sake, in this chapter we have presented three visual languages for defining several stages of the e-learning course design process. The languages have been implemented within SEAMAN, a prototype that has been conceived to allow instruction designers to generate friendly learning environments and enhance their welfare. Experimental results have shown that the use of visual languages can encourage the design of distance courses, as opposed to what happened before with tools using more rudimental interaction paradigms.

We also carried out a usability study of SEAMAN using five lecturers at University of Salerno as subjects. The subjects used the SEAMAN system to produce a complete electronic version of their course. In particular, they have redesigned the following five courses from bachelors' degrees related to computer science: Programming Language Technologies, Databases, Discrete Mathematics, Fundamental of Physics, and Business Administration. All the lecturers underwent an introductory course of six hours on the SEAMAN system and its visual notations. After that they were asked to use the system on their course, having the possibility to invoke individual tutor support. Once they had

completed the design of their course with SEAMAN they were asked to fill in a questionnaire to provide feedbacks on system usability issues. In particular, other than the course name and the lecturer familiarity with diagrammatic languages, the form contained the following three categories of questions: intuitiveness of language symbols and visual sentences, training and usage times, and comprehensive tool evaluation with respect to well-known authoring tools.

In general, we noted that familiarity with diagrammatic notations seems to facilitate tool usage. We also observed that non-computer science professors had more difficulties on the LAD language than on the other two visual languages. Probably, this was mainly due to the fact that although workflows should be familiar in business and many other disciplines, mapping the concept of activity synchronization on real-world problems is not immediate. Moreover, the discrete mathematics professor also had some difficulties on the definition of assessment and self-assessment tests with the TML language. More specifically, she found some problems in understanding the meaning of the true, false, and any joint links, and how they affect the test behaviour at run-time. In conclusion, the SCLO language was the easier to understand and use,

whereas the LAD required some effort for people non-familiar with activity diagram notations. The hierarchical visual language organization appeared to be grasped quite intuitively by all of the lecturers. Regarding the time necessary to enter a visual sentence in SEAMAN this mostly reflected the familiarity with the given notation, although most of the lecturers took reasonable times. Finally, looking at the feedbacks of questions in the third group, it seemed that the use of visual languages in SEAMAN makes e-learning process creation somewhat easier as opposed to traditional authoring tools, and that all of the lecturers involved in this experiment expressed the possibility of using the SEAMAN prototype in the future.

Future work will be devoted to extend the visual languages proposed in this chapter. This has a two-fold goal. On one hand, we aim to introduce less technical and more metaphor oriented visual languages to provide further abstraction in the e-learning design process, and consequently increase system usage among non-technical teachers. On the other hand, we aim to extend our visual languages in order to enable the modelling of additional aspects of the e-learning process. Special interest deserves the specification and the realization of collaborative activities, in order to encourage cooperative and problem-based learning (Laister & Koubek, 2001). In this way groups of students can work together to solve problems, while keeping their diversities. As a result, the learning environments will encourage individual accountability, prompt feedback, and high self-expectations.

Chapter 3.15

coUML: A Visual Language for Modeling Cooperative Environments

Michael Derntl

University of Vienna, Austria

Renate Motschnig-Pitrik

University of Vienna, Austria

ABSTRACT

In this chapter we present coUML, a visual modeling language for cooperative environments. As modern instructional environments have a highly cooperative nature, coUML is proposed as a powerful and effective language for modeling instructional designs in such environments. Being based on UML, it was conceived and refined through application and experience over multiple years, primarily in a cooperative blended learning environment. We present relevant requirements and applications that contributed to the development of coUML, as well as a detailed specification of model elements, characteristics and features that describe its current state.

DOI: 10.4018/978-1-60960-503-2.ch315

INTRODUCTION

This chapter presents the coUML approach to modeling of cooperative learning designs and environments. coUML stands for “cooperative UML.” Its notation is based on UML, and it extends UML with a modeling profile specifically designed to enable the modeling of complex, cooperative learning environments. While coUML clearly focuses on process modeling in cooperative environments, it also allows modeling and integrating relevant structural information such as goals, documents, and involved roles.

While the name “coUML” was coined during the preparation of this chapter, initial ideas and uses of the coUML language date back to 2002, when we were starting an initiative to discover and

document the e-learning practices at our department. During this project the coUML modeling approach proved to be a valuable aid in creating visual models of our teaching and learning activities for documentation, communication, research, and dissemination purposes. The complete and user-friendly specification of coUML in this chapter along with illustrations and examples, is provided to make this approach available to interested readers and practitioners.

The chapter is structured as follows: In the next section we provide some background information on the roots and requirements of the coUML approach. In the third section a detailed specification of the coUML language is provided, illustrated with examples. In the fourth section we present three application scenarios of coUML. This is followed by a discussion on the coUML features and the presentation of a survey on visual instructional design modeling languages among blended learning experts. In the final section we present a conclusion and an outlook on further coUML-related activities.

THE COUML APPROACH

Background

The coUML approach emerged from practice (cf. Derntl & Motschnig-Pitrik, 2005). About 4 years ago, we were searching for a way to capture our teaching and learning designs. Our primary approach to designing the instructional processes for our courses was based on the principles of blended learning (Garrison & Kanuka, 2004). As a traditional university we build on face-to-face meetings in the courses, and we have gradually started introducing online and distant means of collaboration, evaluation, and delivery into our teaching and learning activities. The goal then was to build a comprehensive library of blended course designs or patterns including verbal descriptions and semi-formal models of scenarios

that were already in use at our department. As no visual modeling language was particularly suited for such a task, we started to employ the following simple procedure: First, we write down a verbal description of a course and its activities, including an outline of relevant teaching and learning goals, and the primary teaching approach employed (e.g., project-based learning). The second step is to visualize the course scenario as one or more threads of activities according to the course description. Initially, we used simple symbols for drawing activities and arrows as connectors between activities. Gradually the notation system evolved from requirements drawn from practice and experience, and was finally based on a more formal, standardized notation system. Additionally it was apparent that the current wave of Web-based tools and enhancements not only penetrated educational environments, but any environment where people cooperate to achieve personal and organizational goals, e.g., in projects or communities. Therefore we present coUML as a language that is rooted in, yet not constrained to educational environments.

Requirements and Need

It was clear that a course was, conceptually, not just a sequential thread of activities; we would need additional control-flow structures such as decisions, concurrent flows, and composite activities. We were also interested in a number of additional, instructionally relevant information to be included in the visual models of teaching and learning activities, which are outlined in the following list of requirements:

R1: *Support for logical/temporal arrangement of activities, as well as decisions and concurrent activities.*

R2: *It should be possible to model activities at different levels of detail, which requires a means of refining composite activities. This should allow*

multiple views on complex activities and help to keep the models clear and understandable, even though this introduces layers of abstraction which might be difficult to grasp for many people.

R3: *It should be possible to attach roles to activities, for example that online chat support for urgent questions is provided by a student tutor and consumed by course participants.*

R4: *Most learning activities “consume” and/or “produce” documents (Web sites, reports, slides, evaluations, data, etc.); modeling and visualizing that information would help in document management efforts mostly on the side of the instructors and administrators.*

R5: *It should be possible to model the learning goals planned for a course, in order to show which activities in the learning process are “responsible” for supporting and achieving certain goals.*

R6: *As we are interested primarily in modeling blended learning course designs, we need to tag activities as proceeding in a present (i.e., face-to-face), Web-based, or blended mode. The rationale behind this distinction is explained later in the language specification.*

Language Choice

An existing modeling language that immediately supported all our requirements was not readily available. While there were a number of languages available which would support the basic control flow requirements (R1 and R2), only UML provided additional built-in support for R3 and R4. Additionally, UML offers extension mechanisms to define custom model elements, e.g., based on the modes of presence defined in R6, or learning goals according to R5; for this purpose it was necessary to define a UML extension for modeling blended activities, as specified in the following section.

COUML LANGUAGE SPECIFICATION

In this section, the coUML language and its usage is specified in detail. First, we outline and describe modeling artifacts created with coUML, and then, building on basic UML prerequisites, we define the model types and elements used by coUML.

coUML Modeling Artifacts

Using coUML to model a course design produces a number of artifacts, i.e., models and additional information. These are separated into *primary*, *secondary*, and *auxiliary* artifacts, as described below. The procedures taken and the modeling “toolkit” to understand and create these artifacts are described in detail in subsequent sections.

Primary Artifacts

Course activity model (CAM): The primary modeling artifact of coUML is the *course activity model (CAM)*. It comprises a number of activity diagrams showing the course’s activities from any desired viewpoint. The CAM aims to provide expressive diagrams showing the chronological order as well as the intent of activities (usually both teaching and learning activities) of the course. coUML allows modeling the CAM diagrams at different, arbitrary levels of detail, which might be helpful with complex course designs.

The CAM is the core of the coUML course model—it can be used to model complete and planned course designs, but it can as well be used to model specific course phases during the course design stage. As such, it can be used as a communication and documentation medium among course designers; by instructors as a handy guide to the conduct of the course; and also by researchers as a conceptual model of the course, e.g., for evaluation or analysis purposes.

Course structure model (CSM): Particularly for modeling complex course designs, another primary artifact is needed, which is the *course*

structure model (CSM). The CSM is created and maintained concurrently with the CAM, as it shows structurally which activity diagrams are used in the CAM to provide a comprehensive course model.

Readers might notice that the CSM—as a complement to the CAM—is not necessarily a mandatory artifact of a coUML course model, as CAM diagrams are still valid without the CSM. However, the CSM acts as an overview or entry point to the CAM, and is therefore also considered a primary artifact, especially from the reader’s or viewer’s points of view.

Secondary Artifacts

The secondary coUML artifacts as listed below are used to complement the primary artifacts. These complements can optionally be created to provide additional, more detailed information regarding the following:

Roles: Activities in the CAM are performed by persons taking over specific roles in the course. Typical roles would be instructor, student, or tutor. The role model displays the roles involved, and optionally how they are related with each other. Additional textual information regarding the roles can be provided in structured form as well.

Goals: From an instructional point of view, course activities are designed to achieve specific learning goals. coUML offers the option of creating goal models, which explicitly depict learning goals and, if desired, their relationships with each other. This allows systematically breaking down overall course goals into more tangible, readily achievable learning goals; these in turn can be attached to activities in the CAM to show which activities are intended to support or achieve a goal.

Documents: Instructors typically provide documents and resources as input to learning and teaching activities, and during these activities additional documents and resources might be created or contributed by course participants. To account for this fact, and to provide an overview of which documents and resources are to be provided and

created, coUML enables modeling of all relevant documents. These models can be used to structure and describe the documents and to connect roles with documents, showing the document providers and consumers.

Auxiliary Artifacts

Course package model (CPM). The CPM is intended to provide condensed information regarding the course, so to say its “fact sheet.” It includes a tabular overview of relevant course parameters, and a model comprising a view of all model packages used for modeling the course. This can be used as an “entry point” to the detail models provided for the course, i.e., roles, documents, goals, CAM, and CSM. It is recommended to create the CPM, as it supports easier usage of and navigation in the course models. However, the fact sheet and model overview are auxiliary and thus optional artifacts.

coUML Modeling Procedures

The coUML modeling procedure to be employed heavily depends on the planned intent of the models and on the concrete ID process for a course, particularly on the current course design status and the desired level of modeling detail. coUML offers a number of features and artifacts for which there may be no use in certain stages of the course design process. For instance, for some courses there might be no explicit information available or needed regarding documents. coUML is flexible enough to separate concerns and allow for detached as well as integrated modeling of such course design artifacts.

There is no particular default procedure for creating a comprehensive coUML model of a course. In the following, we discuss two common usage examples and respective procedures.

Modeling a completed course design: The most straightforward use of coUML is for completed course designs. For example, these models

could be used as a “contract” between course administration and instructors; or as a structured course documentation by instructors and instructional designers. In such cases, there exists a verbal or textual description, or at least a consensus, on the design of a course. It could as well happen that the course to be modeled was finished already. Hence, all available coUML modeling features can be exploited in a chronological procedure, which could look like the following:

1. Create the CAM as the primary artifact.
2. Create role-, goal-, and document models according to available information. Leave out or complement missing information.
3. If desired, refine or complement the CAM to include the secondary artifacts defined in step 2.
4. Create a CSM for the final CAM.
5. Create the CPM by identifying relevant course parameters and providing an overview model.

Modeling design-in-progress: coUML can also be used as a tool during the course design stage, e.g., as a more formal communication “language” among instructional designers, or as a personal aid for instructors during course planning and design. In such cases, the steps outlined in the above procedure can typically not be taken in strict chronological order, as working on a later step may require the refinement of artifacts created during an earlier step. Also, optimal and complete information is usually only available for complete (finished) course designs. If coUML is used during the course design process the procedure taken could look like the following: modeling roles, then CAM, CSM, documents, goals, revision of the CAM and CSM, and finally creating the CPM. As we see, there is no use for a standard procedure in the design-in-progress case, even though the primary artifacts such as the CAM and CSM would likely be the first to be created. For

a given design task it might even be sufficient to experiment with the CAM only.

As an example of the design-in-progress case, we want to show how coUML could support the ADDIE process model. ADDIE defines a simple and frequently used ID process comprising the phases: analysis—design—development—implementation—evaluation. The following list shows how coUML could be used as a “generative” tool for supporting the five phases of the ADDIE model:

1. **Analysis:** In this phase, an initial “map” of the course is created by addressing issues such as characteristics of the learners (e.g., their previous knowledge), desired learning outcomes, delivery options and tools available, suitable pedagogies and strategies, and course objectives (e.g., curricular requirements). With coUML, the analysis results can be written down in the fact sheet provided by the CPM. Initial sketches of involved roles, learning goals, and course/activity structure in the CSM and CAM can be created as well.
2. **Design:** During the design stage the course and learning objectives are elaborated in detail, the course structure and activities are designed in detail, relevant course material is collected and structured, instructional strategies are developed, and the evaluation/assessment strategy is specified. coUML can help in this phase with the learning goal models for course and learning objectives, the document model for specifying and structuring course content, and the CSM and CAM for modeling course structure and activities. Integrating coUML secondary artifacts (goals, documents, roles) into the CAM may further facilitate course design.
3. **Development:** For the development of the course content and support systems the coUML models created in the previous model represent a comprehensive documentation of the design; they can be used as a “con-

tract” among developers and instructional designers.

4. **Implementation:** In this phase, a training and delivery plan is developed. The coUML models, in particular the CAM and also the document model, show the crucial points in the instruction to be considered for training and preparing instructors and students, as well as for provision of required tools and learning material.
5. **Evaluation:** coUML models can be used as visual documentation of the whole ADDIE process and thus inform formative evaluation procedures. Summative evaluation procedures can, for example, be supported by the CAM and learning goal models (e.g., for matching actual learning outcomes with learning goals).

UML Prerequisites

Before approaching the specification of coUML model types and elements, we first introduce the relevant model types and elements of UML, upon which all coUML modeling artifacts are based.

UML is a conceptual modeling language that was primarily conceived for modeling static and dynamic aspects of software systems. It was standardized by the Object Management Group (OMG; <http://www.omg.org>) in 1997 and its current version is 2.0. In the past decade it has been established as the “lingua franca” in computer science. It does not explicitly rely on any particular software design process, nor is it restricted to modeling computer systems and software systems. It also offers extension mechanisms that allow modelers to define their own model types and modeling elements, both formally and visually. Hence, UML allows modeling static and dynamic aspects of any system or concept.

UML in its current specification offers about a dozen different model types, of which we only need two, namely activity diagrams and static structure diagrams (commonly referred to as

“class diagrams”). These two model types and their respective elements provide the basic syntax and semantics of all coUML models. Therefore the following sub-sections briefly introduce these model types and their uses for creating coUML modeling artifacts. Understanding these basic UML model types is required for understanding coUML modeling artifacts, which are specified in detail in the coUML specification section below.

All readers who are already familiar with or interested in UML please note that we do not define a full, formally correct UML extension profile in this chapter. This would require including lots of technical background on and references to UML meta-model and semantics, which would contradict the intended practical nature of this chapter. Therefore all relevant coUML model elements and extensions are introduced and described first and only when needed, that is at the point where the respective coUML model types and elements are explained. Also, UML elements and features not needed by coUML are ignored in the following introduction.

Static Structure Diagrams

A static structure diagram, commonly referred to as “class diagram,” is a model type used to build the static structure of a system’s analysis or design model by primarily modeling *classes* and their *relationships* (Eriksson & Penker, 1998). A class is a structural element that represents a concept of the application area as it models a set of objects with shared properties and behavior. For instance, all students share some common properties like postal address, date of birth, attended courses, etc., as well as some common behavior like moving to a new address, attending courses, taking exams, and so on. The class representing these properties and the behavior of persons would be “Student”. Each student would be an *instance* of this class, with concrete values for each property. In UML a class is visually represented by a solid-outline rectangle carrying the name of the class (see Figure 1).

Figure 1. Class “Student”

Classes, or the concepts that they represent, may maintain relationships with other classes. The most important relationships, which are also relevant for coUML, are:

- **Association:** Describes a shared relationship among instances of classes connected through the association. Visually, an association is drawn as a solid-line path between two classes. For example, students can be related to courses they attend; this would require an association relationship between classes “Student” and “Course” (see Figure 2).
- **Aggregation:** An aggregation is a special kind of association representing a part-whole relationship. Thereby, one participating class acts as the aggregate and the other class represents the parts. For example, when each course consists of multiple course units, class “Course” would be the aggregate and class “Course unit” would represent the parts of the aggregate. Visually, an aggregation is drawn like an association adding a hollow diamond at the end of the aggregate class (see Figure 3). On the other end of the aggregation (i.e., at the class representing the parts) the modeler may note the number of parts consti-
- tuting each instance of the aggregate class, either as a range or as a fixed number. So Figure 3 models that a course consists of five course units.
- **Generalization:** A generalization relationship connects a more specific concept with a more general concept. Thereby, the more specific concept “inherits” all features of the more general concept and may add new features. Generalizations are used to (hierarchically) refine concepts. For example, a student is a person and an instructor is a person as well, because both have a date of birth, address, etc., but both may also have special properties which are not common to all persons. Visually, a generalization is drawn as a solid line with a hollow triangle at one end pointing to the more general concept (see Figure 4). The generalization arrow can be verbalized as an “is a” relationship; Figure 4 therefore states that an “instructor is a person” and that a “student is a person.”
- **Dependency:** A dependency constitutes a “weak” association among classes that is usually not structurally relevant to any of the participating classes. For example, a dependency might show that a tutor supports the instructor during a course, which is structurally irrelevant, but still valuable information. Visually, this is depicted by a dashed arrow between involved classes (see Figure 5).

Finally, it is possible to group related model elements together in *packages*. Thereby, a package symbol is drawn around the respective model elements belonging to the package. Visually, a package is drawn as a rectangle with a tab on top of its top-left corner carrying the name of the package (see Figure 6).

Figure 2. Association relationship

Figure 3. Aggregation relationship

Figure 4. Generalization relationship

Figure 5. Dependency relationship

Figure 6. Package

Activity Diagrams

Activity diagrams are used to model the behavior of a system, demonstrating how the objects modeled in the structural model interact dynamically. Mapping this general definition to ID modeling, the target “system” would be the course or instruction to be modeled. In coUML, activity diagrams are used for modeling the course activity model (CAM).

Put simply, activity diagrams mainly consist of *activities*, i.e., states in the process where some action is performed, and directed *transitions*

among activities. After an activity is completed, the outgoing transition moves the current process state to the activity at which the transition is directed. This is to say that activity diagrams arrange activities performed in a process in chronological order. Visually, an activity is drawn as a rectangle with round edges, and a transition is drawn as an arrow (see Figure 7).

There is a special kind of activity which can be used in much the same way as a normal activity; yet it acts as a placeholder for a number of more specific activities. This is called a “*subactivity*”. Subactivities are used to decompose complex activity diagrams into different layers, each with different levels of detail. For example, the subactivity “enroll in a course” would link to a more detailed diagram showing the concrete activities performed by students enrolling in a course, which could be “enter student registration number” followed by “select course” and finished by “confirm enrollment.” Visually, subactivities carry a small icon connecting two circles in the lower right corner (see the example in Figure 8).

Figure 7. Activities and transitions

Figure 8. Subactivity linking to a set of activities

There might be points in a process, where the next step has to be chosen among a number of alternative steps. Activity diagrams account for such cases by offering *decision* nodes that can have multiple outgoing transitions, of which exactly one transition will become active depending on conditions defined by the modeler. Therefore, decision nodes split up the flow of an activity diagram into multiple alternative flows. For example, “write project report” is succeeded by a decision offering as alternatives “revise project report” and “present project report” as next steps (see Figure 9). The decision would depend on the quality of the project report. Good reports are approved for presentation, while bad reports need to be rewritten first. Visually, decision nodes are drawn as hollow diamonds. Often, alternative flows offered through decisions need to be joined back together at a certain (later) point in the diagram. This is done by drawing another decision node at that point, this time acting as a *join* node with multiple incoming transitions. In Figure 9, the decision symbol is used both as a decision and a join node at the same time.

Additionally, there might be phases in a process, where various activities need to be done concurrently. For example, students would “work on projects,” and concurrently “use the online discussion forum.” In activity diagrams this is possible by splitting up a transition into multiple concurrent (or synchronized) transitions through a *synchronization bar*. Visually this is drawn as a thick, solid horizontal line. The end of concurrent activities is indicated through another synchronization bar, which continues the process only when all its incoming transitions are active. This means that all concurrent activities have to be completed before the process can continue (see Figure 10).

Finally, each activity diagram has exactly one *start node*, which may carry outgoing transitions only, and at least one *end node*, which may have ingoing transitions only. Visually, a start node is drawn as a filled circle carrying the title or name

of the activity diagram, and an end node is drawn as a hollow circle comprising a smaller, filled circle inside (see Figure 11).

Extending UML Elements

Each existing model element in UML can be *stereotyped* to represent a more specific concept. The stereotype is named after the specific concept to be introduced. Such new modeling elements can be introduced and readily used without much effort. Visually, the modeler can define his/her own graphical representation of the new model element, or he/se can just attach the stereotype name as text within matched guillemets (« ») to the element. This extension mechanism is powerful and highly relevant to our purpose, as coUML derives all special elements from built-in UML elements by adding stereotypes, such as «goal»

Figure 9. Decision among alternative activities

Figure 10. Synchronization of concurrent activities

Figure 11. Start node (left) and end node (right)

Web Engineering

to classes in the goal model, or «web-based» to activities in the Course Activity Model. For examples of using stereotypes see the following coUML specification section.

Specification of coUML Model Types and Elements

The following sub-sections specify the model types and elements used for creating the coUML course design artifacts as described earlier. All modeling artifacts are specified using a template consisting of five sections: semantics, syntax, example, modeling procedure, and textual information. Regarding examples we try to illustrate the specified models and elements by using a (simplified) course on Web engineering.

The Web Engineering Course

The Web engineering course (hereafter simply “WE course”) is an undergraduate course in computer science. It consists of seven consecutive course blocks including project-based learning in teams and face-to-face lectures. The lectures are held by an instructor who also coaches the team projects (where he/she is assisted by a tutor). All documents for projects and lectures are managed on a Web-based learning platform.

The seven blocks are organized as follows: After an introductory block, five blocks are dedicated to advancing knowledge and experience in Web engineering through applying techniques and theories presented in the lectures on team projects. This includes Web technology basics, requirements engineering, conceptual modeling, Web data management, and Web programming. The arrangement of these topics allows for completing the projects in an incremental development process. The final course block concludes the course with a grading procedure and a course quality assessment.

More details on the course are introduced as required for the specification of new elements.

Note that in this section we only model those aspects of the WE course required for the introduction of the coUML language elements. A more complete case study on modeling a whole course using coUML is provided in Chapter XVI of this handbook.

Course Package Model (CPM)

Semantics

The CPM shows which primary and secondary coUML modeling artifacts are provided for a specific course design. As such, the CPM acts both as an overview and entry point to all coUML artifacts provided for a course design.

Syntax

The CPM is modeled as a class diagram with one super-ordinate package carrying the course title. This package includes other packages, each representing (a group of) a primary or secondary coUML artifact. No relationships are used in the CPM.

Example

The WE course is modeled using coUML including examples of the CAM, the CSM, and the secondary artifacts. The CAM and CSM are contained in dedicated packages, and each secondary artifact (i.e., roles, goals, and documents) is also contained in a dedicated package. The CPM for this course would look like Figure 12.

Modeling Procedure

It is easier to model the CPM when all artifacts are already known and available. However, the CPM may also represent the planned or in-progress state of artifacts. In this case, the CPM would have to be updated if any artifact is added, removed, or renamed.

Textual Information

The CPM is complemented by the course’s “fact sheet” including relevant course parameters. This

Figure 12. CPM for the Web engineering (WE) course

can be used as a quick overview of course facts by course designers, teaching staff, and even students. The fact sheet is presented as a table comprising two columns: parameter and description. The head row of the table shows the course name, and all subsequent rows include relevant parameters in the left column and their respective values in the right column. We propose the following set of parameters, which may be reduced or extended according to specific needs:

- **Summary:** A short summary of the course content and intent.
- **Structure:** A description of the structural organization of the course, e.g., division into multiple blocks with dedicated topics, or weekly lectures, etc.
- **Mode of presence:** Indicates whether the primary mode of presence in the course is face-to-face, online, or blended.
- **Online support:** Lists available online tools and resources, such as course Web sites, learning management systems, etc.
- **Participants:** How many and who are the participants?
- **Teaching staff:** Teaching staff involved in the course, such as instructor, supervisor, tutor, external guest, etc.
- **Instructional strategy:** Description of main instructional strategy employed in the course, such as project-based learning, case-based lab practice, etc.
- **coUML models:** A list of coUML models or artifacts provided for the course design.

Table 1 shows a brief fact sheet of the WE course.

Models for Roles

Semantics

The model for roles is intended to depict roles involved in a course. As a secondary artifact, the role model is created only if deemed to be of significant use to the design team. There are considerable benefits of modeling roles: First, each role must carry a clear and unique name, which facilitates communication and understanding. Second, they can be used as additional information in the document model and the CAM. In the document model, roles are represented as providers and consumers of documents, while in the CAM the roles are used to show areas of responsibility in the course phases and activities. On the other hand, if roles are used in the document model or the CAM, the model of the role must be provided to maintain the internal consistency of the models. In either case, modeling roles requires additional effort and also adds to the complexity of the overall coUML model.

Syntax

Roles are modeled in class diagrams. Technically, a role is represented by a class with stereotype «role». We define our own custom visual representation for this, which is a stick-figure with the role name written below it (see Figure 13; UML experts may note that we reuse the built-in UML

Table 1. Fact sheet of the WE course

“Web Engineering”	
Summary	Integrated lecture and lab course in computer science, held in a blended mode. Relevant Web engineering theory and techniques are presented by the instructor and applied hands-on by the students their team projects.
Structure	The course comprises seven consecutive blocks; each block is conducted in a blended mode integrating face-to-face and online activities.
Presence mode	Blended face-to-face and online
Online support	A Web-based learning platform is available; any required tools for projects are available in the laboratory.
Participants	Twenty undergraduate computer science students with basic knowledge in computers, Internet technologies, and computer programming
Teaching staff	One instructor, one tutor
Instructional strategy	Lectures and project-based learning using a blended learning approach. Projects and subject matter are elaborated in a stepwise, incremental fashion (synchronized with theory input during the lectures).
coUML models	CPM, CSM, CAM, roles, learning goals, documents

Figure 13. The “Instructor” role

actor symbol). Packages may be used to group related roles together.

The following relationships are possible between roles:

- **Aggregation:** Means that each instance of the aggregate role consists of a number of instances of the other role. A typical example would be the “team” role that aggregates the “student” role in the sense that each student team consists of a number of students (see Figure 14 showing that each team comprises four students).
- **Generalization:** This means that a more general role is refined by more specific roles. The more general role provides structural and/or behavioral elements for

each specialized role. For example, there might be activities in a course where both instructor and student roles actively participate; these two roles could then be generalized through a “participant” role (see Figure 15). Consequently, if the participant role is partaking in any course activity in the CAM we implicitly know that both instructor and student roles can be involved.

- **Dependency:** A dependency relationship between two roles indicates that one role supports the other role in course activities. For instance, the tutor role typically supports the instructor role, which is modeled as a dependency carrying the stereotype «support» (see Figure 16). While coUML only specifies the «support» stereotype, the modeler may introduce additional stereotypes as needed. Modeling dependencies among roles is optional; usage of this feature might increase the informational content of the role model, but it also tends to overload the model.

Optionally, roles and role hierarchies can be divided into multiple packages in one or more class diagrams. For example in a more complex role hierarchy it might be useful to separate teach-

Figure 14. Role aggregation

Figure 15. Role generalization

Figure 16. “Support dependency” between two roles

Figure 17. Role model of the WE course

ing roles from learner roles. The decision on this is left to the modeler (see the remarks for “modeling procedure” below).

Example

In the WE course, active roles include the instructor, the tutor, and students. Additionally, we identify the “team” role: In the first session, students are organized into teams of four to work on their web engineering projects for the rest of the course. Therefore, the team role is modeled as an aggregation of the student role. At the student role end of the aggregation, the number “4” indicates that each team consists of four students. Activities performed by the team role for one of the WE course blocks can be seen in the CAM example (see Figure 42).

Modeling Procedure

Identifying the roles for a course is straightforward. Most courses involve at least the instructor, student, and tutor roles. It might be easier to identify roles after the first attempts to model the CAM diagrams, as it makes little sense to conceptually define a role which does not partake in any course activity. Also, with most or all course activities available, identification of participating roles is easier.

As coUML makes no assumptions on role granularity, it would also be possible to refine the role hierarchy into greater detail according to the activities in which they partake. For example the student role could be split up into more specific roles that students take on in different activities. Consider the peer evaluation of student projects: the “student” role could be divided into a “project-contributor” role and a “peer-reviewer” role. The final decision on the granularity of the role model is left to the modeler, however with the advice that fewer roles are clearly easier to handle.

Textual Information

The role model is complemented by a tabular description of the roles. The two columns of the

table expose the role name and a short description for each role. For example the role description for the tutor in the WE course would be, “Supports the students and the instructor during various activities, e.g., facilitating/helping project teams, collecting documents from students, maintaining the online content, seeing through online activity, etc.”

Goal Model

Semantics

The goal model can optionally be used to explicitly model and describe learning goals as well as their relationships with each other. Like the role model, the goal model is considered as a secondary modeling artifact that can be omitted if not needed. However, this model is useful as a tool to explicitly name and relate goals with each other. The modeler is free in setting the focus for the goal model, which means that coUML does not suggest any underlying taxonomy (e.g., Bloom’s taxonomy of learning goals—cf. Bloom, 1956), nor any other assumptions about the learning goals. Nevertheless, coUML allows assigning priorities to learning goals.

If the modeler decides to create this model, the learning goals can subsequently be used as additional content in the CAM, where activities can be connected to learning goals. This is useful for showing which activities support or achieve which learning goals.

Syntax

Goals are modeled in class diagrams. Each goal is drawn as a class with stereotype «goal» above the learning goal name. Additionally a goal identifier (ID) can be placed in the top-left corner of the class symbol, allowing referring to a goal by its ID (can be a number, an acronym, etc.), which is typically shorter than its name. To avoid introducing yet another icon, we reuse the already known class symbol and restrain from defining our own icon for goals (see Figure 18).

Figure 18. Learning goal “Understand basic Web technology” having ID “7”

Note that some existing goal modeling approaches use the UML use-case symbol for modeling goals, while others use stereotyped class symbols. For coUML we preferred to use the latter option as we consider goals as being structural elements; use cases on the other hand are behavioral elements typically used to represent interactions (or events) preformed by users and the system to achieve some goal. With coUML the achievement of goals can be modeled in the CAM.

Goals are modeled in packages and it is also possible to group related goals together. This is achieved by placing the respective goals inside a grouping box, which is drawn as a rectangle with an attached name for the goal group (see Figure 19).

It is possible to assign priorities to goals, if desired. There are several options of doing so: we could attach a text note to the goal that defines its priority (e.g., “Priority 1”); we could group together learning goals belonging to the same priority by using a grouping element like the one in Figure 19; or we could create a diagram consisting of vertical layers, where each layer represents one priority level. The choice is left to the modeler.

The following relationships are possible between goals:

- **Aggregation:** Means that the aggregate goal is decomposed into a number of smaller, typically more concrete goals. Thereby, the aggregate goal is considered

Figure 19. Grouping of cognitive learning goals in the WE course

as achieved after all its sub-goals have been achieved. Figure 20 shows an example of goal aggregation in the context of the WE course. Goal 1 can be achieved by achieving all of its sub-goals 2, 3, and 6.

- **Dependency:** A dependency relationship between two goals indicates that one goal plays a role in achieving or supporting the other goal. Dependencies may be stereotyped to express the particular type of dependency between two goals. The following two stereotypes are defined by coUML (note that this list can be extended according to the modeler's needs):

1. **«require»**, meaning that a goal requires another goal to be achieved first. For example to achieve the learning goal “Implement an application concept in teamwork” in the WE course requires the goal “Understand Web script programming” to be achieved first, as one cannot reasonably implement a Web application without being familiar with Web programming (see Figure 21).
2. **«support»**, meaning that working towards a goal supports the achievement of another goal. This could be interpreted as a weak, inverse form of «require». We could modify the example above to state that Web script programming supports implementation of application concepts, which could also be argued in certain cases (see Figure 22). We see that the choice of dependency relies on the modeler's es-

timation of the real relationship among two goals, so multiple interpretations are possible.

- **Generalization:** This means that a goal is refined by more specific goals. This is an advanced feature which can lead to more confusion than to better understanding among novices. However, generalizing goals is also a powerful concept, as the general goal can be used to provide shared properties for multiple sub-goals: If, for example in a course on writing research papers, learning goal *A* (“Writing research papers”) is a generalization of learning goals *B* (“Writing case-study papers”) and *C* (“Writing empirical papers”), then each relationship that *A* maintains with other learning goals (e.g., with learning goal *D* – “Structuring of research papers”) is inherited by both *B* and *C*. So if *A* requires *D* to be achieved, then *B* and *C* require *D* as well (see Figure 23).

Figure 20. Goal aggregation

Figure 21. “Require dependency” between two learning goals

Figure 22. “Support dependency” among two learning goals

Figure 23. Generalization of goals

Like the role model, the goal model can be divided into multiple packages in one or more class diagrams.

Example

Figure 24 shows the goal model for the learning goals of the WE course. Consider a list of learning goals specified textually by the instructor: To create our goal model, we provide a short name and attach a numerical ID for each relevant. Additionally we include the information that goal 1 is an aggregation of goals 2, 3, and 6, and that goals 4 and 5 are generalized by goal 3. While these relationships might not explicitly be stated in the textual description of the learning goals, the modeler should try to identify the most appropriate representation for goal relationships.

Figure 24. Learning goal model for the WE course

Modeling Procedure

If learning goals are available in structured text form, they can be modeled by identifying relevant learning goals, assigning a short name and an optional ID, and finally – if considered useful – by modeling relationships among goals.

There might be no explicit textual description available for many courses, especially in early design stages. In such cases it would be reasonable to think about and specify learning goals textually and proceed with modeling. If it is not intended to explicitly write down learning goals, it is valid to omit the goal model altogether, or to try to extract the goals from the course activities or other available course information.

Textual Information

The goal model can be complemented by a tabular description of the goals. The two columns of the table expose the ID or the name of the goal and a more detailed description, respectively. See the case study in Chapter XVI for an example.

Document Model

Semantics

The document model shows a structured overview of all documents that are created, provided, and/or used in a course. Moreover, it is possible to show for each document: who are the providers and who are the consumers. This is achieved by

connecting roles from the role model to documents in the document model.

The obvious benefit of creating this modeling artifact is that it is easy to identify, for example, which documents have to be created prior to the course, which documents have to be provided by teaching staff throughout the course, which documents are produced by students, or which resources are generally available. Creating a document model can provide substantial support in the tedious, yet indispensable task of document management in a course.

As we will show in the specification of the CAM, modeling a document model subsequently allows connecting documents with activities in the CAM, to show which documents are input to and output from activities.

Syntax

The document model is provided in class diagrams. Each document is drawn as a class with stereotype «document» above the document name. No special visual icon is defined for documents. Similar to the goal model, a document ID can be placed in the top-left corner of the class symbol, allowing referral to a document by its ID (see Figure 25).

Documents are modeled in packages and it is possible to group related documents together, for example document resources for student projects. This is achieved by placing the respective documents inside a grouping box (see Figure 26) in the same way as in the goal model.

The following relationships are possible between documents:

- **Aggregation:** Means that the aggregate document consists of a number of sub-documents. Figure 27 shows an example of document aggregation in the context the WE projects. The final project report consists of the sub-documents: project assignment, project plan, and project results. The project report is created at the end of the

course, after all sub-documents have been written.

- **Dependency:** A dependency relationship between two documents indicates that one document plays a role in the provision or usage of the other document. Dependencies among documents may be stereotyped to convey the particular type of dependency. Only one stereotype is suggested by coUML (note that the modeler may introduce additional stereotypes as needed): «require», meaning that a document requires another document to be available before it can be provided or used. A typical example would be written feedback: One can only provide feedback on a project report when the project report is already available (see Figure 28).

It is possible to use a dependency to connect a role defined in the role model with a document and vice versa. This would indicate the “*document flow*” among roles. Note that this is modeled without assigning a stereotype to the dependency.

Figure 25. A case study document on requirements engineering carrying ID “RE 2”

Figure 26. Grouping of project resources

Figure 27. Document aggregation

Figure 28. “Require dependency” between two documents

Depending on the direction of the dependency, the following intents are served:

1. A unidirectional dependency pointing from a role to a document means that the document is provided or created by a person embodying that role (see Figure 29).
2. A unidirectional dependency pointing from a document to a role means that the role uses this document for some purpose. So, persons embodying that role are addressees or consumers of the document (see Figure 29).
3. A bidirectional dependency between a document and a role means that the role acts as both provider and consumer of the document (see Figure 30). This constitutes an integration of the two unidirectional cases above.

Like the role model and the goal model, the document model can be divided into multiple packages in one or more class diagrams.

Example

A part of the document model of the WE course is given in Figure 31. It shows which documents are used and created in the third course block (“Block 3: Requirements engineering”): It is apparent that the instructor provides most of the documents,

except the requirements specifications which are created by the project teams and submitted to the instructor.

Modeling Procedure

Documents can be identified by studying the textual course description and particularly by analyzing course activities with respect to their input and output documents. Therefore it might be advisable to defer the creation of the document model until after the CAM is modeled. In this case the document model would have to be refined each time the CAM changes its use of documents.

Figure 29. “Document flow” unidirectional dependencies among roles and documents

Figure 30. A bidirectional dependency between the instructor role and a document

Figure 31. Document model for the third WE course block on requirements engineering

Textual Information

A tabular overview of documents is provided as a complement to the document model. Thereby each document can be specified in great detail according to specific needs. coUML suggests at least providing information on the following properties for each document: ID, name, type (e.g., paper, report, Web site, animation, spreadsheet, etc.), description (more detailed information on the content or use of the document), provider (who is responsible for providing/creating the document?), and deadline (a point of time in the course where the document must be available). See the case study in Chapter XVI for an example of a document table. Additional parameters could include: public (is a document available to other roles?), location, online availability, size, already available, and so forth.

Course Activity Model (CAM)

Semantics

The CAM is the primary artifact of a coUML course model. It is used to model the teaching and learning process of a course or instruction. The CAM may provide any number of activity diagrams showing the course activities from any point of view, in any desired level of detail. Its enormous flexibility makes the CAM a very powerful and versatile resource for course analysis, design, and documentation. Moreover, the modeler may reuse secondary artifacts defined in other models and link them to activities in the CAM, e.g., to show which documents of the document model are needed for which activities.

The most basic use of the CAM is for modeling the arrangement of course activities from an organizational point of view, i.e., aligning activities performed by multiple roles in activity diagrams.

Syntax

The CAM comprises a number of activity diagrams. Each activity diagram depicts a phase of a course, or the whole course at a certain level of

detail and from a certain point of view. The level of detail and the point of view are determined by the modeler according to the course activities to be modeled. The following elements are used to model basic activity diagrams:

- **Start Node:** Each activity diagram must have exactly one start node, which acts as the entry point to the “execution” of the diagram. It carries the name of the current diagram, which is usually the course name (if the activity diagram represents the whole course—see Figure 32) or the name of a particular phase or activity in the course (if the activity diagram models only one part of the course). The latter case may be complemented by placing the course name in smaller letters above the name of the current activity diagram (see Figure 33).
- **End Node:** Each activity diagram contains at least one end node, which represents the end of execution of the current activity diagram. This means that each final activity of an activity diagram must be connected to an end node via a transition.

Figure 32. Start node of the WE course activity diagram

Web Engineering

Figure 33. Start node of the activity diagram for block 3 of the WE course

Web Engineering

Block 3: Requirements engineering

- **Activity:** An activity symbol in an activity diagram represents a state of the execution of the diagram where a specific activity is performed by some role involved in the course. For example, at one point of the course the students have to read a document containing information on the task of creating the requirements specification for their projects. This activity could be modeled as “Read requirements specification guidelines” (see Figure 34). The name chosen for the activity should be meaningful to potential viewers, while keeping in mind that the name should not be too long.

An activity symbol may also be used to represent more than one concrete course activity, which is possible when modeling a diagram at a lower level of detail. Note that, unlike in many other educational modeling languages, in coUML the size of an activity symbol is not related to its estimated or planned execution time. The symbol should just be drawn large enough to accommodate its name. Also, an activity diagram is usually easier to read when all its activities have about the same size.

The modeler may explicitly denote the mode of presence in which the activity is performed, which is either Web-based, face-to-face (present), or blended. This is particularly useful in blended learning environments. With coUML it can be achieved by assigning a *mode-of-presence* stereotype to the activity. The following three stereotypes are defined:

Figure 34. A course activity

1. **«web-based»:** This stereotype means that the activity is primarily performed online, using the Web. It is visualized by filling the activity with light-blue color and by placing the letter “W” (standing for “web-based”) surrounded by a circle in the activity’s right-hand corner. Figure 35 shows an example of the Web-based activity, where requirements specifications for the team projects are submitted online via the Web.
2. **«present»:** This stereotype means that the activity is primarily performed in face-to-face or present mode. It is visualized by filling the activity with light-green color and by placing the letter “P” (standing for “present”) surrounded by a circle in the activity’s right-hand corner. Figure 36 shows an example of a face-to-face lecture activity on requirements engineering.
3. **«blended»:** This stereotype means that the activity is performed in a mixed, blended mode using the Web and face-to-face meetings. This stereotype is visualized by filling the activity with light-red color and by placing the letter “B” (standing for “blended”) surrounded by a circle in the activity’s right-hand corner. Figure 37 shows an example of an activity modeling the blended elaboration of project reports.

Figure 35. Web-based activity

Figure 36. Presence activity

Note that for blended activities the level of detail used in the diagram plays a significant role: At the highest level of detail, blended activities can not be modeled, as each single activity will proceed either Web-based or present. At lower levels of detail, an activity may represent more than one single activity, where presence and face-to-face modes can be mixed. This would make the activity a blended activity like the one in Figure 37. Project reports are elaborated in personal meetings and via the Web by exchanging electronic documents, e-mails, etc., making it a truly blended activity with a low level of modeling detail.

- **Subactivity:** A subactivity is a special kind of activity, which links to another activity diagram. This means that the subactivity represents a number of course activities, which are modeled in more detail in a sub-diagram. Logically, subactivities are only needed when modeling at a relatively low level of detail. The sub-diagram to which the subactivity points, is consequently modeled at a higher level of detail. This means that subactivities are a powerful tool to model course activities at different levels of detail, while providing links between these levels. This supports both the modelers and the viewers, because for example overloaded diagrams can be avoided this way.

Note that for easier recognition the start node of the sub-diagram should carry the name of its parent subactivity. Also note that the modeler can assign a mode of presence to each subactivity in the same way as it is done for normal activities.

Figure 37. Blended activity

For example, if we want to refine the blended activity in Figure 37 with a sub-diagram showing the concrete activities performed in elaborating project reports, the resulting subactivity and its sub-diagram would look like those in Figure 38.

- **Transition:** As already defined, a transition is a directed connection (drawn as a solid-line arrow) between two nodes in an activity diagram. It can be used to connect activities, subactivities, decisions, concurrencies, and start- and end nodes. A transition maintains the “control flow” in an activity diagram; it becomes active when its source node has completed its actions, and it immediately passes control on to its target node. This allows temporal and logical arrangement of activities and other nodes. For example, the activity diagram on the right-hand side of Figure 38 starts with the activity “Write project draft.” After this activity is completed, the transition becomes active and moves the state of execution to its target activity, which is “Project meeting.” After this, the “Finalize project report” activity becomes active. The last transition is directed at the end node.

Figure 38. Subactivity (on left side) and its sub-diagram (on right side) showing the elaboration of project reports

Through transitions the three activities are arranged in chronological order.

- **Decision:** A decision node (drawn as a hollow diamond) denotes a point in a course where the flow of activities is split up into multiple alternative flows. Exactly one of these alternative flows becomes active. To help decide which of the alternative “routes” to take, each outgoing transition of a decision node carries a so-called *guard condition*. If the guard condition of a transition is satisfied, that transition will become active. A flow split up by decisions can be rejoined later in the diagram by another node which is then called a *join* node that is visually identical to the decision node. Consider Figure 39 for example: The instructor lets students choose whether they want the next course unit on data modeling to be delivered as a lecture by the instructor, or as self-study via the Web. Depending on the preference of students, two alternative activities need to be modeled, i.e., a face-to-face lecture and an online self-study. The following join node reconnects the split flow of activities.
- **Concurrency:** A concurrency is used to model separate activity flows which proceed concurrently with each other. Concurrency has a dedicated start and

end. At the start a single transition is split up into multiple concurrent transitions with a synchronization bar symbol (thick, solid line), and at the end these multiple concurrent transitions are rejoined again with the same symbol. During execution of the activity diagram, at the end of a concurrency the flow can continue only after all incoming concurrent flows are finished. Consider Figure 40 for example. After the “Pick up project assignment” activity is completed, the two activities “Elaborate project reports” and “Keep online project diary” take place concurrently with each other. The end of the concurrency can be seen as a synchronization point: If both concurrent activities are completed, the process can continue with “Submit project report.”

- **Temporal constraints:** It might be necessary or useful to explicitly model time slots or constraints such as deadlines for activities. The modeler is relatively free in the way of adding this information. However, the following is proposed for coUML: Points in time are visualized in activity diagrams by drawing a dotted line with a deadline or other date near the activities to which the deadline is relevant. This feature is used in Figure 42; for example, we can

Figure 39. Decision and join nodes

Figure 40. Concurrent (synchronized) activities

see that the submission of requirements specifications by the project teams has to be completed until Sunday in the third week.

Activity diagrams can optionally be extended with elements from secondary artifacts:

- **Roles:** There is a feature for activity diagrams that allows modeling which role is the primary actor in an activity. An area, in which a particular role acts as the primary actor in activities, is surrounded by a so-called “swimlane,” which carries the name of the respective role name. For example, in Figure 42 there are swimlanes for three roles: instructor, teams, and students. Therefore we know that the first activity after the start node (i.e., “Download resources on requirements engineering”) is performed by students. In cases where an activity is performed by multiple roles, the activity can be resized to span or touch multiple swimlanes.
- **Documents:** coUML allows modeling the “document flow” in an activity diagram. To achieve this, simple transitions can be replaced by dashed arrows and an object symbol, which is a rectangle carrying the document name as defined in the document model (if the object represents multiple documents a symbol with two stacked objects is used). The document flow feature is especially useful when a document is direct output of one activity and subsequently direct input to the next activity. For example, in Figure 42, the “Requirements specifications” documents are output of the “Submit requirements specifications” activity and input to the following “Read specifications” activity performed by the instructor. If swimlanes are used for roles, it is a service to viewers to model docu-

ments in the swimlanes of the role or activity that produces the document.

- **Goals:** (Learning) goals can be connected to activities through dependency relationships. In the CAM, learning goals are modeled as objects, just like documents. The name of the object must match the name and/or ID of the goal in the goal model. To explicitly show the specific type of goal dependency, the following stereotypes are suggested:
 - «achieve»: States that the activity achieves a goal.
 - «support»: States that the activity supports the achievement of a goal. This can be considered as a weak form of the «achieve» dependency. See for example Figure 41, where the “Do requirements analysis and specification” activity supports the achievement of the “Conducting a requirements analysis” learning goal.

Interpreting Activity Diagrams

When viewing and trying to interpret an activity diagram, the best approach for novices is to “walk through” the diagram by placing an imaginary execution token at the start node of the diagram. Then, you continue to follow the outgoing transition of the current node, by moving the imaginary token along the transition arrow to the next node:

1. If you reach an *activity* you are at a point of the course where an activity is performed by some role, which can be identified by the containing swimlane of that activity. The

Figure 41. “Support dependency” between an activity and a learning goal

Figure 42. CAM diagram of “Block 3” of the WE course

token remains stationary at this activity until the activity is completed.

2. If you reach a *subactivity*, you follow the (imaginary) link to the activity diagram to which the current subactivity points. The execution token is transferred to the start node of this sub-diagram. After execution of the sub-diagram is finished (i.e., the token reaches an end node), you return the token to the originating subactivity and follow its outgoing transition.
3. If you reach a *decision*, you will notice the multiple outgoing transitions leaving the decision node. It is important that the execution token can only proceed along exactly one of the outgoing transitions. To help decide which outgoing transition to follow, the decision may carry a question to be answered or a condition to be satisfied. Each of the transitions then carries one answer or one possible condition value. You follow the

transition carrying the answer or value that is true/correct for the current token. If you reach a decision node with only one outgoing transition, which represents a join for the most recent decision, you just continue to pass the token along the single outgoing transition.

4. If you reach the start of a *concurrency*, you will also see multiple outgoing transitions. Contrary to decisions, *each one* of the outgoing transitions will become active after the synchronization bar. This can be achieved by splitting the execution token up into a number of concurrent execution tokens matching the number of outgoing transitions. Now place one of the tokens on each transition and concurrently proceed with each token. This concurrent flow of activities is ended by another synchronization bar, which can be recognized by its multiple incoming transitions and only one single outgoing transition.

At this point, you wait until each part token of the previously split-up execution token arrives at the synchronization bar. After the last token has arrived you rejoin the tokens and continue with one single token along the path of the synchronization bar's outgoing transition.

5. If the current transition you follow represents a *document flow* (i.e., a dashed arrow) you pass the token along the document flow, move it past the document node (at this point you know that the current document was produced by the previous activity), and finally on to the following activity or activities.
6. If the current activity node carries an outgoing *dependency* to a learning activity, you know that this activity supports or achieves the respective learning goal. For the execution token, these dependencies can be ignored, i.e., they just provide additional information to the viewer.

Example

Figure 42 shows the activity diagram of the CAM for block 3 of the WE course. Three roles are involved (the *instructor*, the project *teams*, and the *students*) in this blended course block. The temporal constraints also show important points in time during the two weeks covered by the diagram.

Modeling Procedure

Initial attempts at the CAM can be made while ignoring secondary artifacts like documents or learning goals. As an initial step, relevant activities should be modeled at a low level of detail. Each low-detail activity can subsequently be refined in sub-diagrams to achieve a higher level of detail. During modeling it might become apparent that a diagram becomes too complex or bloated, which might require rearrangement or refinement of activities. This process can be iterated until a satisfying and consistent degree of elaboration of

the CAM is achieved. If the modeler decides to add more information, additional elements from secondary artifacts can be included. Typically, roles (swimlanes) are introduced first, followed by the document flow with activities, and finally, if desired, learning goals. Also during modeling, it might be useful to create alternative diagrams for the same course activities, representing a different point of view, a different level of detail, or just to experiment with activity arrangement or available secondary artifacts.

A concrete, effective procedure for a particular modeling/design team and task is best discovered and optimized during modeling practice.

Textual Information

A table should be provided for each activity diagram to describe each activity in more detail. Two columns (name of activity and description) should be sufficient, but additional information can be provided like scheduled start and end time of activities, role responsibility, tool support, etc.

Course Structure Model (CSM)

Semantics

The CSM provides an overview of all activity diagrams modeled in the CAM. As such it acts as a visual aid for users and modelers of a course. Viewers can use it as a guide to “browsing” the CAM.

Syntax

The CSM consists of one or more class diagrams comprising a class symbol for each activity diagram in the CAM. The class symbol carries the name of the respective diagram. There is only one specified relationship between diagrams, which is drawn as a dependency, meaning that the source diagram links to the target diagram through a sub-activity. Packages can be used to group diagrams together. See the following example.

Example

Figure 43 shows the CSM for the WE course. The main activity diagram (indicated with light-gray fill) would be the “Web Engineering” diagram. The CSM shows that this diagram links to seven sub-diagrams detailing each of the seven blocks of this course.

Modeling Procedure

The creation of the CSM follows a straightforward procedure. Start with the main activity diagram representing the whole course, and draw the symbol in the CSM with light-gray fill or pattern. For each subactivity in this diagram, draw a diagram symbol in the CSM and connect the main diagram symbol to it via a dependency. This step is repeated for the whole “tree” of sub-diagrams, sub-sub-diagrams, and so on.

If there are alternative models for certain course activities or phases, another CSM package can be created with links to these diagrams.

Textual Information

The CSM can optionally be complemented with a tabular overview giving a textual description for each diagram.

Figure 43. Course structure model (CSM) for the WE course

COUML APPLICATIONS

This section briefly presents three applications for the coUML approach: first, in its original application area for instructional designs. Second, we expose the coUML language as a means of modeling generic blended learning processes, also referred to as “blended learning patterns,” to enable the reuse of blended learning design experience. And finally, we present a more technology-oriented application for modeling and using the learner context in a course.

Instructional Design

Supporting the instructional design process is perhaps the most relevant use of coUML. As it allows integrated and incremental modeling of structural and dynamic aspects of an educational environment, it can be used in different stages of instructional design, and even when the design process is already completed. A comprehensive example for applying coUML in this respect is provided as a case study on a course on “Introduction to Instructional Design” in Chapter XVI of this handbook. Please refer to the textual case-study description and the respective coUML models provided in that chapter.

Pattern Modeling

The primary objective of the pattern approach (Alexander et al., 1977) is to capture generic scenarios in a way that makes them amenable to reuse. With coUML this can be achieved by providing models of useful and effective courses and scenarios with a higher level of abstraction. The resulting pattern of a scenario can be used as a template or model for instantiating or deriving concrete scenarios in different, but similar contexts. To support this, each pattern is provided with detailed descriptions of intent, motivation, coUML scenario model, parameters, and application examples (Derntl,

2005). Consider for instance the Web-based “Diary” pattern described and modeled in Figure 44 (note that the pattern description in the figure is not given in full detail). The scenario is modeled at a high level of abstraction, featuring only the most essential steps in using Web-based diaries in educational environments. Consequently, the scenario can be applied by adapting it to specific needs, requirements, and available technology- and Web support.

Context-Aware Scenario Modeling

In a recent project (Derntl & Hummel, 2005) coUML was extended by introducing learner context information as an additional secondary modeling artifact. Thereby a learner context model was developed to allow modeling of the learner’s personal context (e.g., name, expertise, etc.), physical context (e.g., location), digital context, and other more technology- and device-related context structures. The learner’s context

can subsequently be attached to activities modeled in the CAM. This extension was used to model a laboratory course that employed wireless devices in an RFID-tagged laboratory environment (RFID stands for Radio Frequency Identification; it allows attaching tags to objects which can be wirelessly scanned by RFID-enabled computers such as laptops or PDA’s). Based on the context-enhanced CAM models a software system was developed that was, for instance, able to display available books and papers on the current course topic if the student entered the laboratory library. This way it was possible to automatically consider and update each learner’s context (e.g., location, learning progress, learning resources, available devices, etc.) during a learning activity.

DISCUSSION

Language Features

coUML is basically an extension of UML. We consider this as an advantage as UML’s semantics are formally specified and well documented. Meanwhile UML has a tradition of being used in several fields such as Web design, business processes and workflows, organizational modeling, context modeling, and many more. For example, there are many commercial and open-source UML modeling toolkits available which could be used for modeling basic coUML diagrams. Additionally, transformation procedures for UML-based modeling (e.g., to XML) are already well-researched and tested, and can be applied to coUML models without “reinventing the wheel.”

The language-related features of coUML can be characterized as follows: coUML is pedagogically neutral; there are no modeling elements, restrictions, terms or assumptions included which would restrict the user in modeling any particular scenario. It is designed to be simple to learn and use, even for non technically-oriented people.

Figure 44. Excerpt of the Web-based “Diary” pattern

Intent: Make participants’ efforts transparent by making them keep track of their work in diaries, especially in collaborative and/or iterative learning processes.

Motivation: Keeping a diary during learning activities has some positive aspects: First, diaries help memorizing and reflecting on experiences, problems, and achievements encountered during problem-solving processes. So diaries are valuable assets to initiate self-reflective thinking. Second, diaries provide the instructor with valuable insight on working progress, activity, and thoughts of participants. Finally, in teamwork scenarios diaries allow for monitoring the (equal) distribution of activities among team members. All of the above points only hold when participants do not treat diaries as annoying appendages but take a stake in keeping their diaries. To facilitate this, it may be worthwhile to provide writing guidelines for participants (e.g., providing a set of questions and points to be considered) and to transparently disclose the intentions of making them keep diaries.

Scenario:

This has turned out to be a tough goal to achieve, as many people are reluctant to use UML, which generally seems to be considered as a tool for pure computer science use. Despite its (debatable) notational simplicity, coUML can be used for modeling processes at almost any degree of complexity and detail; it includes all necessary control-flow structures, and the composite subactivities allow structural aggregation and hierarchical composition of cooperative scenarios through links between activity diagrams. Finally, it can be used for creating new learning designs, analyzing and redesigning existing learning designs, and as a visual toolkit to documenting learning designs. Another aspect, which is presented as an application is its use as a modeling tool for blended learning patterns.

coUML's features particularly related to its artifacts (i.e., models) are:

- Visual presentation of didactical knowledge, in particular of learning strategies such as problem-based learning, inductive derivation of knowledge, deductive learning, knowledge creation, etc.
- Specification of goals, social settings, and roles of learning activities.
- Presentation of learning processes at various levels of detail and arbitrary switching between levels, if that leads to better understanding.
- Knowledge communication between educational scientists and between educators as well as communication between educational scientists and learning-technology developers.
- Supporting the specification of functional requirements on a supporting learning platform.
- Explicitly captured didactic elements such as course phases, threads, and activities can be analyzed and researched in a targeted way, considering different stakeholders' perspectives.

- Specification of the interdependence between process and content flow. This allows for the subsequent derivation of learning activity models and for example the integration of e-content modules.
- Specification, identification, and explicit integration of various means of quality assurance activities into learning scenarios to improve learning processes.
- Specification of different roles as well as modes of presence and interaction involved in cooperative environments. While this is a central feature of coUML, we add that the language is not restricted to modeling of cooperative activities. In fact, it could as well be used to model non-cooperative learning environments.

Language Classification

Using the visual instructional design language (VIDL) classification scheme introduced by Botturi, Derntl, Boot and Figl (2006), coUML's feature and application classification is presented in Table 2.

Expert Survey on Modeling Support

In order to find out whether there is a broader need among researchers and practitioners for visual modeling support in designing blended course environments, we conducted a survey during a business meeting of the "Forum New Media Austria" in November 2005, which was attended by e-learning experts (both researchers and practitioners) from diverse fields such as psychology, pedagogy, mathematics, educational technology, or computer science. During a workshop on blended-learning modeling, we distributed a questionnaire among the participants (N = 27) aiming to survey general perceptions and estimations on modeling support for blended learning. Analysis of questionnaire data indicates that researchers and practitioners are in need of

Table 2. coUML feature and application classification

Classification of features	
<i>Stratification</i>	Layered , as it allows modeling entities of different types and at different levels of detail.
<i>Formalization</i>	Semi-formal ; it inherits formal elements and semantics of UML, yet it allows the modeler to be creative in providing additional visual and textual information.
<i>Elaboration</i>	The primary intent of coUML is mostly conceptual , but it is also possible to model at the levels of specification and implementation.
<i>Perspective</i>	Multiple , as it is possible to model structural (i.e., goals, roles, and documents) and dynamic (i.e., activities) concepts from different perspectives and at different levels of abstraction.
<i>Notation system</i>	Visual , based on UML, with extensions and additional textual descriptions.
Classification of application	
<i>Communication</i>	Can be used as a reflective and communicative tool, depending on involved stakeholders' skills and preferences.
<i>Creativity</i>	Can be used for both generative (design-in-progress) and finalist (documentation) purposes. However, Its origin lies in finalist use.

a visual modeling language to support them in their efforts. While the survey was not specifically focused on coUML, the following general results seem noteworthy:

1. The use of visual modeling techniques (e.g., sketches of processes, overview diagrams) in supporting the design or reorganization of a blended learning course is considered highly useful; $M = 6.88$, $SD = 1.51$, on a scale ranging from 1 ("not at all") to 8 ("very much").
2. More than two-thirds of the participants were aware of existing visual modeling techniques and almost as many are using them in their daily practice: 40% use informal modeling notations like sketches or block diagrams; another 22% use "real" modeling languages like UML or IMS Learning Design (IMS Global, 2003).
3. It is sometimes argued that strict and more formal visual notations are interesting and useful for computer-science people only. The participants unanimously voted against this proposition, even though they admitted that more formalized languages are often difficult to understand and use.

4. We were also interested in the experts' estimate of the use of visual modeling languages for instructional design. A number of relevant use cases were provided in the questionnaire, and participants' responses are highly supportive for coUML's focus: According to the experts, the top-three uses of visual modeling for learning design are "communication among involved actors" (24.7%), "explanation of the design" (18.2%), and "reduction of complexity in the design process" (15.4%). The full distribution of responses to this question is given in the histogram in Figure 45.

Even though the questionnaire was not directly related to coUML, the results show that there is considerable attention towards, and appreciation of, visual instructional design languages. Practitioners seem prepared and willing to use these languages and they are aware of potential support provided by these languages, e.g., for communication among involved actors, for explicating, sharing, and documenting learning designs, or for reducing the complexity in the design process. We hope that the current chapter does convey that these factors were also considered highly relevant in the development of coUML.

Figure 45. Experts' estimate of relevant uses of visual modeling languages for learning design

CONCLUSION

coUML is a simple, powerful visual modeling language for modeling instructional designs. Its notational power unfolds best in a blended course environment, when different modes of presence are aligned to achieve instructional objectives. It is based on UML, which is a standardized modeling language; we used UML's built-in extension mechanisms to define required modeling elements in addition to its basic set of structural and dynamic elements.

ID is an exceptionally diverse and complex discipline, making it an appropriate application area for visual modeling support. In this respect, the primary intended ID application for coUML is modeling of structural and dynamic aspects of blended course designs. We presented results of a small study among blended learning experts, which substantiates our presumption that blended learning designers and instructors are in need of a visual, conceptual toolkit to help them effectively create, analyze, and communicate their designs. We have experienced that the diagrammatic notation can help in sharing the learning design with colleagues and in organizing and researching courses. Also, the choice of proper

abstractions, names, and the provision of multiple grain sizes have proved essential in communicating cooperative designs in general and in contributing to technology-enhanced learning elements in particular.

Future work on coUML will proceed in several major directions. First, we want to extend our efforts of modeling external courses from more subject domains and "teaching cultures" and include these in our pattern knowledge base (see <http://elearn.pri.univie.ac.at/patterns>). In this respect, readers are invited to provide feedback and share their own course designs and experiences. Second, we are working on an easy-to-use modeling tool for coUML users, easing the modeling process with computer tool support. Third, we plan to evaluate the use of the language for different cooperative processes outside of the instructional domain, such as professional community building, interdisciplinary curriculum development, and project management. Last but not least, through this chapter we want to promote the use of coUML among researchers and practitioners for feedback and further improvement.

ABSTRACT

In this chapter, we describe the process of modeling different theory-, research-, and best-practice-based learning designs into IMS-LD, a standardized modeling language. We reflect on the conceptual and practical difficulties that arise when modeling with IMS-LD, especially the question of granularity and the necessary and sufficient elements of learning design. We propose a four-layer model both to ensure the quality of the modeling process and as a necessary step towards a 'holistic' consideration and integration of the design process. These discussions speak

to the core of IMS-LD integration, address the question of usability and end-user friendliness, and urge that more research and design needs to be conducted not only to mainstream (a) the use of IMS-LD and related visual instructional design languages, but also (b) the debate on appropriate and best instructional design practices.

INTRODUCTION

Instructional design is essential for every teaching, training, or instructing position. Where other design fields, like architecture, industrial design, and engineering, have very precise languages to communicate and share design specifications

DOI: 10.4018/978-1-60960-503-2.ch316

within their respective communities, the field of education does not possess such languages (Gibbons & Brewer, 2005). In the field of education, forms of sharing innovations include lesson plans and learning objects, products which implicitly embed design considerations, but do not explicitly address them. Crucial information on the context, the embedded instructional strategies, the theoretical foundations of the design, and the reflections of the teachers or designers are either not explicitly captured as in the case of learning objects, or are not accessible through a general standardized language as in the case of lesson plans.

In the last couple of years, the field of education saw several attempts to fill this gap by developing specific metalanguages or visual instructional design languages (VIDLs; see Botturi, 2005 for an overview). IMS-LD, an extension of the educational modeling language (EML) specification, is a prominent representative of VIDL. IMS-LD was developed to allow lesson plans and best practices to be structured using a common language based on a formal representation, to exist within an XML schema, and to be archived in a machine readable and searchable repository.

As powerful as the design language is, instructional designers, instructors, or teachers are still left with a variety of design decisions, which are not captured by the design language. For example: Which design is the most appropriate for a specific learning outcome? How much detail should be included in the design specification? Which elements are flexible or need to be modified by the context of the implementation? What context information does the design have to include to provide meaningful and sufficient information to subsequent designers, instructors, and so on? In view of these concerns, there are two purposes of this chapter:

- To provide a critical analysis of different design decisions that are pertinent for the use and implementation of IMS-LD, in-

cluding: (a) the questions of boundaries, granularity, and details of the design; (b) the modularity and reusability of smaller learning objects within larger learning objects; (c) sufficient and necessary conditions of a successful reuse of a learning design; (d) the usefulness of detail in the design and reuse of learning designs; and (e) particulars of mapping of activities through IMS-LD.

- To provide a four-layer evaluation model for determining the quality of IMS-LD design. These four layers are: (1) syntax and grammar; (2) best design approaches to model a certain activity; (3) how accurate is the model representing what the learning design was; and (4) how well the models match sound theories or evidence-based research. These two purposes aim to reflect on the usefulness of IMS-LD as a communicative device to share and communicate learning design issues, including the variety of different ways to design the same instructional activity.

This chapter describes the experience developed over a year-long project in which best practice, theory-based, and evidence-based learning designs were formally described with IMS-LD. The presented arguments will be illustrated with a variety of designs, modeled from theories and activities, including behaviorist, cognitivist, and constructivist models, problem-based learning, and lesson plans from the area of K–12 education.

BACKGROUND

IMS LD

The purpose of educational modeling languages (EMLs) and the IMS Learning Design (IMS-LD) specification is to support the crafting of diverse

learning experiences, embodying different kinds of activities and in different contexts. IMS-LD is a metalanguage that focuses on the settings (e.g., courses, course components, programs of study, etc.), associations of settings with content (e.g., multimedia, task descriptions, tests, assignments, etc.), and instructional and pedagogical strategies (e.g., roles, relations, interactions, and activities of students and teachers, etc.). In comparison to pure learning object frameworks, which focus entirely on content, in IMS-LD, activities and roles of students and teachers are directly specified.

The IMS Learning Design is a language that gives bindings in XML to specify learning content and processes. IMS-LD was developed to promote technical specifications for learning technology (IMS Global, 2003). Historically, the basis of IMS-LD is educational modeling language (EML; Tattersall & Koper, 2003), which was developed by the Open University of the Netherlands. Compared to other languages, like “PCeL patterns,” for example (Derntl, 2005), it is independent of any specific pedagogy, and its main focus is to support any kind of instructional design. IMS-LD models who does what, when and which materials or learning services are used to achieve learning objectives. Elements like resources, instructions for learning activities, templates for interactions, and pedagogical models like problem-based learning, learning goals and outcomes, as well as assessment tools are included (IMS Global, 2004). The specification gives a binding in XML, resulting in an XML manifest for each learning process. This XML manifest can then be interpreted by an IMS-LD compliant application.

IMS-LD consists of three parts: Level A, B, and C. There are different XML schemas provided for each level, and each level extends the previous one. Level A is concerned with the basics. At level A, time ordered activities, which are performed by teachers and learners (roles), are specified within an environment of learning objects and services (IMS Global, 2003). At level B, there are also

properties (additional information about persons or roles) and conditions. Notifications, which are added at level C, can trigger new activities, for example, noting whether a teacher has student questions to answer. In order to complete these levels, the best practice guide (IMS Global, 2003) recommends using a narrative description in order to initiate the analysis of an instructional scenario. In the next step, semiformal UML (unified modeling language) diagrams are drawn. Based on the UML activity diagram, the XML document instance is created.

IMS-LD stands as a prototype for the “shift in the e-learning focus from content to process—or activity” (de Filho Moura & Derycke, 2005, p. 2). As de Filho Moura and Derycke (2005) further argue, content issues, the primary focus of learning objects, have distracted and polarized the e-learning community from other important issues and so with IMS-LD, the field could begin turning its attention not only to what to learn but also how to learn.

Since IMS-LD claims to be pedagogically neutral (for a discussion, see Nodenot, 2006), meaning it does not enforce a particular instructional strategy or model (such as problem-based learning, drill and practice, guided, or inquiry), the decisions of design are left to the instructor or instructional designer. Because different instructional models consist of varying assumptions of what: (a) the teachers’ role is; (b) the learners’ role is; (c) activities students are engaging in; (d) which support structures and activities that need to be in place; and (e) sequence or path the students are following or choosing (see an overview by Reigeluth, 1999), there can be no template or even similar design structures when modeling different interactions. For example, since group work in an inquiry based project is different from group work in a guided Web quest, it becomes additionally important how granular the models are and how different interaction patterns can be best represented in IMS-LD.

Main Focus

In the next sections, we describe a year-long project in which we formally described best-practice, theory-based, and evidence-based learning scenarios using IMS-LD. The best-practice and evidence-based scenarios are derived from real lesson plans available at the Web site of LEARN Recit (a service agency for English school boards in the province of Quebec). The Web address is <http://www.learnquebec.ca>. The IMS-LD models are available at Paloma (<http://helios.liceftelugu.quebec.ca:8080/PalomaWebGlobe/>), a learning object repository maintained by Télé-université, Québec. We reflect our modeling process, including our selection process and different learning scenarios, which we modeled with IMS-LD.

We worked with MOT Plus™ (Paquette, Léonard, Lundgren-Cayrol, Mihaila, & Gareau, 2006), an IMS-LD software editor (Level A currently implemented) that allows a visual modeling of learning design and an automatic translation from graphical designs into machine-readable IMS-LD XML files. All of the visual representa-

tions of the models presented in this chapter were created using MOT Plus™. We particularly chose a graphical interface for our learning designs to make our argument more accessible to end users like teachers and instructional designers. We felt the raw XML binding is harder to communicate to novices of IMS-LD than a visual representation.

Context of the Models

The project team decided to work with two different type of scenarios: (1) theory- and evidence-based instructional models and (b) best-practice cases. The theory- and evidence-based models included a behaviorist, a cognitivist, and a constructivist based model. These models were “translations” of theoretical literature and research studies into IMS-LD models. For an overview and a short description of the different models, see Table 1.

The best-practice cases were selected from a publicly available Web site maintained by RECIT/Learn, a nonprofit educational foundation supported by funding from the Québec-Canada Entente for Minority Language Education. RECIT/Learn

Table 1.

Title	Type of model	Pedagogical type	Model describes	Environment structure	Comments
Figure 1: Model of Fieldtrip	Best practice	Inquiry-based learning	Communication process/Collaborative learning	Two or more matched distance separated classes	Define simultaneous interaction
Figure 2: Snapshot of selected area in IMS-Model of constructivist learning	Theory-based	Constructivism	Generic structure for teaching within a constructivist design and teaching paradigm	Nonlinear/flexible	Difficult to model flexibility of choices and sequences
Figure 3: Model of behaviorist teaching	Theory-based	Behaviorism	Generic structure for teaching within a behaviorist design and teaching paradigm	Linear/sequential	Difficult to determine level of detail required for model
Figure 4: Snapshot of model on cognitivist teaching	Theory-based	Cognitivism	Generic structure for teaching within a cognitivist design and teaching paradigm	Linear/sequential	Difficult to operationalize the different steps without a particular context: deeper or broader?
Figure 5: Model of “True Story” learning activity	Best practice	Cross curricular: Language Arts, Math, Art	Collaboration: Brainstorming, problem solving	Linear/sequential	Struggled with questions of granularity

supports and promotes pedagogical collaboration and innovation with information technology and modeling of best practices, primarily by providing teacher professional development in technology integration into the new learner-centered Quebec curriculum. The cases on the Web site were annotated with links to resources, contributed by teachers in the Quebec English Schools Network. Some of the cases included design considerations and reflections by the teachers. As displayed in

Table 2, we designed a rubric to select existing lesson plans for inclusion in our project. The rubric contains criteria which were aimed to: (a) assess the quality of the instructional model and (b) provide quantity and quality indices of the description of the activities, roles, content, and so forth. The rubric served two purposes: (a) to select sound models of instructional design and (b) to ensure that enough high quality information is accessible to transfer the model into IMS-LD.

Table 2. Rubric to select best-practice models

Category	0	1	2	3
Theory/Design	Cannot determine pedagogical theory or instructional design.	Material relies on an unstructured combination or not fully realized collection of theories and design principles.	Material relies on a structured or defined theory or set of ID rules. Could be more complete.	Theory and/or design is easily identified. Modifications are explained.
Qualitative Components	Example contains material that is incomplete – offers little to no detail.	Example contains material that has vague or sketchy details.	Example contains complete material but is lacking information related to teacher and/or student guidelines.	Example contains complete material that offers detail as well as information related to teacher and student guidelines.
Quantitative Components	Example contains too few components to work with.	Example contains some elements but has holes in some areas.	Example contains material in all areas but lacks reference to some resources.	Example contains enough material to create a complete model as well as links to available resources.
Criteria for Assessment	Example contains no criteria for assessment.	Assessment criteria are vague.	Assessment criteria is complete but is missing some information.	Assessment criteria is clear and easy to work with.
Learning Objectives and/or Learning Outcomes	Learning objectives or outcomes are not stated.	Learning objectives and outcomes are poorly stated. Vague. Do not follow theory or ID.	Learning objectives and outcomes follow theory and design but could be more complete.	Learning objectives or outcomes are complete and closely follow identifiable learning theory and/or instructional design models.
Classroom Student–Teacher Interactions	Not applicable or not discussed.	Only vague or very brief guidelines.	Guidelines for interaction are included but could be more complete or more realistic.	Comprehensive and realistic guidelines for interaction are included
Preparation/Pre-Activity Instructional Design	Not discussed. No preparatory ID appears needed or possible, or else discussion of ID includes fundamental misunderstandings of the process or fallacies.	Vague or insufficiently detailed discussion of preparation needed. Some evidence that preparatory ID is needed, but discussion is vague or lacking in detail.	Discussion of preparation and preparatory ID is included but could be more complete.	Discussion of preparation and preparatory ID is complete. Discussion of preparatory ID reflects mastery of ID principles and process.

We utilized this rubric to translate existing learning designs, such as lesson plans, so they could be visualized and shared in different “languages” and modeled with IMS-LD. This rubric can be similarly employed to evaluate the quality of existing IMS-LD models and learning objects. For all the models we created, one person on the team assumed primary responsibility. However, project meetings were utilized to co-model and discuss components of the models.

In the next section, we discuss the individual learning designs, the models (which will be at least partially depicted in graphical format), issues that arose from the modeling, and a preliminary reflection. After we describe our process through a set of models, we will synthesize the reflections by connecting them to literature on IMS-LD modeling and instructional design.

MODEL 1: CONNECTING A VIRTUAL FIELD TRIP WITH OTHER CLASSES

The Context

This model describes the design of a collaborative virtual experience, which also includes an actual field trip. A class that takes the field trip invites other classes, which cannot make the field trip, to join them virtually. Participating classes can send questions, hints, and already researched topics to the field trip class in order to uncover more information. The classes are in secondary education, and the model describes the communication process and the collaborative work used in answering questions.

The Process

This model is a best-practices model, meaning we modeled an existing course activity. The main selection criteria for the activity were the uniqueness of the lesson design, the utilization of a sound, theory-based pedagogical model,

and the availability of accompanying material. For this model, we started building the smallest units first, such as how classes were matched, how questions were answered, which content was available at which stage of the activity, and so forth. After fine-tuning these individual aspects, we designed the overall structure and then modeled the relationships between the different elements. The smaller units or nuggets (Bailey, Zalfan, Davis, Fill, & Conole, 2006) were modeled as autonomous and closed units to ensure that they made sense by themselves and to avoid later reusability concerns. See Figure 1.

Reflection

By modeling this activity, we faced many challenges. The first challenge was to define a unit or nugget in a way that was consistent and had boundaries that were set. In this course, the different activities were intertwined, could be employed nonsequentially, but had a fixed timeline (sequence). In many of the activities, several groups were supposed to be doing the same activity in parallel, and afterwards, they were to forward their results to the other groups. The challenge here was to define these interactions being precise regarding who is sending and who is receiving information. An additional challenge pertained to the distinction between necessary and sufficient information. For example, students were communicating the results back to the other classes via e-mail. For this design to work and for other designers to reuse the design, the decision to use e-mail is not a necessary one. The same communication could have been achieved via video-conferencing, chatting, or producing a Web site. Nevertheless, the concrete activity (e-mail) requires a different model than the use of a discussion board or the creation of a Web site. Therefore, questions remain concerning: (a) how to model the variety of activities or media that could be used; (b) modeling the particulars of the design; and (c) communicating the difference between necessary

Figure 1. Model of field-trip learning activity (based on <http://www.qesnrecit.qc.ca/cc/partners/indexen.htm>)

and optional aspects of the design. By modeling just one activity (e-mail), we felt the design was not as reusable as it could have been. Additionally, the differentiation between two different classes of smaller units seemed important either (a) nuggets, which described a particularly defined activity, or (b) nuggets that served to connect other nuggets to form a larger unit. While the first class is easier to reuse, the second class is much more contextual to the model at hand and harder to reuse.

MODEL 2: CONSTRUCTIVIST TEACHING MODEL

The Context

This theory-based model provides a generic structure for teaching within a constructivist design and teaching paradigm. The constructivist paradigm is characterized by nonlinear content interaction, complex and ill-structured prob-

lems, nonsequential pathways, and a variety of situation and context-sensitive support structures, like scaffolding, modeling, and coaching (for an overview, see Jonassen & Land, 2000). The constructivist paradigm cannot serve as a concrete design application of how to structure, for example, a discussion group around a particular class context. However, the constructivist-based design can provide a design template for building nonsequential, open-ended learning activities within the formalized IMS-LD model. Because it has a clear theory base, the model is more aptly described as a metamodel abstracting concepts from the many different design and teaching situations that were used to inform theory building.

The Process

Because constructivism entails many different forms, our discourse was dominated by how its principles can be operationalized in a design model. Since we worked without the context

of a particular instructional intervention, the components of the design stayed at an abstract level. We struggled with certain components of the process more than with others. For example, in many constructivist design models, not many fixed sequences exist and many student activities are iterative. This learner flexibility means there is a great deal of free choice regarding resource and activity selections, which are repeated with different content or different guiding questions. Our challenge was to design activities and acts that were coherent within the design, which represented the flexibility of the activities and the adaptability of the resources and were not restricted by the design model as to when the activities had to be completed. Additionally, many microlevel elements were hard to incorporate due to the flexible nature of the theoretical underpinnings. Since many decisions within a constructivist learning situation are made by students in cooperation with each other and with the teacher, many conditional aspects needed to be modeled, and many alternative ways of achieving the same learning outcomes needed to be included. See Figure 2.

Reflection

The design of this model raised different questions and provided many challenges for the design team. The main challenge was whether one model would suffice for constructivism, not just because constructivism is an abstract model, but also be-

cause the models can have so many variations. The pedagogical strategies and philosophical assumptions of the paradigm we modeled greatly influenced our approach to modeling. General questions arose, especially concerning how different prototypes of the same model looked when created by different people. We realized different ways of modeling and found that the appearance of any one model was dependent on the personal preferences of the designer and his/her style of modeling. After determining that these idiosyncratic, abstract models of constructivism were syntactically correct with respect to the underlying coding language and were compliant with IMS-LD, questions arose concerning the best way to model a specific constructivist learning activity. Each one of us developed a unique style of modeling resulting in multiple ways of modeling a particular component, each of which was still compliant with IMS-LD. Modeling of learning scenarios was not a standardized activity with a single, clearly described model. It was a process that depended more on the expertise of the modeler, the anticipated level of expertise of the audience, and the preferred styles of visual arrangement, which were used to highlight key instructional elements. These constraints and conditions, however, did not find their way into the models or into IMS-LD itself. In short, by struggling with the design of a constructivist model, we were in need of an annotation language to clarify our IMS-LD models, which we were not

Figure 2. Snapshot of selected area in IMS-Model of constructivist learning

able to do within the model itself. Additionally, we found the need for “best-practice” models on how to model in IMS-LD.

MODEL 3: BEHAVIORIST TEACHING MODEL

The Context

This is a theory-based model, which provides a generic structure for teaching within a behaviorist teaching paradigm. Though it cannot serve as a template for structuring communication pattern in courses, it can provide a design template for aligning smaller aspects of course design within an overall structure. The model is a metamodel abstracting from the many different design and teaching situations that can be classified as behaviorist.

The Process

In this template, it was important for us to connect the classroom activities of the instructor with those of the students along with the preparation of the instructor. In dealing with instructor preparation, the model needed to also explicate what follows in the class. To do so, we spent some time exploring different components in the 2/3D dimensional space of MOT+. The feedback structure of behaviorism made it difficult to place every component in a way that was visually easy to follow. Although not as important as the design aspects, the visual aspects of arrangement, color-coding, and so forth are challenging ones for novice model builders.

The overall structure of the design was determined by the theoretical underpinnings; nevertheless, the modeling process raised additional questions especially with regard to the sequence in which the model had to be expanded. In our experience, determining the level of detail in the model was always a struggle. How much detail should the design contain? In best practice cases,

the availability of material or insights into the design process was often the determining factor, even when we wanted to go into greater depth. In theory-based cases, the material and approaches were endless, and it was so much more difficult to set the boundaries. See Figure 3.

Reflection

The model was a great device for us to develop a better understanding of behaviorist forms of instruction. By engaging in the process, the discussion became focused on the model itself. A big challenge was the syntax and the design process itself. We found ourselves agreeing on the design sooner than on its visual representation and on its compliance with IMS-LD. For the design exercise, the many different ways of representing one element led us to question the validity and utility of a best practices approach to IMS-LD design.

MODEL 4: COGNITIVIST TEACHING MODEL

The Context

This is a theory-based model, and we had to make deliberate choices regarding which body of literature to rely on and operationalize. Though it cannot serve to illustrate the design of communication pattern in courses, the cognitivist approach can provide an IMS-LD design template for aligning smaller aspects of design with overall course structure. The model itself is a metamodel, which abstracts the many different design and teaching situations that can be classified as cognitivist.

The Process

The development of the cognitive model proved challenging. Like the other theory-based approaches, in a cognitivist model, it is hard to operationalize the different steps without having

Figure 4. Snapshot of model on cognitivist teaching

evaluation tasks in which they had to compare one story account with another. Beyond that particular context, the model can be utilized as a template to build cross-curricula instruction and allow the integration of math-, language-, and technology-rich class activities.

The Process

This model took a best-practices approach by modeling an existing lesson. We developed the model following the systematic description that the instructor outlined in the lesson plan. Similar to most of our modeling, we ran into the problem of representing depth and breadth of instruction. Additionally, since we modeled a rather large sec-

Figure 5. Model of “true story” learning activity

tion of a class activity, we questioned the value of modeling this large section and not just little nuggets. Other ones could replace most all of the activities that we built. For example, the discussion of the book could have been done in a multitude of ways. Furthermore, by not directly specifying the discussion process, the instructor left a considerable amount of detail out of the lesson plan. This detail will need to be determined by the individual instructor who reuses the model. The value of the particular structure lays more in the entirety of the plan. The challenge for us was how to model the activities as independently from each other as possible so other usable nuggets could easily replace the existing ones. A particular difficulty of modeling in this “object-oriented” way is that transitional aspects of the model (like leading from one activity to the other) become secondary or redundant.

For our own modeling purposes, we yet have to come up with a way of consistently and systematically distinguishing between core elements of the design and redundant, exchangeable, or even negligible elements within the model. In other words, what are the necessary and what are the sufficient elements and attributes of certain designs? Another example might highlight this difficulty. A set of students (A) is using a discussion board to communicate the results of a research study to another set of students (B) who can ask questions or make requests for additional research in return. While group A utilized a discussion board, they could have used other forms of two-way communication (blogs, e-mails, video-conferencing, etc.). Each form of communication would require different training, calls for different exchange patterns, requires different preparation time between communication periods, and so forth. For the overall design of the course, it is important to model that students engage in two-way communication, but how important is it to model the specific way of communicating and the specific activities associated with the means of communicating? Another teacher trying to adapt the learning design is left

to decide which of the elements are pedagogically crucial, exchangeable, or even negligible for his/her own teaching. To identify the adaptability or redundancy of certain design elements, either pedagogical and instructional knowledge of the design is necessary or the original instructional designer should somehow embed appropriate alternatives.

Reflection

As mentioned earlier, the modeling process is a valuable communicative device to plan and discuss learning design. Additionally, the modeling process becomes a reflective device. Through the modeling of approximately 15 designs, we found ourselves questioning instructional decisions in lesson planning. Unfortunately, it is not very visible within the process how the design grew before we modeled it. Additionally, since most instructors build and adapt their teaching from session to session, we do not see in the modeling process the different alterations and changes the instructor utilized. In that sense, the model has no history or is incapable of keeping history.

SYNTHESIS AND DISCUSSION

We described our process of modeling specific theory and best-practices learning activities. In the following section, we will synthesize issues arising from the modeling experience and discuss and situate them within the larger body of literature on learning design and instructional design.

Granularity

By breaking down and assembling structures and complex performances of instruction, the question emerges as to what constitutes an “atomic” chunk or part. In other words, what is the smallest meaningful unit of modeling and what should the degree of granularity be? The definition of granularity

has implications not only for the boundaries of a model but for the reuse of model components in different designs.

The topic of granularity is not new to the field of instructional design and appears frequently in the learning design and the learning objects literature. Many instructional design guidelines argue for breaking down complex structures into smaller sizes, for example, as argued by learning taxonomy proponents (e.g., Bloom, 1956) and as illustrated in instructional design models (see Reigeluth's 1999 elaboration theory as an example). Traditional conceptualizations of granularity are delivery-centric or as Wiley, Gibbons, and Recker (2000) call it, "media centric." In a delivery-centric view, pieces of the design are well-defined by the hierarchies of a course, the course being the largest grain size and a text element in a course description being the smallest "atomic" element. IMS-LD distinguishes between the smallest elements, combined small elements (which become level 1), and combined level 1 elements (which become level 2).

There appears to be a move away from the conceptualization of granularity as mainly an issue of the size of a learning object to a more "holistic" view in which more factors of the instructional design process are considered. "In determining the robust granularity of a learning object, one might ask, 'what elements of the model, message, instructional strategy, representation, and media-logic layers are compressed within this learning object?' The larger the count, the larger the grain size of the learning object" (Wiley et al., 2000, p. 5).

The move to a "robust" or "holistic" approach to granularity would address several issues: (a) It could provide an alternative picture to the simplistic view of teaching as delivery of disaggregated learning objects assembled in a well-defined preconceived combination (the course structure; see Russell, 2003 for a further argument). (b) It could highlight the very complexity of the instructional design process embedded in

the learning object and so preserve some of the context which learning objects were criticized for leaving behind (see Jonassen & Churchill, 2004 for a detailed criticism).

This move to a more "holistic" approach means that granular or smaller objects of design are similarly complex as larger pieces, so by breaking down complex learning design, we will not facilitate a more manageable task of "divide and conquer" but create rather hydra's head, the beast in Greek mythology which grows two heads for everyone cut off. Implications of this "hydra head" model are numerous: (a) the size of a learning object does not communicate something about the simplicity of complexity of the learning object, (b) there are no simple learning objects, and (c) the larger context or the relationship with other learning objects become more important in order to create or reuse the learning object.

Boundaries/Details

In many of our models, we encountered the problem of specifying the boundaries of a particular learning activity (i.e., how to integrate prior or subsequent learning activities which are linked to the activity at hand). Similarly, issues of external boundaries arose when we debated whether to include the teacher's or instructional designer's activities within our model of a learning activity. This question becomes particularly important considering that most models are not blindly reused but are carefully selected and adapted by other instructional designers or teachers, so additional information on the design process might be useful and provide more context.

In addition to external boundaries (whether and how to include events and material outside the learning activity per se into the design model), internal boundaries of the design have also to be considered. The question of "how much detail should the model include?" sets the direction of the internal boundary of the design model. The structure of IMS-LD with its stage metaphor, in-

cluding activities and acts, might be perceived as already determining the question, however IMS-LD does not provide an answer about the depth of detail. For example, is it sufficient to describe that students are supposed to work in teams or do details on the structure of the teamwork need to be included?

Sufficient and Necessary Conditions/Possibilities

A related question to the issue of boundaries is the determination between necessary and sufficient information. As seen earlier in the model of the field trip (see Model 1), the design asked students to communicate their field-trip results back to other classes. In this particular instance, students used e-mail as the communication medium. However, the design could have asked the students to communicate via a discussion board, video-conference, or by creating their own Web site. All of these interventions fulfill the goal of this aspect of the activity—to communicate results. When breaking down the activities into smaller, detailed acts and processes, all of these different interventions require different kinds of material, training for students, teacher roles, and actions by students. We argue that the goal to communicate is a necessary condition to be modeled, meaning it cannot be missed, but the modeled activity of e-mailing is only a sufficient condition, meaning it can be replaced with other activities, which fulfill the same goal. To illustrate the distinction, consider the following: If somebody is trying to reuse the learning design in another context, the goal needs to be shared (to communicate), but the designer should also be able to integrate other technologies, activities, and associated actions to fulfill this goal. In IMS-LD, no space is provided to communicate sufficient uses or necessary conditions. This does not allow designers to share crucial design decisions. By just modeling one activity (i.e., e-mail), the design would not be as

reusable, especially when certain technologies do not exist.

Ultimately, this could mean that the learning design of an activity would need to draw from a large bank of substitute components, which could replace the actual modeled structure when constraints of a new design require that. Additional metadata on the necessity of the components and an alert on which crucial parts of the design need to be expanded are necessary. If in our example, e-mail communication was exchanged with the creation of students' own Web sites, training for the Web site creation might be a necessary addition when designing the activity.

Furthermore, an additional distinction can be drawn between two classes of design components. There are activity and material components, which describe which activities students are engaged in and which material is utilized. The design model contains also bridge components, elements that are necessary to connect activities with other activities or with necessary resources. In the learning design, bridge components are secondary, because they do not carry many instructions, but rather provide segues between the core designs. IMS-LD does not distinguish between bridge and core components.

Usability and User-Friendliness of IMS-LD

Our experience in the role of end users with IMS-LD through a visual editor confirmed previous systematic usability testing of formal standardized languages to capture learning designs. As van Rosmalen, Vogten, Van Es, Passier, Poelmans, and Koper (2006) describe, the weaknesses of IMS-LD are that the required knowledge of IMS-LD and the complexity of the IMS-LD specific concepts assumes a great deal of knowledge and the editor itself requires considerable training. Finally, the interface is based on a technological view of learning design rather than an educational view (see van Rosmalen et al., 2006, p. 8 for a

detailed description). We experienced very similar issues with the usability and user-friendly aspects of IMS-LD.

The usability of both IMS-LD and the graphical tool cannot be reduced to the techniques, technologies, and processes of modeling, however important they are. There are other large questions of usability in this context. How does IMS-LD connect with the practice and experience of end users? Is the language mature enough to become an every-day tool in the hands of instructors and instructional designers? What other barriers exist before IMS-LD is integrated into every-day practice. These questions go beyond the typical usability questions such as are concepts well-explained, buttons well-placed, and processes well-described. Throughout the work on our particular project, these larger usability questions moved from the background to the foreground. IMS-LD and its graphical editors in their current stage are not sufficient to support IMS-LD becoming mainstream and becoming usable for instructors or instructional designers. Much literature and debate on learning design are still too technical for the layperson to understand and are lacking a connection to the every-day practices of designers and instructors.

FOUR-LAYER MODEL OF DESIGN

Apparent throughout the modeling exercise and the issues addressed in our synthesis, the pedagogical neutrality of IMS-LD adds a layer of complexity and leaves questions which need to be adequately addressed. Of particular importance is the question of the quality of the learning design as modeled by IMS-LD. In this last part of this chapter, we argue for a four-layered model of quality assurance when utilizing IMS-LD. This four-layer model includes pedagogical and instructional criteria not addressed by IMS-LD, but essential for the quality of the learning objects and designs it produces. As can be seen in Figure 6, the four

layers are (1) syntax and grammar, (2) best design approaches, (3) accuracy of the models, and (4) implementation and compliance.

Syntax and Grammar

In the syntax and grammar level, the focus lays on the correct use of the IMS-LD specification to appropriately design the unit and ensure compliance in the exchange process. This includes the correct labeling of relationships between individual components (sequential, free choice), the proper breakdown of the initial unit of learning into activities, actions, roles, and the associated materials and settings (tools and content of the instructional unit). Additional value is placed on the appearance of a structured sequence that maps the learning activity and the sufficient support through proper tools and content resources. Quality in this level is measured by the compliance to the XML structure and whether the design produces well-formed XML. Through its orientation on XML compliance, this level is very technically oriented and does not address pedagogical or instructional quality issues. Most papers, which address the quality of IMS-LD, address this particular level (see for an example Berlanga & Garcia, 2005).

Best Approaches to Model a Certain Activity

Compliance with the IMS-LD data structure (as measured in layer 1) does not guarantee the most appropriate breakdown of the unit of learning into components that make stronger sense than others. Since everybody in our team was modeling components and even the same unit of learning, the question emerged: What determines the better model? Not only could the same activities be modeled differently, some models use more extensively bridge components or nested activity structures, in which activities are embedded in other activities. Some modeling solutions of the same activity in our visual editor became easier to communicate

Figure 6. Four layers of quality in modeling learning context with IMS-LD

or were more elegant or minimalist in their approach. From this level forward, the IMS-LD model should become a communicative device that facilitates the process of clarification between different instructional designers or teachers.

Accuracy of the Model

Going beyond the compliance with IMS-LD standard specifications (layer 1) and the question of the most appropriate way of representing the same learning design (layer 2), the design has to be verified against the initial description of the activities, the interaction of learners, and the lesson plan. The actions of learners and teachers, the interaction between activities and roles, and the material and resources of the model have to be checked to determine whether they are a true representation of what was happening in a classroom or if the model matches the narrative plans for a particular learning unit. At this level,

elements in the learning design are in the spotlight either for being vaguely planned or lacking in information on how they were implemented. Any ambiguities in the process of validation raise additional questions of whether the language is precise enough or whether the process of design needs to be more detailed.

Implementation and Compliance

Since IMS-LD is pedagogically neutral, there is no place to discuss the appropriateness of certain design choices to the learning process within the IMS-LD model. For sharing instructional design and learning design models to guide reuse and inform practice, information on the design rationale in light of appropriate learning theories and models requires sufficient space. This can be captured by either including aspects of the design process in the learning design model itself (i.e., a teacher planning activity component) or by

supplementing the design with links to theoretical or evidence-based research literature.

FUTURE TRENDS

Our proposed four-layered model integrates IMS-LD within the larger context of instructional design and introduces pedagogically sound design back into a standard, which was designed and proclaimed to be pedagogically neutral. Many questions we raised concerning the complexity of instructional design and the intersection with IMS-LD would suggest that IMS-LD's claim of pedagogical neutrality is difficult to uphold. Inevitably, when designing models in IMS-LD, pedagogies find their form, but do not yet find a space to be labeled or reflected upon. While IMS-LD does support different models of instructional design, the process of evaluation and sound learning design is not equally supported in the design of units of learning. While IMS-LD as a technical standard to model learning activities might be mature, the tools available and the standardized language are far from being usable at an end-user level, especially for teachers. More research is necessary to investigate designers' use of IMS-LD and different training strategies to further support IMS-LD becoming a mainstream application.

CONCLUSION

In this chapter, we described the process of modeling different theoretical and best-practices learning designs into IMS-LD, a standardized modeling language. We reflected on the conceptual and practical difficulties that arise when modeling with IMS-LD, especially the question of granularity and necessary and sufficient elements of design. We proposed a four-layer model to ensure the quality of the modeling process and as a necessary step towards a "holistic" consideration and integration of the design process. Finally, we raised the question of usability and end-user friendliness of the IMS-LD specification

and urge that more research and design needs to be conducted not only to (a) mainstream the use of IMS-LD and related visual instructional design languages, but also (b) to mainstream the debate on appropriate and best instructional design practices.

ACKNOWLEDGMENT

This project was funded by Industry Canada through a contract with Cogigraph Inc. The Concordia team thanks Karin Lundgren-Cayrol, Olga Marino, Gilbert Paquette, and Michel Léonard from TÉLUQ—L'université à distance de l'UQÀM, Montreal. Thank you to Marie-Claude Lavoie for her contribution to the models.

KEY TERMS AND DEFINITIONS

Boundaries of Design: Refers to the scope of the design model and which borders are drawn.

Granularity: Refers to the definition of size of a learning object. There is a distinction between delivery-centric and holistic granularity. Delivery-centric granularity is structurally oriented on a course (activities, assessment). Holistic granularity is focused on the embedded instructional design in every object and not just in the role the object plays within a course structure.

IMS-LD: An XML-based language for specifying learning content and processes.

learning design: The entirety of design that is invested to create a learning environment, including material design, media design, instructional design, and activity and assessment design.

Nugget: Refers to small stand-alone learning objects, which can be combined with others to build larger units.

Syntax of Design: In this chapter, the syntax of the design refers to IMS-LD specifications as implemented in the XML structure. Compliance with the XML specifications is one step of the proposed four-layer model.

Visual Instructional Design Languages (VIDLs): Visual languages or notation systems

that let instructional designers represent their instructional design visually. VIDLs are often compared to blue prints of buildings or architectural drawings. Examples are the Educational Environment Modeling Language (E²ML) or IMS-LD.

This work was previously published in Handbook of Research on Learning Design and Learning Objects: Issues, Applications, and Technologies, edited by Lori Lockyer, Sue Bennett, Shirley Agostinho and Barry Harper, pp. 352-372, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Section IV

Utilization and Application

This section discusses a variety of applications and opportunities available that can be considered by practitioners in developing viable and effective instructional design programs and processes. This section includes over 30 chapters which review certain utilizations and applications of instructional design, such as Internet citizenship and expanded access for the visual and auditory impaired. Further chapters show case studies in Africa and Australia, and the impact of globalization and standardizing languages for instructional design. The wide ranging nature of subject matter in this section manages to be both intriguing and highly educational.

Chapter 4.1

Wireless Computer Labs

Lawrence A. Tomei
Robert Morris University, USA

INTRODUCTION

In February 2000, three seemingly unrelated events came together to present a unique challenge at one mid-Atlantic university—a challenge that is being experienced more and more by colleges and universities across the country.

First, the faculty approved a new undergraduate teacher preparation curriculum that would include instructional technology in both the first two semesters of the freshman year and three semesters in their junior and senior years—12 new sections of technology-based training. Second, a graduate degree in instructional technology was growing beyond even its most optimistic predictions. In less than four semesters, enrollment increased from 24 to 140 students. Third, funds, staffing support, and classroom space had not been pro-

grammed for yet another much-needed computer facility and renovations to available space were cost-prohibitive.

To meet the demands for more technology resources, a new multimedia classroom was proposed. Estimated to cost over \$200,000, the proposal was rejected by senior administrators due to budgetary considerations. It was clear that to resolve this dilemma, the program director needed to think “outside the box”.

Enter the wireless lab. With 29 multimedia-ready classroom and student computer labs already on campus, weaknesses in pedagogy had been recognized for years. Increasingly, labs contain outdated hardware and software. The inflexibility of scheduling, location, and access to desktop capabilities made computer labs unattractive to many faculty members. And the cost! For the price of a single multimedia-ready classroom, a department can purchase 3-4 portable wireless

DOI: 10.4018/978-1-60960-503-2.ch401

labs, incorporating the power of technology with the more traditional classroom. Wireless carts can be rolled into classrooms, making scheduling conflicts a thing of the past. CDROM, printers, and overhead projectors can be appended to the cart with little hassle. And, perhaps most important, with the deployment of a wireless access point, only one network connection is required to make all 24 computers Internet-ready.

The wireless lab was identified as the most promising technology to address these issues. It enables an entire class to be online at the same time—simultaneously surfing different Web sites, accessing e-mail, creating documents, and swapping files through a single Internet connection. It seems the perfect cost-effective solution for schools with limited budgets and facilities at capacity or those who simply want a more flexible networking solution. The specific advantages of a wireless lab are best represented by examining how it was integrated into six university courses and programs.

The university's *Introduction to Educational Technology* course is similar to many such first-year familiarization courses. It provides an introduction to the various classroom technologies. Students use the wireless lab to master the complete set of basic skills and competencies required before entering the masters program. Using the laptops, students are introduced to word processing, spreadsheets, graphics presentation, and the Internet. The lab offers students more opportunities for both abstract and concrete, practical hands-on experiences. Using wireless labs frees the multimedia facility for more classroom-centered teaching (and technology-intensive applications) while offering the complete suite of software, hardware, and network concepts demanded of the graduate program in technology. One anecdotal comment lifted from a student's evaluation claimed, "When then instructor rolled in that wireless lab, learning really took off."

A companion course, *Assessment of Instructional Technology*, evaluates "best practices" for

using instructional technology in the classroom and was previously taught without technology due to space and access considerations. The wireless lab allows students to simulate online quizzes, download test banks, and demonstrate educational software. The flexibility provided by the wireless lab made all the difference in student understanding of the material while providing them the ability to work at their own pace.

Two other non-technical courses, *Social Studies Methods* and *Elementary School Administration*, advanced the practical applications of the wireless lab. Two faculty members needed online access at the same time, so another innovation was initiated in the school. The wireless lab was divided into two to serve both classes simultaneously. Faculty simply rolled the cart into the third floor hallway, distributed 14 machines to one class and 10 machines to the other—and both classes were up and running within minutes.

Even more flexibility was demonstrated in the *Behavioral Disorders* course for special education teachers. Providing a current overview of the field of education for persons with serious emotional disturbances, research is paramount as students explore diagnosis, assessment, treatment, intervention, and prevention strategies. The course validated on-demand technology in the classroom. The wireless lab was used several times during the semester when the class explored factors contributing to behavioral classroom disorders. The instructor was not always able to plan exactly when the research phase of each topic would begin; as a result, scheduling was haphazard and conflicts were common. Using the wireless lab as an on-demand technology resource created the flexibility to re-locate the cart to any classroom equipped with a single network connection. Theory and "book learning" were the previous means of exploring these topics. With the introduction of the wireless lab, students were able to conduct both individual and group discovery learning exercises. Initial feedback from students was extremely positive, some even claiming that the

portable computers helped them understand the practical side of special education.

A special program for preparing school district superintendents found the wireless lab a perfect tool for introducing senior administrators to laptop, wireless technology. The lab was brought into their seminar room and, together, the participants explored the Internet locating information pertinent to school board issues, budget and funding school districts, in-service training programs for their teachers, computer purchases, student safety issues, and so forth. Practicing administrators found a resource suitable for small group learning situations, from 3-5 student seminar rooms with an overhead projection system and printing capability suitable for classroom discussion. The wireless lab was equally effective in this small seminar room environment. The portable laptops permitted the instructor to break down the class into focus groups, with each group using the computers to access information particular to their assigned topic. Participant comments included: "The wireless lab was absolutely wonderful. Convenience and practicality are just two words to describe this innovation. I would love to have this in our schools." (Assistant Superintendent of Schools, Pittsburgh). Here's another, "...very innovative approach in linking us to technology to work together as a team on a grant proposal as we were circled about each at one table. I found that the lab provided us convenience (never leaving our classroom), accessibility to the Internet, better communication in working as a team, and personal instruction" (Director, Special Education).

ISSUES

Of course, with any technology, serious debates are needed to ensure the appropriate application of the technology for teaching and learning, so, too with wireless labs. Here are some particularly poignant concerns for consider.

Keeping Laptops Safe

Most student desks do not provide adequate space for a laptop which can lead to accidents. Security can also be an issue with laptop computers; their size makes them easy targets to slip one out of the classroom undetected. In fact, a recent theft from one middle school computer lab reduced the number of laptops from 51 to 32 in one week-end incident. Most schools will lock down their carts when not in use and store them in a secure location. Often theft is reduced by the demand for laptops to recharge after each extended use, making them tied to a power source that is often dedicated only to the cart and contained within a secure area. Laptops are most vulnerable at the end of a class period when instructors as well as students are moving quickly to their next class. After school opportunities for theft are also numerous. A balance must be maintained with the flexibility of laptops, the convenience of wireless carts, and the vulnerability of both to pilfering. It takes a diligent teacher to keep laptops from being broken, vandalized, or stolen outright.

Maintenance Issues

The most time-consuming maintenance task associated with computer labs of any kind is updating software and removing viruses. Although, theoretically, wireless laptops can be updated in their cart, often the wireless network bandwidth has not been sufficient to allow the simultaneous updates. Although the technology is advancing geometrically, most schools must connect their laptops to a local area network in an existing computer lab to appreciate the much higher data transfer speed (100MB) needed to complete these tasks in a reasonable time frame. Another solution to this problem is to reconfigure the laptops to use Ethernet for updates, or individually update each laptop, both of which are time-intensive processes.

Response Issues

As mentioned earlier, the technology is moving rapidly; however, for most educational environments, wireless protocols continue to present problems, especially in technology-intensive courses. For instance, 30 laptops accessing the access point simultaneously inevitably results in dropped connections or extremely slow transfer rates. Slow response rates are also a particular problem at the end of class when students clamor to save their work to the server or when the instructor leads students through a step-by-step example. Since the wireless lab is being used in the classroom, an educational technician is not usually available resulting in frustrated teachers and irate students. A nearby technician ready to troubleshoot (or at least recognize and explain) these issues encourages wider use of mobile labs.

Flexibility and Savings

Although continuously improving, wireless still lags behind hard-wired connections in terms of speed. However, its tremendous flexibility proves attractive to many school systems. Wireless networking removes barriers to school-wide network access and provides more flexibility when designing new school systems and their desired learning environments with respect to effective technology-oriented learning space layouts. Teachers with access to wireless technology use them much more frequently. When teachers can simply roll a cart into a room, plug it into an electrical outlet, connect it to a data drop, and pass out computers to each student, the wireless carts become an integral part of the daily curriculum. The speed of wireless is typically adequate for classroom activities (even in higher education) because the communication between the access point and the laptop is minimal. Using wireless laptops, teachers, students, and administrators are connected to anywhere and anyone on campus. In the classroom, students can experiment with

new knowledge, collaborate with their peers and instructors, and provide feedback quickly. In libraries, they conduct their own research and in physical education courses, they track their fitness progress. Carts that contain multiple laptops also come in handy for faculty in-service and administrative meetings.

Another benefit of wireless is its ease and speed of installation. Because it is so easy to incorporate wireless within an existing hard-wired infrastructure, many schools use it as a backup or an extension of their wired local or wide-area network. If fibers are cut, for example, a quick switch to the wireless network maintains uninterrupted connectivity. Handheld devices, which many schools are just beginning to use, also integrate easily into a wireless network. From a technical perspective, wireless provides an environment where solutions are otherwise not feasible.

Wireless is also an excellent choice for schools with small classrooms that lack space for stationary computers or schools that were built in the era of brick and mortar where drilling for hard-wire connectivity is cost-prohibited. Wireless carts can be secured on adjacent locations when not in use, leaving room for other teaching activities. Further, when schools outgrow their facilities and revert to temporary classrooms and administrative offices, wireless is the quickest (and least expensive) way to provide connectivity. Most institutions have integrated wireless connections into their long-term strategic plans. While wireless is not necessarily less expensive than wired connectivity, it is becoming more competitive as schools, companies, even cities are opting for this more flexible networking environment. Most find that they can quickly recoup any initial investment expenses because of the efficiency of the hardware. Instead of hard-wired computers sitting idle in unoccupied classrooms, a cart of laptops is apt to be in constant use as it travels throughout the educational building.

Designing Through the Technology

The designs of educational facilities are changing in response to the increased sophistication of teaching, learning, and administration. Some applications require larger classrooms to accommodate technology. For example, projectors that display data from the teacher's console take up more room than monitors. On the other hand, wireless laptops take up much less room than fixed machines. Power requirements have increased dramatically and air conditioners have increased in size because of the tremendous heat generated by the technology, but not so for wireless laptops. A new computer lab once required planning for electricity as well as connectivity; with laptops, a dedicated circuit to handle recharging of a cart-full of computers is all that is necessary.

Current and future technology needs demand careful planning for renovations and new buildings. Technology can enhance learning and related academic and administrative work only if it is accessible. Architectural structures designed initially with aesthetics in mind may serve a dual purpose as ports that accept wireless signals. The location of data drops is another important consideration. Placed too close to a cabinet or in some out-of-the-way place and connectivity is impeded. In wiring a whole new building, current thinking is that antennas should not be installed in classrooms but in hallways so they can cover the rooms on both sides of the building. For both hard-wired and wireless applications, schools must work closely with architects and engineers in the design of wiring schemes for buildings. All new or updated buildings should consider wireless networks or, at the very minimum, a combination of hard-wired and wireless infrastructure. Such environments promotes learning areas that extend outside the traditional classroom into the cafeteria, hallways, student and faculty lounge areas, video presentation rooms, and technology learning centers.

Planning for Technology

Architects and engineers design buildings and then consider technology—at least that is how buildings were planned. With the emphasis and weight placed on today's instructional technology, buildings are now designed around specific educational needs. Engineers integrate conduits for networking and communications cabling. Architects are asked to consider classroom size and width of hallways with technology in mind. And, proper design of wireless systems ensures available connectivity to cable networks and antennas. The continuing rapid changes in technology make planning ahead a true challenge. Many institutions plan 5 to 10 years into the future. With technology, that is oftentimes impossible. Again, the use of wireless technology contributes to successful long-range planning and simplifies upgrades and renovations along the way. Whether hard-wired or wireless, institutions can translate student learning needs into functional designs by involving users (e.g., students, faculty, administrators, and others) during their engineering, architecture and technology planning, strategic planning efforts, and facility upgrade requirements.

ADVANTAGES/STRENGTHS

In the journal, *From Now On*, author Jamie McKenzie summarizes why wireless networks utilizing mobile computers have become the media of choice preferable to the desktop machines in classrooms and computer labs and, by so doing, offers readers a list of the key strengths of wireless technology (McKenzie, 2001):

- **Ease of Movement:** Stand-alone laptops are readily moved to any location within a building without considerations that make desktop machines seem so inflexible. Wiring, electricity, lighting, special furniture, and so forth are non-factors when us-

ing laptops in a wireless environment. On the down side, battery life remains a strong consideration for classes conducted in several-hour blocks of time. Also, connectivity to other technology resources (backups, printers, etc.) also restricts laptop usage.

- **Strategic Deployment:** Wireless devices are deployed on rolling carts (in the case of laptops) or in a pocket (in the case of handheld devices). They go where they are needed most, creating unique learning opportunities that traditional methods of placing hard-wired computers throughout a school do not provide and are just now being realized by instructors.
- **Flexibility:** Wireless laptops are easily re-configurable to changing conditions, teaching styles, and learner experiences as well as team, group, or individual preferences. Wireless laptops place no additional demands on furniture or space.
- **Cleanliness:** Consider how computer labs looked in the past. Cables and electrical cords introduced numerous tripping hazards, monitors, desktops, keyboards, mice, printers, and speakers all presented clutter and confusion. The elimination of cables, wires, and peripherals not only removes many of these hazards but opens the room to better utilization of space for instruction.
- **Low Profile:** Unlike desktops, students are not prone to hide behind large monitors. The low profile of wireless laptops allows better two-way communications and feedback between instructors and students.
- **Convenience:** Wireless laptops are easily stowed in specially-made carts that make them more likely to be used. A disadvantage for some instructors is the unwieldy size and weight of a fully-loaded cart. However, pre-positioning of a wireless lab reduces lost classroom time for setup and simplified technology demands on the part of instructors and students. For most ap-

plications of wireless, the time has come where the technology itself is becoming secondary to the undertaking of learning.

- **Simplicity:** The simplicity, comfort, and reliability of wireless laptops promote a focus on learning rather than the technology. Simple as that.

CONCLUSION

Wireless access has become the environment of choice for educators, corporate trainers, tech-savvy entrepreneur, and the ordinary business traveler. In addition to laptop computers, cell phones, personal digital assistants (PDAs), two-way pagers, and other compact gadgets all use the same wireless technology that makes hard-wired computer labs a technology on its way out.

Wireless-enabled laptops make it possible for students to use their time more efficiently, access databases and information from the Internet, and work collaboratively. Using conferencing software and portable laptops, learners are able not only to electronically store documents and data and retrieve them instantaneously, but also to successfully engage in document sharing and collaborative writing from various locations on and off a campus environment. With the implementation of more flexible learning approaches, they succeed in selectively incorporating critical input from peers and instructors, then revise documents based on their own interpretation of facts and theory.

Continuous improvements in wireless technologies will only serve to advance new pedagogical practices that take advantage of the full range of educational psychologies. Such learning practices incorporate higher-order skills like problem-solving, reasoning, and reflection. The integration of mobile learning environments and wireless computing also has implications for many other educational venues such as business schools, science programs, corporate training,

medical nursing schools (including nursing), and law schools.

In summary, the advantages of wireless computing include education are its breadth of scope, prolific portability, and broad applicability for both individualized and collaborative learning projects. Access extends to home, office, classroom, leisure, airports—virtually everywhere and all the time, providing the means to integrate computers into every aspect of teaching, learning, and research.

Certainly, wireless labs have proven themselves highly adaptable to both the personal teaching styles of classroom instructors and the learning strategies of traditional and adult students. There are few inherent weaknesses in laptop capability compared to similarly-equipped desktop computers. Plus, they have added advantages and flexibility only laptop computers provide. They seem to support all aspects of teaching and learning, including abstract values and concrete ideas; behavioral, cognitive, and humanistic psychologies of teaching and learning; and, all levels of human development from elementary through post-graduate doctoral students.

For considerably less than a multimedia classroom, the wireless lab provides an appropriate venue for teaching at the college/university level. With the power and flexibility of today's laptops and the requisite pedagogy on which to base teaching with technology appearing more often in the research, schools should at least consider the wireless lab for their next technology enhancement.

KEY TERMS AND DEFINITIONS

IEEE 802.11 Wireless Standard: 802.11 is the IEEE (Institute of Electrical and Electronics Engineers) standard for wireless networking—sending Ethernet data packets through the air. The standard allows for wireless integration with wired Ethernet networks using devices called access points or base stations. IEEE 802.11 wireless standard supports all standard Ethernet network protocols including TCP/IP, AppleTalk, NetBEUI, and IPX.

Access Points: An access point or base station is a radio receiver and transmitter that connect to a wired Ethernet network. Through these devices, wireless nodes such as desktop computers, notebooks, and laptop computers equipped with wireless network cards, have access to wired local area network services such as e-mail, the Web,

printers, and more. Operating range, management capabilities, wireless network security, and number of users supported are determined by the capabilities of the access point.

Broadband: Faster than modems but slower than Ethernet, several different forms of broadband access are available from local Internet service providers, phone companies, and cable providers. The most common forms of broadband are DSL, ISDN, and cable modems. DSL and ISDN use special adapters to send data over your telephone line without tying it up. Cable modems send data over your cable TV connection. DSL and ISDN availability is limited based on geographic location and telephone line quality. Cable modem availability varies with each cable company.

Data Transmission Modes And Throughput: There are two modes, encapsulation and translation, for transmitting data over a wireless network. Encapsulation mode encloses the 802.3 Ethernet packets inside 802.11 frames for transmission through the air, whereas translation mode converts 802.3 Ethernet packets into 802.11 packets for transmission. Recently translation has emerged as the defacto standard, but support for encapsulation as well ensures maximum flexibility in networks where both addressing modes may be used.

Ethernet: The standard individual connection for many offices, classrooms, labs, and residence hall rooms as well as corporate office and training environments and complexes. Ethernet operates at speeds up to 10 megabits per second, is available 24 hours a day, and does not require a phone line. Fast Ethernet connections that operate at 100 megabits per second are available but usually reserved for server applications.

Local Area Network: The term local area network is usually defined by its size; it is small and

generally contained within a single room, a single building, or perhaps a small cluster of buildings.

Operating Range: Factors that affect the operating range of any wireless device include the strength of the access point, the number of walls inside a building, the construction materials used within a building (concrete vs. steel vs. wood), and the data transmission speed. Most access point manufacturers offer enhanced antennas for increased range. Manufacturers recommend that access points be deployed 150ft. (50m) apart to ensure full coverage and maximum data throughput rates for roaming computer users.

Soft Access Point: As an alternative to deploying an access point for wireless connectivity to a wired Ethernet network, a computer that is physically connected to an Ethernet network, outfitted with a wireless network card, and running a software routing solution, can act as the gateway between the wired network and the wireless network.

Wireless: Wireless networks currently operate at speeds up to 11 megabits per second in both indoor and outdoor locations. A great convenience for mobile computer users, wireless does have some drawbacks. Because it uses radio waves to transmit data, wireless networking is inherently insecure. Also, the bandwidth within each coverage area is shared between all users on that "cell".

Wireless Management and Security: Certain wireless client solutions provide utilities to monitor the strength of the signal and data throughput speeds and provide computing users real-time network statistics. Additional wireless network management capabilities are incorporated into the access point and depend on the manufacturer and model.

Chapter 4.2

Personalised Learning: A Case Study in Teaching Clinical Educators Instructional Design Skills

Iain Doherty

University of Auckland, New Zealand

Adam Blake

University of Auckland, New Zealand

ABSTRACT

The authors consider personalised learning in the context of delivering a specialist postgraduate course – ClinEd 711, ELearning and Clinical Education – at the Faculty of Medical and Health Sciences, University of Auckland. They describe the pedagogical theory underlying the course design and their experience of delivering ClinEd 711 with particular reference to the personalised learning process that the course design facilitated. They present their research results for the student experience of ClinEd 711 and discuss changes made to the course as a result of student feedback. They make reference to the introduction of student-led modules to further personalise the students' learning experience. ClinEd 711 is a specialist postgraduate course with low student

numbers; with this in mind the authors discuss the implications of their pedagogical approach for those educators involved in teaching larger classes. They conclude their paper with a discussion of the role of the educator in personalised learning.

INTRODUCTION

The Learning Technology Unit (<http://www.fmhs.auckland.ac.nz/faculty/ltu/>) and the Centre for Medical & Health Sciences Education (<http://www.fmhs.auckland.ac.nz/faculty/cmhse/default.aspx>) at the Faculty of Medical and Health Sciences, University of Auckland jointly offer a fifteen week course – ELearning and Clinical Education (ClinEd 711) – as part of a clinical education postgraduate degree program. The overall objective of ClinEd 711 is to bring the learners – who are typically educators in the field of medical and

DOI: 10.4018/978-1-60960-503-2.ch402

health sciences – to the point of understanding themselves as instructional designers capable of converting one of their traditional face-to-face courses for flexible/distance delivery. ClinEd 711 was offered for the first time in Semester 1, 2007 as a fully online distance education course. The course was offered for a second time in Semester 1, 2008 and at the time of writing (March 2009) the course is being offered for a third time. From the outset, ClinEd 711 was designed to locate the student at the centre of the learning process in order to provide students with a personalised learning experience. However, as a result of feedback from students and after critical analysis of the first iteration of the course, ClinEd 711 was re-designed to create an even more personalised learning environment. This was achieved through the introduction of student-led modules in which the students had to take responsibility for the creation and delivery of a particular course module to be “studied” by their peers.

In this chapter we: outline our understanding of personalised learning; detail the research approach that we took in designing and evaluating ClinEd 711; explain how the course was designed to situate the learner at the centre of the learning process; describe the personalised learning processes that the approach facilitated; outline the differences between the first and second iteration of the course; and provide the reasoning behind the changes that were made for the second iteration of the course. Our chapter will make particular reference to the student-led modules that were introduced in the second iteration of the course, as the rationale for this innovation was to provide students with greater learning autonomy and with greater responsibility for their learning outcomes. As we shall see, these are two of the central features of personalised learning. We are aware that ClinED 711 is a specialist postgraduate course with a relatively low number of student enrolments and with this fact in mind we will discuss the potential challenges of offering this particular form of personalised learning to larger class

sizes. We conclude our chapter by discussing the relationship between the role of the educator and the independence of the student in a personalised learning environment before briefly considering future research directions.

PERSONALISED LEARNING

A key characteristic of personalised learning is that the student is located at the centre of the learning process. Personalised learning meets the individual learning needs of a diverse range of students whilst encouraging independent learning (Johnson, 2004) through learners taking greater responsibility for their own learning and through learners being more actively engaged in the learning process (Hannafin & Land, 1997; Ong & Hawryszkiewicz, 2003). It is the design of a particular type of learning environment “shaped by its foundations and assumptions about learning, pedagogy and the learner” that provides the conditions for personalised learning (Hannafin & Land, 1997, p. 197). For example, teachers can facilitate personalised learning by adopting teaching strategies that meet the needs, abilities and aptitudes of each student thereby providing for an individual learning pathway (Sun & Williams, 2004). This can be achieved through shifting responsibility from the teacher to the student for discovering, organising, analysing and synthesising content (Brush & Saye, 2000; Downes, 2005). Such strategies can maximise student motivation and attainment so that students realise their full potential (Johnson, 2004). However, the role of the educator remains crucial if students are to succeed (Hannafin & Land, 1997) with the educator fulfilling the necessary roles of facilitator and mentor (Johnson, 2004; McLoughlin & Lee, 2007; Ong & Hawryszkiewicz, 2003).

In cases where class sizes are large with lecturers often being “time-poor” (Goodyear, 2005, p. 2), it has been said that personalised learning must necessarily be about offering students learn-

ing choices within the framework of a particular curriculum or course (Johnson, 2004). In practice this means providing a teaching framework that offers a solution to the problem of teaching to a large group of students whilst also meeting the diverse learning needs of each particular student so that learners, “are actively engaged in the learning experience with their preferred content” (Sun & Williams, 2004, p. 2). The Harvard University virtual world project “River City” – a project to teach school aged children science – provides an excellent example of a development that seeks to achieve a balance between providing a standard framework for learning whilst also offering learners individual choice in order to cater to diverse student abilities (Clarke, Dede, Ketelhut, & Nelson, 2006). In “River City” this balance is achieved through providing standardised features in the virtual world whilst also offering customisable features within the environment. For example, “River City” has an individualised guidance system in which student activities are logged in a database. The database maintains a personalised history of the activities undertaken by each student with levels of guidance in the form of “hints” being offered for each individual student in terms of the student history of interaction in “River City”. This – along with other design features – has enabled the creators of “River City” to offer an educational innovation that meets the diverse needs of learners and educators.

ClinEd 711 is a specialist postgraduate course and the number of students enrolling has been relatively low. We did not, therefore, have to deal with the challenge of providing personalised learning opportunities to a large numbers of students. Even so, we found that it was challenging to create and manage a learning environment that allowed learners to engage in the learning experience in terms of a project of their own choosing and with their preferred content. Whilst creation of ClinEd 711 was time consuming, the essential difficulty that we faced had to do with the demands placed on the tutor in terms of supporting students in

their learning and in terms of marking assessed work. We will discuss both of these challenges in this chapter. We will also discuss the extent to which the learning design implemented for ClinEd 711 might be “scaled up” and implemented on a course with much larger student numbers. This will involve us in critically considering how to provide a standard teaching framework that provides a solution to the problem of offering a personalised learning environment when student numbers are large.

It should not be thought that our conception of personalised learning is synonymous with “individual” learning. Rather, interactional theories of cognitive development (Bruner, 2006; Vygotsky, 1978) posit that the social dimension of learning is crucial in pedagogical terms so that students are exposed to a variety of opinions and perspectives that will challenge and inform their own perspectives (Hannafin & Land, 1997; McLoughlin & Lee, 2007). Thus, students might work cooperatively so that their learning is “participatory and social” (McLoughlin & Lee, 2007, p. 664) whilst retaining choice concerning their learning content, their preferred learning style and their use of particular types of social software for communication and collaboration (McLoughlin & Lee, 2007). Students can also be offered flexibility concerning where and when they learn. ClinEd 711 is very firmly rooted in a social constructivist pedagogical framework. Again, despite relatively low student numbers, managing the ‘social’ component of the learning process led to distinct challenges that will be discussed in this chapter.

BACKGROUND

We deemed design research to be an appropriate research methodology for our ClinEd 711 research project – particularly when compared with research approaches grounded in an objectivist and scientific methodology (Collins, Joseph, & Bielaczyc, 2004; Reeves, Herrington, & Oliver,

2005). Whilst design research has had difficulties gaining traction in the broader research community (Collins et al., 2004), it is a method that is being applied successfully and is championed by a number of prominent researchers (Bannan-Ritland, 2003; Clarke et al., 2006; Herrington, Oliver, & Reeves, 2002; Kelly, 2003; McKenney, Nieveen, & van den Akker, 2006; Reeves, 2000, 2006; Reeves et al., 2005). Our research approach utilised six design research tenets as explicated by Reeves, Herrington, & Oliver (Reeves et al., 2005):

1. A focus on broad-based, complex problems critical to higher education;
2. The integration of known and hypothetical design principles with technological affordances to render plausible solutions to these complex problems;
3. Rigorous and reflective inquiry to test and refine innovative learning environments as well as to reveal new design principles;
4. Long-term engagement involving continual refinement of protocols and questions;
5. Intensive collaboration among researchers and practitioners, and learning communities;
6. A commitment to theory construction and explanation while solving real-world problems.

We considered the question of how to engage lecturers in a “pedagogically principled way” (Burden & Atkinson, 2008, p. 4041) with technologies for teaching and learning to be a challenge that was sufficiently broad based and complex to warrant adopting the design research approach. We also conceived of the creation of ClinED 711 as a real world problem. The reasons for coming to these conclusions included the fact that the Medical Faculty is the largest Faculty within the university with five Schools and, potentially, a pool of very diverse students. Teaching with technologies is an issue that affects all five Schools because of a demand for delivery of flexible/distance postgraduate courses and because of a perceived need to produce technology-enhanced

teaching materials for undergraduate students. In addition, factors at a Faculty and University level – such as lecturer time to learn new skills and prepare new content, cultural ethos, pressure to engage in discipline research and the question of incentives for teaching with technologies – all potentially impact on whether or not students on ClinED 711 actually implement what they have learned. At the outset, we had a long-term commitment to the ClinED 711 research project with the University of Auckland ethics committee approving the research project for a period of three years. A long terms commitment to educational research is important in order to avoid the mistake of conducting an isolated one off study that is of questionable value in terms of meaningful research results. The way in which the remaining tenets of the design research approach have been put into practice will be made evident in the following sections as we describe the creation of ClinED 711 and the revisions that were made in light of our teaching experience on the course.

COURSE DESIGN

Both iterations of ClinED 711 have been based upon social constructivist theory (Gillani, 2003; Mergel, 1998). This pedagogical philosophy (Goodyear, 2005, p. 85) “guides learners to conduct and manage their personalised learning activities and encourage[sic] collaborative and co-operative learning for critical thinking and problem solving” (Sun & Williams, 2004, p. 2479). At the level of the individual, constructivist theory suggests that learning is a search for meaning or significance. Students learn in terms of a pre-existing conceptual schema or framework within which they ideally fit new knowledge. Constructivism should therefore be understood as a description of the way in which individuals might go about their learning rather than as a description of the way in which they do in fact go about learning. It is the job of the educator to provide the conditions

in which constructivist learning might take place. This is achieved through providing an educational framework in which course content and activities might be personally meaningful for the students. At the social level, interaction with others can serve to change an individual's conceptual structure or personal interpretation of particular phenomena whilst simultaneously influencing the collective interpretation of those phenomena. In the context of designing a learning environment, educators can create experiences that are personalised – that is individually meaningful, relevant and tailored as far as possible to a learner's particular needs – whilst also ensuring that the learning experience is social thereby exposing individual learners to the perspectives of other learners.

Regarding the second tenet of design research – the integration of known and hypothetical design principles with technological affordances to render plausible solutions to complex problems – ClinEd 711 was designed around six pedagogical principles with the first principle bearing directly on the constructivist learning philosophy:

- Learning should be meaningful for the learner (Ausubel, 1963; Bransford, Brown, & Cocking, 2000);
- Learning should be organised around core concepts and cognitive flexibility to develop expert rather than novice knowledge (Ausubel, 1963; Bransford et al., 2000; Driscoll, 2005);
- Learning tasks should replicate real world problems in an authentic context (Bransford et al., 2000; Lave & Wenger, 1991; Lemke, 1997);
- Learning should involve the collaborative construction of knowledge thereby providing learners with multiple perspectives on particular issues and concepts (Bruner, 2006; O'Donnell, 2006; Vygotsky, 1978);
- Learning should employ strategies that appeal to multiple sensory modes and cognitive capabilities (Driscoll, 2005; Gardner,

1983; Mayer, 2003; Paivio, 1986; Spiro, Feltovich, Jacobson, & Coulson, 1995);

- Learning tasks should encourage meta-cognitive capabilities and reflective practice (Bransford et al., 2000; Schön, 1987).

In line with recommendations for publishing design research as it unfolds, the research basis for implementing these design principles has been reported elsewhere (Blake & Doherty, 2008; Doherty & Blake, 2007). In this chapter we will be focussing on those aspects of the learning environment that pertain directly to personalised learning and on the challenges of providing personalised learning to students.

COURSE CONTENT AND LEARNING PROCESS

The postgraduate degree programme in clinical education within which ClinEd 711 is offered is aimed at health professionals and academics (doctors, nurses, pharmacists and others) involved in clinical teaching. Students might be full time academics or they might primarily be clinicians with some teaching responsibilities within the Faculty. This is an interesting point with respect to meeting the needs of all learners. Whilst academics with some clinical responsibilities will have a professional identity defined to a significant degree by their teaching, clinicians who teach only part time are much more likely to have a professional identity that is defined by their clinical responsibilities. This point obviously bears upon offering personalised learning to students since the course tutors have to be sensitive to the fact that some students will not come to ClinED 711 with an understanding of themselves as teachers. Students participating in the first 2 iterations of the course have had the characteristics described in Table 1.

Whilst student enrolments have been relatively low, we can see that students on ClinEd

Table 1. Characteristics of ClinEd 711 students, 2007 and 2008

	<i>Field of clinical education practice</i>	<i>University of Auckland staff member?</i>	<i>Resident in Auckland?</i>
First course iteration, 2007 (4 students)	Psychiatry	Yes	Yes
	Palliative care nursing	No	Yes
	General medicine	No	Yes
	Pharmacy	Yes	Yes
Second course iteration, 2008 (6 students)	Anaesthesia	No	Yes
	Surgery	No	No
	Psychiatry	Yes	Yes
	Mental health nursing	No	Yes
	Physiology	Yes	Yes
	Psychology	Yes	No
n (total) = 10		UoA staff = 5	Auck. resident = 8

711 have been diverse in terms of their field of clinical practice. We can also see that the majority of students have been resident in Auckland with half of the students being Auckland University staff. Since this was a wholly distance course, the physical location of the students was not a factor in the student learning experience since all content and interaction was carried out online. Both iterations of ClinEd 711 required students to progress through the course in terms of an eLearning project of their own choosing. In this way, students engaged in authentic, personalised and meaningful learning through selecting one of their own courses for their project and through developing that course for flexible or distance delivery.

The emphasis in ClinEd 711 was on the personal relevance of the learning for the learner's teaching and learning philosophy and for their clinical education practice. The reference to clinical practice is important as it bears upon the sixth tenet of design research, "A commitment to theory construction and explanation while solving real-world problems". ClinED 711 emphasised that students needed to consider how their teaching practice would impact on real world health care problems. There was, therefore, an emphasis in

ClinED 711 on students creating flexible/distance courses that would lead to, for example, improved health care in the workplace. Students were directed to take ownership of their learning from the very beginning of the ClinED 711. This situated them at the heart of the learning process and as a result the course became personally relevant and meaningful to the students. Students typically chose to focus on a course that they were already teaching, although in some cases they chose to create a new course. This provided each student with an individual pathway through ClinEd 711. Progression through the modules of ClinEd 711 was centred on two core instructional design documents that are used within the Learning Technology Unit at the Faculty of Medical and Health Sciences for eLearning project developments. The use of these two core documents provided an authentic, real-world learning scenario in which learners could learn to think like instructional designers.

The first document – Needs Analysis Document – clarifies the potential social and pedagogical usefulness of the project and captures key information necessary for converting a traditional face-to-face course for flexible/distance delivery. The Needs Analysis Document asks for the fol-

lowing information: project goal; project rationale; staff who will contribute to course development; whether the course is university approved; completion date for development work; current course format and mode(s) of delivery; new provisions required; available budget; frequency of updates for the completed development; staff available to carry out the updates and head of school approval. The document therefore functions to ensure that there is a clear reason for converting the course for flexible or distance delivery and completion of the document also indicates broadly that the project is viable in terms of the development work required during the allotted timeframe of fifteen weeks. In project management terminology, the Needs Analysis Document is the functional equivalent of a project mandate document, which serves to determine in broad terms whether, or a not a project is worthwhile. Students on ClinEd 711 were expected to complete the Needs Analysis Document during the early weeks of the course. The course tutor then marked the Needs Analysis Document. In the real world of project management the Needs Analysis Document is crucial as it provides the information required to gauge whether or not the project is viable. The same is true in the context of ClinED 711 and, therefore, students were made aware of the importance of completing the document to a high standard. The course tutor marked the Needs Analysis Document and if the document did not meet the required standard – that is, if the document did not define the project as both worthwhile and viable – students were given the opportunity to revise the document.

The Second Document – Course Development Document – requires students to detail the pedagogical thinking and development work required to successfully convert their course for flexible/distance delivery. This is the project management equivalent of a project initiation document which functions to ensure that the project has a sound basis. Since the Course Development Document is so central to ClinED 711, we have

provided an example of the document in Appendix One. Completion of this document ensures that the student's chosen course is appropriately developed in terms of meaningful course content, meaningful student activities, and meaningful student-teacher and student-student interaction (Hutchins, 2003; Rourke, Anderson, Archer, & Garrison, 1999). This is achieved through requiring the student to detail for their chosen course development project: module topics and associated learning tasks; student roles and activities on the course; delivery mode or modes; teaching and learning resources; tutor support roles; and methods of assessment and feedback. Students on ClinED 711 completed the Course Development Document as they progressed through the course modules so that by the end of the semester the students had a "blueprint" for developing and implementing their own flexible or distance learning course. We can see, therefore, that the student learning was both authentic and personalised as the module content related directly to the students' own projects in terms of completing the Course Development Document.

Subject content for ClinEd 711 was selected in terms of key concepts and knowledge required for the practice of instructional design and the course was structured to foster reflective practice (Bruce, Edwards, & Lupton, 2006, p. 5). The ClinEd 711 modules included:

- The major learning theories of behaviourism, cognitivism and constructivism.
- Instructional design principles and practice;
- Methods for quality assurance in developing flexible and distance courses; and
- Sourcing particular learning objects whilst justifying their pedagogical value, and demonstrating an understanding of copyright issues with respect to their chosen learning object.

The primary theme running through course tasks and assessment was for students to relate course concepts to their personal pedagogical beliefs and their own teaching context. Thus, in addition to the personal relevance of choosing their own eLearning projects, students were encouraged to engage in learning processes that enabled them to see the meaning of what they were learning as it applied to their own teaching practice. With respect to social participatory learning, learners engaged in collaborative exercises through participating in online discussions and through engaging in peer critique exercises. Reflective practice and metacognition were encouraged through peer critique activities, self-reflection activities and through comprehensive feedback provided by the course tutor in accordance with detailed marking rubrics. Finally, the course utilised a variety of media including text, images, multimedia resources and podcasts in order to accommodate different learning preferences.

FIRST ITERATION TEACHING, LEARNING AND ASSESSMENT

The first iteration of ClinEd 711 encouraged personalised learning in terms of students choosing their own eLearning project and in terms of requiring each student to reflect on their own teaching and learning perspectives. For example, having chosen their own course to develop for flexible/distance delivery in ClinED 711, online discussion of topics prompted students to relate course concepts from each module to their own teaching beliefs and teaching practices. The purpose of this self reflection was to encourage students to think about how their beliefs about teaching and learning impacted on their teaching approaches. For example, having learned about constructivist learning theories students might reflect on the educational value of constructivist learning and on whether or not their own approach to teaching included constructivist elements. This

sort of reflection was particularly challenging for students who came to fundamentally question their approach to teaching and the tutor providing feedback on the reflective exercises had to exercise a degree of sensitivity and understanding as students questioned beliefs about teaching that had not previously been considered.

Although learning was personalised for students in these ways, the tutor extensively managed the first iteration of ClinED 711. This was particularly evident in the assessment activities. Each of modules 2-10 required submission of an assessed piece of work. One of the authors acted as primary course tutor and assessor, with the second tutor providing assessment moderation for all student submissions. There was, therefore, a tension between the desire to offer personalised learning – particularly in terms of students taking responsibility for their own learning – and the requirement for students to conform to a rigid assessment schedule throughout the course. The disjoint between the assessed activities and the aim of encouraging students to take responsibility for their own learning only became apparent to the tutors as the course progressed. The tension caused by the assessed modules is evidenced by the following overview of course tasks and assessment activities provided in Table 2.

ClinEd 711 course web pages providing detailed course information and the overview of tasks, interaction, and resources for each module were created using MindManager mind mapping software (<http://www.mindjet.com>). MindManager was chosen because one of the course tutors preferred a visual approach to development work and had used the software extensively. MindManager further recommended itself because it has an export feature that quickly and easily allows the user to export the Mind Map as a set of HTML pages to be uploaded to a server. The exported web pages were hosted within the university's Learning Management System (LMS). Online discussion was facilitated primarily via threaded discussion in the LMS. Students were supported

Table 2. Overview of ClinEd 711 course tasks and assessment (first iteration, 2007)

Coursework item	Module(s)
Online group discussion around course-related material demonstrating critical reflections on your learning and linking of learning to your own context (15%)	Modules 1-10
Completion of Needs Analysis Document (15%) (formative feedback provided prior to final completion)	Module 2
Literature-based development of principles around learning technology and media (5%) (small group/pair assignment)	Module 3
Literature-based development of principles around the role of the teacher (5%) (small group/pair assignment)	Module 5
Sourcing and applying learning objects (10%)	Module 7
Course Development Document (50%), comprising:	
Reflective commentaries on completion of key aspects of the Course Development Document (20%)	Modules 4, 5, 6 & 10
Critique of a peer's draft Course Development Document (10%)	Module 8
Completion of final document (20%)	Modules 9-10

in setting up individual blogs using Blogger (<http://www.blogger.com>) in order that they might post their reflective commentaries. For the two small group/pair assignments (detailed in the table above), students were supported in using PBWiki (<http://pbwiki.com/>) to collaborate, but were also encouraged to experiment with any other collaboration environment of choice. For example, in the second small group/pair assignment, one pair used the collaborative concept mapping application, Bubbl (<http://bubbl.us>).

Despite the low student numbers ($n=4$) on the first iteration of the course, students were relatively active in the threaded discussion forums (135 student messages contributed during the course). Students appeared to have little difficulty with the practical aspects of posting discussion forum messages. Students also found setting up their blogs and wikis relatively easy. We would attribute the lack of difficulty with the various technologies to the fact that students were provided with detailed step-by-step instructions for these tasks. This is one of the ways that we ensured that we designed ClinED 711 in terms of the total student learning experience (Alexander, 2001), taking into account not only course content but also supports required to ensure the quality of the

student learning experience. Although the initial intention had been for students to post their Course Development Documents to their blogs for peer critique, the inability to post file attachments to blogs meant that the LMS discussion forum tool was used for this activity.

As detailed in Table 2 above, students were required to create a reflective commentary on their completion of key aspects of the Course Development Document. Students were provided with a blog to facilitate their reflective practice and a 'blogs' tab was provided within the LMS, with links to each of the student's blog. Because students showed little inclination to post comments in response to their peers' reflective commentaries, the course tutor used a blog conglomeration tool, Blogdigger (<http://blogdigger.com>) to collate all of the blog entries in chronological order on one webpage. The tutor also provided a link to the collated blogs within the LMS. The aim was to make it easier for the students (and the tutor) to review the postings, and to provide more of a sense of connection within the group in relation to their reflective postings. However, students still did not engage in interaction by way of commenting on their peers' blogs. One of the reasons for this may be that no marks were associated with

posting comments on other students' blogs. As we shall see below, we attempted to address this issue in the second iteration of the course.

Students were provided with rubrics detailing the key areas of performance required for each assessed task. The rubrics described 5 levels of performance for each area ranging from exemplary through to inadequate. The course tutor used these rubrics, with an additional column added for comments, to provide feedback to each student on each of the assessed tasks. Students used the Course Development Document rubric to provide critique on their assigned peer's work. Using rubrics in this way worked well to provide clarity on task requirements and to communicate high expectations of performance. However, those high expectations create a matching expectation for quality feedback; if a student was graded as not having achieved exemplary performance within a particular area of a task, then the tutor was responsible for clearly showing how that student had failed to meet expectations. The tutor also had a clear responsibility to show students how they might improve their performance.

In our introduction we made reference to the fact that providing a personalised learning experience for students was challenging on ClinED 711 despite the fact that student numbers for each iteration of the course were relatively low. The challenge concerned the creation of the course in the first instance as we sought to create a course with both standardised elements and individualised elements (Clarke et al., 2006). Whilst the creation of a new course is always time consuming, the commitment to designing a course that would deliver a personalised learning experience for students entailed a substantial number of hours spent in course design. In particular, we spent a lot of hours creating a learning environment that would be personally relevant for the students. We also spent a considerable number of hours in creating authentic or "real world" learning activities. Finally, the creation of the assessed activities together with detailed marking rubrics for each

activity also took a considerable amount of time. Whilst it is not possible to be specific in terms of the time taken to create ClinED 711 compared with the time taken to develop other ClinED courses, we are very aware that we committed considerably more hours to course creation than tutors who followed a more traditional route.

As we shall see below, the time that we spent on creating the course was worthwhile with the external assessor remarking on the quality of the course particularly in terms of the learning activities and tutor teaching practice. With these points in mind we would certainly deem the time and effort spent on ClinEd 711 to have been worthwhile. However, the number of assessed tasks throughout the course combined with the detailed feedback entailed by the marking rubric meant that assessment and feedback activities were extremely time-consuming despite low student numbers. For example, in the first iteration of the course the tutor spent approximately twelve hours assessing the Needs Analysis Document and the Course Development document for the four students. We can see quite clearly that higher enrolments would lead to the need for additional tutors to deal with marking and to monitor the message board. There would certainly come a point at which the format for this course would become unfeasible because we would not be able to commit the requisite tutor time to the course. This would be true even if we employed additional tutors. It is difficult to specify the point at which the ClinEd 711 format would no longer be feasible. However, we can safely say that this level of tutor support would not be possible with a class of two hundred students. Whilst this scenario is unlikely to occur for a specialised Masters course, the question of appropriate learning designs for personalised learning in large classes is a real one.

The difficulty with dealing with large class sizes comes down to offering students an individualised and authentic learning pathway in which they take greater responsibility for their learning in the context of a structured and somewhat

standardised framework provided by the educator. We believe that there is an issue here to do with course creation – discussed above – as the creation of a course that offers personalised learning opportunities is time consuming when compared to offering a course that consists solely of standard components. The second issue is the amount of time that the tutor has to spend supporting each student throughout the course and, in particular, providing appropriate feedback on assessed tasks. Whilst, as already suggested, this problem might be overcome initially by employing additional tutors, this will not always be feasible and even when it is feasible there will come a point when student numbers are too great even with the use of additional tutors. The question then becomes how to continue to offer an individual learning pathway with authentic learning activities in a way that does not place impossible demands on teaching staff.

A peer review process – in which students take responsibility for marking the work of other students – suggests itself as a possibility to overcome demands on tutor time. However this option still requires that tutors oversee the peer review process with a minimum requirement being that they moderate peer reviews across a range of allocated grades. The peer review option also requires an appeal process so that students who feel that they have not been marked fairly by their peers have recourse to the tutor. A second possibility is to reduce the number of assessed tasks. In the case of ClinEd 711, for example, we might reduce the number of assessed activities to two; the first assessed activity would be completion of the Needs Analysis Document and the second assessed activity would be completion of the Course Development Document. Other activities – for example, peer critique of the two core course documents – might be built in to the course structure but not assessed. Students would then be responsible for engaging with others in order to learn from others and to contribute to the learning of others. Unfortunately, our experience

on ClinED 711 together with research in the area would suggest that students engage in online group activities only when marks are allocated for those activities. In the final analysis, motivation is extrinsic; students want to see tangible rewards for their efforts. Reducing the tutor workload through putting more of an emphasis on students' self-learning may not, therefore, be feasible.

The previous paragraph highlights issues that will be encountered when attempting to create a personalised learning environment for a large class. Whilst we have not offered a solution to the problem, we have identified a core issue to do with tutor time spent on providing formative feedback and marking assessed activities. It is our opinion that the learning design for a large class size would of necessity look very different from the learning design for a small class such as ClinED 711. The specialist nature of our course means that we are extremely unlikely to find ourselves in a situation in which we have to fundamentally change our learning design.. However, we know that the learning design is a good one – measured in terms of feedback from the external moderator and in terms of student feedback – and it is therefore a design that we would look to implement for other courses including courses with larger student numbers. We will, therefore, have to continue to think about how to transpose the teaching principles to courses with larger numbers.

FIRST ITERATION RESEARCH RESULTS

In line with the sixth tenet of design research – a commitment to theory construction and explanation while solving real-world problems – the research project associated with ClinEd 711 was originally designed to allow us to answer a number of key questions with respect to teaching clinical educators about developing their courses for flexible or distance delivery. In particular we were concerned with:

- The preparedness of lecturers to teach with technologies;
- The success or otherwise of ClinEd 711 in terms of teaching clinical educators instructional design skills;
- The factors that impacted positively and negatively on lecturers' intentions with respect to flexible or distance learning development once they had completed the course.

For the first iteration of the course, students were given a pre-course survey to determine their extant levels of knowledge concerning teaching with technologies. The same survey was administered at the end of the course. Students also completed a university evaluation questionnaire concerning the course, and following standard procedures for first-time delivery, the course underwent review by an external assessor. Finally, a one-year follow up telephone interview was conducted with students. However, this did not take place before the development of the second iteration of the course and is not reported here.

The outcomes of our research into the first iteration of ClinEd 711 have been reported in detail elsewhere (Blake & Doherty, 2008). In summary, indications were that the course was very effective overall. The external assessor praised the course design and teaching practices writing that, "The creative and practically-oriented assessment tasks are to be lauded. It seems that the course teachers are modelling excellent tutoring techniques." Students reported that: the course motivated them to learn; was intellectually stimulating; and enabled them to enhance their teaching practice. Each student successfully developed a design blueprint for their chosen course, demonstrating learning outcomes that focussed on improved patient care. Areas of concern on the part of the students related to volume of work and the pace of the course. The external assessor also queried the assignment load and recommended greater

assessment weighting for collaborative tasks together with a reduction in the number of assessed components on the course. This bears on the point that the number of assessed activities was at odds with the desire to provide a personalised learning environment and this feedback from the external moderator was considered to be particularly useful. Our experience of teaching the course was one of finding the teaching experience rewarding whilst being aware of several challenges. It should be noted that whilst the number of assessed tasks was deemed problematic, the rationale for including a large number of assessed activities was sound; we wanted to provide students with frequent feedback.

From a teaching perspective, it was very rewarding to be involved with the students as they engaged with learning theory and design issues as part of online discussion, collaboration and reflection tasks, and to see their insights deepen as they developed sound eLearning design blueprints for very worthwhile health education projects. The large number of assessable tasks, each with a detailed rubric, meant that students received frequent and detailed personal feedback. The volume of course tasks however led to expressions of fatigue by students late in the course and meant a fairly high instructor workload despite low student numbers. Although students were generally active in collaboration and communication, the low student numbers also meant that for the most part there was a lack of the 'critical mass' that enables really productive discussion forum exchanges to develop (Blake & Doherty, 2008, p. 100).

In terms of the third tenet of design research – rigorous and reflective inquiry to test and refine innovative learning environments as well as to reveal new design principles – the outcomes of these initial evaluations together the comments from the external moderator and considered reflection on the part of educators, led to a desire to revise the course so that students would:

Personalised Learning

- Experience a greater sense of independence and control over their learning.
- Maintain and deepen their engagement with course concepts while dealing with less assessment.
- Engage in authentic communication and collaboration with their peers beyond the ‘standard’ online threaded discussion.
- Gain more experience of ‘hands-on’ teaching with technologies.
- Be inspired to tap into their creativity to further personalise their learning.

SECOND ITERATION TEACHING LEARNING AND ASSESSMENT

For the second iteration of the course we responded to the assessor and student feedback by:

- Removing the two small-scale collaborative tasks implemented in the first iteration;
- Combining individual reflective tasks within a broader course-long “discussion/research/reflection” assessment category;
- Providing a new academic social networking environment (ClinEd711 Network) for course communication;
- Restructuring the content to reduce the number of modules;
- Introducing student led modules.

An overview of the revised course tasks and assessment is provided in Table 3.

The ClinEd711 Network for course communication and file sharing was facilitated using the open source software, Elgg (<http://elgg.org>). The software was installed and configured on one of the university’s servers by a web administrator, and the course tutor was then able to administer student access. Since there were only six students this was not a particularly onerous task. One can see, however, that administering student access for two hundred students would be a somewhat more time consuming affair. For ease of access, a tab was added within the course in the LMS, providing a link to the Network. Elgg features include a personal profile page for each student, a blog, file storage space, and RSS feeds. All blog entries were collated and presented in date order on a scrolling page to enable students to view peer contributions and to respond by way of comments. The six students who took part in the second iteration participated comfortably in the ClinEd711 Network from the beginning of the course. We did not, therefore, have to spend time supporting students in the use of the social software. Over the duration of the course a total of 124 original blog entries were posted along with 204 comments [note however that this includes the course tutor’s postings, which the threaded discussion forum total of 135 for the first iteration did not]. One of the drawbacks with Elgg was that it did not offer

Table 3. Overview of ClinEd 711 course tasks and assessment (second iteration, 2008)

Coursework item	Module(s)
Online discussion/research/reflection throughout course demonstrating critical reflections on content and others’ contributions, locating and sharing relevant resources, and linking learning to your own context (25%)	Modules 1-8
Completion of Needs Analysis Document (20%)	Modules 2-3
Student-led module: Creation/moderation of content/learning activities/discussion for one module (20%) (small group/pair assignment)	Module 3, 5, or 6
Course Development Document (35%), comprising:	
* Critique of a peer’s draft Course Development Document (10%)	Module 7
* Completion of final document (25%)	Module 8

a feature to easily view the most recently posted comments. At our request, the web administrator reconfigured the software to provide this feature.

Combining all discussion and reflection tasks within a single discussion/research/reflection task (with amended rubric) relieved the pressure on students to post reflections at fixed times and in response to set questions. Pressure on the course tutor to provide rubric-based feedback on these reflections was also relieved, with feedback being provided more informally by comments in the Network from both peers and the tutor. For two of the students, participation levels and depth of reflection were perhaps lower than might have been the case if they had been required to post reflections. To help focus students on the depth of engagement that was expected, the course tutor provided each student with formative feedback half way through the course using the discussion/research/reflection rubric. Unfortunately this did not solve the problem of lack of engagement on the part of the students in question. It is the view of the tutors that the original reflective tasks structure would have obliged the students in question to contribute. The revised structure meant the students were penalised less for their lower level of contribution. This points to a tension between the control exercised through assessed tasks and the responsibility students have for their own learning in a personalised learning environment. Overall, however, the new assessment structure and networking environment appeared to provide a greater level of personalised learning by promoting greater intrinsic motivation to engage with peers and course concepts. Additionally, the course tutor experienced the workload as manageable although it has not been noted that marking the Needs Analysis Document, the Course Development Document and the student led modules (detailed below) still took a considerable amount of time.

STUDENT-LED MODULES

The second iteration of ClinEd 711 provided for students to lead one of three modules (out of a total of eight modules) that had previously been tutor-led in the first iteration of ClinEd 711: Technologies and Media, Role of the Teacher, or Quality in ELearning Design and Teaching. The student-led modules were created as collaborative tasks in which a pair or small groups of students (up to 4) would be assigned to one of the three designated modules. Students were provided with only a brief introduction to the module together with a set of learning objectives that they were to assist their peers to achieve. Each module lasted 2 weeks, with students expected to collaborate ahead of the scheduled start date to ensure their module was ready to 'go live' on the due date. As we have seen, one of the key aspects in personalised learning concerns students taking responsibility for their own learning. Providing student-led modules, therefore, made a significant contribution to ClinED 711 as a personalised learning environment. The social component of ClinED 711 was further enhanced through the fact that students were also taking responsibility for the learning of their fellow students. If the students allocated to a particular module failed to complete the learning activity, then their fellow students would not have the requisite content for that particular module. The overview of the task provided to students is set out in Figure 1.

Of the 20% of the total course mark allocated to the student-led module task, 12% was for the creation of a web-based module resource. The description provided in the rubric for the ideal performance for this task was:

Group members provide an engaging website, wiki, blog or other resource for the allocated module with original content and links to relevant scholarly materials together with case studies or other interactive tasks that can serve to stimulate discussion and reflection. Taken as a whole the

Figure 1. Overview of the student-led modules for students in the ClinEd 711 course

Student-led modules

The student-led modules provide you with a hands-on opportunity to work with one or more assigned colleagues to take the learning objectives for an assigned module (Module 3, 5, or 6) and create an engaging online module that will help your colleagues to achieve the module's objectives.

During Module 1 your instructor will notify you of your assigned colleague/s, and the module you will be preparing and moderating.

The student-led modules provide you with an opportunity to:

- become more familiar with the literature as you conduct your own research to locate suitable readings for your assigned module
- use software tools for collaboration, planning & production of web-based resources
- apply learning theory to the design of an online module
- build a 'teaching presence' into online materials
- set up and moderate online discussion
- reflect on the process of creating and moderating the online learning for your module.

You may wish to use the [module layout](#) used in this course (and the questions included there) to help inform your work.

You and your assigned colleague/s are able to choose which software platform you will use to create and moderate your module. Options include:

- A [wiki](#) or [blog](#) (both of which enable content to be presented and discussion to take place via a 'Comments' function)
- The [eXe eLearning editor](#) (which is able to produce webpages that can be uploaded to the ClinEd 711 course in Cecil), in conjunction with discussion conducted via a wiki or blog, or in the ClinEd 711 Network
- Setting up a Community in the [ClinEd 711 Network](#), which enables files to be uploaded and discussion to occur in the community's blog
- Some other web-based option that will enable you to present your content and links to readings, as well as to facilitate online discussion (if you're unsure, ask your instructor).

We appreciate that this is a challenge! Your instructor will be available to assist.

Assessment

Your collaborative efforts on your student-led module are worth 20% of your total mark for the course. Detailed information and assessment rubrics are set out [here](#). **Make sure you use the detailed rubric for the Collaborative Module to guide your work. Note the weightings for each category, and use the description of ideal performance for each category as your target.** If you do not carry a fair share of the workload you may incur a penalty.

resource provides a sound platform for peers to successfully fulfil the module's learning objectives.

A further 5% was allocated to moderating module tasks and online discussions engaged in by peers as they undertook the module, and the remaining 3% to accurately evaluating the success of the module design, resource, and moderation.

STUDENT RESPONSE TO THE STUDENT-LED MODULES

As noted earlier, we had initiated our redesign for the second iteration of the course (including introduction of the student-led modules) in the hope that students' engagement with the course concepts, with their peers, and with educational technology tools would be enhanced. The student-led modules embodied all of our 6 core learning design principles, but there was a particular focus on the first principle: that learning should be personally meaningful for the learner. Our

hope – indeed our design conjecture (Sandoval, 2004) – was that the challenge of collaboratively creating and moderating a module for peers would lead to positive intermediate outcomes or “observable patterns of behaviour predicted by a model of how an embodied conjecture functions to support learning” (Sandoval, 2004, p. 215). We predicted that these intermediate outcomes would include student research activity in order to offer a variety of resources and perspectives, creative module learning designs, use of a range of technologies, and engaged moderation of tasks and discussion during the modules.

Our predictions were largely fulfilled in the manner in which students engaged with the student-led module task. All three pairs collaborated successfully to produce online modules that were ready on time. The first pair used the open source eXe eLearning editor (<http://exelearning.org>) to produce their module resource, and moderated peer discussions in the ClinEd711 Network social networking environment. The second pair used a wiki (<http://www.wikispaces.com>) to both present

their resource and to facilitate discussion. The final pair used an eLearning development tool (CourseBuilder) created by a web developer at the University of Auckland, and facilitated peer discussions in the ClinEd711 Network. Each pair took a different design approach to achieve their module's learning objectives, and provided a range of readings and resources for their peers to draw on in undertaking module tasks and discussions. One of the modules was exemplary when measured objectively in terms of the marking rubric. Moderation of discussions was inconsistent for one module, but the student pairs were otherwise active in moderating their modules. Students reflected well on their learning designs for the modules that they created, on the moderation that had been effective, and on what they would do differently next time.

At the end of the course, students were asked to complete the revised post-course questionnaire. This included questions regarding the student-led modules. Five out of six students who undertook the course completed the questionnaire. Students were asked:

Was it helpful for your learning to collaborate with a peer to develop and moderate your student-led module? Why or why not?

All respondents answered in the affirmative with three of the respondents referring directly to the benefit of gaining a different perspective on their topic, two students referring to the benefit of sharing the workload and one respondent expressing the view that the task provided an insight into expectations that are placed upon their students. Students were also asked:

Did you learn more from the student-led modules (led by your peers) than from those led by the course coordinator? Why or why not?

Some students answered from the perspective of developing and moderating their own student-

led module whilst others responded in terms of their participation in the modules that were led by the other students. Three of the five respondents indicated that they had learned more from the student-led modules with one respondent referring to the need to actively learn about a module in order to present it effectively and two respondents reporting on the value for their own learning of leading a module.

Finally, in engaging with this research over two years we have shown fidelity to the fifth tenet of design research: intensive collaboration among researchers and practitioners, and learning communities. We have achieved this through working as academic partners in reflecting on and refining teaching approaches and course and research design, working with ClinEd 711 students as academic colleagues who can offer valuable insights into the effectiveness of the course design, and through our informal discussions with other researchers about the project. At the time of writing we are in the final year of our research project and we are committed to carrying out evaluations of the their iteration of the course in order to improve ClinED 711 further.

THE MORE THINGS CHANGE, THE MORE THEY STAY THE SAME

The technologies available today may open up a wider world for information gathering and provide for multiple means of social interaction through, for example, the use of Web 2.0 applications and services such as blogs, wikis and social networking spaces such as FaceBook. However the fundamental model of personalised learning with a social dimension, in which students make use of multiple media sources to work collaboratively on a particular problem, is not new. The issues and challenges faced in previous implementations of what can be considered to be personalised learning – albeit under the different name of student centred learning (Brush & Saye, 2000; Hannafin

& Land, 1997) – need to be borne in mind in the current educational climate.

We are all I suspect familiar with the now somewhat tired notion of the shift from the sage on the stage to the guide on the side and possibly even the meddler in the middle (McWilliam, 2008). However, the question of the changing role of the educator in a personalised learning environment – and by implication the role(s) of the students – is significant. Whilst personalised learning may shift responsibility for learning to the student, it is the educator who is designing the learning environment thereby providing the parameters within which the learning takes place. Thus, whilst learning may be personal, that learning has to be focused on something and that something has to do with course objectives, learning outcomes, provision of content and appropriate forms of assessment. In other words, there must still be careful course and lesson planning. If not, then students may experience a sense of “frustration” and “disorientation” (Brush & Saye, 2000, p. 79 & 88) with some students failing to understand the nature of the task or problem that has been set for them (Brush & Saye, 2000, p. p.90). Whilst it may not be in vogue for educators to transmit knowledge, they are still subject matter experts in their particular field and they need to fulfil the essential roles of advising, guiding, supporting, discussing and critiquing the student’s learning (Salmon, 2001).

Educators need to accept that students who are engaged in personalised learning are going to find resources, develop perspectives and create work that will fundamentally challenge the educator as subject matter expert. In the opinion of one writer, the educator will become “a usefully ignorant co-worker in the thick of the action” (McWilliam, 2008, p. 263). Whilst the notion of the educator as an ignorant co-worker is certainly ill considered hyperbole – a heart surgeon with twenty years experience and a wealth of theoretical knowledge to impart is anything but ignorant – it is true that personalised learning is a very different scenario

from the lecturing scenario in which the lecturer as “guru” (McWilliam, 2008, p. 266) is distanced from the students and transmitting knowledge. In contrast, personalised learning brings proximity – the educator in the midst of the learning – and the concomitant challenges that come with proximity; for example, the educator has much less control over the actual learning process and may find him/herself in unfamiliar territory both in terms of subject matter and technologies. This suggests that educators require support (Brush & Saye, 2000; Hannafin & Land, 1997) in transitioning from a traditional role to a new role in a personal learning environment. This is particularly apparent if we conceive of a student’s personal learning environment (Downes, 2005). In this case, the learner is situated at the heart of the learning environment whilst being connected to communities of interest, learning communities, communities of practice, social spaces, Web 2.0 tools, multiple sources of information and, finally, to multiple forms of media. Amine provides an excellent graphical representation of such a personal learning environment (Amine, 2007).

Teacher management strategies remain important in a student-centred learning environment (Brush & Saye, 2000, p. 92). It cannot be assumed that students will simply work effectively either as individuals (Hannafin & Land, 1997, p. 191) or in groups (Brush & Saye, 2000, p. 88). Educators need to structure activities in terms of, for example, “individual accountability, group goals and rewards, and, most importantly in the case of student-centred learning, methods for providing students with opportunities to learn and practice group management and decision making skills” (Brush & Saye, 2000, p. 81). The educator must also retain the role of ensuring that student interactions are both socially and academically appropriate. For example, maintaining appropriate decorum on message board discussions or, if the learning space is physical, within the classroom (Brush & Saye, 2000, p. 88). However, if the educator is successful in the task of establishing

an environment conducive to personalised learning then s/he can gradually fade into the background as students develop the requisite skills to become self-directed learners (Hannafin & Land, 1997, p. 194). It is at that point that we might describe the learning environment as truly personal. We would note, however, that the tutor still has a role at this stage. That role covers both the affective activities conducive to good teaching – encouragement, support and understanding for example – and the ‘intellectual’ activities that are a part of teaching well. Examples of such activities would include providing students with sources of information, assessing their work at both a formative and Summative level and providing constructive feedback to help students improve.

FUTURE RESEARCH DIRECTIONS

It is time perhaps for a slight confession. We have two issues with our future research direction. The first issue concerns the use of design research as an appropriate research methodology. We are fundamentally questioning the value of this approach to research. Our concerns in this area lie with whether or not the research results warrant the time and effort that has to be spent analysing the quantitative and qualitative data. Despite the fact that student numbers have been low on ClinED 711, we have put considerable time into analysing student coursework, student blog postings and student discussion board postings in order to determine whether the changes that we made to ClinED 711 resulted in an “improved” learning experience for students. Whilst we would say that our changes have led to improvements in the course – particularly in terms of personalising the learning for students – we are of the opinion that reflective teaching practice might have achieved the same results with considerably less work. Reflection can be understood as “learning through questioning to lead to a development of

understanding” (Loughran, 2002, p. 134). This questioning is prompted by something that is common to all reflection; the centrality of a problem in a practice setting (Centre for Support of Teaching and Learning, 2008; Loughran, 2002). Reflection would differ from a more formal research approach in terms of the fact that changes to particular courses would be made in terms of the judgment and experience of the practitioner. Furthermore, reflective practice does not necessarily result in peer reviewed publications of any sort. Whilst we have not focused on research methodology in this paper, the point is an important one in terms of the feasibility of carrying out this sort of research on a larger scale. Just as there would be problems scaling up the pedagogical approach of ClinED 711 in order to offer the course to much larger class sizes, so there would be problems scaling up the research.

Our second issue with our research concerns where to go next. The fact is that ClinEd 711 has been rated very highly by both the external examiner and by students. We have made a number of changes to the course with the result that we have provided a more personalised learning experience for students and our current judgement is that whilst we might make minor revisions to the course, ClinED 711 provides a quality learning experience for students. Furthermore, ethics approval for our research comes to an end this year (2009) and we are not envisaging asking for an extension. It is time to look for a new research direction. We have made mention throughout this chapter of the fact that student numbers on ClinED 711 are relatively low. However, the Learning Technology Unit produces distance postgraduate courses where student numbers are considerably higher. Nursing, for example, regularly offers postgraduate courses with student numbers approaching two hundred. One logical direction for our research would be to consider how we might take the learning principles applied in ClinED 711 and apply them to courses with much larger

class sizes. In essence this would entail considering how we might offer meaningful and authentic learning tasks with students taking responsibility for their own learning whilst also learning according to their preferred learning style. Taking over the pedagogical tactics (Goodyear, 2005) or the specific learning activities from ClinEd 711 is unlikely to work for reasons already cited; the demand on the teacher's time would simply be too great. The challenge will be, therefore, how to apply our pedagogical philosophy (social constructivism) and high level pedagogy (meaningful and authentic learning tasks) whilst changing our teaching tactics (Goodyear, 2005).

If we are to scale up the pedagogical approach that we have taken in ClinED 711 then there are number of key areas that we need to consider. At the level of the learning activities in which students engage we will have to address the issue of monitoring blog entries and discussion board postings. In a course of two hundred students or more the potential workload for the teachers responsible for monitoring discussions and postings is enormous. We would also have to look at the nature of our assessed activities. With large student numbers it would just not be feasible to be marking – for example – two hundred discussion board postings against a detailed marking rubric that required extensive feedback for students. It is interesting that the idea of students taking responsibility for their own learning is one of the key elements of a personalised learning environment. If students really did take responsibility for their own learning – and by extension the learning of others in a social constructivist framework – then the tutor role might be reduced to one of providing guidance throughout the course whilst also providing extensive feedback on two major assessed activities. Taking this direction would make the teacher workload much more manageable. The core research question would then be one of how to increase the intrinsic motivation of students. There is a certain logic

in considering this question since the heart of constructivist learning theory is the notion that student learning is a search for significance or meaning. If this is the case, then one of the key roles of the educator would be to understand the student, particularly in terms of what motivates each student to learn. This would be – in part at least – a question of eliciting already held beliefs from the student. It would also be a question of understanding student attitudes. For example, which students are taking the course simply to progress their careers? Which students are taking the course because they are passionate about learning? Which students prefer to learn individually rather than in a group situation? These seem to be important questions if one adheres to a constructivist teaching philosophy and yet these questions are seldom asked (Holt, Smissen, & Segrave, 2006).

CONCLUSION

In this chapter we have described the process of designing and delivering a personalised learning environment for students. We have acknowledged that the course in question – ClinED 711, EL-learning for Clinical Educators – is a specialised postgraduate course with relatively low enrolments and we have discussed the difficulties of “scaling up” the course design in order to deliver a course based on similar principles to much larger student numbers. Finally, we have recognised that there are two areas that require further research; the first is the implementation of constructivist learning theory and the second is how to offer personalised learning to larger classes. Overall, student feedback together our own experience of teaching ClinED 711 suggests that personalised learning is a valuable approach to teaching that results in a rewarding learning experience for students.

Chapter 4.3

Creating Supportive Environments for CALL Teacher Autonomy

Renata Chylinski

Monash University, Australia

Ria Hanewald

La Trobe University, Melbourne, Australia

ABSTRACT

This chapter reports on a study undertaken on the impact of pedagogical and technological innovations in language teaching and language learning, with a special focus on creating online institutional environments to support teachers' autonomy in computer assisted language learning (CALL). This study took place at MUELC, a self-funded teaching institution that belongs to a network of Australian universities offering English Language Courses for Overseas Students (ELICOS). Significant expansion in student enrollments has resulted in programs across four locations with all language teachers involved in CALL delivery. Fostering and supporting teacher autonomy became the key premise for the creation of multifaceted in-house CALL support initia-

tives, one of them an online portal containing resources for teaching and learning as well as tools for reflection on practice and opportunities for professional development. Language teachers have been building this intranet portal site using the theoretical frameworks of practitioner-based inquiry and organizational change management. The evaluation of this study reflects the duality of the research aims; namely, the features of the developed product and the learning process of the teachers involved. This may be of value to other language institutions embarking on similar online projects.

INTRODUCTION

The research site is a university English language center established in 1988, initially with about 80 to 100 students. The first CALL classroom was

DOI: 10.4018/978-1-60960-503-2.ch403

fitted in 1992 with a CALL specialist employed to promote the value of computers in language learning. Since then, the center has been offering weekly language sessions in a computerized environment that aims to equip students with computer literacy and lifelong learning skills to assist them in diverse sociolinguistic contexts.

Increased student enrollment resulted in a serious shortage of specialist CALL teachers, ensuing a conscious decision to involve all language teachers in the delivery of CALL. In order to achieve consistency and quality of CALL delivery across programs, language teachers needed to be adequately prepared and supported. This was (and continues to be) achieved by removing barriers to using technology for teaching and, specifically, through organizational efforts supporting teacher autonomy. As a direct result of these activities, teachers' attitudes to CALL have become more positive. CALL in-house training, support programs, and other means of removing barriers to teaching with technology have been a major contributing factor to this change (Chylinski, 2005).

The current study has directly evolved from these organizational initiatives aimed at supporting teachers in CALL delivery and professional development. Due to continuous expansion, the center now operates on four campuses. This necessitated some of the support structures for CALL programs to become independent of their physical locations. The main project aim was thus to create a common space online that would centralize access to CALL materials, ensure consistency of information available to all campuses, and assist with professional development in CALL, thus supplementing current work practices. The other aim was to record all factors that influenced the instructional design process and record thoughts, feelings, actions, and behaviors of the research members. The qualitative, practitioner-based inquiry approach chosen for this study meant all these factors could be meaningfully interpreted.

BACKGROUND

There is a large number of acronyms and terms used to describe teaching and learning with new technologies. For this chapter, the term Computer Assisted Language Learning (CALL) was chosen, as it emphasizes "the whole range of possible roles the computer could play in language learning" (Levy, 1997, p. 82) and because this is the term by which computer-aided instruction is referred to at the language center in question.

The theoretical grounding and literature for this chapter focus on professional development in CALL informed by the fields of second language acquisition, adult learning theories, Information and Communication Technology in Education (ICTE), diffusion of innovation theory, and action research methodology. Figure 1 depicts this chapter's focus, main knowledge fields, subthemes, and how they intertwine.

History of CALL with Some Insights to Teacher Professional Development

Warschauer and Healey (1998) identified three phases of CALL in their overview of the use of computers for language teaching in the last 30 years. They observed gradual but irregular transition from the behavioristic phase of CALL through to the communicative and, most recently, its integrative phase. An alternative and, we would like to argue, more encompassing attempt at the analysis of the history of CALL is provided by Stephen Bax in his paper titled *CALL—Past, Present and Future* (Bax, 2003). Rather than describing phases, Bax provides three approaches to CALL teaching; namely, restricted, open, and integrated. He argues that this helps to alleviate confusion with time periods and methodologies and allows for a better description of teaching and learning practices.

Figure 1. Literature focus, themes, and subthemes and their overlap

Leaving these discussions aside (not because they are unimportant but because analyzing them is beyond the scope of this chapter), the following section will briefly review developments in CALL with particular emphasis on language teachers and their professional relationship with computer technologies.

Initially, CALL was influenced by behaviorist theories of learning in the 1950s, with repetitive language exercises based on *drill and practice* courseware. During the 1960s and 1970s, main-frame computers were used, with computers being seen as a patient tutor able to give instantaneous feedback for repeated vocabulary drills, grammar exercises, and translations. These were relatively easy to program by early CALL software developers, as they utilized set instructional sequences. Each step required a learner response, followed by computer feedback (Ellis, 1997). Professional development for CALL teachers focused on computer operating skills, labeled by Jackson (1971) as the *defect view* because this development focused on helping teachers overcome deficiencies in their computing skills. This remedial type of professional development was mechanical and consisted of a singular event focusing on the use

of the technique, whether it was appropriate from a pedagogical point of view or not.

According to Warschauer and Healey (1998), the introduction of microcomputers and, more importantly, the shift at the theoretical and pedagogical levels toward the communicative approach, allowed for the second phase of CALL to commence. Dissatisfied with behaviorism and realizing that learning was not just a *stimulus-response* reaction, researchers actively investigated other theoretical frameworks. The concept of *individualistic* learning began influencing educational practice and gradually became the dominant learning theory of the time (Jones & Mercer, 1993). This concept had implications for software design and evaluation of computer-based classroom learning and created a problematic relationship between language learning theories and educational computer programs (Jones & Mercer, 1993). This significant pedagogical shift resulted in moving from the paradigm of an instructional approach toward a collaborative and facilitative approach. This move has been reflected in the terminology of the field: *language instruction* was now seen as *language acquisition*, and the term *foreign language teaching and learning* changed to *second language acquisition* (Krashen, 1982).

In CALL, skill practice was provided through courseware that offered language games, paced reading, and text reconstruction. These choices were giving learners numerous options, decision power, and interaction in discovering the correct answers. The previous view on computers as tutors was reconceptualized, with the computer being seen as a stimulus and a tool. Software was used to provoke discussion and critical thinking as well as to teach language aspects through the use of word processors and their features (Warschauer, 1996).

The previous defect approach to professional development of CALL teachers gradually lost its appeal since it emphasized the latest educational fads and prescriptive techniques concentrating on simple or behavioral aspects of teaching. Instead, the *growth approach* (Jackson, 1971) was observed more frequently. This approach recognizes that teachers are continuous learners who desire to solve instructional and organizational problems and wish to be involved in the decision-making processes.

The next historical phase of CALL was facilitated by advances in technological developments; namely, multimedia computers and the Internet. Numerous media (e.g., text, graphics, sound, animation, video) could now be accessed and used by the learner through the keyboard or the mouse, or by listening through headphones or speaking into a microphone. Authentic on-screen environments allowed application of all four macro skills within one activity while giving learners control over the pace and path of their learning. This was achieved through revising or skipping specific parts as desired and by managing the levels of difficulty. The main focus of instruction was not merely on the content and language forms but also increasingly on learning strategies. However, the quality of available programs, combined with technological limitations, prevented hypermedia having a significant effect on language learning (Warschauer & Healey, 1998).

In contrast, the expansion of electronic communication and the World Wide Web (WWW) in

the late 1990s offered a cheaper, easier, and more convenient means for using language across all aspects of the curriculum. Initially, materials on the Internet were textbooks, grammar exercises, and collections of random activities. Using e-mail to share messages, documents, graphics, sounds, and video files offered other meaningful, authentic, and immediate language learning opportunities (Warschauer & Healey, 1998). Currently, the immediate access to authentic materials in the target language on the WWW (i.e., newspapers, radio broadcasts, podcasts) and opportunity for publication of texts and multimedia materials by learners (i.e., blogs, wikis, and digital storytelling) created by the Web 2.0 social software, facilitates an even more communicative approach to using CALL. No longer restrained by difficult and time-consuming authoring shells and the static, self-contained courses on CD-ROMs, language professionals increasingly use these new, user-friendly technologies in their teaching (Godwin-Jones, 2003).

Current technologies have opened up possibilities for creative development of language learning and teaching materials, thus enhancing and also necessitating increased teacher autonomy.

Supporting Teacher Autonomy Through an Online CALL Portal

As previously stated, MUELC is committed to CALL teacher support and provides a range of in-house initiatives in this area. These aim for teacher autonomy through structured professional development opportunities, provision of relevant teaching resources, flexibility in the choice of materials and methods, and opportunities for reflection on practice. In this study, the MUELC research team wanted to test whether providing all these support functions through an online portal was at all possible or desirable, and whether it would aid CALL teachers' autonomy.

Research Aims and Questions

The key axiom, frequenting all practitioner-led inquiries is the identification of a problem emerging from the tension between research and practice (Dick, 1999). Similarly, the context of this research was not purely academic but also pragmatic. The aim was to involve teachers at the language center in creating a Web-based CALL teacher portal that would support teacher autonomy through professional development provisions, transparent access to resources, and reflection on CALL practice.

The overarching research question was “*Can online portal support teacher autonomy in CALL?*” with the following three lines of inquiry:

1. In what ways do teachers feel that the Web-based CALL teacher environment can assist them in their professional development in CALL?
2. Can access to resources, from the teacher’s point of view, be improved with this online environment?
3. Do teachers feel the need for professional discussion and collaboration in CALL ?

Would they reflect on their CALL practice using the new Web-based environment?

The graphic representation of these aims in Figure 2 demonstrates how they evolved from contemporary CALL support structures at MUELC (Chylinski, 2005) and their placement within the theoretical and pedagogical assumptions of teacher autonomy.

Research Methodology and Supporting Literature

The emphasis of this study was on instigating a process of positive change and on the recording of factors influencing the research and the research subjects. Most fitting for this purpose was action research, defined by Geoffrey Mills as follows:

[A]ny systematic inquiry conducted by teacher researchers to gather information about the ways that their particular school operates, how they teach, and how well their students learn. The information is gathered with the goals of gaining insight, developing reflective practice, effecting

Figure 2. Research aims in relation to current MUELC practice and underpinning theory

positive changes in the school environment and on educational practices in general, and improving student outcomes. (Mills, 2003, p.4)

Action-research, or practitioner-based inquiry, usually assumes participation and is occupationally relevant and responsive (Dick, 1999). Participation of the teaching staff was of significant importance during this project; team members were expected not only to use and evaluate an online environment but also to engage in its design right from the conceptual stage. Their active involvement had better potential to deliver a product that would meet CALL teachers' needs. It was also hoped that a collaborative and collegial exchange of ideas would foster greater understanding of ICT in language education, thus contributing to teachers' professional development. This intention was in line with the views of Moon (2000) on professional reflection as an effective learning tool for practitioners.

The choice of action research for this particular project was further supported by two other bodies of literature; namely, managing organizational change and instructional design.

The literature on managing change at educational institutions stresses the importance of staff involvement in the process of instigating change. Such involvement of colleagues increases the ownership, improves understanding of the process of change, and builds a critical mass of change agents (Eckel & Kezar, 2003).

The literature on instructional design strengthens this view and proves that in order for multimedia projects to be successful, collaboration should occur between experts of the content and experts of multimedia design (Clark & Mayer, 2002; Sinclair, Alfred & Smith, 2002). Researchers also advise against educational technology projects being totally dependent on individuals or a few impassioned professionals. Such projects are usually short-lived because they are not entrenched in the work culture of the place (Sheely, Veness & Rankine, 2001).

The design of the CALL Teacher Portal research was informed by a wide range of literature on Instructional Design Models (IDMs) and specifically by works of Andrews & Goodson (1991), Sims (2000), and Sheely, et al. (2001). Gustafson and Branch (2001) surveyed instructional development models and categorized them according to scope and purpose into Classroom Oriented Models, Product Oriented Models, and Systems Oriented Models. In accordance with their definition, the design of the CALL Portal is likely to fall into the *Systems Oriented Models* focusing on analysis of a large environment and assuming a large scope. The articulation of such a model usually encompasses the process of theoretical conceptualization (Conceptual Stage/Analysis); the process of designing of a platform (Product Design/Prototype); the process of production, dissemination, and adoption (Development, Dissemination/Adoption); and finally, the process of evaluation.

These stages, according to Sims, rarely occur in a chronological manner. His dynamic I³D model (Interactive Instruction Influence Model) describes particularly well project management and quality control practices at MUELC (Sims, 1997).

An important element of the way the design of the CALL Teacher Portal was managed was the context analysis (added as an important ingredient of IDMs to the analysis stage by Tessmer and Richey in 1997). Focusing on context allowed us to analyze learner background, incentives, resources, organizational culture, and available group support.

The CALL Teacher intranet has been designed to provide for, among other functions, teachers' professional development in CALL. Therefore, the quality of the interactivity constructs have been of significant importance to the project. Designing interactivity may seem to belong more to a world of computer games. However, it plays a prominent role in all instructional design environments. There is more to interactivity than just the physical

interaction with software. Sims (2000) seconds Aldrich, Rogers and Scaife (1998) to move “the emphasis away from the level of physical interactivity at the interface (i.e. button pressing and mouse clicking) to a consideration of cognitive interactivity (i.e. learning activities which are supported when interacting with the software)” (p.331). Sims (2000) provides an in-depth analysis of interactivity through taxonomies and levels while defining four dimensions of interactive constructs: interactivity and learners, interactivity and content, interactivity and pedagogy; and interactivity and context. It is within those four dimensions that the interactivity constructs of the CALL Teacher intranet will be discussed later in this chapter. (Table 1)

Account of the Process and Data Summary

The Action Research Team consisted of six teaching English as a second or other language (TESOL) experts with various degrees of CALL experience and proficiency. The selection process was completely voluntary.

Data were gathered in several ways: detailed notes from the team meetings with verbatim quotes from participants, journal entries, questionnaires, and field documents (archived CALL reports and in-house publications). In keeping with action research approaches to data analysis, once data collection was complete, a theoretical framework was used to enable analysis and evaluation. All data were categorized and evaluated according to the conceptualization of the action research process in relation to teaching a language with ICT and teacher autonomy frameworks.

The research took six months in all, with the main part of the project having three distinctive stages: conceptual design, platform design, and project evaluation. On average, team members worked one hour a fortnight over four months on the main research component. There were nine meetings in all. The purpose of these meetings was to set an action plan and decide on priorities, read excerpts of relevant literature and discuss its understanding, explore thoughts and feelings as reflected in the journals, and review the data gathered from previous meetings to clarify accuracy if necessary.

Table 1. Research and action elements at various stages of the project

Project Stages	Research Process → People (as researchers and adopters)	Action Product → Online Portal (as a learning environment)
Stage 1 Conceptualization	Who is involved? How do they work? What paradigm do they associate with? What is their educational context? What are their skills, knowledge, and theoretical framework? What do they want to achieve?	What is its purpose/rationale?
Stage 2 Platform Design	Who are the users? What are their needs? What is their IT context (expertise, access, and support)? What is their CALL context (expertise, access, and support)?	What will the interactivity constructs be? What media should be deployed? What is the publishing model? What are the quality assurance procedures?
Stage 3 Project Evaluation	Do users feel the product meets their needs?	Is the product being used as intended?

The main characteristics of action research are, as its name suggests, *action* and *research* (Dick, 1999). The action aspect of this research was to create an online environment that empowers CALL teachers, while the research aspect was to instigate and evaluate the learning process and to reflect on practice with a view of professional and organizational growth.

During the first stage of the project (Conceptualization), the team engaged in discussion of research background, context, and aims, while reflecting on their reasons for joining the action research group. Responses revealed that all team members regarded this as an opportunity for professional development and wanted to make a contribution and be part of positive change, believing in research as a way of implementing new ideas.

Reading of Patton's *Common Principles Undergirding Qualitative Inquiry and Humanistic Values* ensured common understanding of qualitative methods of action research and, particularly, understanding the idea of *process use* (the process as important as the outcome) as opposed to *findings use*, the former being of a greater learning value to the process participants and to the program being developed (Patton, 2002).

The focus then moved to defining types, or categories, of CALL teachers in the language center and specifying their respective needs in order to become autonomous. The distinction was based on teachers' CALL experience and skills (Novices, In-Transition, Experienced/Confident, Power Users), attitudes to CALL (Luddite or Debutante, Chrysalis, or Explorer), and mode of employment, which intertwined with time and access factors (Sessionals, Contract, Emergency Teachers, Part-Time, and Full-Time).

During Stage 2 of the project, the Platform Design stage, needs for each CALL teachers' category were prioritized and the issue of a model design considered through questions such as "Can or should the online portal meet these particular

needs and how, and what functions should it fulfill? The list of desired functions and items for inclusion was then matched against the aims of the research. Then, the team reflected on the discrepancies between the project aims and the proposed project's design thus far. The exercise revealed that the collaborative and reflective functions of the intranet portal had not been sufficiently addressed by the team. The general discussion that followed aimed to ascertain if teachers regard collaboration in teaching and teaching CALL in particular as important.

Finally, teachers had input into the proposed site structure, learning some basic principles governing Web design and usability issues (Krug, 2000). The team members also took part in a hands-on session on the functions of the discussion board settings and blogs, which for some was the first encounter with online collaborative environments.

During the final, evaluation stage of the project, participants were asked what they judged as measures of success and/or failure in assessing both the product and the professional development benefits of the project. Finally, the future of the CALL intranet portal was contemplated and the recommendation for further evaluation and development discussed.

DISCUSSION

The two-step process of a final evaluation reflected the duality of the research aims; namely, the learning process of the teachers involved and the features of the developed product. The next section of this chapter aims to ascertain whether subjects of this study felt participation in the research developed them professionally as hypothesized and whether the designed product was indeed perceived as supporting teachers' autonomy in CALL.

The Teachers

Providing for CALL teacher autonomy was a principal theoretical concept behind the design of the CALL teacher portal. Team discussions on autonomy during the first stage of the project found teacher autonomy important, though difficult to achieve, and perhaps in some circumstances not entirely desirable:

- “it is essential for teacher satisfaction” (Participant B)
- “essential in our environment, due to variability in course structure and programs” (Participant F)
- “too much autonomy may not be desirable to teachers with no CALL experience” (Participant C)
- “not all teachers want CALL autonomy (in particular novices, those not confident)” (Participant D)

These discussions led to specifying needs of CALL teachers according to their position on the path to full autonomy. Members agreed that the needs of novices and in-transition teachers were quite similar, these needs being immediate, highly specific, and of a survivalist nature. Without trying to patronize, the team felt these teachers needed to be closely guided through lesson plans for technically uncomplicated CALL classes. These lesson plans “should not only explain what to do, but also how to do it” (Participant E) to ensure the greatest possibility for success, thus boosting the confidence of a novice teacher. Providing access to technical information, a ready-made list of logins and passwords, instructions on the use of CD-ROMS and other resources were also seen as paramount. The need for access to CALL theories and research was ranked low on the list of priorities, although the need for explaining differences between CALL and non-CALL language classes was seen as important.

There was also a consensus that meeting the needs of novices and in-transition CALL teachers would simultaneously meet the needs of a much wider group: emergency teachers, teachers with limited access to technology, and those new to the center.

The needs of the Experienced/Confident and Power Users (i.e., professionals specializing in CALL) were not seen as a priority by the team: “It is not relevant to them” (Participant C), “they are already autonomous” (Participant A), “they are power users” (Participant C). This issue was revisited when the Power Users voiced their hope for their needs to also be considered in the project.

When the issue of the missing collaboration and reflective functions in the design of the CALL intranet portal surfaced, we probed into their importance to the research participants. Some observations made on this issue included:

- “it is important especially in technology applications” (Participant A)
- “I believe in collaboration” as it “enriches our teaching but doesn’t preclude individualization and autonomy” (Participant B)
- “is essential to understanding of both relative and absolute values” (Participant C)
- “increases both variety and cohesiveness of teaching” (Participant D)
- “broadens one’s own outlook,” supports “learning from others” (Participant E)
- “reflection on practice brings the biggest benefits” (Participant F)
- collaboration in CALL is “more important than other areas of language teaching because there is more to know and the knowledge base is expanding exponentially” (Participant F)

The *collaboration* function, it was therefore decided, should be an integral part of the portal and would take a form of either an asynchronous discussion board or reflective blogs. After learning more about Web usability principles and in

order to ensure consistency of layout, the team decided to adopt the global university template as the template for the CALL portal.

Finally, issues of quality control and proofreading led to major decisions that all student handouts should be produced using a special template and that an editorial panel for the project should be formed to decide on priorities for further developments, to proofread the texts, and to assist with recordkeeping.

The Product

The process of conceptualizing and analyzing the unique needs and circumstances of CALL teachers at MUELC resulted in a development of a prototype that avoids lock-step and linear progression and allows for the model to be adapted for a variety of CALL programs, to be able to expand as new resources become available, and to be developed further when the context analysis prompts such a necessity.

The CALL teacher intranet model also borrows on the cognitive apprenticeship theme, reflecting situated cognition theory and adhering to a number of its principles (Anderson, 2000). First, it aimed at presenting knowledge in an authentic context; namely, settings and applications that would normally involve that knowledge. Second, it provided modeling and explanation on the *how* and *why* of the learning process. Third, it encouraged learning through social interaction and collaboration. In addition, it was hoped that the environment would gradually reduce assistance in favor of encouraging independent performance (Vygotsky, 1978). Finally, it aimed to provide opportunities for reflection where tacit knowledge becomes more explicit, helping teachers to analyze their performance and making the computer a *cognitive tool* (Lajoie, 2000).

One of the aims of this research was to build an online environment that would enable teacher autonomy in CALL. To facilitate this goal, this online site was to perform three main functions:

provide easier access to resources, professional development opportunities, and reflection on practice. This initial conceptualization of the core intranet portal areas might suggest that they form discrete elements of the site, accessed perhaps through distinctively separate points of entry. However, in the design developed by the team, this is not the case. The intranet portal was created within the learning theory of constructivism, and so it is ultimately its users who determine what role each design element plays in the process of their learning.

The resources area, for example, can be accessed as a separate entity, giving an overview as well as details of digital resources (CD-ROMs and online) available to CALL teachers (see Figure 3). However, it can also be accessed through the *Lesson Bank* area, where specific lesson-related resources are discussed. The Lesson Bank itself can be considered a resource, but it can also function as a professional development tool through the provision of lesson exemplars and models. Similar blurring of function boundaries applies to the *reflection on practice area*, as professional reflection can now occur not in one, but in many ways. Teachers may reflect on their methodology by analyzing lessons submitted to the lesson bank, by reading publications on CALL theories, and by collaborating through internal and external discussion boards.

Sims (2000) defines four dimensions of interactive constructs: learners, content, pedagogy, and context. He advises instructional designers to analyze these interactive constructs in detail in order to ascertain how effective the user-software interactions (and therefore the learning process) might be. Looking at the CALL intranet portal through these lenses provides a number of observations: first, that the platform was designed with the explicit *underlying philosophical and pedagogical concept* (teacher autonomy), and therefore, its *content elements* and the media used were selected to serve that purpose; second, that the underlying pedagogy is based on a constructivist

Figure 3. CALL Teacher Portal home page (© 2008 Monash College Pty Ltd., used with permission)

learner model, and therefore, the resulting design allows for the learning focus to change for different users; and third, we can observe that the design caters to different users because its interactive constructs are a function of the stage at which *teachers* (as *learners*) find themselves (e.g., Novice, Explorer, Power User and/or Emergency, Sessional, Full-Time/Part-Time). This also determines the *when* and *where* of the learning process, the *contextual* elements of the intranet.

If analyzed in the context of diffusion theories (Rogers, 1995; Surry, 1997), the product displays four attributes that increase its likelihood of success. First, it has been designed and trialed on a limited basis, with the opportunity for improvement before the product reaches a wider group of users. Second, it has an advantage over the status quo by providing more flexible access to CALL resources, professional development, and discussion completely independent of time and place. Third, the system is not overly complex and caters to any level of CALL expertise. Finally, it is compatible with existing practices and values; namely, current Second Language Acquisition theories, CALL pedagogy, and CALL professional development practices at the language

center, which greatly enhances its prospects for wider adoption.

The following section should be viewed as a commentary on screen captures of various areas of the intranet CALL portal. The first to be shown there is the *resources area*, which contains a description of in-house digital resources and examples of their applications in CALL classes (see Figures 4 and 5).

The second area, the *professional development area* of the portal, contains tutorials on various aspects of teaching languages with ICT tools such as word processing, animated presentations, electronic publishing, and electronic communication. These tutorials are accompanied by examples of linguistic applications and teacher-developed classwork materials that utilized these tools. Figures 6 and 7 provide sample pages from the professional development area, titled *Teaching English with a Word Processor*, and one of its subtopics, *Dragging*.

To cater to novice CALL teachers, a lesson bank for all programs and levels was established. It is a steadily growing area of the intranet portal, where all contributing teachers are acknowledged. It contains handouts for students with step-by-step

EASE CD: Essential Academic Skills in English

How to play:

Note: You cannot play this CD from home

1. Double click on a desktop folder that reads "CD Roms".
2. Double click on the desired CD title.

Overview:

It is a video-based CD-ROM designed to help students whose first language is not English with their studies at English-speaking universities with an emphasis on **Listening to Lectures**. It contains 85 video clips from 40 different lectures in 25 different departments across the humanities, social sciences and sciences. There are more than 300 pages of interactive tasks based around these video clips. These are designed to help students improve their academic listening and language skills. You can view screen shots at this website: <http://www.ease.ac.uk/samples.htm>

There are six units which guide students through the key language skills involved in listening to lectures. These units are:

Unit	Lessons	Suitable for (as discussed and agreed by the MUELC review panel)
Unit 1: Openings of lectures	- opening a lecture - introducing a topic - structure and content - talking about earlier lectures - structure and structural phrases - questions as structure - note-taking - vocabulary	ELBP, ETP 5&6
Unit 2: Structure and organisation of lectures	- opening and closing summaries - structure and structural phrases (signalling) - mainline (forward, backward, identifying) - transitions - note-taking (topic: Indian cinema 1945-1970) - vocabulary (idioms, synonyms, connotations, word analysis)	
Unit 3: Functions (i)	- defining - classifying (topic: economies) - comparing and contrasting (topic: novels)	ELBP, ETP 5&6
	- exemplifying - note-taking (pre-teach or research HIV AIDS) - vocabulary (pre-flags for 'not')	ELBP, ETP 6
Unit 4: Functions (ii)	- Referring to Sources - Evaluating sources - indicating cause and effect - indicating purpose - interacting - Recap - Note-taking	ELBP, ETP 6
Unit 5: Significance and Attitude		ELBP, ETP 6
Unit 6: Argumentation		ELBP, ETP 6

[top](#)

instructions and additional resources for the teacher. The lessons are technically uncomplicated and do not require multitasking (see Figure 8).

The CALL Teacher Portal, as was previously explained, also enables teachers to access both in-house and external communities of practice, and to set up and maintain their own blogs for reflection on practice. Figure 9 depicts an ex-

ample of the page encouraging exploration of an online discussion board (Nicenet.org).

EVALUATION

At the first meeting, members stated that the main reasons for joining the action research team was their willingness to contribute to the process

of change and willingness to learn more about CALL. Their comments during the final stages of the research confirmed their satisfaction in achieving both of these goals. When asked if the involvement in the action research process met their expectations, they provided comments such as the following:

- “Yes, because (i) I feel I had input into the final prototype, (ii) I learned about how to design/ implement a project in a CALL environment, and (iii) I expanded my theoretical basis of understanding in this field” (Participant A).
- “Insofar as I expected that there would be a tangible outcome—the intranet—and that it would be a collaborative process” (Participant E).
- “Yes, I am aware more about the process and the product” (Participant D).
- “I wasn’t sure of what to expect at first—I thought we were going to ‘put things on the intranet,’ but I was happy to be involved in the ‘how’ rather than the ‘what’” (Participant C).

The participants commented on their increased awareness of the complexities behind developing

Creating Supportive Environments for CALL Teacher Autonomy

Figure 8. Example of a lesson bank for pre-intermediate levels (© 2008 Monash College Pty Ltd., used with permission)

Monash University > Monash College Group Intranet > Labs > Call > Es

ES 3 Pre-Int - Module A

At the end of the 10-week course student should demonstrate the following ICT skills:

- ICT1 Can create and format simple wordprocessed documents using basic tools from the Formatting Toolbar and Picture Toolbar. Can use Spellcheck tool
- ICT2 Can use a search engine to search for images. Inserts and manipulates images in a wordprocessed document
- ICT3 Can reorganise a wordprocessed text using cut/copy or dragging

When creating CALL course teachers have an option of:

- designing own integrated lessons
- creating a 5-week project or using an [existing project](#)
- using lessons from the weekly [lesson bank \(if available\)](#)

Students need to be introduced to the following digital resources

- [That's Life CDROM](#)
- [Interactive Picture Dictionary CDROM](#)
- [Issues in English 2 CDROM](#)
- [Tense Buster Lower Intermediate CDROM](#)
- [Monash English Self Access \(MESA\) website](#)

Lesson bank

Note: raw documents for students are located in: My Computer/Student/ES classes

Monash University > Monash College Group Intranet > Labs > Call > Pcollaboration

Discussion Board (Teacher's Hub on Nicenet)

Teacher's Hub can be used for practice in using an online discussion board (here: Nicenet) and for professional reflection.

Instructions:

- go to [Nicenet](#) homepage
- click "Join a class" (because you are going to join a "class" called the "Teacher's Hub".
- Type in the class key: BZ32442T39 (you only need it once, when you join)
- Fill in your details (your username and password should be the same as the one for MUEL) and click Join the Class

Once inside:

Navigate through/click on various links on the left hand side and see what they do.

Experiment:

- submit a document (plain text),
- submit a link,
- create a conference posting,
- reply to existing postings

a worthwhile instructional design environment, especially one that aims to cater to a range of user types. Some team members found it beneficial to learn about action research methodology and to extend their knowledge of Web design principles.

All teachers found the most rewarding aspects of their involvement to be the team approach to the research and to the portal design process. They appreciated the fact that many points of view were expressed and taken into account, which resulted in a comprehensive needs analysis and, it can be inferred, a superior product. Some comments on this issue were the following:

- “Views and opinions of all people involved at the various stages were represented and responded by the researcher. It was a committee, and the ‘chairperson’ was in charge, but in a good way—kept us on track and took on board design changes, and so forth” (Participant C).
- The strength of this process was “team and the task orientation” (Participant E).
- The strength of this process was “team-work and great direction and super well-structured (i.e., we knew exactly what was required and no pressure given” (Participant D).

The main weakness, as the team repeatedly stated, was the difficulty in arranging team meetings and time allowance:

- “How to ensure team members all had enough exposure prior to each meeting to contribute and how much time was available for team members to experiment between meetings in a class environment” (Participant D).
- “Not everyone is able to put in time commitment as required (time factors)” (Participant E).
- “Time for group meetings” (Participant A).

These findings confirm the common knowledge of time-pressures and their effect on teachers’ professional development. Results highlight the tension between the necessity for thoroughness and adherence to the required stages (analysis, product design, dissemination/adoption, and evaluation) and the need to maintain interest and momentum to deliver tangible outcomes within a reasonable time frame.

The teachers saw this research as a “goal-oriented, cohesive and targeted” process (Participant B), which resulted in a “tangible gain” (Participant D) and was “a rewarding and productive experience” (Participant A). They all believed that the project achieved its aims and catered to their needs as CALL teachers. In relation to the three fundamentals of teacher autonomy (i.e., knowledge, choice, and reflection), they felt that the self-designed intranet portal holds the potential to support them in professional development, in selecting teaching materials and resources, as well as in sharing experiences and on reflecting on CALL practice.

At the time of evaluation, the system had been in place for only a few weeks. Not surprisingly, when asked to establish measures of project success, team members initially thought of an external evaluation; that is, an evaluation achieved through another study and conducted with a group of teachers not involved in the intranet portal design. This was beyond the scope of the research in question and would certainly require another research cycle.

There are at least three other strong indicators suggesting this process was successful in implementing positive organizational change. The first indicator is the product, the intranet portal itself, and its superiority when compared to earlier environments created without teachers’ input and accompanying research. The second is the members’ clear interest in the future developments of the intranet portal and their ongoing willingness to contribute to the process as a means of keeping abreast of its changes, adoption rate, usefulness, and relevance in promoting teacher and

student independence. All members voiced that the action research process should be an integral part of further intranet portal developments, and most expressed their interest in maintaining their involvement, although with a lesser degree of engagement or under a condition of time release. This last caveat is symptomatic of the professional development program's intensity if conducted in the way it was and considering its impact on teachers' busy schedules.

The third indicator of success is the grassroot aspect: the upward direction of this change, the voice and strength it gives to the efforts for improvement. This is no longer the voice of a lonely impassioned individual, but rather the voice of a team of language teachers interested in their professional development with the goal of improving the learning experience of their students.

SUMMARY

The analysis of the evaluation feedback is very encouraging, proving that the intranet portal has fulfilled its professional development aims by providing relevant and immediate, just-in-time training opportunities (McKenzie, 2001).

The research process and the product of this research were equally important, and both achieved or have the potential to achieve tangible professional development outcomes for MUELC teachers. These outcomes include increased awareness of CALL principles; better understanding of teacher autonomy in light of second-language acquisition theories; greater acceptance of action research methodology as a method for professional reflection; and finally, improved appreciation of research processes required for collaborative development of instructional design environments.

This study corroborated the findings of other proponents of action research who have stressed the relevancy, active participation in the learning process, knowledge focus, and collegial support

as most effective for professional development (Borko, 2004).

The project's predicted future developments are collaborative material development, raising teacher awareness, a review, an external evaluation, and adapting the model to other programs at MUELC. The process of evolution, according to the team, should continue for as long as it will be required and for as long as it will serve its purpose.

CONCLUSION AND FUTURE TRENDS

The promise of CALL—the utilization of computers for teaching or enhancing second-language acquisition—remains largely unfulfilled. Barriers are the technical problems and the limited capabilities of computers, which still lag behind the way language teachers and learners would like them to perform, and administrative constraints (Felix, 2003). Issues to do with the role of the teacher in CALL, effects of the technology on the methodology, integration, and evaluation, remain central (Levy 1997).

The previous lack of consensus on second-language acquisition (Nulman, 1996) is bridged by the re-emergence of the eclectic approach (Mellow, 2002) and the incorporation of cultural dimensions (Liddicoat, Papademetre, Scarino & Kohler, 2003). Despite epistemological differences, language specialists agree on the most basic principles or conditions under which language instruction should take place: students should be exposed to rich language and cultural input, have authentic opportunities to interact, and be actively involved. They should be encouraged to reflect on their learning and to take responsibility for their own learning (Liddicoat et al., 2003).

When new and emerging technologies are juxtaposed with these basic conditions for language learning, they do indeed hold great promise. There is no question that the Web and other technolo-

gies provide greater access to authentic and rich intercultural language input, although not all languages are equally well represented. Web 2.0 social software such as blogs, wikis, and voice and text chat lend themselves to interactivity and personal engagement but also to reflection on learning strategies. Human Language Technologies (HLT) such as Natural Language Processing, Machine Translation, Corpus Linguistics, Speech Technology, and artificial intelligence will make a significant impact on CALL (Davies, 2007), as will indeed the developments of virtual worlds and virtual tutors.

However, the majority of language teachers do not feel adequately versed in or prepared for teaching with the use of computers (Hubbard & Levy, 2006). Thus, the vision of normalized CALL (Bax, 2003), where computers in language learning and teaching are used with the same normality as books and pens, is still seen as a distant and future goal for the profession.

This is an issue of concern because many argue that the most significant impact on the effectiveness of CALL in the future will be the ability of teachers to create appropriate learning contexts and learning, to allow students to create, and to share their own content through discovery and experimentation within cyber-communities. Such fostering of learner growth and language development will generate even greater necessity for teacher and learner autonomy, and it is thus of paramount importance that learning organizations not only allow for teacher autonomy but also *actively* support its three fundamentals: access, knowledge, and reflection. The research described in this chapter is an example of how such support might be provided. It signifies how adherence to proven methodologies of action research informed by instructional model development theories can bring tangible results and desired improvements.

KEY TERMS AND DEFINITIONS

Adult Learning Principles: The field of adult learning was pioneered by Malcom Knowles (1913–1997), who theorized that self-concept and motivation to learn, previous experience, readiness to learn, and a problem-centered approach to learning are the main principles.

Computer-Assisted Language Learning (CALL): An approach to language acquisition that utilizes computer technology to assist with the teaching and assessing of material, often including various interactive elements.

Communicative Method/Approach: A way to teach and learn language(s) with the goal of communicative competence. It stemmed from dissatisfaction with previous grammar-based and audiolingual approaches, and focuses on the processes of communication in various sociolinguistic contexts.

Constructivism: Jean Piaget (1896–1980) is credited with the development of this theory whereby learners construct new knowledge from their experiences through processes of accommodation and assimilation. Constructivism describes how learning should happen, and it is often associated with “learning by doing.”

English as a Second Language/English as a Foreign Language (ESL/EFL): These abbreviations are often used interchangeably to describe the science of teaching English to non-native speakers. ESL denotes teaching English to Non-English Speaking Background (NESB) persons in countries where English is dominant, such as Australia, Canada, the UK, or the USA. EFL

denotes teaching English to NESBs in countries where English is not the official language.

Teachers of English to speakers of other Languages/Teaching English as a Second or other Language (TESOL): Both interpretations are used for the abbreviation, causing significant confusion. The first refers to the professional associations and their members, whereas the second construct is often used as the umbrella term for ESL and EFL.

Instructional Design Models: Robert Mills Gagné (1916–2002) is one of the leading theorists in models of instructional design. Models offer structure and meaning to Instructional Design problems by helping negotiate the design task through sequenced components. The context of use determines the value of a particular Instructional Design Model.

Diffusion of Innovations Theory: Everett Rogers (1931–2004) suggested a five-stage model for the diffusion of innovation (Knowledge, Persuasion, Decision, Implementation, Confirmation) and five types of adopters (innovators, early adopt-

ers, early majority, late majority, and laggards) in his 1962 book titled *Diffusion of Innovation*.

Practitioner-Based Inquiry (PBE): Small-scale, applied educational research activity by practitioners in fields such as school teaching, nurse education, and social work to address professional concerns.

Second Language Acquisition (SLA): The process by which learners acquire an additional language, often termed the target language. SLA focuses on the language system and learning processes of naturalistic acquisition of language. Stephen Krashen used the term “language acquisition” to differentiate from formal language learning.

Teacher Autonomy: Involvement in and ownership of the change process. It encompasses professional freedom, self-directed professional development, transformation through dialogue, critical reflection, and analysis of the teaching process.

APPENDIX

Description of Participants in Relation to Their (Self-Perceived) CALL Experience and Training

Participant A. Usually teaches CALL in a few five-week courses a year and considers herself a teacher who had some limited experience in CALL and only through her work at MUELC. She did not study CALL as a university subject or as a short course. Her only training was received through MUELC's Professional Development workshops.

Participant B. He teaches CALL at least once a week in a few five-week courses a year and believes he possesses practical knowledge of CALL with some past experience, which he considers "very out of date," gained by choosing CALL as a unit at a postgraduate level. He also attended short courses in CALL.

Participant C. Teaches CALL at least once a week in almost every course, seeing it as good fun for students as well as an opportunity to be creative in learning English and increase their computer skills in a nonthreatening way. She did not study CALL at a tertiary level and did not attend any short courses in CALL.

Participant D. The fourth member of the team is involved in teaching a few CALL courses a year and thinks he has a practical knowledge of CALL, which was also a subject he has done at a tertiary level.

Participant E. He teaches mainly CALL and has a sound theoretical and practical knowledge of CALL gained through his Master's degree course.

Participant F. He teaches CALL regularly, one or two classes in almost every course in the year. He sees himself as a teacher with sound theoretical and practical knowledge of CALL. He completed a semester unit in CALL at a university level, which was quite in-depth, and though some years have passed, this knowledge is still functional.

This work was previously published in Handbook of Research on E-Learning Methodologies for Language Acquisition, edited by Rita de Cássia Veiga Marriott and Patricia Lupion Torres, pp. 387-408, copyright 2009 by Information Science Reference (an imprint of IGI Global).

Chapter 4.4

Learning Object Based Instruction

Alex Stone
*VLN Partners, LLC., * USA*

INTRODUCTION

Imagine a vast repository of digital materials that includes an unlimited supply of instructional videos, interactive multimedia exercises, links to Web sites, reading exercises, recorded interviews with experts, interactive graphs, charts, diagrams, photographs and maps—and nearly any other form of digital instruction—all organized according to academic standards, instructional objectives, and specific topics addressed. Teachers could log in to the repository via the Internet, type a simple search string and instantly access hundreds of pertinent instructional sequences that they could use to enhance their teaching practices in both the classroom and in the virtual learning environment.

This vision has been the driving force behind a form of instructional technology called learning objects (LOs), and it is becoming an increasingly relevant topic within the field of instructional technology today.

The idea that instructional content can be systematically encapsulated, retrieved, transmitted to others, and then reused is the driving force behind the LO movement. In the face of such enormous potential, the field of instructional technology has made little progress since 2002 when it comes to defining a practical method for populating LOs with meaningful instructional content and research that addresses the pedagogical effectiveness of using LOs in the K-12 learning environment is scarce. As yet, no practicable model for implementing this technology in a “real world” setting exists.

DOI: 10.4018/978-1-60960-503-2.ch404

BACKGROUND

Perhaps the most widely accepted definition of the term learning object comes from David Wiley (2002). Wiley (2002) states that a learning object is any digital resource that can be reused to support learning (p.7). While Wiley's definition and other attempts to define the true nature and function of learning objects are important efforts, varying views regarding the true nature and function of learning objects have caused a great deal of confusion within the field of instructional technology concerning this technology (Sosteric, 2002; Welsch, 2000). In any event, the fundamental theme that ties every perspective together is the basic idea that digital instructional content can be encapsulated, stored, and reused in the appropriate context. To put it more succinctly, learning objects are reusable and interoperable. These core attributes make learning objects both appealing and controversial.

The term "learning object" appears in the vernacular sometime around 1994 and is often attributed to the work of Wayne Hodgins (Wiley, 2002, p. 4), but the basic concept of reusing digital resources to streamline computing practices for programmers and to introduce uniformity of experience for end-users can be traced back to the work of Ole-Johan Dahl and Kristen Nygaard from the Norwegian Computing Center, Oslo, Norway, in the mid 1960s with their work on a programming language called SIMULA. This work led to a form of computing called object oriented programming that has had a profound impact upon the field of computer science and information technology. Object oriented programming gained momentum in the 1970s with the work of Alan Kay and became increasingly popular as a result of the work conducted in the 1970s and in the early 1980s by Bjorn Stroustrup with his efforts to apply the basic concepts of object oriented programming to the C computer language to create the commercially successful and widely accepted C++ computer language. Soon after that, a group at Sun led by

James Gosling introduced a derivative of C++ called Java that has gained increasing popularity with the expansion of the Internet.

While the effective implementation of learning objects (LOs) will undoubtedly continue to require formative input from the field of computer science, the fields of instructional technology and education will need to add more formative input to the conversation if LOs and learning object based instruction (LOBI) are to reach their full potential. To date, the majority of work concerning LOs has been focused upon establishing metadata referencing and retrieval schemes that can be used to quickly access LOs. In the 1980s and early 1990s, several metadata referencing initiatives began to address the need to categorize and quickly retrieve digital content and various tagging schemes began to emerge. In the fall of 1997, the U.S. Department of Defense, the White House Office of Science and Technology, the Department of Labor, and others, kicked off the Advanced Distributed Learning (ADL) initiative that established the metadata referencing standard called the Sharable Content Object Referencing Model (SCORM). Since it was introduced, SCORM has come to be the most prominent metadata referencing standard in the United States, but other metadata standardization efforts—like the IEEE's LOM project—also address the same need.

The introduction of, and further refinements to metadata referencing standards like SCORM and LOM are a critical step that must be taken to allow different content publishers to create learning objects that can interoperate within different learning management systems (LMS), but these efforts have little or nothing to do with pedagogical effectiveness of the LOs themselves. These efforts were an important first step because they addressed the need to ensure that LOs are retrievable and interoperable, but they do not address exactly what instructional materials a LO should contain to be instructionally effective (Welsh, 2002, p.2).

The first attempts to address the need for LO content standards are typically attributed to the

work of M. David Merrill from Utah State University in his work in the 1990s. Other early pioneers in the effort to devise a content model for LOs include L'Allier (1997) and his efforts with the NETg Learning Object Model and Barritt (1999) and others from CISCO who introduced the RLO/RIO content models. Verbert and Duval (2004) present a thorough overview of such efforts.

In 2002, Macromedia released a white paper that clearly identifies SCORM as a referencing standard only and acknowledges the fact that

the intent of SCORM is not to promote uniform content, but to enable conformant content to work better in a technical level. What content goes into the Learning Object (LO) is determined by the learning designer and not governed by SCORM. (p. 4)

Other efforts at around the same time, like The Masie Center's white paper (Masie, 2002), the Learnativity content model (Duval & Hodgins, 2003), and the SCORM content aggregation model (Dodds, 2001) all attempted to meet the demand for a content model that addresses the actual instructional media contained within an LO. Despite these early efforts, the confusion between the function of SCORM and how it does (or more appropriately, does NOT) affect the content of a LO remained—and it is still present today. Soon after this flurry of activity, the collective attention of the field of instructional technology moved toward the formation of LO repositories and the issue of how best to populate LOs with instructional content still needs to be addressed in a practicable way.

Much of the recent activity in the LO community has been devoted to building LO repositories like MERLOT, Wisc-Online, EduSource in Canada, CELIBRATE in Europe, and the newly introduced commercial product from Discovery Learning, Inc. called Cosmeo; but, there has been surprisingly little research and discussion surrounding the use of learning objects within the

learning environment (Haughey, 2005). While these repositories represent a great deal of progress and they are, indeed, a critical accomplishment; they are only a first step toward widespread implementation of LOBI in the K-12 environment, and ultimately into every day learning and teaching practices in public schools across America. Table 1 Includes some of the more prominent learning object repositories that are available today.

Each of these projects has made significant contributions to the advancement of LOBI. They are, however, only a first step toward implementing LOs into the main stream of the field of instructional technology and, ultimately, into every day teaching practices.

The Need for a Widely Accepted Content Model

SCORM imposes few restrictions upon the content to which it refers and the position that SCORM is a referencing model only (Brown, 2002) is an important one because it underlines a need to somehow define the parameters of the instructional content contained within the learning objects to which it refers. Just like the Dewey Decimal System refers to all kinds of different media in your local library ranging from microfiche, to encyclopedias, magazines, and classic novels, and so forth, the SCORM metadata referencing model is concerned with brief descriptions and access—it has little-to-nothing to do with the quality and/or the quantity of media to which it refers. Friesen (2001, p. 2) acknowledges the dichotomy between function (metadata) and form (content) by noting that metadata standardization efforts are a start, but there remains a need to answer the basic question “What is the relation between learning object metadata and content?”

The responsibility to practically answer this question and provide some guidelines for populating LOs with meaningful instructional content falls upon the shoulders of the field of instructional technology. The questions remain, however, ex-

Table 1. Partial list of existing LO repositories

actly how that content model will be formulated and how it will be embraced by the educational community as a whole.

A Suggestion for Meeting the Need for a Content Model

Hodgins and Connor (2000, p. 1) claim that revolutionary changes do not take place without widespread adoption of common standards, but, ultimately, those standardization efforts have to address a common need in a delivery environment. The fact that resources currently exist (LO repositories) and that there is a growing demand within the K-12 learning environment for a practicable model for teaching K-12 online learners underlines the need for such an environment that accommodates the natural evolution of this LOBI.

Consider how various forms of recorded media are interwoven into our daily lives. It can be argued

that stored digital media like movies, songs, and television shows adhere to at least three types of guidelines that make them meaningful for us. First, they meet the technical requirements of the delivery mechanism—they must be recorded in a way that can be broadcast so we can experience them. Second, they fit within the publishing norms for their respective medium, and third, they must meet an intrinsic need in the target audience. First, there is typically an elaborate process that ultimately results in the creation of a physical artifact that is compatible with projectors, CD players, and/or TV broadcast equipment. Second, the content of that particular production adheres to established standards for publishing content in that particular medium (it is rare to come across a 12 hour movie, a song that is so high-pitched that only your dog could hear it, or a TV production without characters or a plot line), and finally, each of these forms of recorded media meets an

intrinsic need within the target audience. They fit into our lives in such a way that they have value for us—they are *used*.

In each of these examples, guidelines, or standards, have emerged that drive distribution, content production, and adoption. Ultimately, it is the iterative interplay between content production and adoption within a target delivery environment that refines the adoption of the particular form of recorded media—and the content publishing standards themselves. To date, the field of instructional technology has (perhaps necessarily) focused its attention upon the interplay between distribution (or retrieval) standards and content production standards. But like any other form of recorded media, it will be the interplay between content production efforts and adoption in the delivery environment that will have the greatest impact upon the development of standards that will guide the widespread implementation and acceptance of LOs. To facilitate this formative process, a theoretical framework that accommodates the interplay between published artifacts (LOs) and the intrinsic needs of learners in the target delivery environment must emerge.

Rather than continuing to rely upon rigid and abstract theoretical perspectives to guide the development of learning objects and the implementation of LOBI, the field of instructional technology has evolved to the point where more pragmatic approaches to instructional design (Visccher-Voerman, 2004) can be employed. Shank (2002, p. 4) suggests that a good opportunity for semiotic research in education will be to create an a-priori set of meaningful concepts that can serve as the basis for a new model for educating in a particular setting. Rather than a “one size fits all” approach to creating a content model for LOs, several types of native interactions will be identified and then specific types of LOs that accommodate those interactions will be developed. The specific methodology that will be employed to transform and translate these different types of native interactions into LOs that are woven into

the proposed theoretical framework is what C.S. Peirce calls abduction, or the creative process of reasoning to a satisfactory explanation, of creating a structure in which our observation makes sense (Buchler, 1955).

Curriculum Directors: The Missing Link

Every lesson that uses learning objects needs to be assembled. Just like any other well designed lesson, someone has to analyze instructional goals and learning objectives and then create a strategy for conveying information to the learners that will help them meet those objectives. The fact that LOs are self-contained, meaning that the instructional message is already inherently part of each learning object greatly streamlines the process of creating a lesson and, as search techniques become more and more refined and repositories become more and more standardized, it may be possible for classroom teachers piece learning objects together to make online lessons, but this is not presently a practical reality.

In the meantime, LOBI will be implemented by a select few curriculum directors who work with classroom teachers to “hunt and gather” pertinent learning objects from existing repositories and deliver them online in a learning management system. This development process is an extension upon Wiley’s (2002) manual assembly techniques and has come to be known as *the collaborative model for distance education*. This process effectively enables classroom teachers to “broadcast” lessons online that mirror the instruction that they present in their classrooms. Ultimately, this simple assembly process opens the door to many exciting possibilities for students who are absent from the classroom for any number of reasons because it effectively blends virtual instruction with traditional classroom instruction in such a way that effectively accommodates the existing infrastructure of public schools and utilizes stored

media as a performance support tool for classroom instructors.

By analyzing native instructional design documents like lesson plans as a guide, curriculum directors can employ rapid prototyping techniques (Tripp & Bichelmeyer, 1990) and situated instructional design methods (Wilson, 1995) to quickly assemble online learning object based lessons that mirror the instruction presented in the traditional classroom environment. More recent advocates of this approach include Suhonen and Sutinen (2005) with their work on formative methods in sparse learning environments. Other instructional technology visionaries like Hodgins (2000, p. 14) agree that the best way to arrive at a future that embraces LOBI, it is most practical to adopt a backward approach, and more mainstream instructional designers like Wiggins and McTighe (2005) advocate this approach as a practicable way to achieve results in a learning space.

FUTURE TRENDS

The apparent benefits of decoupling stored, reusable, and self contained digital instructional content and retrieval and delivery mechanisms is a fundamental aspect of LOBI and computer mediated

instruction that opens the door to many exciting opportunities for educating K-12 students, but also poses fundamental challenges to paradigms that guide existing classroom practices. More specifically, if facilitators in a computer mediated learning space that accommodates LOBI can rely upon stored and reusable instructional content to convey the instructional message to their students, it becomes possible for them to devote their energies to other critical aspects of the teaching and learning process (like behavior support and more individualized instruction). This interplay between stored media and facilitated learning is one of the great strengths of LOBI that makes it more suitable for the K-12 audience than other forms of distance education because children often need more guidance in learning activities than adults.

Haughley and Muirhead (2005, p. 2) suggest that “learning objects do not have value or utility outside of instructional contexts and that their value is in their application to classroom settings and to online learning environments where teachers may or may not be present.” Currently, teachers in the traditional classroom setting follow a model for presenting information that simply does not accommodate the use of LOBI. The very nature of how information is presented in the ideal delivery environment differs so dramatically from

Figure 1. Using the collaborative model for distance education to refine a content model for LOs in the K-12 online learning environment

traditional classroom practices (lecture-based instruction vs. inquiry-based facilitated learning), that introducing LOBI into a traditional classroom setting requires a complete rethinking of the role of the teacher and the way that information should be presented in the target delivery environment.

In a sense, learning objects are an anachronism—they are artifacts that are available in an environment that does not yet know how to use them. While LOs themselves will undoubtedly be transformed and refined as the educational community develops learning environments and practical pedagogical principles that accommodate LOBI, the majority of the evolutionary change will happen within the learning environments themselves. As may be expected, sociocultural approaches to learning and teaching that view LOs as semiotic tools and/or social resources that can mediate the link between the social and the individual construction of meaning (Hung, 2002, p. 175) will play a formative role in the adoption and development of LOBI. Ultimately, LOBI will be defined by the environment in which it is delivered and, like any other form of instruction, its efficacy must be determined by the effect it has upon learners themselves.

CONCLUSION

Since the introduction of learning objects in the 1990s, the field of instructional technology has struggled to develop implementation models that fully take advantage of the vast potential that this form of instructional technology affords. While nearly all instructional designers and technologists currently acknowledge the nearly endless possibilities associated with LOs, several obstacles remain that make practical implementation of LOBI difficult. At this point in the evolution of computer assisted instruction, LOs and LOBI are being under utilized and only when these barriers are isolated and addressed (and/or eliminated), will learners and teacher reap the benefits that LOs can provide.

KEY TERMS AND DEFINITIONS

Collaborative Model for Distance Education: The term used to describe the process formative and iterative of using native resources to guide the translation of classroom instruction into learning object based instruction so it can be delivered online.

Content Model: A commonly accepted set of specifications that developers can use to guide their efforts when they create media. Commonly used interchangeably with the term *publishing standard*.

Curriculum Director: In the collaborative model for distance education, the curriculum director is the person who is responsible for analyzing classroom instruction, searching through a repository to collect learning objects that address the same topics, and then delivering those learning object to end users in a learning management system.

Learning Object: Any digital resource that can be reused to support learning.

Learning Object Based Instruction (LOBI):

The process of utilizing assembled learning objects to teach in a learning environment. LOBI is a form of facilitated instruction, or performance support, as opposed to direct instruction and/or lecture based models for presenting information to learners.

Metadata: The standardized information that is used to describe learning objects. Typically metadata comes in the form of completed form fields that describe the formative characteristics of a learning object.

Metadata Referencing Scheme: A shared, syntactical approach to the use of metadata that programmers can use to ensure that learning objects are retrievable and interoperable.

Publishing Standard: A commonly accepted set of specifications that developers can use to guide their efforts when they create media. Commonly used interchangeably with the term *content model*.

Pragmatic Paradigm: An instructional design approach that emphasizes environmental factors like adoption and use in the test when evaluating the validity and efficacy of learning materials.

Rapid Prototyping: The process of quickly analyzing instructional needs in a learning environment and selecting relevant instructional materials that meet those needs.

Shareable Content Object Reference Model (SCORM): A set of guidelines that The Learning Technology Standards Committee of the IEEE began their efforts to come up with one set of metadata guidelines that can be used to systematically categorize digital content. Currently, this effort is being refined by the U.S. Department of Defense's Advanced Distributed Learning Division (ADL).

Situated Instructional Design: Brent Wilson's theory for instructional design that posits that implementation and design are ultimately inseparable.

ABSTRACT

Someone has to prepare faculty who are in need of technology skills. For example, in Louisiana, in response to Hurricanes Katrina and Rita, every faculty member at the university level has to have a Blackboard presence and a disaster plan so that classes can continue in the event of a catastrophe. Those faculty called upon to assist their peers in complying with the directives are often chosen only because they are more comfortable than others with technology. Often, trainees are uncomfortable in such training, and senior faculty, often later “digital immigrants,” can be resentful. The researchers and authors of this paper have garnered \$443,658 in grants involving training faculty in instructional technology. Through

their experiences, the authors and researchers have isolated seven key practices that make such training successful. This article describes those practices and supports the findings of the primary research with secondary research on andragogy and Marc Prensky’s ideas of the literacy divide that exists between “digital natives” and “digital immigrants.” By considering the basic tenets of adult education, we can be better facilitators of valuable training sessions that will bridge the digital divide.

INTRODUCTION

John Dewey was a pioneer in the field of education, namely with his contribution to educational theory. One of the basic tenets of Dewey’s 1938 publication *Experience and Education* is the idea

DOI: 10.4018/978-1-60960-503-2.ch405

of a democratic educational experience, also known as the progressive movement. Dewey believed that education should be both “accessible and [enjoyable]” (p. 34) rather than the traditional authoritative experience in which the teacher is the holder of all relevant knowledge and the student is an empty vessel to be filled with that knowledge. Like Freire (1977) decades later, Dewey valued the prior individual experiences of the learner and claimed that “all genuine education comes about through experience” (Freire 1977: p. 25).

In 1973, another educational pioneer, Malcolm Knowles, introduced us to his theories of education. While Knowles’ predecessors theorized about learners in a more general way, Knowles himself focused on the adult learner. With Dewey’s progressive theories in mind, Knowles established the “groundbreaking” idea of “andragogy and the concept that adults and children learn differently” (Knowles, et al, 2005, p. 1). Knowles and his co-authors define andragogy, in part, as “an honest attempt to focus on the learner” (p. 1). Whereas Knowles pioneered the actual theory of andragogy, Galbraith (1990) and others have made significant contributions where actual teaching methods are concerned. In Galbraith’s *Adult Learning Methods* text, eight chapters focus on foundational perspectives of adult education, a few center on instructional design, and this text, currently in its third edition, clearly has college instructors in mind, which is the focus of our research in this article. Specifically, we will examine, in part, the literacy divide that exists between “digital natives” and “digital immigrants,” terms coined by Marc Prensky (Prensky 2001). Then we will use that information to support and explain what we have found to be best practices in educating digital immigrants in instructional technology. Our best practices are derived from over ten years of educating high school and college-level faculty in instructional technology. This training was funded by \$443,658, total, in grant funds from Louisiana Systemic Initiatives Program (LaSip) (\$222,741), Louisiana Board of Regents Traditional Enhance-

ment Grant Program (\$120,159), Louisiana Board of Regents SELECT Grant Program (\$89,258), and Louisiana Tech University Research (\$11,500). The result of our primary and secondary research is a list of seven key “do’s” when training faculty in instructional technology.

BACKGROUND

When the term “digital divide” was first mentioned in a 1995 report from the National Telecommunications and Information Administration (NTIA), physical access was the primary topic of discussion. The subtitle alone, “A Survey of the ‘Have Nots’ in Rural and Urban America” attests to the goals of this report on the digital divide (*Falling*, 1995). But since the publication of this report, researchers (Warschauer, 2002, 2003; Cooper & Weaver, 2003; Solomon, et al, 2003; van Dijk & Hacker, 2003; Enoch, Y. & Soker, 2006) have noticed other trends—cultural ones rather than physical ones—that prevent certain people from reaping the benefits that technology has to offer. Some of these barriers include gender, social class, urban versus rural community, and age. In US society, as some researchers (van Dijk & Hacker, 2003; Warschauer, 2003) have discussed, physical access to technology is widespread; therefore, “the key issue is not unequal access to computers but rather the unequal ways that computers are used” (Warschauer, p. 46). Indeed, there exists a clear gap between digital natives and digital immigrants in terms of how these groups utilize available technology.

In Prensky’s words, “Today’s students—K through college—represent the first generations to grow up with this new [digital] technology” (2001, p. 1). So if we think about this fact from the perspective of established faculty members, it is apparent that many of us are the immigrants whereas our students are the digital natives. This potential dilemma places faculty members in the interesting position of being behind the learning curve when it comes to our students and technology.

Educational theorists such as Dewey and Knowles have already established that we as educators do not really know as much as we might think. Rogers goes so far as to say that the role of the teacher is “vastly over-rated” (Rogers, 1969, p. 103) and that we should view ourselves as mere “[facilitators] of learning” (pp. 164 – 166). But what happens when university instructors, perhaps because of the age factor of the digital divide (because they might be “digital immigrants”), are unable or unwilling to try and bridge the gap between them and their students in terms of technological literacy? The problem here is not that the instructors are merely behind their students when it comes to digital literacy; the problem is that these instructors may be missing out on the potential benefits that technology in the classroom can afford them.

BENEFITS OF TECHNOLOGY

Knowles, et al, (2005) “see technology as a force that presents great opportunities for andragogical adult learning” (p. 236). According to the authors, enhancing classroom instruction with technology “directly caters to adults’ desire to be self-directed in their learning;” it allows students opportunities “to tailor the learning experience to fit [both] their prior experiences” as well as “their real-world problems;” and “it often allows them to access ‘just enough’ to solve the problems that led them to the learning in the first place” (p. 237). Building on and valuing prior experience might be key when it comes to engaging digital immigrants in technology workshops (Knowles 2005).

In terms of experience, Journet (2007) suggests that to engage digital immigrants in learning new technologies, we (the facilitators) should “recognize the expertise senior faculty bring and make connections between their interests and yours” (Journet 2007:117). In other words, the prior experiences of the trainees must be valued. While she discusses digital literacy in terms of senior

faculty members specifically—or those faculty who have “settled in until retirement in terms of career, institution, rank, and work responsibilities (in Sorcinelli, 1999, p. 63)—Journet’s ideas easily carry over to digital immigrants in general, whether they are new faculty, mid-career, or senior faculty. Of course, newer faculty members are less likely to fall into the category of “digital immigrants” than are their more seasoned colleagues.

It is important to remember that learning new technologies benefits not only us as faculty but our students as well. If the instructor is well-versed in digital literacy, then he or she can act more efficiently as a facilitator to help prepare students to make the most of the available technology in the classroom environment. However, if the instructors themselves are not using available technology, then it is not possible to facilitate this type of learning; moreover, these digital immigrants may not even have the very basic technological skills that are becoming more and more commonplace, such as use of Blackboard, email, and presentation software. Hence, the remainder of this paper will focus on the importance of training university faculty (at least those of us who fall into the “digital immigrants” category) to be more skilled in various areas of digital/technological literacy, not only so they can become better facilitators within the classroom, but also so that they can gain the more basic digital knowledge that will keep them on par with new (and probably younger) faculty.

One might wonder how teaching technology relates to college writing—that is, perhaps one might if one did not actually teach college writing. Writing is no longer the province of the pen and typewriter. For students to be successful writers in the college classroom, they must be able to use the tools of the college classroom—often the computer. Research happens as often in cyberspace as it does in a library. And dictionaries are often accessed via computer. Not all composition instructors are fresh out of an electronically-saturated graduate school environment. Someone has to prepare college instructors who are in need

of technology skills, for example, in response to the Blackboard initiative in Louisiana (every faculty member at the university level has to have a Blackboard presence and a disaster plan) instituted as a result of Hurricanes Katrina and Rita.

Many of us as university faculty who are more comfortable with technology than our peers might be have been called upon offer faculty development workshops on a variety of topics, including

- Blackboard
- email basics
- PowerPoint
- webpage creation using html coding and various html editors such as Adobe Go Live and Dreamweaver
- Hot Potatoes
- MS Word's comment feature
- Adobe Photoshop
- Tegrity
- Taskstream
- Inspiration
- Camtasia

Obviously, as university faculty members, we appreciate the extra time and effort faculty are giving to gain new skills to better instruct students. In addition, we also know that they want the shortest, most efficient, and most effective training they can conceive of—nothing dissolves a faculty development's session participant's patient goodwill more quickly than a general feeling that the participant's time is being wasted.

TRAINING FACULTY: A BASIC LIST OF "DO'S"

When we began training faculty to use instructional technology, we drew upon the closest resource we had for do's and don't's—our own experiences as participants in instructional technology workshops. One first don't was clear—don't run an instructional technology workshop without al-

lowing participants access to the technology. This "don't" came from one researcher's experiences: the first instructional technology workshop she attended as an instructor was a lecture on various types of technology—with no demonstration, and certainly no hands-on activities. We felt that sort of training was a waste of time and were sure that others would, too. Our list of "do's" became

- Do tell participants to bring some type of storage device—floppy, jump drive, etc. If possible provide participants with such devices as a prize for attending the session.
- Before the training session, contact participants or potential participants and tell them what the software can do for them and give them ideas to come to the session with. Tell participants to come with some sort of project in mind to work on. Plan for participants to have a "take away"—either a completed project, or a project under construction for a class they are working on or currently teaching.

The preceding two "do's" are in line with Thorndike's notion of "teaching as the control of learning by the management of reward" (in Knowles, et al, 2005, p. 76). In other words, providing participants with a storage device as a prize, albeit a useful one, could prove to be a good incentive for participation in the first place. Of course, if participants are not "interested, problem-oriented, and attentive" (p. 76) to begin with, then our task as trainer may be daunting. Nonetheless, with a practical topic such as learning new technology, perhaps we can, as Knowles, et al, suggest, "manipulate the learning situation so that the learner accepts the problem posed because of the rewards involved" (p. 76). Sorcinelli, in discussing "measures of reward and recognition" for faculty development workshops, suggests that recognition in campus publications, plaques, or some other form of acknowledgement might be good incentives for the amount of time

faculty put into these kinds of training workshops (1999, p. 69).

Of course, a physical reward, such as a storage device or a plaque, is only part of the actual prize; the practical knowledge gained is as much of an incentive, even if we have to convince the trainees of this fact. But the topic of incentives is certainly worthy of consideration. To engage digital immigrants in learning new technologies, we might need to specifically address the question of “What’s in it for me?”

It is interesting to point out that certain colleagues might be less inclined to attend training sessions. In terms of faculty development, studies “indicate that senior faculty are somewhat less likely than junior faculty to seek out individual consultation or partake in teaching development workshops on their own (in Sorcinelli, 1999, p. 67). Therefore, as facilitators of technology workshops, we must provide an answer to the above question. Journet suggests offering digital immigrants “chances to engage in both the production *and* the analysis of their own multimodal compositions so that they can get a sense, for themselves, of the powerful affordances of different modalities” (2007, p. 117). In other words, we must help them to see firsthand how digital literacy can benefit them.

- Do allow participants access to the technology being presented, and make sure they will have access to the technology for their own use later (either give them the software at the presentation or let them know how to download it or access the computer lab with the software when they need to use it).
- Do present the schedule of activities and session goals at the beginning of the training session—a hard-copy detailed schedule is not too much to give adult learners. It’s also useful if they have to write a report on the training later (in case they are being reimbursed, for example).

The preceding “do” will, in part, satisfy one of the typical challenges of training or teaching adults: “to discover the problematic element that will arouse and maintain the interest of adult learners regardless of their global or specific motives for learning” (Long, 2005, p. 28). If the trainees can actually see in advance what they will learn in the session, then they will be more likely to participate actively in the session. So it would be wise to include not only a schedule of events, but also some clearly stated ways that the training will benefit the learner.

- Do limit training to two hours, and whenever possible, try to make the second hour a voluntary workshop targeting participants who need more help or who just want to keep working on projects with the availability of assistance.

The preceding “do” is partially in line with Long’s (2005) list of physiological variables that must be considered when teaching adults. These variables apply mostly to older faculty members, or senior faculty, but these physical characteristics are nonetheless important to consider, even if only a portion of our trainees fall into this category.

However, it is these senior faculty who often fall into the category of digital immigrants; therefore, we should consider the possibility that many of the learners in technology workshops will be senior faculty who may exhibit one or more of the characteristics Long discusses, such as “diminished auditory and visual acuity, reduced energy levels, and increasing frequency of health problems” (pp. 28-29). So the point here is that we should not expect all of our learners to be physically comfortable sitting through an all-day workshop, and if participants are not comfortable, then they will not learn efficiently. But regardless of the preceding physiological concerns, it is important to “Offer professional development opportunities that meet the needs of senior faculty” (Journet, 2007, p. 117) or of any

faculty members who are in need of technology training. One simple way to do this is to consider “scheduling between terms or in the summer months” (Journet, 2007, p. 117).

- Do make yourself available to participants after the training in case they have questions, run into difficulties, or just want more information. The training doesn’t end when the session ends.
- Do encourage participants to veer off course and play or move ahead in the training. Participants will learn more and have more fun if they are in charge of their experiences.

The preceding “do” is in line with some theories of self-directed learning (Brookfield, 1986; Candy, 1991; Knowles, 1975; Knowles, et al, 2005). Here, we will use Knowles, et al’s definition of self-directed learning, which “is seen as self-teaching, whereby learners are capable of taking control of the mechanics and techniques of teaching themselves a particular subject” (Knowles, et al, p. 185). Citing Candy’s (1991) ideas of autodexterity, Knowles, et al (2005) state that when learners take ownership over their learning, it “leads to an internal change of consciousness in which the learner sees knowledge as contextual and freely questions what is learned” (p. 186). So in these technology training sessions, we would encourage faculty to work at their own pace and to practice self-teaching as much as possible. Another benefit of this “do” comes from Journet’s own experiences, which suggest that “the allure of pleasure or creativity” (2007, p. 117) when engaging learners in new technologies should not be underestimated. In other words, if we allow trainees the opportunity to play with the technology and to see that it might actually be fun, then they might be more likely to learn it.

DIGITAL IMMIGRANTS VS. DIGITAL NATIVES

At the 2006 Beyond Boundaries: Integrating Technology into Teaching and Learning conference at the University of North Dakota, we heard Marc Prensky, CEO of games2train in New York and author of *Don’t Bother Me Mom—I’m Learning!* presented two sessions, one entitled “Engage Me Or Enrage Me: Educating Today’s ‘Digital Native’ Learners.” While we actually disagree with a lot of what Prensky says about students and student needs today—for example, none of us are going to consider letting our students use their cell phones to call their friends during exams—we think everyone was struck with the accuracy of his example of digital immigrants vs. digital natives. Just as natives are born in a country and speak the native language and are comfortable with the native customs, digital natives are the generation born in the digital age, the students who grew up never knowing a world without computers. They are comfortable with technology and have handled and used it all their lives. And just as persons who immigrate to another country at a young age may adapt very well to the new environment, they are still immigrants. They may still have accents and still think along the lines of the native country and not the new country. It has been commented that digital natives use their cell phones to tell time, while early digital immigrants may be very technologically savvy with the latest cell phone gizmos, but will still wear watches to tell time. Another test to tell the digital native from the early digital immigrant and later digital immigrant involves handing the test subject a digital camera and asking the subject to perform a desired function. A digital native, understanding that the technology should be intuitive, would begin to play with the camera. The early digital immigrant may also begin to play with the camera, or may Google the instructions for the function on the Internet. The later digital immigrant may likely look for

the box the camera came in to attempt to find the instructions. Those who immigrated at a young age can be contrasted to recent immigrants who have thick accents and a hard time figuring out the ways of the new country. We think many instructors at this point in time are digital immigrants in some form—even though we may have very slight accents. After all, when we want to know what time it is, we look at our watches, not our cell phones. We know our cell phones display the time, but we are still used to the ways of the “old” country. We want watches.

The problem encountered throughout the research into best practices in teaching faculty instructional technology was that those who are tapped to lead such faculty development workshops are often tapped because they are “good” with technology. Their first reaction is to play with the technology in an unstructured way, and since instructors often create teaching materials to meet their own learning styles, early faculty development workshops in the research were unstructured to cater to the early digital immigrants. The result was frustration on the part of learners because they were generally not early digital immigrants, but later digital immigrants. The learning materials did not match the intended audience, and this problem led to the research and resulting key “do’s” that we found.

As stated previously, many of the faculty who fall into the later digital immigrants category are considered senior faculty. We all have heard the clichés which suggest that we as humans tend to become set in our habits, that we often fear change. Such is the case for senior faculty members (and even some faculty who are mid-career) who avoid technology of any kind. We all know our colleagues who are recent, and perhaps unwilling immigrants into the digital country, who never think about “Googling” to find out the weather for tomorrow. One of our digital immigrant colleagues recently received an Adobe file as an attachment and could not get it open. When he returned it to the sender with a message that the file would not work, he

was informed that it was an Adobe file. He called a colleague into his office to ask about the situation and asked, “Do I know Dr. Adobe? Is that a new dean?” Those of us who “immigrated” at an earlier age, when presented with an unknown file form, would probably turn to the web to help us access the information needed to solve the problem. We can function in the old country, but we are usually comfortable in our chosen digital home.

The digital natives, however, our students (with some exceptions), are fluent with the new and ever-changing technologies in a way that the immigrants can never be. It’s a different way of thinking and functioning, and it has some bearing on different types of adult learners in instructional technology workshops because those of us running the workshops—the earlier digital immigrants—can make assumptions that are frustrating to the faculty who have the most to gain from the instructional technology workshops—the later digital immigrants.

The key difference in the two types of faculty stems from the last “do.” Earlier digital immigrants are like digital natives in that when we receive a new piece of technology or software, we “play” with it until it works. It’s not uncommon for a colleague to hand one of us a digital camera or cell phone and ask us to make it perform a function. We can do it—usually in a few minutes—but we have great difficulty telling the owner how we made the technology perform the desired task. Why? We understand that the road to achieve the goal is not linear. The technology has been programmed to be intuitive. We’re comfortable with looking for the logical buttons to push until the goal is achieved. And we are having so much fun in solving the problem, that we forget that this knowledge needs to be translated into a series of linear steps for our more recently immigrated colleagues. In other words, those of us who are more akin to digital natives tend to forget the very theories of adult education that we have studied, the methods that will better ensure assimilation into the digital society that is upon us. Fortunately,

we have put aside this forgetful tendency because we realized the potential benefits that technology can afford to all faculty members.

FUTURE TRENDS

Faculty will likely always need professional development in instructional technology because instructional technology constantly grows, changes, and improves. For example, operating systems upgrade, and with those upgrades come new interfaces on old software standbys or even new features and functions. Old programs are phased out and new programs are phased in. Another training opportunity arises when an expensive favorite piece of software becomes available for free in a similar form via open source software. Training is here to stay. However, face to face training such as the type advocated here for later digital immigrants is becoming a thing of the past. Many companies and universities have already made widespread use of Just in Time (JiT) or desktop training, where employees access the technological training they need from the desktop. As this trend grows, the seven key “do’s” could be adapted thus:

- Provide participants with portable storage devices such as jump drives or flash drives as incentives for completing desktop training.
- Provide participants with a real person behind the desktop training. Before the training session, that person should contact participants or potential participants and tell them what the software can do for them. If possible, design the training to assist participants with projects they are currently working on.
- Do allow participants access to the technology being presented, and make sure they will have access to the technology for their own use later.

- Do present the schedule of activities and session goals at the beginning of the training session. Make it printable so the participant can make a hard copy and refer to it throughout the training, if desired.
- Do limit training time and make desktop training in easily accessible segments tailored to suit the immediate needs of the participants. Ten minutes is a good time limit for a desktop training session.
- Do make a real person available to participants after the training in case they have questions, run into difficulties, or just want more information. The training doesn’t end when the session ends.
- Do encourage participants to veer off course and play or move ahead in the training. Participants will learn more and have more fun if they are in charge of their experiences.

CONCLUSION

Journet (2007), who considers herself to be senior faculty, “[came] to digital media later in [her] career,” (p. 107), and she has discovered, as no doubt many faculty members have, the multiple benefits of learning digital media. Journet, a composition teacher, lists a few concerns typical of digital immigrants when it comes to learning new technologies:

- How do new media mesh with what many of us have traditionally (and over a lifetime) considered our responsibilities as composition teachers?
- How do we negotiate difficulties attendant on becoming a learner in areas where we are accustomed to being experts?
- How can we find appropriate opportunities for professional development? (p. 108).

If we consider the basic tenets of adult education, then perhaps we can become better facilitators of training sessions that will help bridge the gap between digital immigrants and digital natives. A digital divide does exist in terms of age, and often mid-career and senior faculty fall into this gap, becoming what has been termed “digital immigrants.” It is important to remember that becoming more technologically literate will benefit not only the faculty members themselves, but also their students. If we can bridge the gap, even partially, between digital immigrants and digital natives, then all of us will be better off. Therefore, it is crucial to address the concerns of our colleagues, and by adhering to the preceding list of “do’s,” we hope to do address the above concerns (and any other concerns that arise) as well as possible.

The most successful method of directing instructional technology workshops with faculty requires that the facilitators provide printed out, step-by-step instructions relevant to exactly what the faculty will be learning. In addition, faculty should be advised to arrive at the workshop with a storage device, a syllabus, a textbook, and a specific goal—and the facilitators should suggest specific goals to help the instructors best prepare. Whenever possible, faculty should be provided with “prizes” or incentives such as software, thumb drives, or other desirable items as a “thank you” for attending training.

The authors would like to thank the following grant granting agencies for their support of this project: Louisiana Systemic Initiatives Program (LaSip) (\$222,741); Louisiana Board of Regents Traditional Enhancement Grant Program (\$120,159); Louisiana Board of Regents SELECT Grant Program (\$89,258); and Louisiana Tech University Research (\$11,500).

Chapter 4.6

Internet Citizenship: Course Design and Delivery Using ICT

Henry H. Emurian

University of Maryland – Baltimore County, USA

Malissa Marie Carroll

University of Maryland – Baltimore County, USA

INTRODUCTION

This article presents the design of an undergraduate course that focused on how the Internet¹ may be used as a medium for discovering information about citizenship, in general, and for advocating and practicing citizenly conduct, in particular. The goal is to share with the reader a set of guidelines to specify course objectives and requirements, to select relevant materials, to engage students in self-directed learning, and to appreciate the process of working with the students over a semester. Applications of information and communication technology (ICT) were integrated into the course management and delivery, and they also formed the basis of the topic for the course content.

The title of the course was “The Voice of an Engaged Citizen: Vote, Advocate, Volunteer, Respond, Act...How?” This course was one of 14 first-year seminars² (FYS) intended to be taken by high-achieving freshman at the University of Maryland–Baltimore County (UMBC).³ These seminars, which are limited to 20 students, are intended to create an active learning environment. The students’ development of effective oral and written communication skills and the mastery of techniques to seek and evaluate information are the cornerstones of these seminars. This particular course was intended to explore the ways that ICT could foster the practice of citizenship. The course also had the objective of teaching students to use the Internet to search for reputable evidence in support of the Internet’s use in such an application area.

DOI: 10.4018/978-1-60960-503-2.ch406

COURSE DESCRIPTION

First, the students taking part in this course should use the Internet to learn what citizenship is. From there, they can look for ways that the Internet can be used to practice citizenship. Practicing citizenship via the Internet may include, but is not limited to, finding and evaluating Web sites that provide information about important issues and that provide the opportunity to communicate with our representatives. Likewise, students are also encouraged (1) to look for research that has been done to see if and how citizens are using the Internet to participate in democracy, (2) to seek information about political activist groups on the Internet, and (3) to determine how effective those groups are in attracting members and influencing decision making. Students should then attempt to find out if the Internet has information about character development and the learning of moral values.

The overall objectives for the coursework are formulated as the class progresses. This way, the class will allow itself the flexibility to pursue an avenue it finds interesting. The format of the work should include group discussions and seeking out information on the Internet. During some of the classes, students present their findings for discussion, ensuring that the students learn how to prepare and deliver PowerPoint presentations and how to write evaluative essays of journal articles and other material.

COURSE MANAGEMENT AND DELIVERY

A Blackboard site was available in support of this course where material, such as readings and Web site links, were posted for the class to review. It should be noted that the “syllabus” of this course evolved in the form of an “Assignments Log” posted on the Blackboard site that specified the requirements for each particular class. This log

evolved because there was flexibility in the pacing and type of assignments required from the students; typically, the due dates for written essays and presentations were posted two weeks in advance.

However, the most important use of Blackboard was its function as a forum for students to provide immediate written comments on class events, whether led by the instructor or by the students themselves. Furthermore, Blackboard was also used for students to post their PowerPoint presentations, their review essays of journal articles, and their evaluations of Web sites so they could be reviewed by the instructor as well as other members of the class.

COURSE CONTENT AND STRUCTURE

This particular seminar course met twice each week for 75 minutes over a 14-week semester. Class time was devoted to the following types of activities.

First, the instructor (HHE) posted on Blackboard a collection of journal articles (Evans & Yen, 2005; Froomkin, 2002; Thomas & Streib, 2005), related reports (Best & Wade, 2005; Clift, 2002; Emurian, 2004; Noveck, 2004; Vance, 2000), and surveys (Horrigan, 2004). This material was used for reading and discussion in class. The preferred style for engaging this material was found to be a type of “round robin” where each student would lead and read several paragraphs, later passing that role to another student. The student leader and reader was free to make comments and ask questions as he or she engaged the material, and other class members were encouraged to present their own questions and comments. At the conclusion of a reading and discussion, each student posted his or her own thoughts on the reading on a designated Blackboard discussion forum. Students were encouraged to give an evaluation of the material read and discussed in relationship to the overall objectives of the course. These class

exercises, which were interspersed throughout the semester, provided the occasion for open discussion and the rehearsal of tools of analysis that were applicable to the students' written reviews of journal articles that they themselves selected.

Second, as briefly mentioned above, each student reviewed six journal or other reputable articles throughout the semester (Coleman & Norris, 2005; Gil-Garcia, 2005; LaVigne, Simon, Dawes, Pardo, & Berlin, 2001; Lourenço & Costa, 2006). Each review was based upon a set of guidelines⁴ for evaluating an article, ultimately resulting in a two-to-three page, single-spaced essay. The articles selected by the students were posted on the Blackboard site for approval, and the review served as a basis for a PowerPoint presentation to the class. The set of guidelines was discussed in class, and anonymous examples of reviews written by students in similar seminars were also presented and discussed. For the first review, the instructor met with each student individually to provide feedback on a draft of the review. This meeting ensured that both the students and the instructor were in agreement with regard to what was expected from the review; consequently, both the instructor and students found this initial feedback session to be invaluable to the production of subsequent quality essays.

Third, several classes were devoted to examination and open discussion of various Internet portals and Web sites thought to be relevant to the course topic of Internet citizenship. This activity was made feasible since the class was able to meet in a PC lab or in a seminar room, depending upon the needs for each particular class. Based upon the feedback from the students during these open discussions, it was decided that PowerPoint presentations would be delivered by each student to evaluate a Web site. Consequently, each student shared his or her findings with the class. The pace of this course allowed each student to make three of these PowerPoint presentations. Among the cornerstone sites investigated, in open discussion or by student presentations, were the following:

1. <http://www.advocacyguru.com/>
This site contains a wealth of Web sites organized into the categories below. From among the many sites presented within a category, one example is presented for each category.

- a. Advocacy Resources

CITIZENOUTREACH

(www.citizenoutreach.com)

- b. E-Government General

E-DEMOCRACY

(www.e-democracy.org)

- c. Communicating with Elected Officials

YOUR CONGRESS

(<http://www.yourcongress.com/>)

- d. Nonprofit Resources

NONPROFIT BASICS

(www.nonprofitbasics.org)

- e. Online Political Networks and Conversations

E-THE PEOPLE

(<http://www.e-thepeople.com/>)

2. <http://first.gov/>
 - This is the U.S. Government's official Web portal.
3. <http://www.regulations.gov/fdmspublic/component/main>
 - On this U.S. Government Web site, you can find, view, and comment on regulations for all federal agencies.
4. <http://www.nifi.org/>
 - The National Issues Forums help people of diverse views find common

- ground for action on issues that concern them deeply.
5. <http://www.studycircles.org/en/index.aspx>
 - The Study Circles Research Center helps communities develop their own ability to solve problems by exploring ways for all kinds of people to think, talk, and work together to create change.
 6. <http://h2oproject.law.harvard.edu>
 - The stated vision is to encourage the growth of a more open set of intellectual communities than those spawned by the traditional university system.
 7. <http://www.americaspeaks.org/>
 - AmericaSpeaks is developing a national infrastructure for democratic deliberation that institutionalizes the links between decision-makers and citizens in determining public policy.

An initial attempt was made for the student presentations of the Web sites to be a demonstration; that is, the student would show the features of the Web site by navigating through it in front of the class. This approach turned out to be awkward and unsupportive of communicating the evaluation

of a site. Therefore, embodying the student led nature of the class, the students decided that the presentations of the Web site should follow the PowerPoint presentation format similar to that used for presenting the review essays. By using this format, screen shots of the features of the Web site were able to be included into the presentations, and it became easier to point out the strengths and weaknesses of a site. Figure 1 presents an example of a screen shot used for a student presentation. The screen shot was more beneficial than an open navigation Web site presentation because it allowed the student to focus on a specific aspect of a given Web page. In this example, the student chose to focus on the types of study circles offered in the state of Maryland.

In addition, classes that were scheduled between assigned deliverables consisted of such exercises as the investigation of Web sites that occurred during the third class of the semester.

1. Overview in class

a. Congress.org

(<http://www.congress.org/congressorg/home/>)

b. U.S. Senate Portal

These portals were investigated and discussed in class and the students used them to express an opinion, anonymously to the other students and instructor, on a topic of interest.

STUDENT MILESTONES, CONTRIBUTIONS, AND FEEDBACK

In administering the course, there were several milestone instructional events that provided the occasion for the students' acquisition of background skills and knowledge that became instrumental to the successful deployment of this seminar to undergraduates.

One such instructional event was posted on the Blackboard site on the date of the second class, and it was due on the date of the fourth class:

This assignment is to prepare a PowerPoint presentation covering the below three topics. Find sources on the Web for this exercise.

- a. Give a definition of citizenship,
- b. Give core values needed for the practice of citizenship, and
- c. Give specific behaviors regarded as exhibiting the practice of citizenship.

Give your opinion on the quality of the sources of information and defend your opinion. What makes a resource of information have high quality? Give the links on your PowerPoint presentation.

This was the first major assignment for the students in this class, providing the occasion for each student to express his or her opinions on the course's content while challenging each one of them to provide reputable support for those opinions.

Another one of these instructional events occurred during the second class of the seminar. It consisted of a lecture by a reference librarian⁵ who taught the students how to search for information using the library's various databases, research portals, and search engines. The importance of this lecture cannot be overemphasized. Students were familiarized with access to electronically available journal articles and other material that were essential to their success in seeking information related to the topic of this course. Although most students were highly experienced in using Internet search engines, the library offered additional and secure paths to information that many students had yet to explore. Other instructors would be well advised to offer this type of lecture early in the academic careers of students, to include graduate students where necessary.

One very important class milestone occurred during the fourth class, as given in the Assignments Log:

1. Founding Documents
 - a. <http://www.constitution.org>
 - b. We will read in class the Declaration of Independence and parts of the Constitution, to include the Bill of Rights.
 - c. Assignment: *Post your comments* today about your reaction to reading these formative documents.

The instructor and students shared the reading of these documents, accessed via the Web site above. As it turned out, the Declaration of Independence and the entire Constitution were read during the 75-minute class. This class event turned out to be a vital as well as inspirational milestone for the students and the instructor.

Last, the final milestone, which, as the schedule would have it, occurred during the last class, consisted of student presentations of "Reflections on Internet Citizenship." These presentations were summative evaluations of the course by the

students in terms of what was accomplished by each learner. Through these presentations, students were given the opportunity to share lessons they learned while taking this seminar as well as express their opinions about how they believed the course could be improved for future classes. The strengths and weaknesses addressed in those presentations even served to aid the writing of this instructional article. A collection of observations made by several students is given below:

- The Future of E-Government:
 - Overall, E-Government seems to have a bright future
 - People are “getting out of line and getting online”
 - “E-the-People”
- Article Reviews:
 - One of the best parts about this class
 - Very unique activity for a FYS class
 - One activity provided tons of knowledge for future reference
 - Learned a new writing format
 - Improved critical thinking skills
 - Preparation for graduate school
 - Really enjoyed the fact that this activity will be of use to me in furthering my education—kind of like a “heads up”
 - Excellent “plan-as-we-go” class that developed us as writers, presenters, and analysts of academic writing.
 - All assignments had a purpose and we achieved the goals together.
 - I also learned how to critique.
 - Finding trustworthy articles and sites
 - Determining methodology
 - Finding strengths and weaknesses
 - Enjoyed going over articles in class.
 - I liked the course.

- The ability we had to discover such a variety of information in such detail through the presentations of topics we each went out and chose on our own was really neat.

CONCLUSION

This article presented an effective design for structuring and implementing an undergraduate seminar course on the topic of Internet citizenship through the applications of ICT.

It is very important to note that the evolution of this course from a flexible “Assignments Log” allowed the students to undertake a wide variety of activities, from writing those aforementioned journal article reviews to giving Web site presentations using PowerPoint technology. Furthermore, the types of activities pursued in this seminar class (as well as in most other seminar courses) served to strengthen the students’ overall writing and presenting skills, which will continue to be of use to them as they proceed with their education. In the same sense, the student-led nature of the course allowed the class to pursue topics within the concept of Internet citizenship that they saw as particularly intriguing, ensuring that the students remained actively involved in the course content throughout the entire semester. This was easily accomplished, as much of the coursework was designed for the individual student (e.g., allowing each student to select his or her own journal articles to review). As a result, while one student may have chosen to investigate the security concerns surrounding Internet citizenship, another student could have decided to research the technology needed to further the practice of Internet citizenship. Such material variety kept the coursework fresh and interesting as the semester progressed.

Overall, student feedback indicated that the approach described here regarding the instruction of an undergraduate seminar course on Internet citizenship was highly effective. Both the stu-

dents and instructor gained valuable insights on the course content through the interactive group activities that became one of the cornerstones of this class. Similarly, having the opportunity to make several presentations clearly had a positive impact on the students' skill level as it was observed that students' presentations increased in length and quality over the semester. Therefore, it is the hope of the authors that, after reading this article, the reader will have gained a better understanding of the undergraduate seminar program offered at the University of Maryland–Baltimore County and will also be able to execute successfully the methods previously described to create an Internet citizenship seminar of his or her own in the future.

KEY TERMS AND DEFINITIONS

Citizenship: Although the typical definition of citizenship refers to the rights and privileges of those designated legally to be citizens, the concept was extended in this article to include motivation to participate in shared governance.

First Year Seminar: At UMBC, outstanding freshman are allowed to enroll in a course that has a seminar format similar to what graduate students might experience.

ICT: Information and communication technology was used as the medium studied for political engagement and for course delivery and management with Blackboard.

Internet: The term “Internet” includes the World Wide Web because that is a common way to refer to the media for electronic communications and exchanges of information.

Internet Citizenship: This reflected the use of the Internet for political engagement and empowerment, from local, state, and national perspectives.

Instructional Design: In the present context, this refers to the techniques that were adopted to encourage the students to seek and evaluate information and to provide written and oral reports to the instructor and to the class.

ENDNOTES

- ¹ Internet is used here to include the World Wide Web because that is a common way to refer to the media for electronic communications and exchanges of information.
- ² http://www.umbc.edu/undergrad_ed/fys/index.html
- ³ The junior author (MMC) was a student in this seminar. The senior author (HHE) was the instructor and is an associate professor of information systems.
- ⁴ <http://nasa1.ifsm.umbc.edu/courses/ReviewGuidelines/ReviewGuidelines.html>
- ⁵ The authors appreciate the lecture by Drew F. Alfgren to this and other classes and his ongoing support of our students’ development of research skills.

Chapter 4.7

The Real World Buffalo*: Reality TV Comes to a Charter School

Marion Barnett

Buffalo State College, USA

Kim Truesdell

Buffalo State College, USA

Melaine Kenyon

Buffalo State College, USA

Dennis Mike

Buffalo State College, USA

ABSTRACT

Videoconferencing is one form of distance learning that can enhance teacher-education programs by linking students in higher education with Pre-K–12 schools. As part of a Preparing Tomorrow's Teachers to use Technology grant (PT3), a teacher-education program utilized distance learning to link college classes with an urban school. Mediated observations of specific literacy practices were integrated into a traditional introductory literacy course. Preservice teachers observed urban teachers teaching literacy. Immediately following these observations, the preservice teachers were granted the opportunity to reflect on the lesson by conversing with the teachers via distance learning. Initial

findings suggest that students acquired positive attitudes toward teaching in urban classrooms and preferred this virtual field experience to a traditional in-school placement.

INTRODUCTION

Two children collide and tussle over some props in the dramatic play area of a kindergarten classroom. Tempers flare and arms begin to flail. Twenty teacher-education students are sitting in a campus distance learning room miles away from the classroom. Their eyes are fixed on TV monitors watching for the teacher's response to the children's struggle. The teacher calmly intervenes and mediates the struggle. The college instructor "voices over" the ongoing scene, describing to

DOI: 10.4018/978-1-60960-503-2.ch407

the students the importance of body position and eye contact, and explains the conflict resolution strategy of active listening and validating feelings, which the students are observing. She prompts them to listen to the teacher's language and to watch the children's faces for signs of what they might be thinking and feeling. The college instructor briefly connects what the teacher is doing with points made in the chapter on guidance and discipline from the course textbook. Ten minutes later, the kindergarten teacher, on site at the school, enters a distance learning room (the collaboratory) and spends fifteen minutes answering questions and commenting on the 30-minute lesson. Students question the teacher about the conflict, and the teacher provides answers interspersed with her own reflections, a critical component in understanding teacher behavior. She returns to her classroom, and the live video session concludes. The college instructor urges the students to think more about the conflict scenario. She queries them: "In your experiences, what are some of the ways you have seen teachers resolve conflicts among children? What did this teacher do that worked? What did she say? What else might she have done? How do you think the children felt at the end? What will you need to know and be able to do to resolve a conflict with children?"

The setting above describes an ongoing transformation in teacher preparation programs. Research suggests that the more classroom experience that preservice teachers have, the better it is for their expanded repertoire of teaching strategies, by providing for more thoughtful decision-making when responding to children (Darling-Hammond, 1998). Experiences over time are needed for preservice teachers to acquire teaching confidence, make connections from theory to practice, and engage in reflection on teaching; however, time constraints, lack of access to classrooms, school safety issues, and liability concerns are some of the issues prompting teacher-education programs to find alternative ways to design and structure early field experiences (Adcock & Austin, 2002).

Though the nature and frequency of early field experiences is changing and expanding, the diversity, quality, and consistency of the experiences can be greatly enhanced (from what existed in the past) by using the technology available to students and faculty in teacher-preparation programs. The videoconferencing technology described in the opening scenario is just one means of using telecommunications. The range of technologies and their use in teacher-education programs is growing and expanding to include both videoconferencing and Internet protocol videoconferencing.

This chapter describes the collaboration between a teacher-education program and a unique urban charter school equipped with the technology to broadcast live teaching episodes from four primary classrooms. The project began using videoconferencing technology with preservice teachers to conduct guided observations of children and teachers working and learning in an inner-city charter school. Encouraged by positive feedback from students and faculty who used the technology, a pilot program was implemented examining the potential of the technology to mediate reflection with preservice teachers. Two different Preparing Tomorrows Teachers to Use Technology grants (PT3) from the U.S. Department of Education funded the work. The first grant, Project Access¹, enabled the development of the consortium between higher education and a high-need urban school, and provided the technology for real-time video linkages with four primary classrooms. The second PT3 grant, Reflective Mediation Through the Use of Technology², continued the work of the first with the development of a research-based set of best practices for supporting reflection with technology.

CHANGING FIELD EXPERIENCES AND THE ROLE OF TECHNOLOGY

Teacher-preparation programs in the sixties and seventies often had the luxury of a laboratory

school on campus (usually attended by the children of faculty and staff). Eager, inexperienced preservice teachers were able to observe and occasionally participate at the lab school for short field experiences, testing their “teaching wings” prior to the student teaching year. Many of these schools had rooms equipped with one-way mirrors and microphones allowing guided observations to occur for a whole college class. The sixties version of “high-tech” classrooms enabled students to unobtrusively see and hear the culture of a classroom under the interpretation and mediation of an instructor. If time permitted, the teacher might join the college class to talk about their teaching and answer any questions. This provided a less intrusive way for an entire class to watch teaching in action.

Evidence suggests that labs schools have been in a steady decline since the 1970’s. In 1964, a survey had responses from 186 schools, while in 1980 there were around 100 lab school respondents (Levin, 1990). As college budgets tightened, lab schools became financial burdens and less of a priority. Faculty began seeking natural settings for fieldwork more representative of the increasing diversity of modern classrooms. Laboratory schools were converted into child development centers, office, and classroom space, and teacher educators turned to the schools in the community to provide classrooms and teachers for early field experiences in addition to the capstone semester of student teaching.

MacNaughton and Johns (1993) suggest that the professional development schools (PDS) movement was the next step in the evolution to improve connections between university-based and field-based teacher-preparation components. College faculty began negotiating with schools interested in forming collaborations for the purpose of mentoring preservice teachers by providing early field experiences, methods classes, and student teaching on-site in school buildings.

Professional development schools made sense because they involved multiple players (college

instructors, preservice and in-service teachers, and the students and their families) in helping to reduce disconnect between theory and practice. Darling-Hammond (1992) identified professional development schools as positioned to provide accountability “by ensuring that they (preservice teachers) have the tools to apply theory in practice and by socializing them to professional norms and ethics” (p. 91). Others (Levine, 1992) argued that typical schools are ill-suited to provide the right environment and support for professionalization, and that the cooperating teacher/student clinical practice model implemented in most teacher-education programs does not support the “reflection in action” necessary for the preparation of quality teachers.

In the movement for professionalization of teaching, teacher-education programs seek accreditation to improve outcomes for teacher-education candidates and to distinguish their programs. In the past, teacher-education programs could become accredited if they could demonstrate their curriculums provided the appropriate experiences for candidates to become knowledgeable in both content and pedagogy. There was little emphasis on early field experiences before the student teaching year. Current standards from accreditation organizations like the National Council for Accreditation of Teacher Education (NCATE) call for field experiences that are clearly defined by individual teacher-education programs. Candidates should have “diverse, well-planned, and sequenced experiences in P-12 Schools” (NCATE, 2002, p. 4). The PDS Standards Project of NCATE has identified 28 highly-developed PDS sites, which in a survey described their practices, goals, and funding sources. These data, along with a literature review and other commissioned papers, were used to develop a set of standards for PDS endorsed by the Unit Accreditation Board Standards Committee in March, 2001 (Teitel, 1999). Work of the PDS movement, along with more clearly-defined statements from accreditation councils and state boards of education, seems

to suggest that preservice field experiences are equally as important for preservice teachers as the student teaching year and should be given careful attention. Teacher education programs are encouraged to give consideration to the quality of the setting, number of hours, and how the placements are supervised.

With the challenge to meet high standards, teacher-education programs have been pushed to improve in many areas simultaneously. Technology, diversity, and quality field experiences are three areas that have been targeted as needing improvement (Cochran-Smith, 1995; Irving, 2000; NCATE, 1997). Research has documented the value of using technology in teacher-education programs, and teacher educators are asked to model the integration of technology to ensure that future teachers will include technology in their own classrooms (Strudler & Wetzel, 1999). Many have documented the effectiveness of early, ample, and well-supported field experiences and focused observations in urban schools in order to facilitate confidence, commitment, and readiness to succeed in teaching in urban schools (Groulx, 2001). Classroom observations are enhanced when preservice teachers are able to engage in collaborative reflection with urban teachers and college faculty (Fountain, 1994).

With increased emphasis on enriching the number, quality, and diversity of preservice school experiences, and preparing preservice teachers to utilize technology, the following questions could be posed to assess the effectiveness of any changes as to how teacher education programs implement and structure field experiences:

1. How have technology innovations been able to reproduce and improve the experience of the guided observation (allowing students to observe a common teaching episode) as it unfolds live and unedited?
2. Can the quality of students' reflections be changed and enhanced by the opportunity to

watch a common teaching episode while an instructor mediates what is being observed?

3. Can students be encouraged to use a higher level of reflection if the field experience is technologically-mediated instead of actively participating in a randomly-assigned classroom?
4. How have technology-mediated observations reduced students' stereotypes of working in an urban classroom?

These are some of the questions under investigation in a project using technology to mediate reflection involving teacher-education students and the teachers and children at one charter school.

A UNIQUE URBAN SCHOOL: THE KING CENTER CHARTER SCHOOL

In the mid 1980's, a 100-year-old church scheduled for demolition in inner-city Buffalo was given "historic landmark" status, thus saving it from destruction. A committee was commissioned to study possible adaptive reuses for the building. It was agreed, since the hope for reviving this community would reside in ensuring the education and well-being of its children, that the facility would be used to provide the highest quality of education for this predominantly African-American community's youngest children. Support from local colleges and universities would be essential to the project.

After years of fund raising and planning, a Pre-K through Grade 2 program, designed to model a high-quality, research-based, holistic education opened as the King Center, and was housed in an early childhood center in a public school until the church was renovated and ready for occupancy.

In 1993, Yale University's Bush Center in Child Development and Social Policy designated the King Center as New York State's first "School of the 21st Century" (Hoot, Massey, Barnett, Henry,

& Ernest, 2001). As New York State joined other states in passing a charter school law, the King Center submitted a proposal to the SUNY board of trustees for a charter. The King Center School's application to begin a K–3 school for 80 children was approved, and the school opened in August, 2000. Grade 4 was added in 2002.

Phase I: Videoconferencing Technology and Guided Observations at the King Center Charter School

The school's virtual learning collaboratory (distance learning room) has the capability to bring professors from area colleges/universities and their students together with teachers and children for the purpose of observing "real-time teaching" using a distance learning environment. Four classrooms (K-3) are equipped with corner-mounted cameras. The teacher is provided with a microphone and camera remote pack. A laser-tracking device follows the teacher's movements in a limited range within the classroom. The microphone picks up conversations between the teacher and children. Typically the children know when the camera is on for an observation, but within minutes they are usually absorbed in their work, easily ignoring the presence of the camera.

The school utilizes the technology for many projects. For example, the director of the school has asked each teacher to videotape several lessons and decide on one to use for performance evaluation and assessment of teaching skills. From the initial installation of the cameras, however, the school was primarily interested in linking with higher-education institutions for consultation and to serve as a virtual urban lab school. Buffalo State College responded to the invitation to partner and subsequently included King Center Charter School in two PT3 grants acquired in 2001 and 2003.

Teacher Participation

The PT3 grant project relied on teachers from the school to volunteer. In the beginning, all classrooms were equipped with cameras, but only two teachers agreed to participate. After several guided observations, the two teachers shared their enthusiasm with the rest of the staff at the school. All were continually encouraged and invited to join *when they felt ready*. Within two years, all teachers were hosting guided observations for students in teacher-education programs.

The four participating teachers have two to fourteen years of teaching experience. One was designated as a "master" teacher when she was employed in the public school system. Two of the teachers have been with the school since it opened in 2000. The school enrolls 100 children in five classrooms, with the same building leader since inception. There is cohesiveness in the philosophy, teaching strategies, and behavior management that preservice students see during each virtual observation.

Participating teachers comment that they get nervous before each session begins and are constantly aware that twenty to twenty-five preservice teachers are watching every move and hanging on their words. Every teacher expressed the realistic worry that a child might have a "meltdown" while the camera was on. On the positive side, teachers state that participating in the guided observations makes them conscious of teacher language, lesson materials, and student feedback.

I try to model appropriate and logical consequences for students' misbehavior. I try to make sure that I model various strategies for motivating and engaging students in a lesson.

I find that I try to stress positive teacher language and consistency when the college students are watching me teach. I try to be explicit with logical consequences.

I try to model using a quiet voice and redirecting in a neutral tone. I try not to become emotionally charged when students make poor choices regarding behavior/conduct. I try to model a deep sense of respect and reverence for the individual humanness of each student. I model my relationship as a nurturer/caretaker.

In spite of the pressures and responsibilities of normal classroom teaching, the added complications of scheduling videoconferencing sessions, and the need to leave the classroom and their children to talk with the college students, the teachers continued to volunteer because they believed in professional development and giving back to teacher-education programs by sharing their experiences and expertise, even at a beginning or emerging level. Their continued willing participation highlights the critical importance of trust in relationships between partners. This seemed key to sustaining the work. For the teachers in this project, knowing that a person who knew both their work and them professionally and personally was stationed in the college distance learning room, interpreting and moderating the videoconference for the college students, kept them volunteering and participating in the program.

Technologically-Mediated Guided Observations

Buffalo State College education faculty were invited to schedule a session (during their regular class time) in the distance learning room on campus and participate in a “guided observation” of an unedited, live teaching episode. Initially there was concern that the project might be overwhelmed with requests. If so, it would not be possible to burden the four participating teachers and the children at the charter school with too many interruptions in one week. However, as Boccia, Fontaine, and Lucas (2002) found in their “Looking into Classrooms Project”, the college faculty seemed reluctant to take time out of scheduled

class meetings to have students participate in this unique new format for guided observations. After a campus-wide mailing, posting flyers, scheduling a demonstration seminar, describing the project, and inviting people to sign up, the project has sustained a small group of regular participants who typically requested one observation each semester. Once instructors had a direct experience using the technology, they were eager to repeat the process with students each semester.

The teacher education classes that participated came from several departments, including Elementary Education, Early Childhood, and Art Education. The students enrolled in the classes were in the first three years of their teacher-education program. For most students, the guided observation experience represented only one piece in a collage of early clinical field experiences prior to student teaching. The college instructor of the class and the project liaison mediated every distance learning session. As is the case with all college/school collaborations, the project was possible because a level of trust had been established between the teachers at the charter school, their director, and the higher education project director, prior to the implementation of the first grant. Teachers were more comfortable being observed knowing that a person that they knew and trusted (the project director) was on-site and available to clarify for students what they were observing.

The guided observations were structured for different purposes, depending on the request of the college professor. For example, an Introduction to Education class asked to observe 15 minutes in each of the kindergarten through third-grade rooms. The instructor wanted students to look at room arrangement, transition techniques, activity level across grade levels, and behavior management techniques. A reading methods instructor requested an observation of a guided reading lesson. A literacy methods professor wanted to observe the kindergarten teacher model interactive writing or sharing the pen (something which had been difficult for students to observe in their live field

placements). With prior planning, requests were easily accommodated in the classroom teacher's normal daily schedule. Teachers e-mailed the lesson plan prior to the scheduled observation. Students were encouraged to follow the plan and match what they observed with what had been planned. Detours taken from the original lesson plan were frequently a source of questions and reflection in the debriefing talks following each observation.

Immediately following the 20- to 30-minute observation, the classroom teacher moved to the school's collaboratory and held an interactive session with the college students, including questions and answers. Initially, students seemed quiet during the question-and-answer period. In spite of this generation's increased use of technology, seeing themselves on TV and being asked to speak into a microphone as the camera focused on them was novel and unsettling for them. Almost all students who participated reported that they had never been in the distance learning room prior to the guided observation. The students seemed to need encouragement and prompts for asking questions. It appeared that they felt uncomfortable voicing a question to the classroom teacher in front of peers while the camera focused on them. Students were encouraged to write down a question or thoughts that occurred during the observation, with the intent of asking the teacher during the debriefing. Additionally, the project leader and the instructor would pose questions (during the observation) about what the teacher appeared to be doing and saying, and suggested that students should ask the teacher to clarify these points during the debriefing. Questions commonly asked by the students centered around specific aspects of a lesson plan, the reaction of the children to the lesson, and what the teacher planned to do in a follow-up lesson. Students asked about teaching strategies, the children's behavior, curriculum requirements, discipline, family involvement, and differences between charter and public schools. Students frequently queried the teacher about a

specific child's behavior and the teacher's use of different behavior management strategies. Another common question was how the teacher acquired ideas for a particular lesson, and how long it took to prepare and plan the entire lesson.

Students' Reactions

From surveys collected during the initial phase of the guided observations, students reported a positive reaction to this virtual field experience and an increased understanding of the realities of teaching and urban schools. It was revealing to read some of their misunderstandings and sobering to realize the work still needing to be done in teacher-education programs to uncover and discuss misperceptions and biases.

The obvious strength of this experience is being able to look over the shoulder of a skilled professional as she demonstrates the concepts we have read and talked about. Nothing (short of actually doing it) makes a concept clearer than seeing it actively and accurately portrayed in real-world settings.

This experience gave us an unedited picture of a teacher and students in action. It was great to see what we've learned about in every education class in an actual setting, not just words in some text.

I have gained more confidence. It is easy to read information in a textbook or watch videos, but to actually see everything implemented live by a teacher who is unable to go back and redo or erase mistakes...This was so inspiring and gave me a realistic view that everything is not always going to be perfect and that it does not have to be either.

I expected a bunch of wild, out of control children. What I saw was a group of bright, well-behaved children with just as much potential as other children.

I was much more afraid of urban schools before this experience. There are a lot more similarities to suburban schools than I previously thought.

REFLECTIVE MEDIATION-IN-ACTION

Mediated reflection using a virtual field experience evolved and changed over several semesters. After three semesters of scheduling guided observations and receiving positive student feedback, the project added additional open observation times and invited all students enrolled in any section (usually six or seven) of Introduction to Literacy, an early course in the teacher-education program, to take advantage of the opportunity to watch good teachers teach literacy.

A graduate student was hired to monitor the open sessions, but the teachers at the school were unable to leave their classrooms for the question-and-answer period due to the frequency of the open observation times (three mornings a week for one-and-a-half hours).

The open observation model proved problematic for many reasons. Few students were able to come to the distance learning room in the mornings because of other course commitments. Instructors had other teaching responsibilities and could not be there to observe alongside the students. The classroom teachers at the school felt burdened by having to “go live” so many hours in one week.

Reflecting on the data collected, we found that the students reported experiences of using video-conferencing to conduct the guided observations as valuable. The guided observations, though valuable and positive, were still disconnected and needed to be included in the content of individual courses if faculty were to become convinced to use class time to fulfill the field experience requirement. Following one semester of combining some scheduled guided observations including student/teacher debriefing sessions, and adding open observation times which proved ineffective, we decided to develop a model using

a class-embedded virtual field experience. One course section of the Introduction to Literacy class served as the pilot for the project.

After assessing feedback from preservice teachers, instructors, and the classroom teachers, it seemed that the true value of observation for preservice teachers lay in the opportunity to hear classroom teachers reflect on their teaching immediately after a lesson, to have their instructor mediate discussion, and to integrate the virtual observation into college classroom conversations and activities. This led to reconceptualizing and implementing phase two of the virtual field experiences.

Phase II: Using Technology to Mediate Reflection in a Course-Linked Virtual Field Experience

Reflection is a complex, abstract concept. Though most educators state that it is an important trait for teachers to possess, it has become a difficult term to concretely define and even more difficult to determine how to prepare teachers to be reflective practitioners, especially in unfamiliar cultural contexts. The preservice teachers quoted in the Instructor’s Vignette show how traditional field experience conditions perpetuate limited opportunity for reflection. Frequently, instructors send class participants to different schools for short periods of time with no opportunity to integrate what they observe in schools to course content or class conversations. In essence, students are left to observe and participate in individual field placements with limited opportunities for any meaningful discussion or reflection with an instructor or mentor.

To complicate matters further, reflection is not generally associated with teachers. Teaching is seen as immediate action, whereas reflection is perceived as a more academic action (Hatton & Smith, 1995). Additionally, it has been suggested that preservice teachers tend to revert to traditional notions of teaching and learning during student teaching.

These assumptions may be further reinforced in a traditional teaching environment. If these beliefs are firmly held, teacher candidates are resistant to reflection and change (Yost, Sentner, & Forlenza-Bailey, 2000). Furthermore, it is often difficult for teacher candidates to even know what to reflect about (Dieker & Monda-Amaya, 1997). It is important, then, for teacher educators to facilitate this reflection before the teacher candidate reaches the point of student teaching. In the course-embedded virtual field experience, preservice teachers were engaged in mediated reflection on teaching from three different viewpoints. Preservice teachers were watching and reflecting on the classroom teacher's teaching. Simultaneously, the college instructor was watching, reflecting, and talking with them about the classroom teacher's teaching, and finally they were hearing the classroom teacher reflect on their own teaching during the question-and-answer period. Contrasted to the traditional field experience, where the preservice teacher is alone in a classroom watching and observing and returns to campus without time for debriefing with a classroom teacher, the virtual field experience can simultaneously provide four two-way communication opportunities: students and classroom teacher, instructor and students, instructor and classroom teacher, and student to student.

The teacher educator must "induce disequilibrium and cognitive conflict" in the learner to prepare him/her for critical reflection (Yost et al., 2000, p. 42). As the instructor's reflections in the vignette suggests, the instructor can mediate reflection through a common virtual field experience. The instructor can facilitate reflection by posing questions before, during, and after the observation (Appendix B). Preservice teachers can observe the classroom teacher's thought processes while she/he responds to questions posed following each observation.

Reflective teachers and teacher candidates develop a *habit* of continually learning from experience. According to Whipp (2003), reflective teacher candidates have the ability to stand back

from their own assumptions and biases to notice problems in their practice. They can then reframe problems in light of multiple perspectives and take action that is informed by reframing. As shown in the students' comments, preservice teachers were forced to confront their biases and assumptions of urban schools and children by having the opportunity to observe, reflect on what they were seeing, and then speak directly with the classroom teachers following each observation.

Reflectivity appears to develop in stages. Researchers have found that teachers who are reflective move from a singular focus on technical issues surrounding the delivery of lessons when they first enter the teaching field, to critical reflection, where master teachers regularly examine the technical, practical, social, and moral issues inherent in their design of the learning environment in their classroom from multiple perspectives. Master teachers are also able to make changes to their teaching that improve student learning based on a variety of sometimes competing factors. These teachers take responsibility for their own learning and that of their students (Giovannelli, 2003; Hatton & Smith, 1995; Truesdell, 2004; Yost, Sentner, & Forlenza-Bailey, 2000).

Videoconferencing, as described in this project, provides a unique forum for preservice teachers to be in a field experience environment where reflection dominated the conversations with the college instructor and the classroom teachers. For example, they might (and did) question teachers about the details of their lesson plans by asking how long something took to plan or prepare (singular focus), yet have the opportunity to hear a response from the teacher who would speak with them about how that lesson looked in the first year that she taught it and the changes that had been made based on her own reflection on practice.

Our attempt in both phases of this project was to move preservice teachers from reporting what they observed, which is evidenced in early iterations of the traditional field experience, to more critical reflection based on a common mediated experience.

Box 1. Instructor's vignette

Instructor's Reflection

The first semester, I taught the Introduction to Literacy class using a traditional field experience model. Throughout the fifteen-week semester, students went to various schools to observe in the classroom for a total of ten hours. The students kept observation logs and wrote a culminating paper describing their experience. This field experience was problematic in a number of ways. Because many of the preservice teachers were non-traditional students and local schools are at capacity with teacher education students (there are nine institutions preparing teachers within a fifty mile radius), placing students for observations was always difficult.

A second difficulty with traditional observations was students were watching one 45 minute to one hour lesson with no context of what happened prior to or what would happen in the future. There was no way to control for good, bad or indifferent teaching, and I was unsure whether the students would even recognize the quality of the teaching they observed. The students were very quick to judge the teachers and the children's behaviors without reflecting on what they were seeing. They just reacted. Compounding that, students all observed different classes at different times, so it was impossible to have class conversations regarding the observations. Often what they observed in their separate schools was disconnected to the conversations, readings and activities taking place in class.

These issues led to a discussion with the project director about other possible formats for observation. The following semester we decided to have students utilize an open observation plan at the distance-learning laboratory. The teachers agreed to take turns being observed for three mornings a week for one and a half hours at a time. After the observations occurred, the preservice teachers were excited to talk about what they observed. Again though, only two to three students of a class of twenty-four observed the same lesson, and I, as the instructor, was unable to observe any of the lessons. A major complaint of the preservice teachers was that the open observation times were not convenient for them since the school taught literacy in the morning and most college students had a full schedule of classes in the morning. There were issues with the technology not working on several occasions further frustrating the preservice teachers.

Once again, with the help of the project liaison, we re-conceptualized the field experience. This time, we decided to utilize class time to facilitate and mediate the field experience observations. Because this is a critical course, prior to the field-based literacy methods classes held in professional development schools, agreeing to give up class time were very difficult. One stipulation was that the observations had to be integrated with the content of our college course. The project liaison and I met with the teachers from the school. The teachers were each given a copy of the syllabus with topics, assignments, and dates (Appendix A). We discussed which topics would be best for observation and which teacher's style was best suited to that topic. We determined that, after the lesson, the teacher would go into the collaborative and reflect on her teaching and answer the preservice teachers' questions. We agreed on six observations and determined the dates to correspond with course content. After each observation, I posted one question on a collaborative Web-based discussion group site (Appendix B). All students were required to respond. They were encouraged to respond to others' postings.

My misgivings about relinquishing precious class time for the observations were eliminated about ten minutes into the first observation. The students (and I) were mesmerized by the classroom teaching. The discussions on Blackboard and in class were far richer than the old "field experience paper" that was required during previous semesters. Because we all had a common observation experience connected to our classroom readings and discussions, we could dialogue based on our personal interpretations. This allowed us to debate, break down stereotypes, and change some of our notions of teaching. After the final observation, I posed the following questions:

On a scale of 1 (poor) to 10 (great), how would you rate the usefulness and the relevance of our observations in the distance-learning lab? How did these observations enhance your learning? What did you get in the observations that would not have been possible by observing in person? Do you feel you missed out on anything by not observing in person? What might it have been? Every student rated the experience an 8, 9 or 10. Comments from students included:

...one of the great things about observing in the lab was that you were able to communicate with the teachers and have them do plans on what we were learning about in class...

We didn't have to get into a car and drive somewhere and only spend 30 minutes in the classroom. Then the students are not going to behave normally because someone is new and they will act up for the time that I am there.

We did not interrupt their learning process and got to see how the kids really do act during a typical day.

...we could talk about the events from the observation as a class and we had the opportunity to observe the things that we were learning about.

I did like that we did this as a class, so that all of us were on the same page and could discuss some of the effective as well as ineffective practices that some of the teachers were taking. If we would have all went to different schools, and seen different exercises being implemented in the classroom, our discussions would not have gone very far as none of our classmates would have known what we were talking about. Also, we cannot be guaranteed that what we would have observed would have reinforced the concepts that we were learning about in the classroom.

In my opinion, one of the best things that came out of these observations is the knowledge that we gained as a result of talking with the co-operating teachers. When doing observations in classrooms, it is rare that we are able to talk with the teacher after we have seen her in action. Talking with the teachers after observing them allowed us to grasp a true understanding of what they did and why, and allowed us to ask them questions if we were unclear about any of the exercises that they did with their students.

It seems clear the mediated field experiences were more meaningful to the preservice teachers and enhanced the classroom readings, discussions and activities. Final evidence of the success of the virtual field experience came from the department evaluation which all students are required to fill out at the end of the semester. In response to the question "What aspects of the course were most beneficial to you?" eleven students out of twenty, unprompted, mentioned the distance learning lab observations. Clearly I'm encouraged to continue to use this model. The evolution of planning for and thinking about this integrated field experience has enabled me to reflect on my own teaching. I find myself more intentional about including what we see in the observations into class activities and conversations. On one occasion we observed a vocabulary lesson. Following this, the students were required to present, with a group, a vocabulary mini-lesson. The students incorporated several strategies they observed the teacher from the charter school model during her vocabulary lesson into their mini-lessons. Rather than feeling students missed out on instructional time, I think the students have been enriched and their professional development supported by the video-conferencing experience.

Figure 1. Opportunities for mediated reflection in traditional and virtual field experiences

NEW TECHNOLOGIES BRING BOTH CHALLENGES AND PROMISE

Distance learning via interactive television (programmable two-way audio and video signals for communication using television monitors as a display) began at Buffalo State College in 1995 when the campus was granted funds to purchase equipment to create two distance learning classrooms and join the Western New York Fiber Network. At its peak, the network included over 100 classrooms in K-12 schools throughout the western eight counties in New York State. Buffalo State College built two of the original distance learning classrooms for two consortia within the network, Buffalo CityNet and Project Connect.

Over the past 11 years, the network was quietly phased out by nearly all of the original schools. The initial contracts with Verizon for access to the network were for ten years; for many school districts in Western New York, this contract period has ended. Using E-Rate funds, the original local BOCES centers have entered contract discussions with local cable companies to create a Gigabit Ether Network (Gig-E), which will continue to provide high-speed connections not only into specially-equipped classrooms but, via videoconferencing technologies, having the potential to make any classroom, any laboratory, or any media center into a distance learning facility.

The distance learning classrooms at Buffalo State College were built with a diffusion fund and

grants via Buffalo's local telephone company, Verizon (formerly Nynex). Each classroom in the network contained the same equipment: eight 32-inch SONY television monitors; one teacher station that included a touch panel to control the equipment; a computer with Internet access; an Elmo document camera to display items; a telephone/fax machine; and two VCRs, one to play videotapes and the other to record class sessions to tape. Each classroom had a multifaceted sound system, student area and teacher station microphones, and separate student view and teacher cameras. Students and teachers in each classroom were able to see and hear each other at television broadcast quality audio and video.

Despite the successes, there have been challenges which discouraged the use of the present model for more preservice field experiences in teacher education. Access to high-quality schools with distance-learning facilities is unique and not commonly found. The consortia fees enabling the college to connect to King Center Charter School and belong to both Project Connect network the CityNet were \$40,000 annually. Scheduled sessions are sometimes abruptly cancelled (due to unforeseen occurrences at the charter school), or the technology at one of the sites fails.

Many factors contributed to the decline in use of the original distance learning classrooms. Maintenance and repair of the equipment was costly and required trained technicians. All of the classrooms were built with grant or diffusion funds and, at the

conclusion of the grant, there were districts that could not continue with the expensive consortia fees (approximately \$16,000 yearly).

Given all of the changes to the original Fiber Network, the college and the charter school have continued their involvement due in part to the successful relationship of this project involving the education department and the charter school. The college will leave CityNet consortium this year, having recently purchased a videoconferencing unit that will allow expanding virtual field observations and offering college courses to other locations in Western New York and around the world.

The new videoconferencing unit, a Tandberg 6000 codec, costing \$19,000, will be integrated into the old Fiber Network classroom. The classroom will be redesigned with upgrades to accommodate the change from fiber to Internet protocol (IP) video conferencing. The eight SONY television monitors will be removed and replaced with two movie-sized projection screens. Two projectors will be mounted to the ceiling of the classroom, one to display the teacher view and one to display the student's view of the other distance sites. A new teacher station will be incorporated, one that is consistent with other teacher stations in smart classrooms on campus, in order to facilitate faculty use. New furniture will be added along with wireless microphones, new cameras, and, with an eye to the future, an expandable option that will allow the college to add on video capture software and other emerging technologies.

Transferring from the current system will be expensive for both partners, but, in the long run, will potentially save thousands of dollars each year. The old system relied on a local phone company with fees and a network manager with additional fees. The new system will allow for an organization to manage the site internally. While even more cost-effective solutions (such as using the Internet with cameras positioned at both locations) are a possibility, closely monitoring these

less-expensive solutions for quality of the virtual field experience is important.

While the use of interactive videoconferencing continues at educational institutions worldwide, there are other emerging technologies that will impact teaching and learning. As the cost of videoconferencing equipment and broadband connections continue to decline, and the quality of the audio and video increases, more schools may have the opportunity to become involved in virtual field experiences and other technology-supported preservice-education activities.

FUTURE TRENDS

This model suggests potential for addressing key issues in teacher preparation. Since the literature states that students tend to default to the model that they experience in student teaching, it seems important for teacher-education programs to search for ways to increase the quality, diversity, and number of early field experiences which preservice teachers encounter. Observing and reflecting on many different teaching behaviors in a mediated environment prior to student teaching, preservice teachers have the opportunity to internalize multiple responses and, rather than defaulting to what they experienced as children in school or to their one student-teaching model, are prepared to respond more appropriately to individual children.

Feedback from the guided observations conducted in phase one of the project suggested the power of a single virtual observation in helping students alter their perceptions and attitudes about urban classrooms and teaching. With repeated mediated observations, students saw numerous respectful student/teacher interactions, more examples of positive behavior management and culturally-responsive teaching, and many targeted literacy strategies. Students could begin to rethink their notion of teaching and learning and move further along the continuum of internalizing reflec-

tive teaching rather than relying on a singular reactive response applied uniformly for all children. This leads us to speculate that repeated selective observations in different classroom settings (rural, exceptional education, culturally-responsive, and linguistically-diverse classrooms) would enable preservice teachers to have a repertoire of responses, strategies, and behaviors to bring to the first years of teaching in any setting.

Additional work by Garrett and Dudt (1998) suggests that videoconferencing can be effectively used to supervise student teachers. In a project using three wired sites and 24 student teachers, preliminary findings suggest that videoconferencing for student teaching supervision works across settings and disciplines with minimal preparation. Students, cooperating teachers, and supervisors can effectively collaborate in the supervisory process. Similar to the participants of the charter school project described in this chapter, Garrett and Dudt (1998) found that the human aspects of the planning, scheduling, and conferencing were more important to the quality of using distant supervision than the technical aspects (problems and quality) of using videoconferencing equip-

ment. Initial findings from the project described in this chapter suggest some benefits for all stakeholders (see Figure 3). Unique to this project is the opportunity for preservice teachers, college instructors, and classroom teachers to engage in observations and conversations simultaneously reflecting on the process of teaching and learning.

CONCLUSION

While the use of interactive videoconferencing continues at educational institutions worldwide, there are other emerging technologies that will impact teaching and learning. As the cost of videoconferencing equipment and broadband connections continue to decline, and the quality of the audio and video improves, more schools may have the opportunity to become involved in virtual field experiences and other technology-supported preservice-education activities. While we cannot prepare preservice teachers for every situation that they will encounter, we can do a better job of diversifying their teacher-preparation experiences by using opportunities like technology-mediated virtual field experiences.

Table 1. Benefits for stakeholders

Preservice teachers can... • Observe one teacher and classroom at the same time • Eliminate travel time and transportation issues • Concentrate without being distracted by being inside the classroom environment • Gain more opportunities for mediated reflection with an instructor • Ask questions about what is happening immediately and in later class sessions Talk simultaneously with college instructors and classroom teachers about teaching and learning
College faculty can.... • Request and plan specific lessons related to course readings and assignments • Supervise all students in their virtual field placement simultaneously • Have the opportunity for “in-the-moment” reflection on teaching practice and refer back to scenarios that the whole class observed • Ask questions of the classroom teacher in the presence of the preservice teachers to raise teachable moments, thus intentionally connecting theory to practice Talk simultaneously with classroom teachers and preservice teachers about teaching and learning
Classroom teachers can... • Eliminate the distraction of too many adults in the classroom • Model good practices and think more intentionally about their teaching and student learning • Influence the curriculum of teacher-education preparation • Participate in research influencing teaching and learning • Learn more about current theory and practice in teacher-education programs • Share “practical experiences” gained from classroom teaching • Talk simultaneously with college instructors and preservice teachers about teaching and learning

APPENDIX B

Discussion Board Questions Posted Following Classroom Observations

Observation 1: How did Ms. Lockhart model reading, writing, listening, and speaking? How did it enhance the children's learning?

Observation 2: What dispositions did Miss Ortiz display that are important for teachers of young children? Why are these important? How do these dispositions enhance learning?

Observation 3: So far in our observations, we observed lessons in kindergarten and first grade. This week, we observed a 3rd grade classroom. What did you notice about the comparison in pacing and length of activity, conversations between teacher and child, and behavior management strategies? Thinking about the text reading, activities/discussions in class, and the observation, were the teacher's vocabulary strategies effective? Explain. What was one strength? What would you have done differently?

Observation 4: What were your thoughts and feelings about the content of today's lesson (poetry in 2nd grade), what the children brought to the lesson (and how they responded), how the teacher handled the interactions, and anything else you reflect on what you observed.

Observation 5: Ms. Schwartz discussed early on that she was going to do assessment rather than testing with the students. How does this correlate to our discussion in class on assessment versus evaluation? How can this type of assessment be useful to you as a teacher?

Chapter 4.8

Research on the Effects of Media and Pedagogy in Distance Education

Lou Yiping
Louisiana State University, USA

INTRODUCTION

Do media influence learning? This is a historical debate in the field of educational technology, which started when Clark (1983, 1994) argued that media are “mere vehicles” and it is the content and pedagogical methods that are the “active ingredients” influencing student learning. Others (e.g., Kozma, 1994; Cobb, 1997) disagreed and argued that special media attributes can make certain types of learning more effective or cognitively efficient. In this chapter, I will first review the key arguments for and against media effects in distance education (DE). I will then review several meta-analyses that attempted to analyze the effects of media and pedagogy based on quantitative syntheses of the empirical research in DE. Finally, I will discuss directions for future research.

DOI: 10.4018/978-1-60960-503-2.ch408

BACKGROUND

Arguments for and against Media Effects in Distance Education

The media effects debate has continued in the context of distance education (DE), especially regarding the need for comparative studies. Clark (2000) believes that comparing media-supported DE versus classroom instruction is similar to the old studies on computer-based instruction and that the research on the effects of DE has the same problem of media and method confound. Therefore, he calls for conducting multi-level evaluation studies on student perceptions of motivation using both quantitative and qualitative data such as questionnaires and cost-effective issues of DE programs instead of experimental studies.

Smith and Dillon (1999) argue for the continued need of comparative studies. They feel that the

way to solve the media and method confounding problem is to describe not only the physical characteristics of delivery media but also how media attributes are used to support student learning in the studies. Such features may include bandwidth of a delivery system, whether the communication is one-way or two-way, synchronous or asynchronous, and interface design. A media attribute associated with bandwidth is realism, which may be used to support the learning of concrete versus abstract symbols. Media attributes associated with one-way/two-way communication are interactivity and feedback, which can facilitate active engagement and adaptation to learners. A media attribute associated with interface is branching, which may support learner control and self-directed navigation. They believe that by describing these media attributes and how they are used to support student learning in DE should help researchers un-entangle the media and method confound, thereby, providing theory-based research evidence to direct effective design of distance education.

Early Synthesis Effort

Regardless of Clark's argument and repeated call against media and DE comparative research (1983, 1994, 2001), a considerable number of DE comparative studies have been and continue to be conducted, esp., after each wave of an emerging information communication technology. As is the case in most educational research, some studies found positive effects favoring DE, some found no significant or negative effects.

Russell (1999) compiled and annotated 335 studies published from 1928 to 1998 that reported no significant difference between mediated DE and classroom instruction. The collection does not include any studies that report significant findings, either positive or negative. Russell's rationale for compiling no significant difference studies only was that these studies considerably outnumbered those that reported significant findings. Based on

his collection, Russell concluded that the results support Clark's theory of no media effects on student learning. Although the study was widely cited, the selective vote-counting approach has been most criticized for its lack of rigor and incomplete picture of DE effects (Bernard et al., 2004; Layton, 1999).

Meta-Analysis

Meta-analysis was first developed by Glass and his colleagues (Glass, McGaw, & Smith, 1981). It employs effect size as a standardized mean difference between an experimental and a control condition so that findings across studies can be statistically combined to estimate an overall average effect size. It also allows researchers to explore variability in the findings to identify potential moderating factors based on study features.

Hedges and Olkins (1985) further developed the meta-analysis techniques. The weighting by the inverse of a sampling variance procedure further reduces bias from studies of different sample sizes. The homogeneity analysis tests if the aggregated findings are consistent or heterogeneous.

MAIN FOCUS OF THE CHAPTER

A total of 12 meta-analyses have been conducted and published from 2000 to 2007, attempting to synthesize the empirical DE research findings using a variety of different meta-analytic procedures (see Table 1). Some focused on one type of DE and others were more inclusive.

Video Conferencing or Telecourses

Two meta-analyses focused on video-conferencing or tele-courses only. Machtmes and Asher (2000) synthesized 19 studies published in 1943-1997 comparing the effects of live and pre-produced telecourses with classroom instruction at the adult and high education levels. They found an overall

Table 1. Meta-analyses on the effects of DE

Author	N of studies	Education Level	Outcomes	Effect Size
<i>Videoconferencing or Tele Courses</i>				
Machtmes & Asher (2000)	19	Adult and high education	achievement	-0.0093 heterogeneous
Cavanaugh (2001)	19	K-12	achievement	0.15 heterogeneous
<i>Online courses</i>				
Ungerleider & Burns (2003)	8 4	Secondary and university	achievement satisfaction	0.000 -0.509* Homogeneity not analyzed
Cavanaugh et al. (2004)	14	K-12	achievement	-0.028 homogeneous
Williams (2006)	25	Undergrad. and graduate applied health science	achievement	0.15* Homogeneity not analyzed
Jahng et al (2007)	20	Undergrad. and graduate	achievement	0.023 heterogeneous 0.0259 homogeneous after removal of 4 studies
<i>Synchronous and Asynchronous DE</i>				
Allen et al., (2002)	25	Not described	Satisfaction	-.031 ¹ heterogeneous; -.090 ¹ homogeneous after removal of 3 outliers
Shachar & Newmann (2003)	86	High education	achievement	0.37* heterogeneous 66% favor DE
Allen et al (2004)	54	Not described	achievement	.048 heterogeneous
Zhao et al. (2004)	51	K-20, military, adult	Mixed	.10 Heterogeneous 2/3 favor DE
Bernard et al. (2004)	232	K-20, adults	achievement attitude retention	0.013 heterogeneous -0.081* heterogeneous - 0.057* heterogeneous
Lou et al. (2006)	103	Undergrad.	achievement	0.016 heterogeneous

mean effect size of -0.0093 and that the findings were significantly heterogeneous. Through univariate study features analyses, they found that studies that were published in the last decade had significantly more positive effect sizes favoring DE ($ES = +0.23, p < .05$) than earlier studies. They also found that studies where two-way interaction between students and instructor were available via either video or audio during live instruction produced significantly more positive effect sizes than one-way pre-produced telecourses.

Cavanaugh (2001) synthesized 19 studies published in 1980-1998 on the effects of telecommunication courses at k-12 levels on student achievement. The overall mean effect size was +0.15 favoring DE but not statistically significant.

The findings across studies were significantly heterogeneous. Although Cavanaugh coded and analyzed a number of study features including use of delivery system, duration, frequency, and mode of DE, grade level, year of publication, outcome measure, test sequence, sample size, grade level, subject areas, and study sources, no significant moderators were identified.

Online Courses

Four meta-analyses were conducted synthesizing studies on the effects of online learning compared with classroom instruction. Ungerleider and Burns (2003) synthesized a total of 12 studies published in 2000-2003 on the effects of online and networked

learning (not exactly distance learning) on student achievement and satisfaction at the secondary schools and universities. The overall mean effect size was 0.000 (N=8) on achievement and -0.509 (N=4) on student satisfaction. The latter is significantly negative favoring classroom learning. Neither homogeneity analyses nor study features analyses were performed on either dataset.

Cavanaugh, Gillan, Kromrey, Hess, and Bloemeyer (2004) synthesized 14 studies published in 1999-2004 that compared the effects of online courses at k-12 virtual schools with classroom instruction. The overall weighted mean effect size was -0.028, which is not significantly different from zero. The findings across studies were significantly heterogeneous. Similar to Cavanaugh (2001), they coded and analyzed a number of study features including grade level, content area, duration and frequency of the distance learning experience, instructional role of the distance education, pacing of the instruction, role of the instructor, timing of the interactions, and types of interactions, as well as various study quality and invalidity factors, but failed to identify any moderating features that account for the significant variability in the findings.

Williams (2006) synthesized 25 studies published in 1990-2003 that compared online courses with classroom instruction in applied health science at the undergraduate and graduate levels. The overall mean effect size was +0.15, which is significantly positive. Although the homogeneity analysis was not conducted, Williams found that effect sizes were significantly more positive for students who were working professionals (ES = +0.74) than traditional students (ES not significantly different from zero). The researcher also classified DE into three categories (p.129):

- *A distributed classroom:* Synchronous learning in which students receive instruction at a set time in a satellite classroom off campus.

- *An independent classroom:* Asynchronous learning in which students complete course content at home on their own time.
- *An open classroom:* Synchronous and asynchronous learning in which students complete course content independently gathering collectively throughout the course to discuss content.

He found that the effect sizes were significantly more positive in distributed synchronous classrooms (ES = +0.24, $p < .05$) and open classrooms (ES = +0.25, $p < .05$) than in asynchronous independent classrooms (ES = -.06). Williams also analyzed several instructional design features based on Olcott's (1999) distance education ID components (p.129-130):

- *Interaction* included the technical delivery methods for communication between instructor and student as well as student and student such as e-mail, audio/video conferencing, fax, telephone, and instant messaging.
- *Introspection* included instructional activities such as use of examples, simulations, laboratory exercises, demonstrations, group discussions, small-group projects, student presentations, guided imagery, outlines, journals, and reflective writings.
- *Innovation* included instructional activities with two or more learning styles targeted, coded according to the type of learning being examined such as visual learning (i.e., textbooks, in-class videos/slides/overheads), auditory learning (i.e., lecture), and/or tactile learning (i.e., computer-assisted instructional programs).
- *Integration* included instructional activities such as case studies, role playing, skill-building techniques, and handouts.
- *Information* included instructional activities such as quizzes, comprehension checks, and other assessment measures to

determine whether the student was gaining the knowledge and/or skills necessary for advancement.

He found that effect sizes were significantly more positive when instructional design components were present: innovation ($ES = +0.18$, $p < .05$), introspection ($ES = +0.26$, $p < .05$), information ($ES = +0.39$, $p < .05$), and interaction ($ES = +0.29$, $p < .05$) than when they were absent and that there was a positive relationship between the number of ID components present and achievement.

Jahng, Krug, and Zhang (2007) synthesized 20 studies published in 1995-2004 on the effects of online courses over classroom instruction on student achievement at the graduate and undergraduate levels. The overall mean effect size was $+0.023$, which is not significantly different from zero. The effect sizes across studies were significantly heterogeneous. After removal of 4 studies, the mean effect size was $+0.0259$ and homogeneity was achieved. One significant methodology study feature was identified: the studies where students received a pre-test and a posttest had significantly more positive mean effect size than studies where students received a posttest only. It is not clear, though, whether the pre-test scores were subtracted from posttest scores in the effect size calculations.

Synchronous and Asynchronous DE

The other six meta-analyses are more comprehensive, including studies on the effects of all types of DE. Shacher (2003) synthesized 86 studies published in 1990-2002 that compared the effects of DE and classroom instruction at all levels of high education. The mean effect size was $+0.37$, which is statistically significant favoring DE students. Similar to most other meta-analyses, the integrated effect sizes were significantly heterogeneous with two thirds positive favoring DE. Based on a fail-safe analysis, Shacher concluded

that it would need 3,062 additional unreported studies with average non-significant findings to refute the conclusion. Shacher did not code or analyze any study features.

Allen, Bourhis, Burrell, and Mabry (2002) synthesized 25 studies published in 1988-1997 on student satisfaction in traditional classrooms over distance education. The overall mean effect size was 0.031 and significantly heterogeneous. Homogeneity was reached after removal of 3 outliers. Two study features, type of media used for conveying information (video, audio, and written) and presence of interaction (full two-way video, limited audio or email feedback, and none during instruction), were coded and analyzed. Student satisfaction appears to differ for different types of delivery media. When video was used in DE, students had similar satisfaction level as students in traditional classrooms; when only written communication (fax or emails) was used in the DE condition, students reported significantly lower satisfaction level than traditional classroom students ($r = 0.247$, $N = 4$).

Allen, Mabry, Mattrey, Bourhis, Titsworth, and Burrell (2004) synthesized 54 studies published in 1962-2001 comparing the performance of students in DE versus traditional classes. Similar to their earlier meta-analysis on student satisfaction, each study was coded for type of media used for conveying information and presence of interactions. No significant differences were found for either of the two coded study features.

Zhao, Lei, Yan, Tan & Zhao (2004) synthesized 51 studies published in 1982-2002 comparing the effects of distance courses versus classroom instruction on a variety of outcomes. The overall mean effect size was $+0.10$. The findings were significantly heterogeneous with 2/3 favoring DE. Nineteen study features were coded and a few were identified as significant moderators including publication year, researcher as instructor bias, instructor involvement, synchronicity of student-instructor interaction, and media involvement. However, because the study features analyses

used the whole dataset with different types of outcomes, the results may be confusing and not easily interpretable.

A common problem with analyzing individual study features separately is that some study features may correlate with each other. This is especially misleading when study quality is not controlled, impacting on the validity of the findings on significant moderating factors. Two recent comprehensive meta-analyses (Bernard, Abrami, Lou, Borokhovski, Wade, Wozney, Wallet, Fiset, & Huang, 2004; Lou, Bernard, & Abrami, 2006) employed multiple regression analyses to control for the quality of research methodology and correlation among study features.

Bernard, Abrami, Lou, Borokhovski, Wade, Wozney, Wallet, Fiset, and Huang (2004) quantitatively synthesized a total of 232 DE comparative studies published in 1985-2002. In addition to estimating the average effect size of DE effects on student achievement (+0.013, $p > .05$), attitudes (-0.081, $p < .05$) and drop-out rates (-0.057, $p < .05$), they first analyzed the difference between synchronous DE (e.g., online courses) and asynchronous DE (e.g., video-based telecourses) and then analyzed the relative importance of media, pedagogy, and research methodology quality through multiple regression analyses of 51 coded study features for each of the three outcomes. The results indicate that on average, effect sizes were more positive for asynchronous DE than synchronous DE. Methodological Quality explained a significant amount of variance in both synchronous and asynchronous DE outcomes (49% and 12%, respectively, for achievement). Pedagogy explained a significant 10%-13% of variance after controlling for methodology quality. Media were only significant when entered at step 1. These results show that pedagogy appears to explain a larger amount of variance in the findings and that media and research quality study features are highly correlated.

Lou, Bernard, and Abrami (2006) synthesized 103 DE comparative studies on student achievement conducted at the undergraduate

level. They further examined how media were used to support different types of DE pedagogy: instructor-directed, independent, or collaborative. The specific codings are (p. 151-152):

- *Instructor-Directed DE*: Synchronous videoconferencing, one-way satellite TV broadcast with two-way synchronous audio, or audiographics were used to deliver teacher-directed instruction and there was no report of discussion among students or group activities.
- *Independent DE*: Only asynchronous one-way TV, video tapes, and/or Web-based resources were used and there was no report of discussion among students or group activities.
- *Collaborative DE*: Discussion board, email, listserv, audio-conferencing, telephone, or chat was used for collaborative discussion among students.

The results showed significantly more positive effect sizes for Collaborative DE than either Instructor-Directed DE or Independent DE (see Table 2). While students in Collaborative DE achieved significantly higher than those in traditional classrooms ($ES = +0.11$, $p < .05$), no significant difference was found in student achievements between remote and host sites in synchronous instructor-directed DE ($ES = -0.04$). Similarly, no significant difference was found in student achievement between students in Independent DE and in traditional classrooms ($ES = -0.04$). Homogeneity analyses indicate that the effect sizes for instructor-directed DE were consistent across the 49 independent findings integrated.

Since the effect sizes for Independent DE and Collaborative DE were both significantly heterogeneous, further analyses were conducted to examine how media and pedagogy were used to support three types of student interactions: student-content, student-instructor, and student-student (Moore, 1989) and their relative impact on student

Table 2. Weighted mean effect sizes for three types of DE pedagogy in undergraduate studies. (Source: Lou, Y., Bernard, R. M. & Abrami, P. C., 2006)

DE Pedagogy	<i>k</i>	<i>G</i> +	95% CI	<i>Q_w</i>
Instructor-directed	49	-0.038	-0.108/+0.032	53.48
Independent	41	-0.038	-0.086/+0.011	223.143*
Discussion among students	30	+0.109	+0.030/+0.188	165.278*

* $p < .05$

achievement using multiple regression analyses. The study features included in the analyses for each of the three interactions and the results of the regression analyses are summarized in Table 3. The non-significant features in each type of interaction appear to be significantly correlated with those that are significant. These results indicate that the best practices of DE that produce higher student learning than traditional classrooms are instructional design and learning activities that enhance: 1) student-content interaction through multimedia and interactive CBI, and 2) student-instructor and student-student interactions through opportunities and learning activities that encourage such interactions.

FUTURE TRENDS

The quality of DE primary studies, as in educational technology research in general, has been repeatedly

criticized by a number of researchers and is often cited as a problem for media and method confound (e.g., Clark, 1983, 1994, 2000). One way to ensure best evidence syntheses is to select only best quality studies such as randomized experiments as advocated by Slavin (1987). This is often problematic due to the limited number of randomized studies in education (Slavin, 2008), especially in DE. Coding and analyzing methodology study features as is done in several of the DE meta-analyses can help identify potential influence from research methodology quality. However, simply identifying significant methodology factors by analyzing each study feature separately without controlling for them is not enough. Bernard, Abrami, Lou, Borokhovski, Wade, Wozney, Wallet, Fiset, and Huang (2004) and Lou, Bernard, and Abrami's (2006) multiple regression approach provides a feasible way in controlling for methodology quality and thereby identifying the unique variance due to media and pedagogy features.

Table 3. Results of multiple regression analyses of the interaction study features after controlling for research methodology quality. (After source Lou, Y., Bernard, R. M. & Abrami, P. C., 2006)

<i>Student-content interaction</i>	• Systematic instructional design (ID) • Use of one-way broadcast TV or videotape* • Use of computer-based instruction (CBI)* • Use of Web-based course materials
<i>Student-instructor interaction</i>	• Opportunity for face-to-face meetings with instructor* • Provision for synchronous technology-mediated communication with instructor • Use of asynchronous CMC with students • Activities that encourage student-instructor interactions*
<i>Student-student interaction</i>	• Opportunity for face-to-face contact with other students* • Provision for synchronous technology-mediated communication with other students • Use of asynchronous CMC with other students • Activities that encourage student-student interactions*

* $p < .05$

As technology-mediated DE is becoming increasingly popular for meeting a variety of education needs, it is time to go beyond simply comparing DE with classroom instruction. Future DE primary research should focus on directly examining the media and pedagogy factors in DE. More research is needed to investigate how different media can be effectively used to support a variety of sound instructional strategies for more effective student-content, student-student, and student-instructor interaction and more effective learning. For example, up to now, two-way communication such as video conferencing has been used mainly to support instructor-directed lecture presentation. An interesting line of future research would be to investigate how synchronous video, such as desktop or portable video conferencing, chat, and Instant Messenger may be used to support student-student interactions (e.g., group projects, peer tutoring) and student-instructor interactions (e.g., project advising and providing interactive feedback).

Future primary studies should also provide more complete descriptions of instructional conditions including media attribute uses, instructional strategies, and methodological procedures, not only of the experimental conditions but also of the control conditions, so as to build a better understanding of the media and pedagogy effects in DE.

CONCLUSION

The DE meta-analyses reviewed in this paper have provided a considerable amount of cumulative evidence on the effects of DE versus classroom instruction as well as a variety of media and pedagogy factors that significantly moderated the effectiveness of DE. While the overall effect size of DE versus traditional classroom instruction ranged from a moderate positive effect favoring DE to no significant difference or negative effects, significant heterogeneity in the findings indicate that the overall means are not representative of all the findings integrated.

Study features analyses in several meta-analyses indicate that both media and pedagogical strategies are important in facilitating student learning in DE. Media and pedagogy that support interaction with the instructor and other students are as important as media and pedagogy used to establish individual student interactions with content only. These results support Keegan's (1996) differentiation between "distance teaching" and "distance learning". The traditional reference of media as "delivery media" may not be sufficient. In effective DE, media should not only be used for delivering instructional materials and teacher directed instruction and feedback but also for facilitating student-student collaboration.

KEY TERMS AND DEFINITIONS

Asynchronous Communication: Delayed time communication between the instructor and students or among students using discussion board, emails, and etc.

Computer-Based Instruction: Instruction such as tutorials, drill-and-practice, and simulations that are provided through a computer.

Effect Size: A measure of standardized mean difference between the experimental and control conditions.

Media: Delivery media such as television, Internet, and video used in teaching and learning.

Meta-Analysis: A literature review method that quantitatively synthesizes the effects of an experimental treatment.

Method: Instructional and pedagogical strategies used in instruction.

Synchronous Communication: Real time communication between the instructor and students or among students using two-way communication media such as telephone, video or audio conferencing, and chat, etc.

Systematic Instructional Design: Conventional instructional design practices and principles used in developing the course and course materials.

Chapter 4.9

Application of E-Learning in Teaching: Learning and Research in East African Universities

Michael Walimbwa
Makerere University, Uganda

ABSTRACT

The challenges of an increasingly borderless world, as seen in the advancements in information technology, have brought reform in universities and re-conceptualized what constitutes learning, teaching, and research. E-learning is often implemented as a response to increasing educational demand and an increasingly networked community. E-learning is considered as an interactive means to provide an alternative environment that stimulates practical learning and equips learners with the skills to manage technological change and innovations. This chapter evaluates the initial phase of e-learning, the importance of a rightful attitude, context, and instructional design in digital learning environments in Makerere University, Uganda, University of Nairobi, Kenya and Uni-

versity of Dar es Salaam, Tanzania. The increase in enrollment in these universities brings in many challenges in service provision, negatively affecting instruction, learning, assessment and research services. A crisis-solving approach is presented as stimulating a creative context for the meaningful introduction of e-learning. It is also discussed whether the environment created so far through computer-mediated learning motivates institutions to integrate e-learning further. The sample involved instructors and learners from three universities in three different countries of Eastern Africa. Findings conclude that an e-learning environment must be introduced by creating relevant awareness to change attitude and empower users with an authentic approach without too much technological complexity. Review of curriculum, assessment and training around e-learning environments are also imperative as these interrelated factors form part of the e-learning process.

DOI: 10.4018/978-1-60960-503-2.ch409

ORGANIZATION BACKGROUND

Some of the problems in higher education of countries of Eastern Africa are the huge numbers of learners and fewer instructors that eventually affect the quality of teaching, learning and research. There have been attempts to tackle some of these major problems by the introduction of e-learning through integration of information and communication technology (ICT) into teaching, learning and research situations. E-learning, begun with the use of radios and television sets in instruction followed by the instructor led systems (audio) where cassettes were recorded for learners to use independently with minimum help of the teachers. In all these phases, there was support of printed media to enable independent and self-paced learning on the side of the learner. In East African universities, e-learning is a recent technological initiative, which started with few computers and basic networks. Makerere University, Universities of Nairobi and Dar es Salaam were connected to an internet service provider (ISP) that enabled them to periodically download e-mails. These Universities, with little knowledge of the potential of e-mail in instruction and limited networks left internet service to the wits of a few individuals, who later abandoned it (Tusubira, 2002).

The three universities share a common context of location in Eastern Africa and have a common challenge of increasing education demands amidst limited resources. During colonial days, these three were constituent colleges of the University of London, specialized in some programs. For instance, students who wanted to do law in East Africa would go to the University of Dar es Salaam as it was not offered in either of the two. In 1963, the three universities became constituent colleges of the University of East Africa: Makerere University College in Uganda, University of Dar es salaam in Tanzania and Nairobi University College in Kenya. Since then, these Universities have grown in terms of student intake, academic units and academic programs. Naturally, the numbers

were manageable then, and quality training was guaranteed. Makerere University, which had less than 5,000 students in 1990, had increased this enrolment to 30, 000 students by 2005. There were equivalent increments in student enrolment at universities of Nairobi and Dar es Salaam to 20,000 and 16,000 respectively. With the large number of students, traditional modes of teaching became quite limiting, compelling the universities into innovations to ensure quality service. From analogue file management system of large box files with immense papers, there was a dig through the digital world of computing and networking as innovations. In these universities, using ICT is so popular now that it has a Swahili language name, TEHEMA: “*technologia, ehabari mawasiliano*”

SETTING THE STAGE

Computers, multimedia (mm), interactive data-banks and communication platforms in e-learning stirs expectation of the potential of ICT in education. Institutions of learning embarked on connections to the internet, formulation of ICT policy master plans and acquisition of learning management systems (LMS) sometimes called learning platforms. Meanwhile, there was demarcation of e-learning centers and intensive set up of other appropriate facilities for e-learning. It was felt that ICT in education have the potential to increase not only the effectiveness of the educational process but also its overall efficiency whether in terms of classroom activities or administration (Omwenga, 2003). Jonassen (2001) asserts that e-learning conforms to constructivism- a teaching and learning paradigm that allows one to learn what they want, at their own pace and to construct knowledge in a social environment. Jonassen describes a constructivist-learning situation as:

Active: where students are able to meaningfully process their own information into valuable personal and social knowledge.

Cumulative: where new learning bases and builds on prior learning; why personal experiences are a good basis for instruction.

Integrative: where learners elaborate on new knowledge and inter relate it with their current knowledge, just to suit the knowledge into prior knowledge.

Reflective: where learners consciously reflect on what they know and need to learn. This is a basis for transfer of learning and situational or practical learning.

Goal directed and intentional: where learners subscribe to goals of learning; enabling focus on ideas that fascinate learners most.

Deriving from constructivism, Omwenga (2003) presents five modes of using ICT in technology enhanced learning environment (TEL) as:

Support mode: This is aimed at increased accuracy and enhancing presentation of work. Tools for use in this mode include word processing, PowerPoint, computer aided design and desktop publishing among others.

Exploration and control: Learners are able to explore, examine, experiment with and build situations. Simulations, expert systems and statistical packages are mostly used for this purpose in TEL.

Tutorial mode: Information is presented at an appropriate level and pace giving learners an opportunity for feedback on progress.

Resource mode: Technology is used to access information and other resources whether online through internet or offline through CDs and other software.

Link mode: Communication between individual learners and instructors, examples of e-mails, net meetings and video conferencing.

Notably however, these modes are not exclusive of each other, they tend to be blended for effectiveness.

Constructivism is a teaching and learning paradigm in which people are assumed to act interactively and socially to create knowledge. Methodologies of instruction are being recast to leverage new learning media and honor multiple e-learning styles to fit learning situations. Ravenscroft (2001), in a study, remarks that most TEL initiatives have been technology-led rather than theory-led. Leading thinkers from both within and outside academia are exploring radically different approaches to teaching and learning based on theory; e-learning, among them.

In Africa, information and communication technology use in educational environment is far from being fully realized as in many incidences, there are a number of encumbrances. In a research done by Karen (2008), in several African primary schools, there was an interesting finding about information and communication use. Most of the schools surveyed reported no functioning computers, and no internet. Interestingly, the report indicates that contacts between African and United Kingdom schools were by e-mails mostly. This study though done in primary schools has an implication on higher education as it is the products of primary schools that end up in Universities. But it is interesting to say on this basis that the will to use ICT is there though with limitations.

Curran (2004) makes interesting conclusions that indicates that universities adopted a strategy of e-learning due to their inherent characteristic of adaptability in use and flexibility in application. Though Curran's study was done in European environment, it informs this study that the major reason why a strategy for e-learning is taken is because of flexibility, if things don't work, there is a lot of freedom to do something else. There is no use clinging on a strategy that is failing in a given context just because it worked in another context. In certain situations, the integration of ICT in teaching and learning has failed because of the implementers attempting the "Everest syndrome".

Application of E-Learning in Teaching

Table 1. E-Learning tools used in teaching and learning

TEL "tool"	Uses and advantaged	Principle for good teaching
COMMUNICATION		
Homepage	Good way of introducing instructors to students, last minute changes can be made, other resources.	Student-instructor contact
Bulletin board or discussion tool (asynchronous)	One-to-many communication moderated discussions, anonymous interaction, debate, peer assessment, group work, searches, introvert students get involved, more writing by students, attachments can be posted	Student-instructor contact, cooperation among students.
Chat rooms (synchronous)	One-to-many communication, brainstorm, virtual office hours, immediate feed back	Cooperative learning, gives prompt feed back
Calendar	Posting of target dates, reminders, last minute changes, full calendar available with dates of activities	Emphasizes time on task, communicates high expectations.
E-mail	One-to-one and one-to-many communication, private communication, reminders of specific dates, personal motivation, groupwork, searchable medium, documents can be sent as attachments	Student-Lecturer contact, cooperation among students
TOOLS FOR AVAILABILITY AND ENRICHMENT OF CONTENT		
Content module: linked pages	Gives the feeling of flow, easier navigation, can add video, audio, graphics	Encourage active meaning
Self assessments	Students asses their own knowledge of the subject, instructors can include detailed feedback, tests can be repeated until students are sure that they mastered it, drilling is good for memory.	Encourages active learning, gives prompt feedback
Hyperlinks and references	Gives links to other pages which can be interactive and credit to referred to material	Encourages active learning, respects diverse ways of learning
Syllabus (course content folders)	Gives a description of the module content, lecturer information, outcomes, textbooks and expectations	Emphasizes time on task, student-lecturer contact
STUDENT ACTIVITY AND STUDY TOOLS		
Search facility	Students can find material electronically	Encourages active learning, respects diverse talents.
Grade tool	Students get their marks rapidly and can determine if they have to put in more effort for a module	Gives prompt feedback (depends on what and how much is made available), high expectations
Help files	Explains to students what is necessary to be successful	Encourages active learning, gives prompt feedback
ASSESSMENT TOOLS		
Quizzes: Timed, Randomized and multiple	Formative / summative assessment, immediate feedback. Students must have mastered the work to complete it in the set time. Students get different sets of questions, generated randomly from the database	Encourages active learning, Expectations, emphasizes time on task, gives prompt feedback, Diverse learning.
Assignment tools	Students can submit assignments electronically, grade assignments and the grades and feedback are immediate	Emphasizes time on task, gives prompt feedback
Group projects	Gives students the opportunity to help each other as they become aware of each other's strengths and weakness, prepares students for future jobs, in which group work is becoming vital.	Cooperative learning

Adapted from Van Der Merwe (2004) Evaluating the integration of ICT into teaching and learning activities at a South African higher education institution, p. 124-126.

In a study in an African context, Van Der Merwe (2004) describes the salient issues in a

technology enhanced learning environment summarized on Table 1.

Multimedia refers to text, sound, graphics, animations, imaging, and spatial modeling into computer systems. Multimedia involves the integration of more than one medium into a form of communication. E-learning and communication theory combines for effectiveness. With the surfacing of computers into education, multimedia has been strengthened and is popular. Multimedia holds a special place in technology enhanced learning because as Jonassen (2001) argues, it attracts and holds attention. A multimedia computer is able to capture sound and video. High-resolution monitors, sound cards and increase in random access memory (RAM) and processing speed of personal computers, can be exploited to transform teaching and learning environments. Multimedia may be very useful where learners use multitasking, but not every learner can be able to do this.

Jonassen (2001) further states that past research has proved that multiple-channel and complimentary channels improve e-learning situations while information from different channels which are inconsistent worsens a learning situation. This compares with the position of Mayer (2001), Clarke and Mayer (2003) as cited in Merrill (2005) who contends that when a presentation contains three elements: graphics audio and visual, there is a decrease in learning. Nevertheless, the integration of multimedia as a tool in e-learning is very vital to enhance instruction and learning situations as long as it is carefully used, given the fact that it goes far beyond what could be possible in a normal face-to-face lecture room situation.

However, Merrill (2005) is critical of designed e-learning materials, saying most so called e-learning materials are merely information transferred to the Internet without appropriate demonstration, practice, feedback, and learner guidance. This is what I call using ICT to give learners *electronic notes*, instead of enabling them to learn at ease. He hastens to add that the letter 'e' in e-learning has to be replaced with *enervative, endless* or *empty* learning meaning that many of the designed

e-learning materials available weakens or destroy the capacity of learning. Merrill is critical of e-learning material because they are designed badly. Though Merrill makes this comment, it should be noted that the beginning phase of e-learning in is characterized by this, so no university should despair that their materials are in this start at the beginning. This is a very big leap forward.

CASE DESCRIPTION

The initial days of the use of ICT in instruction were filled with excitement and prophecies about the great potential and improvement in education (Alessi and Trollip 2001). The same was felt at the three universities under this study. This projection has not been realized, many years down the road and one wonders why. Challenges as understanding, change of attitude and training are still prevalent (Omwenga, Waema and Wagacha, 2004). The persistence of these challenges and ignorance about ICT in education hinders any real utilization of e-learning as a resource that facilitates educational environments (Fonseca, 2001). These issues made this research inevitable. The three universities have heavily invested in e-learning infrastructure in the initial phases; this case study looks into the benefits being realized, if not then why?

The Study

The present study in an attempt to evaluate e-learning for teaching, learning and research in three universities was conducted with the following objectives:

1. To identify the features of e-learning in the universities;
2. To describe the utilization of features of e-learning; and
3. To outline the attitude towards the use of e-learning in teaching and learning.

Evaluation approach as a research design was used because the aim of this research was to study the practice of e-learning in its natural setting in order to interpret it in terms of the meaning people accord to it. The required data mainly concerned actions and feelings about the practice, usage and attitude to a digital learning environment (DLE). The data required was for evaluating practice that made a qualitative design suitable. Data relating to e-learning was collected from Makerere, Nairobi and Dar es Salaam universities. The universities are chosen purposively, to enable a baseline for Makerere University's e-learning project and make the study a comparative one. Additionally, all the three universities were engaged in piloting e-learning at different levels, introduction, implementation and evaluation. The target population was faculty students and instructors (under-graduate and post-graduate).

Purposive sampling was considered because e-learning is a pilot project thus few students and instructors are deeply involved and the characteristics of e-learning practice and indicators needed to be studied intensively. The respondents needed to be reached by discussion groups, observation, and interviews that required a small sample size as the purposive research required only those respondents with relevant data.

The collection of data was done using instruments: observation checklists, structured interviews and focus group discussion guides. Observation enabled the researcher to get first hand information through personal experience. Focused group discussions enabled the researcher to participate in live discussions while noting attitudes and opinions of the respondents. Interviews enabled in-depth examination the practice of e-learning in Makerere, Dar es Salaam and Nairobi universities. The discussions were held because it was vital to facilitate informants' interaction and therefore generate a wider response, while directly observing group reactions and feelings. Focused group discussions consisted of 20 students each, 5 focus group discussions from Makerere, and

two for each of the universities of Dar es Salaam and Nairobi respectively. This technique helped in getting data faster by way of brainstorming.

Structured interviews and focus group discussions involved intensive probing questions using a structured guide to reinforce group discussions and get information from instructors. Participant observation and checklists helped the researcher get and record rightful data from the practical ground. The researcher made observation tours of Nairobi and Dar es Salaam universities and e-learning centers during data collection. Observation checked inter-rater agreement and inter-rater reliability because of poor observation sometimes.

Secondary data was used as universities had extensive documents, some of them posted on the university websites and e-learning platforms. Many other publications from textbooks, journals, magazines and compact disc read only memory (CD-ROM) were studied and analysis of the same done (Jansen and Vithal, 2005).

The findings of the study are summarized below under broad headings of Features of e-learning, Utilization of e-learning, and Attitudes towards use of e-learning.

Features of E-Learning

Computing history of learners and instructors in all the three selected institutions is average. Most of the respondents had used computers for more than two years. The instructors had used computers in daily work while the students used them while being taught, most of them during high school. This has made the introduction of technology enhanced a little easy as the struggle to train in basic computer may be sidelined. Computer literacy is high, with the highest literacy noted at the University of Nairobi. There were therefore not many courses organized as induction into e-learning for students. For instructors, there are several induction and refresher courses in e-learning. Sometimes, it is easy for both students and instructors to find their own way into e-learning. Most of the users said

that they learnt how to use the electronic platforms by themselves, but sometimes only after a very limited induction. In fact some of the students access internet from mostly other places outside the university internet cafes.

There is use of various computer applications in the design of e-content with macromediaTM and Microsoft officeTM often being used in all the institutions. Macromedia is software that is used to design e-content in hypertext markup language (HTML). This enables instructors to create hyperlinks to content outside the designed content to enable further self discovery and learning. Microsoft officeTM is used very frequently though respondents were not conscious that they were using the software in almost all the daily routines. For instance, you would find an instructor with several presentations in power point, or students with a number of typed course works, but when you ask them of the software they use in their digital learning environments, they would say, they have none.

E-learning platforms exist in all the universities, Moodle for Makerere, BlackboardTM and WebCTTM for Dar es Salaam and WedusoftTM for Nairobi with the internet as electronic learning platforms in the institutions. Makerere, had

KewlTM and BlackboardTM at the beginning but has now opted for Moodle which is open source. Most of the features as described in the Table 1 given earlier are existent on the platforms. The features make the learning environment highly engaging and interactive both in synchronous and asynchronous ways.

Internet connection exists with the intranets though the access points and facilities are still inadequate. Nonetheless, these universities have tried their best to increase access points. In Makerere University for example, there is wireless in several places and in many lecturer rooms and offices, there are access points. Network plans like the one given in the Figure 1 have been a very salient feature in the introduction of e-learning. None of the universities could have gone any step without such plans.

In all the universities, there has been a complete digitization of libraries. Students can research online as the universities have been able to get journals, books and other literature, which they have subscribed to and can be accessed by students. The University of Nairobi had been able to do this with support of AVIOR, a Belgian support organization. By the time of this write up, the University of Nairobi had over 20,000, Dar es

Figure 1. Network plans at Makerere University

Salaam 25,000 and Makerere had 19,000 journals they could access. Research literature is more up to date and global compared to the earlier times.

Utilization of E-Learning

Findings on the utilization of e-learning in the three universities relate to technology concerns, technology components, management and organization. To design e-content materials instructors utilize the features of e-learning existent in the universities in e-learning. The design skills are provided in the several e-learning workshops. At the University of Nairobi, all courses on the electronic learning platform are a property of the university. The University of Nairobi, among the three universities had the best (as rated by the researcher) management of the technology they had, where the University of Dar es salaam had the best organization of the technology. At the University of Dar es salaam, there was a very well organized e-learning unit under the University computing center, but Makerere was only trying to put in place such a unit.

Instructors need enough time to concentrate on the design of e-content though this time is hard to be availed to them by the institutions. The conventional teaching methodologies are equally demanding for the time that would have been used to design e-content. Even if there was enough time, the change is so fast in technology. The trap has always been to change with the technological change and pay little attention to the real pedagogic issues and needs required in using technology in education. The management of time to engage in e-learning and to teach is clashing. E-learning at this level is used as a supplement to traditional methods of instruction best described as blended learning approaches. Makerere University learning platforms had more e-content courses than the other institutions though the quality of these courses was still low with little or no interactivity in most of them being electronic lecture notes and Microsoft PowerPoint™ slide shows. The courses

at the universities of Nairobi and Dar es Salaam were better compared to those of Makerere. This variation may be because of the deliberate e-content design workshops at these universities. Naturally, Makerere has a lesson to learn from this as it had no deliberate e-content design workshops. Though the institutions evidently had some e-learning equipment that could produce quality multimedia e-content, multimedia content was not common, because they require more time and technicality to make. The quality of technology to produce and deliver quality multimedia is limited. Currently broadband that has increased the internet bandwidth all over East Africa has come and universities are attempting to increase on their bandwidth. Before, to download only a small image would take too long or sometimes, it would time out because of the bandwidth. This had been a major bottleneck for the universities to effectively implement e-learning.

Effective administration and support enhances the use of technology enhanced learning. There was some evidence of effective administration and support. At Makerere, the support team did not ably handle the e-learning user demands. As stated before, Makerere was at the beginning phase of piloting e-learning. However, many things have drastically changed for the better and now there is an established e-learning unit only awaiting senate to discuss and pass a policy for its total implementation. There are student internet kiosk attendants for the effective management and delivery of e-learning. Though, more is needed for the efficiency of this system.

E-learning takes place through effective communication where an instructor is at one end and the student at another; able to interact in a virtual way just like they were more or less face-to-face. Instructors need time wherever they are to communicate to their students in both, asynchronous and synchronous ways. Instructors did not report effective communication and its use in e-learning because on many occasion, they did not create enough time to communicate with their students.

Students on the other hand were more enthusiastic in communication as they would chat with each other, send emails, and join discussion forums, activities that they instructors had created for them. This comes about because in Makerere for instance, though wiring has done up to offices, very little attempts have been made to put computers in them. In most occasions, staffs who are interested in e-learning have had to buy their own computers. This has been detrimental to the pace of e-learning. On all the main university intranets of Nairobi, Dar es Salaam and Makerere nonetheless, there are a number of issues related to announcements, jobs and other important announcements. Related to this communication, of later, some of the faculties at Makerere University have established state of art video conferencing facilities that will facilitate real time technology enhanced learning.

Attitude towards Use of E-Learning

It was rather difficult to get a general attitude towards the operation of e-learning in all the three institutions, as it required more time than the research had. Nevertheless, some instructors see technology enhanced learning replacing face-to-face sessions and some students use e-learning to dodge face-to-face sessions. At the University of Nairobi, an instructor asked, if e-learning will not take away all students from the lecture room as they would have all they need in terms of notes, assignments and coursework. This comes because of the factor that most instructors do upload all the notes they would have given in class. It would not be appropriate for one to upload the notes that the students will have in class, as this will not make any big difference between technology enhanced learning and electronic notes. It requires time to put notes design materials for uploading in a right format. E-learning would appropriately be a blended instructional method. This is the reason why some instructors have avoided getting involved in electronic instruction as they are used

to face-to-face instruction. E-learning is viewed as demanding considerable amount of time for one to make an effective contribution or use of it.

The presence of multimedia and interactive content in e-learning enables users to formulate a different perception about e-learning. Most of those who are not very conversant with computer use feel that e-learning is very complicated and needs very high intelligence for success. This may be the case but what is basic is, one should leave programming for computer scientists and look at the potential of multimedia in instruction. All that is needed are only the basics, which bring in the fact that there is need for teamwork in e-learning between computer scientist, administrators, teachers etc. The kind of support and administration in an e-learning environment also gives users a platform for different attitudes.

There are different motivational factors for engagement in e-learning both intrinsic and extrinsic in all the institutions. But the operational initiation of e-learning has an impact on its success. The universities are using a top-down approach and in this way, those who engage in e-learning might feel that it is imposed on them. On the contrary, if a bottom-up approach is used, it will bring in more ownership of the technology enhanced learning initiative. These approaches serve as either intrinsic or extrinsic motivators.

Users in all the three universities saw many benefits in e-learning including the ability to access advanced content, availability of content all the time, independent study and more effective communication. All these have changed and shaped the way institutions deliver and package their services now. For example, the University of Nairobi had a completely digitized library during the time of this research. The Universities of Makerere and Dar es Salaam have since then also embarked on digitizing their libraries (this publication has been done when the digitization is also complete), where catalogues, journal books and most services are becoming digital. All these bring in the perception that e-learning solves all

the problems which of course is not true. General comments indicated that in e-learning, users go for learning aspects including interactivity in e-content and the potential to improve teaching not technological issues.

Challenges of participation in e-learning exist in all the universities that included limited accessibility due to limited access points, high degree of computer illiteracy among both staff and students, incoherent policies for e-learning, and the need for mindset change among them. These are very limiting factors in the e-learning pilot given the fact that they relate to psychological orientation. Issues of computers being expensive can be solved by getting a few finances but issues of mindset are too personal. It is hoped that all institutions will try to engage in some sensitization to create awareness in ICT use.

CONCLUSION

Technology enhanced learning in the universities of Dar es Salaam, Makerere and Nairobi is here to stay. It is an evolving and gradual process. It has just started and has not yet reached the climax and users have a lot of expectations from e-learning. The universities are aware of this fact that the e-learning will not replace face-to-face teaching and learning but will be a complementary and blended aspect of learning in which learners have a diversity of media in learning. Users need patience with e-learning because it has just started and is not going to perform miracles. It is a journey. We can equate the introduction of e-learning in these institutions to a newly born baby, it is breast fed, and it sits, crawls, walks and one time it will run. The following are generic conclusions that may be generalized to all institution at the beginning of an e-learning journey

- There are scanty but clear indications of e-learning in the universities of Nairobi, Dar es Salaam and Makerere as seen from

the infrastructure available. There is internet connection, learning platforms, and e-content so far designed and developed. There is also a potential skill in users in the operation of e-learning. However, in all the universities, e-learning demand is outgrowing supply if measures are not taken to curtail this.

- There is utilization of e-learning infrastructure in instruction, learning and research in the universities of Dar es Salaam, Makerere and Nairobi. Utilization of e-learning has been the design of e-content, provision and search for content in a given course unit with little emphasis on the pedagogic issues. The potential of e-learning in instruction learning and research is therefore yet to be fully tapped. Technological and managerial concerns related to e-learn still prevails in these universities.
- Nevertheless, there is generally a very positive attitude towards technology enhanced learning in all the three institutions. Students, instructors and other administrators concur that e-learning presents a choice for them to operate in an environment they like best. Knowledge about many aspects of e-learning is still limited for some misconceived reasons. This hinders the real utilization of e-learning in teaching, learning and research.

In the Universities of Makerere, Nairobi and Dar es Salaam, based on the earlier discussions, the following specific conclusions can be obtained relating to the practice of e-learning:

- E-learning is clearly taking shape in institutions where there exists computer infrastructure, intranet, internet, learning platforms, e-learning policies and e-content course materials.
- E-learning in its first phase is being used for distribution of content though there is

an apparent move towards more interactive materials

- Students need effective communication and guidance from instructors concerning aspects of content in an e-learning environment
- E-learning use has not realized its full potential
- There is general satisfaction among users with regard to the use of e-learning in teaching and learning. This is supported by the fact that there is more strong agreement with perceived advantages and disagreement with disadvantages of e-learning.
- The potential benefits of e-learning in teaching and learning manifest but do not reflect in most instructors due to lack of course redesign.
- Motivators into participation in e-learning are intrinsic: teaching and learning issues (such as increased benefit to students).
- There is effective team management and administration of e-learning infrastructure.

RECOMMENDATIONS

On the basis of the findings of this project, in order to improve on the practice and enable change of attitudes towards the practice of e-learning, the following recommendations may be considered;

- Get more computers connected to the internet and liberalize accessibility in the institutions. In some e-learning centers there was evidence of numerous computers but with very few connected to the internet. This limits the number of access terminals for e-learning.
- Better infrastructure: computers, printers, e-learning centers, networks for more practice and utilization in e-learning.
- Greater sensitization about the practice of e-learning is called for to make it more

popular among all participants in the selected institutions.

- Develop a curriculum in e-content development similar to that used by the case with the University of Nairobi.
- Regular training and workshops should be encouraged to popularize e-learning amongst users in Nairobi, Makerere and Dar es Salaam Universities. In these workshops however, aspects of learning and effective communication and not technology should be emphasized.
- Specialized training in design of instructional materials. Many of the instructors are not teachers by training thus needing pedagogic training to make more appropriate instructional material in all the three universities. The capacity to exploit e-learning depends on users' skills.
- Increased bandwidth in all the three universities as the networks are still slow.
- Improve the kind of support given in e-learning centers, particularly in Makerere University though it may be applicable in all the three institutions. Learners complained about the technical support people and uncooperative end user personnel. This necessitated that people apt in use of ICT but with some background pedagogic training can do a better job than computer technicians in e-learning.

KEY TERMS AND DEFINITIONS

Attitude: The feeling towards e-learning. This feeling comes either before or after engaging in e-learning

Blended Learning: Learning which is delivered using a mixture of both traditional methods like lecturers and technology enhanced instruction

E-Learning/ Technology Enhanced Learning: The delivery of learning, training or education program by electronic means. It involves the use of a computer or other electronic device in a way to provide learning material

E-Content: Materials that have been transformed from those that are delivered in the normal lecture room, to those that are highly interactive and allows self paced learning.

Application of E-Learning in Teaching

Digital Environment: A situation where there are electronic devices being used in instruction, learning and research

TEHEMA: Is a Kiswahili acronym (*technologia ehabari mawasiliano*) for Information and Communication Technology.

Multimedia: The act of a lesson integrating audio-visual and video interactions to make learners more engaged in a study.

Intranet: Is a local area network, where a university can use the available computers to access information from within the campus.

Chapter 4.10

Asynchronous Online Foreign Language Courses

Leticia L. McGrath
Georgia Southern University, USA

Mark Johnson
University System of Georgia, USA

INTRODUCTION

In 1999, the Board of Regents of the University System of Georgia (USG), in collaboration with a number of its member institutions, began developing a fully online set of courses that allows a student to complete a core curriculum that is transferable across the USG. The result of this effort is the USG's eCore® Program, developed by the Advanced Learning Technologies (ALT) unit of the USG. The eCore® Courses were created using a collaborative course development process that engaged teams of USG faculty, technical support and an instructional designer from ALT. The collaborative course development process was utilized in order to take full advantage of the expertise of the team members and to incorporate multiple perspectives of the content into

the courses. In addition, a set of guidelines for the development of eCore® courses was established to ensure the courses were of the highest quality possible. The eCore® course array was developed over a period of seven years. While many of the courses were well suited to the asynchronous online approach, there were content areas that were more controversial, such as physics, chemistry and foreign languages, due to the highly specific requirements in each of these disciplines.

The last courses to be developed for the USG's eCore® Program were two that comprised the Intermediate Spanish sequence. This course development process began with an intensive examination of the viability of an online language course by a team of content experts from a team of USG Foreign Language faculty. Foreign Language (FL) courses, by nature, must incorporate exposure to the target language and extensive practice communicating in that language. Technology is

DOI: 10.4018/978-1-60960-503-2.ch410

increasingly becoming an integral part of the FL classroom as students use computer-mediated communication (CMC) to practice the language with their peers, instructor, and native speakers of the language via chat rooms and message boards. The following discusses the development and implementation of the Intermediate Spanish levels I and II courses for the USG eCore® Program.

BACKGROUND: COMPUTER-ASSISTED LANGUAGE LEARNING (CALL)

The study of Computer-Assisted Language Learning (CALL), an emerging topic for educators and researchers, has provided language instructors and learners a great realm of possibilities in Second Language Acquisition (SLA). Warschauer (1997), in his study “Computer-Mediated Collaborative Learning: Theory and Practice,” provides a succinct review of relevant research in the second half of the twentieth century, confirming the relationship between the significant increase in investigation in the 1990s with the advent of the internet and the rise of the accessibility of computers. Warschauer firmly asserts that online communication “encourages collaborative learning in the classroom” (p. 472). Some of the more salient studies (Kern, 1995; Warschauer, 1997; Kinginger, 1998; Abrams, 2003; Poza, 2005) emphasize the advantages of incorporating CMC into face-to-face language courses. Kern contends that:

new medium-specific conventions . . . compensate for the absence of prosodic and paralinguistic features found in face-to-face oral communication. For example, facial expressions such as smiles [:-) I, frowns [:-) (I, or winks [;-)] become icons, and tone of voice is represented by capitalization, underlining, exclamation marks, and other symbols. (p. 459)

Many researchers agree that text-based computer conference technologies create a setting in which students experience a decrease in anxiety when compared to face-to-face conversation (Beauvois, 1994, 1996, 1999; Kivela, 1996; Lee, 2004; Meunier, 1998; Skinner & Austin, 1999; Warschauer, 1996). In addition, research shows that students indicate they feel a significantly lower fear of negative evaluation via the computer (Beauvois, 1996; Chun, 1994; Kelm, 1992; Kivela, 1996).

Recent advances in computer conferencing technologies expand communication from simple text-based tools, such as email, chat rooms, or bulletin boards, to voice-based technologies, further enhancing the language learning environment by allowing students to communicate with their own voices on their own time. Little research exists concerning the use of voice tools for CMC in foreign language classes; however a recent doctoral dissertation, “The Effects of Asynchronous Computer Voice Conferencing on Learners’ Anxiety When Speaking a Foreign Language” by Poza (2005) provides an in depth study of the many advantages of online oral interaction. Poza’s research utilizes an asynchronous voice web board developed by Wimba, a software company dedicated to the online education market. As defined by one of the co-founders and former CEO of the company, K. W. Ross (2003): “Asynchronous voice is the interactive communication process of people leaving voice messages for other people and the other people responding to their voice messages” (p. 60). The results of Poza’s investigation reveal that “a number of students experienced reduced anxiety attributable to both the elimination of the time pressure of the classroom, as well as the opportunity to edit their contributions before posting them to the voice board” (108).

DEVELOPING AND IMPLEMENTING ECORE® INTERMEDIATE SPANISH I AND II

In the spring of 2003 The Foreign Language Team (FLT) was formed to investigate the efficacy of an online eCore® Spanish course. This team was made up of USG Spanish, French, German and English faculty. The FLT report, (Barron, et al., 2003) was a comprehensive evaluation of the “state of the art” of online language education and offered a set of specific recommendations for developing asynchronous online language education courses for the USG eCore® project. The report began with the following:

This report examines issues surrounding the implementation of 2000 level online foreign language courses and makes specific recommendations to the University System of Georgia regarding implementing such courses as part of its eCore® program. In our examination, we consider outcomes and standards, pedagogical approaches, instructional materials, technology, teaching activities, and transferability issues.

The central challenge in designing an online foreign language course is to use technology effectively to assist in developing the students’ skills in reading, writing, speaking, and understanding. A related challenge is to create an online course that will effectively assess the students’ performance and growth. (p. 2)

In addition, the FLT recognized the importance of students having a foundation in the target language prior to taking online courses. This resulted in the implementation of the eCore® Spanish courses at the intermediate level with a prerequisite of elementary Spanish in a traditional classroom setting.

While this report provided an important framework for the eCore® Spanish courses, the actual development of the courses would be a greater

challenge. Beginning in April, 2004 a team of four Spanish language faculty, an instructional designer and a programmer began to develop the courses. As the FLT report emphasized, skill development and assessment were crucial components of any successful language course.

The first challenge was to determine how the oral aspect of language education could be accomplished in an online environment. The FLT recommended several possible technologies including Wimba, a suite of “voice tools” specifically designed for online language education, a voice enabled web conferencing program called Elluminate, as well as telephone and tape recorded audio sessions. After careful consideration, Wimba was adopted because of its ease of use, asynchronous application, and compatibility with Blackboard Vista, the course management system used within the USG. Wimba allows students to record their oral exercises and post them to a “voice board” where they can be retrieved by the instructor for review and comment. In addition, the application includes voice email, a voice recorder that allows faculty to record audio and a synchronous component called voice direct.

Next, the team developed the actual course content including the lessons, labs and assessments. While there are many Intermediate Level Spanish textbooks, *Enfoques* by Vistas Higher Learning had several advantages that led the development team to adopt it for the courses. One of the primary advantages of *Enfoques* is the online lab, Web SAM (Student Activities Manual) provided by Quia Books. The labs, which include the workbook, laboratory manual, and video manual, are based on the textbook and this saved the team countless hours of development time. In addition, the textbook package includes CD-ROMs with video, audio and tutorials that are also linked to the textbook. These ready-made resources allowed the development team to focus on writing the course content.

In addition to the written course content the development team had native speakers of the

language record readings that allow the students to experience in-depth recitations of literature in the target language. Finally, the team used the USG's Interactive Media Object Development Tool (IMOD) to develop flash cards that presented key vocabulary in each unit. These cards show the Spanish and English spelling of word along with audio of the word being spoken in Spanish.

The pilot eCore® Spanish course began in the spring of 2006 at the intermediate level with eleven students. Because the textbook, *Enfoques*, is integrated into the online course, students are able to use its many resources to guide them as they work through each lesson. *Enfoques* includes a unique and engaging situational comedy video episode in every lesson featuring native speakers from several different Spanish-speaking countries. As students watch the video, they see the structures they are learning put to use in the everyday lives and adventures of the owner and his employees of the lifestyle magazine *Facetas*. In addition, in every odd-numbered lesson, students watch an interesting short film by a contemporary Hispanic filmmaker. Because the textbook emphasizes authentic language and practical vocabulary for communicating in real-life situations, students are provided with abundant opportunities to both experience the language in context and practice speaking it in communicative activities, all of this despite the fact that the students may never meet face-to-face. In addition, in each lesson there are literary readings, cultural viewpoints, fine art, and quotations by famous Hispanics that recognize and celebrate the diversity of the Spanish-speaking world and Spanish speakers.

When students sign in to their eCore® Spanish course, they enter into a Spanish-speaking world, an environment where they can listen to the language in authentic situations via the videos, the interactive CDROM, the mp3 files, the comprehensive laboratory activities, the recordings within the course in each lesson, the Wimba voice boards, and the iMods. Using the materials within the WebCT course and the textbook with

its ancillaries, students have maximum exposure to the language, providing them with ample opportunities to improve their ability to speak, read, write, and understand Spanish.

Individual student language acquisition was the top priority in the design of these courses. One of the key features of the online eCore® courses is the dictation done by native Spanish speakers of much of the course content imbedded within the course itself. Students experience much of what students in a face-to-face class experience in that aspect, as they read along while the instructor explains the material to them from the textbook. As a follow up, the students are asked questions concerning the context and vocabulary of the lesson, and they must answer by recording their own voices to the Wimba voice bulletin board. Also accompanying each new grammatical structure is an additional explanation (in addition to the textbook) in Spanish for students to use as a guide. At the end of each chapter, students have the opportunity to listen while they read pieces of literature. Face-to-face students, for the most part, are unable to enjoy this luxury due to time limitations in the classrooms, but one can imagine how effective it would be to have a native speaker recorded for each piece of literature that is introduced in class.

One of the greatest advantages of an online FL course is the increase in communication in the target language among all students. In face-to-face classrooms, FL instructors often find it challenging to convince each student in a classroom to participate openly in oral activities. Poza (2005) affirms "that there is a strong relationship between anxiety and risk-taking in oral participation in a foreign language," and that "if foreign language educators can provide an environment where students can concentrate on language and meaning, rather than on fear of failure and negative evaluation, their level of anxiety will be lowered, and they will be able to speak more often and openly in the target language. (p. 18-19). The affective filter, an expression used to describe the negative emotional environment created by high

anxiety and low self-esteem in acquiring a second language, is indeed reduced in CMC. Students in a face-to-face classroom who fear negative evaluation, either from the instructor or their peers, are less apprehensive when communicating online, given the absence of both certain social cues and the intimidating presence of others nearby. In addition, “people with disabilities and those who would otherwise be reticent to participate in the communication act feel more inclined to take part in the interaction” (Poza, 2005). The online Intermediate Spanish eCore® courses provide a comfortable learning environment in which students communicate with ease. In addition to the added benefits of lowering student anxiety, CMC allows for students to produce more language with a richer vocabulary than they do in face-to-face conversations (Beauvois, 1997).

The scope and sequence of the eCore® Intermediate Spanish I and II courses is shown in Table 1. (taken from *Enfoques*):

Due to the quantity of topics and structures covered in each chapter, the eCore® Intermediate

Spanish courses are more time consuming for both the instructor and the student than the equivalent face-to-face courses. The activities within the textbook that are designed for use within the classroom are now assignments that students must complete on their own. Students type their answers to the corresponding textbook activities listed within each lesson in WebCT, record their voices in specific exercises, and complete the workbook activities, video manual, and laboratory manual on the Quia Books web site. The first semester that Intermediate Spanish I was offered in eCore®, spring 2006, the course included lessons 1 through 6, and students turned in each textbook activity separately, inundating the instructor’s assignment dropbox with dozens of submissions each chapter. Over the summer of 2006, the course was restructured to incorporate only lessons 1 through 5 and revised so that students would compile their textbook activities on one document per chapter and submit those at the end of each lesson.

Table 1.

eCore® INTERMEDIATE SPANISH I Lesson 1 - Las Relaciones Personales ➤ describe in the present ➤ narrate in the present ➤ express personal relationships Lesson 2 - Las Diversiones ➤ express actions in progress ➤ avoid redundancy ➤ describe your daily routine and activities ➤ express personal likes and dislikes Lesson 3 - La Vida Diaria ➤ narrate in the past ➤ express completed past actions ➤ express habitual or ongoing past events or conditions ➤ describe how, when, and where actions take place Lesson 4 - Los Viajes ➤ express past events and conditions ➤ make comparisons ➤ express your attitude toward actions and conditions Lesson 5 - La Salud y el Bienestar ➤ express will, emotion, doubt, or denial ➤ express uncertainty and indefiniteness ➤ convey purpose, condition, and intent ➤ give orders, advice, and suggestions	eCore® INTERMEDIATE SPANISH II Lesson 6 - La Naturaleza ➤ describe and narrate in the future ➤ express what you or others would do ➤ express events that depend on other events Lesson 7 - La Economía y el Trabajo ➤ reference general ideas ➤ express ownership or possession ➤ create longer, more informative sentences ➤ relate ideas more smoothly to other ideas Lesson 8 - La Religión y la Política ➤ describe actions in the passive voice ➤ express surprise or unexpected occurrences ➤ express contradiction to previously stated information Lesson 9 - La Cultura Popular y los Medios de Comunicación ➤ narrate events that depend on past events ➤ describe the position of people or objects ➤ express choice and negation Lesson 10 - La Literatura y el Arte ➤ express what will have happened ➤ express what would have happened ➤ make contrary-to-fact statements about the past ➤ describe changes in a mental, emotional, or physical state
--	---

The second offering of this course, fall 2006, was more efficient and better organized. In both the spring and fall semesters of 2007, two courses of Intermediate Spanish I and one course of Intermediate Spanish II were offered. Both courses are currently undergoing another revision due to a new edition of the textbook, *Enfoques*. These changes will provide the student with more contemporary cultural activities with the integration of a new and exciting video series titled *Flash Cultura*, which depicts on-location scenes of real-world events and real Spanish speakers. In addition, *Enfoques* includes a new Supersite online which features an expansive set of tools and resources for both students and instructors.

FUTURE TRENDS

As mentioned above, there are few studies on the use of voice tools in online language courses. There is a great opportunity for research in this area, especially concerning student evaluation both prior to and following taking the fully online course. As video conferencing is gaining in popularity, it would provide another avenue of research for the possibility of incorporating into these online Spanish courses. In addition, podcasting has become an excellent way to reach students via their most chosen media, providing them the opportunities to view video and/or listen to audio files via their iPods as they approach learning a foreign language in a fully online classroom.

CONCLUSION

As of the spring of 2006 over 13,000 students had taken eCore® courses in 489 sections of the 25 courses offered. One advantage of these courses is that their credits are accepted system-wide by the 35 USG institutions. This flexibility, combined with the fact that the courses are offered in an “asynchronous” or anytime-anywhere format, has

a wide appeal to non-traditional students. Nearly 45% of the students enrolled in eCore® courses are over the age of 25, 72% are female, and there has been a steady increase in the number of minority students to almost 30% since the inception of the program. In the Intermediate Spanish courses now offered in eCore®, students are quite pleased with the many resources available to them, and several have expressed interest in continuing the language as a minor, perhaps even a major field of study.

KEY TERMS AND DEFINITIONS

Affective Filter Hypothesis: The hypothesis credited to Stephen Krashen, an expert in linguistics, that declares that a student's anxiety, low self esteem, or lack of motivation can serve to cause a mental block preventing the successful acquisition of a second language. If the "affective filter" is lowered by creating a learning environment in which students are more motivated and suffer from less anxiety and low self esteem, the possibility of success in achieving SLA is greatly improved.

Asynchronous Course: A course that does not typically meet for regularly scheduled class meeting times and is available any time, any place and at any pace. This allows students to participate from any location. These courses generally make use of the Internet, CD-ROM, independent study, or a combination thereof. Students access the course material from a course web site or a course management system.

Computer Assisted Language Learning (CALL): A wide encompassing term that represents a methodology of language teaching and learning that involves the utilization of computer technology in assessment, reinforcement, interaction, communication, and presentation.

CALICO: The Computer Assisted Language Instruction Consortium, a professional organization whose members emphasize the combination of technology with language teaching and learning.

Computer-Mediated Communication (CMC): Any communication between two or more individuals using a computer as the means to exchange data.

Quintessential Instructional Archive (QUIA) : A web site (found at <http://www.quia.com/books>) that partners with textbook publishers to produce online workbooks and textbooks where students are engaged with interactive exercises, many of which provide immediate feedback.

Second Language Acquisition (SLA): The process by which people learn languages in addition to their native language(s). The term second language is used to describe any language whose acquisition starts after early childhood (including what may be the third or subsequent language learned). The language to be learned is often referred to as the “target language” or “L2”,

compared to the first language, “L1”. Second language acquisition may be abbreviated “SLA”, or L2A, for “L2 acquisition”. Synchronous Course: A course that meets for regularly scheduled class meeting times.

USG’s eCore® Program: eCore®—short for electronic core curriculum—allows University System of Georgia students the opportunity to complete their first two years (the “core” curriculum) of their collegiate careers in an online environment. While originally designed for the non-traditional student, many currently enrolled students find eCore® presents an opportunity for increasing flexibility and convenience in their course load management. eCore® consists of online freshman- and sophomore-level courses designed, developed, taught, and supported by faculty and staff from the University System of Georgia. eCore® offers courses in English, mathematics, science, history, and the social sciences. Courses comply with ADA standards to meet the needs of students with disabilities or special needs.

Chapter 4.11

The Application of Sound and Auditory Responses in E-Learning

Terry T. Kidd

University of Texas School of Public Health, USA

INTRODUCTION

Prior to computer technology, several studies have concluded that multiple senses engage the learner to the extent that a person remembers 20% of what they see, 40% of that they see and hear, and 70% of what they see, hear and do. In general, the participant engages what is seen and what is heard. With this implication, instructional designer or developers try to use design guidelines to identify the main uses of sound in e-learning as multimedia agents to enhance and reinforce concepts and training from e-learning solutions. Even with such understanding, instructional designers often make little use of auditory information in developing effective multimedia agents for e-learning solutions and applications. Thus, in order to provide the learner with a realistic context for learning,

the designer must strive to incorporate the use of sound for instructional transactions. By sharing knowledge on this issue, designer can create a more realistic vision of how sound technology can be used in e-learning to enhance instruction for quality teaching and participant learning.

BACKGROUND

Prior to computer technology, many studies concluded that multiple senses engage the learner to the extent that a person remembers 20% of what they see, 40% of that they see and hear, and 70% of what they see, hear and do. “Human beings are programmed to use multiple senses for assimilating information” (Ives, 1992). Even with such understanding, instructional designers often make little use of auditory information in developing e-learning. “This neglect of the audi-

DOI: 10.4018/978-1-60960-503-2.ch411

tory sense appears to be less a matter of choice and more a matter of just not knowing how to ‘sonify’ instructional designers to enhance learning” (Bishop & Cates, 2001). The major obstacle in this development is that there is not a significant amount of quantitative study on the why, when, and where audio should or should not be used (Beccue & Vila, 2001).

In general, interface design guidelines identify three main uses of sound in multimedia agents in e-learning: (a) to alert learners to errors; (b) to provide stand-alone examples; or (c) to narrate text on the screen (Bishop & Cates, 2001). Review of research on sound in multimedia applied to effective e-learning solutions reveals a focus on the third use cited above. Barron and Atkins’s (1994) research found that there were few guidelines to follow when deciding whether audio should replace, enhance, or mirror the text-based version of a lesson. The results of her study showed equal achievement effectiveness with or without the addition of the audio channel. Perceptions were positive among all three groups. Shih and Alessi’s (1996) study investigated the relative effects of voice vs. text on learning spatial and temporal information and learners’ preferences. This study found no significant difference on learning. The findings of Beccue and Vila’s (2001) research supported these previous findings. Recent technological advances now make it possible for full integration of sound in multimedia agents to be employed in e-learning solutions. Sounds may enhance learning in multimedia agents, but without a strong theoretical cognitive foundation, the particular sounds used may not only fail to enhance learning, but they may actually detract from it (Bishop, 2001).

The three audio elements in multimedia production are speech (narration, dialogue, and direct address), sound effects (contextual or narrative function), and music (establishing locale or time; all of these identify characters and events, act as transition elements between contrasting scenes, and set the mood and pace of presentation (Kerr,

1999). Silence can be used to set a mood or to provide a moment for reflection.

Mayer and his associates (Moreno & Mayer, 2000a, 2000b; Mayer 2003) have conducted a number of experiments with older learners, demonstrating the superiority of audio/visual instructions. These studies have shown that, in many situations, visual textual explanations may be replaced by equivalent auditory explanations, and thus enhance learning. These beneficial effects of using audio/visual presentations only occur when two or more components of a visual presentation are incomprehensible in isolation and must be mentally integrated before they can be understood.

Because some studies suggest that the use of multiple channels, when cues are highly related, is far superior to one channel, the more extensive use of sound may lead to more effective computer-based learning materials. In order to have design guidelines in using sound in e-learning, instructional designers must understand the cognitive components of sound’s use and the ways sound contribute to appropriate levels of redundancy and information in instructional messages. Bishop and Cates suggested that research should first explore the cognitive foundation. “Such theoretical foundation should address information-processing theory because it supplies a model for understanding how instructional messages are processed by learners; and communication theory because it supplies a model for structuring effective instructional messages.”

MAIN DISCUSSION: THEORETICAL FOUNDATIONS FOR THE USE OF SOUND IN INSTRUCTION SOFTWARE

Bishop and Cates proposed a theoretical foundation for sound’s use in multimedia instruction to enhance learning. They studied the Atkinson-Shiffrin information processing model, which

Figure 1. The Atkinson-Shiffrin information processing theory model and illustrations

addresses the transformation from environment stimuli to human schemata and their limitation factors due to human cognitive constraints. They adopted Phye's categorization of this process to three main operations: acquisition, processing, and retrieval. Figure 1 summarizes the Atkinson-Shiffrin information processing model and its limitations. "Information-processing theory addressed human cognition.

Communication theory, on the other hand, addressed human interaction" (Bishop & Cates,

2001). Bishop and Cates also investigated the Shannon-Weaver Communication model and its limitations. They also adopted Berio's suggestion that learning models in terms of communication generally begin with and focus on how messages are received and processed by learners. The work of a number of authors identifies the three levels or phases of learning selection, analysis, and synthesis. Figure 2 summarizes the Shannon-Weaver communication model, its limitations, and the three phases of learning.

Figure 2. The Shannon Weaver communication model and illustrations

Built on these two theories, Bishop and Cates proposed an instruction communication system where acquisition, processing, and retrieval operations are all applied, in varying amounts, during each phase of learning. This orthogonal relationship is depicted in Figure 3. “Instructional communication systems could fail because of errors induced by excessive noise” (Bishop & Cates, 2001). Limitations within three information-processing operations can contribute to problems in instructional communications. Noise encountered within each operation is also shown in Figure 3.

The three diagonal cells highlighted represent the heaviest operation within each learning phase. During selection, learning calls on acquisition heavily while during analysis, processing is central. During synthesis, learning calls on retrieval most heavily. The relative strength of potential noise increases and the consequences become more serious at each deeper phase of learning when following the cells vertically down the information-processing operations. Bishop and Cates suggested that adding sound to instructional messages may help optimize communica-

tion by helping learners overcome various information processing and noise encountered at the selection, the analysis, and at the synthesis phase of the instructional communication process.

In overcoming acquisition noise, Bishop and Cates suggested that sounds could gain learners attention, help learners focus attention on appropriate information, and keep distractions of competing stimuli, engage learner’s interest over time. Bishop and Cates believed that sounds could help learners elaborate on visual stimuli by providing information about invisible structure, dynamic change, and abstract concepts. And because of the nature of sound to be organized in time, where images are organized in space, Bishop and Cates believed that sounds could provide a context within which individuals can think actively about connections between new information, therefore overcome processing noise. Bishop and Cates cited Gaver’s (1993) research that when we hear the sound of a car while walking down the street at night, we compare what we are hearing to our memories for the objects that make that sound, drawing from and linking to existing constructs and schemata to support our understanding of what

Figure 3. The Bishop and Cates instructional communication system--a framework of instructional communication system

	Acquisition Noise Competing internal and external message disrupts the signal transmission process	Processing Noise Students fail to isolate the communicated instructional input from other sounds	Retrieval Noise Elements or structure of the message fail to trigger link to existing schema structures
Selection	Learner has trouble directing attention to the instructional message	Relationships between the instructional part of message are not isolated/recognized from other stimuli	Prevents evoking the correct prior knowledge structure from memory
Analysis	Learner has trouble focusing attention on instructional message	Semantic difficulties cause interpretation errors and poor organization of the information	Learning cannot build upon prior knowledge structures
Synthesis	Learner has trouble sustaining attention to the instructional message	Learn cannot elaborate on the information in the instructional message	Message prompts fail to support learner's efforts to construct broader transferable connotative meanings.

is happening, and we step out of the car's path. However, if we hear the same automobile sound in a cartoon, we would be able to depict this event in terms of another existing knowledge of event, therefore draw different conclusion. "Sounds could tie into, build upon, and expand existing constructs in order to help relate new information to a larger system of conceptual knowledge, therefore overpower the retrieval noise" (Bishop & Cates, 2001). (Figure 4)

Most researchers acknowledge that it is important to employ multiple sensory modalities for deeper processing and better retention. Bishop and Cates used the example provided by Engelkamp and Zimmer that seeing a telephone and hearing it ring should result in better memory performance than only seeing it for hearing. Instructional designers could suppress information-processing noise by anticipating communication difficulties and front-loading messages by using redundancy—sound as the secondary cue. Bishop and Cates defined redundancy as the part of information that overlaps. They further explained that in order to overcome the acquisition, processing, and retrieval noise, instructional designers could use sound to employ content redundancy,

context redundancy, and construct redundancy respectively. Sound's content redundancy ("What I asked was, can you pick up some things on your way home?") could contribute to the instructional message addressing the learner's attention difficulties at each of the three learning phases. Sound's context redundancy ("No, I am baking a pie, I need flour not flower.") could contribute to the instructional message addressing the learner's trouble with information manipulation. Finally, sound's construct redundancy ("I am baking a pie for tonight's desert.") could assist learners in connecting new information to existing schemata. Bishop and Cates concluded that sound's contribution to optimize learning in e-learning could be in the form of secondary cues. Systematically adding auditory cues to instructional messages based on the proposed framework might enhance learning by anticipating learner difficulties and suppressing them before they occur.

Figure 4. Summarization of Bishop and Cates framework for sound usage in multimedia based instruction Instructional communication system

	Acquisition Noise	Processing Noise	Retrieval Noise
	Content Redundancy	Content Redundancy	Content Redundancy
Selection	▪ Gain Attention ▪ Hold Attention ▪ Help Focus and Engagement Over Time		
Analysis		▪ Provide information about abstract ideas ▪ Distinguish multiple temporal information ▪ Help make connection among the information	
Synthesis			▪ Build upon and expand constructs relating to new information

Suggested for sound potential role in e-learning

INSTRUCTIONAL COMMUNICATION FRAMEWORK

Bishop and Cates's (2001) instructional communication framework provided a theoretical foundation for answering the question of why we should incorporate sound into multimedia agents for effective e-learning solutions. Barron and Atkins (1994) also suggested that when complex graphics are involved, it might be more feasible to deliver instruction through audio than through text because there is insufficient room on the screen for the text. Shih and Alessi (1996) stated that each medium has its own characteristics and interacts with other media to produce different effects when put together. Their report also stated the advantage auditory system has over text: (a) voice is generally considered the more realistic and natural mode than displayed text; (b) voice has the advantage such as being more easily comprehended by children or poor readers; (c) voice does not distract visual attention from stimuli such as diagrams; (d) voice is more lifelike and therefore more engaging; and (e) voice is good for conveying temporal information. Bishop and Cates's framework provided the answer to how, where, and when instructional designers could use sound in designing software to enhance learning. Instructional designers should understand the cognitive components of sound's use and the ways sounds could contribute to appropriate levels of redundancy. By using sound as the secondary cue to complement the primary message and to provide new information, instructional designers could systematically add sound in the multimedia agent to e-learning to lead to more effective computer-based learning materials. This research leads to a wide range of research questions.

1. **Quantitative data collection:** The next step in supporting Bishop and Cates's framework is to conduct experiments with collection of quantitative data. Overcome channel noise. What is the appropriate redundancy level?

Which sound should be used to overpower channel noises?

2. **Audio quality:** Pacing, pitch and volume all play a role in setting the mood of instruction. The voice of a male or female and how its expressiveness affects learners are worth exploring.
3. **Cognitive load:** How can sound be incorporated into e-learning without exceeding learners' channel capacity?
4. **Redundancy between audio and graphics:** Research showed that the word-for word narrates redundancy could not improve learner achievement because no new information is supplied. Will there be appropriate redundancy between a complex graphic and audio?
5. **Interference factors:** Multiple channel cues might compete with each other, resulting in distraction in learning. A syntax and connection needs to be established between primary and secondary cues.
6. **Learner control:** Learners tend to achieve better performance when they have control of the learning experience.
7. **Logistics:** The speed, volume, and the repeatability should take into consideration when designing e-learning using sounds.
8. **Demographic:** Is there difference among gender, age group, and ethnic background in achievement and perception? How will learners speaking English as the second language learn differently from a native speaker? How will this affect the design of e-learning using sound?
9. **Content area:** Are there different consideration factors when designing e-learning using sound for different content subject such as math and science?
10. **Second language:** In designing e-learning teaching foreign languages, will sound be incorporated as the redundancy or should sound play a more essential role? What are the design guidelines for such software?

11. **Learning modality:** What is the relationship between learner's preferred learning modality in terms of sound and the delivery mode?

CONCLUSION

While the debate over pedagogical strategies for sound to reinforce the learning process in e-learning rages on, researchers and instructional developers continue to seek theories for effective applications of sound in the teaching and learning process via e-learning. It seems clear that sound and audio multimedia interventions are permanent fixtures in the future landscape of e-learning. If appropriately employed, the multimedia within the e-learning program not only becomes a stand alone learning reinforcement agent, but it also helps to extend the learning capabilities of the user, thus assisting the learning in their efforts to gain the concepts and knowledge presented in the e-learning program. As we continue to look to the future for new innovative strategies developed out of research, we can begin to harness the power of adding effective multimedia agents in the teaching and learning process for e-learning, thus reaching the goal of providing quality teaching and effective training solution via e-learning for organization performance improvement.

KEY TERMS AND DEFINITIONS

Cognitive Load Theory: A term (used in psychology and other fields of study) that refers to the level of effort associated with thinking and reasoning (including perception, memory, language, etc.). According to this theory people learn better when they can build on words and ideas they already understand. The more things a person has to learn at a single time, the more difficult it will be to retain the information in their long term memory.

Communication: Communication is the process of exchanging information and ideas. As an active process, it involves encoding, transmitting, and decoding intended messages.

Information Processing Theory: The information processing theory approach to the study of cognitive development evolved out of the American experimental tradition in psychology. Information processing theorists proposed that like the computer, the human mind is a system that processes information through the application of logical rules and strategies. Like the computer, the mind has a limited capacity for the amount and nature of the information it can process. Finally, just as the computer can be made into a better information processor by changes in its hardware (e.g., circuit boards and microchips) and its software (programming), so do children become more sophisticated thinkers through changes in

their brains and sensory systems (hardware) and in the rules and strategies (software) that they learn.

Instructional Design: Instructional design is the analysis of learning needs and systematic development of instruction. Instructional designers often use Instructional technology as a method for developing instruction. Instructional design models typically specify a method, that if followed will facilitate the transfer of knowledge, skills, and attitude to the recipient or acquirer of the instruction.

Instructional Software: The computer programs that allow students to learn new content, practice using content already learned, or be evaluated on how much they know. These programs allow teachers and students to demonstrate concepts, do simulations, and record and analyze data.

Multimedia: The presentation of information by a combination of data, images, animation sounds, and video. This data can be delivered in a variety of ways, either on a computer disk, through modified televisions, or using a computer connected to a telecommunications channel.

Sound: The vibrations that travel through air that can be heard by humans. However, scientists and engineers use a wider definition of sound that includes low and high frequency vibrations in air that cannot be heard by humans, and vibrations that travel through all forms of matter, gases, liquids, and solids.

Chapter 4.12

The Influence of Visual and Temporal Dynamics on Split Attention: Evidences from Eye Tracking

Florian Schmidt-Weigand
University of Kassel, Germany

ABSTRACT

This chapter introduces eye tracking as a method to observe how the split of visual attention is managed in multimedia learning. The chapter reviews eye tracking literature on multirepresentational material. A special emphasis is devoted to recent studies conducted to explore viewing behavior in learning from dynamic vs. static visualizations and the matter of pacing of presentation. A presented argument is that the learners' viewing behavior is affected by design characteristics of the learning material. Characteristics like the dynamics of visualization or the pace of presentation only slightly influence the learners' visual strategy, while user interaction (i.e., learner controlled pace of presentation) leads to a different visual strategy compared to system-paced presentation. Taking

viewing behavior as an indicator of how split attention is managed the harms of a split source format in multimedia learning can be overcome by implementing a user interaction that allows the learner to adapt the material to perceptual and individual characteristics.

INTRODUCTION

“Before information can be stored (...), it must be extracted and manipulated in working memory.” (Paas, Tuovinen, Tabbers, & Van Gerven, 2003, p. 64).

In multimedia learning environments, a learner often has to extract and integrate information from different sources of information like words and pictures. Empirical evidences as well as theoretical considerations led to various instructional design principles to present those different sources of

DOI: 10.4018/978-1-60960-503-2.ch412

information in a learner supporting fashion (e.g. Mayer, 2001, 2005; Sweller, van Merriënboer, & Paas, 1998). The attentional, perceptual, and cognitive demands of multimedia instruction, however, are mostly *inferred* from learners' performance on subsequent tasks or self-reported difficulties with the materials at hand. In order to advance theoretical approaches and to refine instructional design principles process-related but subjective measures (e.g. cognitive load) and objective but product-related measures (e.g. learning outcomes) need to be complemented with more objective *and* process-related measures (Brünken, Plass, & Leutner, 2003; Paas et al., 2003). An often suggested, well suited, albeit – in multimedia learning – seldom-used process-related observation is the learner's viewing behavior during acquisition.

The absence of studies applying, for example, eye tracking methodology in this area may at least partly be explained by a lack of satisfying theoretical understanding of how the presumably complex cognitive processes involved in multimedia learning correspond to viewing behavior. The chapter tries to take a step towards an understanding of such viewing behavior in multimedia learning environments. Before we can discuss and further investigate how a particular viewing behavior may correspond to a particular learning outcome it is necessary to explore, if and how multimedia design actually affects viewing behavior. Reviewing the eye tracking research on combined presentation of text and pictures and providing recent research results of eye tracking studies in multimedia learning the chapter aims to answer the following questions:

1. How do learners split their visual attention during learning from a multimedia instruction? And
2. Which attributes of a multimedia instruction *moderate* a learner's viewing behavior?

BACKGROUND

Currently, research on multimedia learning and instructional design is influenced by two theoretical frameworks, cognitive load theory (Sweller et al. 1998) and Mayer's (2001) cognitive theory of multimedia learning. The main aim of these theoretical approaches is to base instructional design on "how the human mind works" (Mayer, 2001, p. 41). The most central concept of human cognitive architecture in both, the cognitive load theory and the cognitive theory of multimedia learning, is working memory. The central role of working memory for the matter of understanding and learning stems from the assumption that, simply stated, working memory is the gateway between the external world and the internal cognitive entities. Meaningful learning requires the learner to select relevant information, to organize that information in a coherent structure, and to integrate this structure into existing knowledge. Working memory plays an essential role since it is here, where the selection, organization, and integration processes are assumed to take place.

Among the various models and theories of working memory (for an overview, see Miyake & Shah, 1999) consensus exists on two aspects that are relevant to multimedia learning. First, most theorists agree that working memory resources are limited, and second, in most models of working memory there are, apart from a central regulation system, two or more separate subsystems. The notion of separate subsystems comes into play whenever information is presented in different codes (e.g. words, pictures, etc.) and/or different modalities (eye, ear, etc.) as it is the case in multimedia learning. In accordance with Baddeley's (1986) working memory model cognitive load theory and the cognitive theory of multimedia learning assume different subsystems or processing channels for visual and auditory information. Visual information is processed in a visuo-spatial sketchpad; auditory information is processed in an auditory loop. The limited

processing capacities of the subsystems are easily exhausted by multimedia learning material. Consequently, the commonly assumed positive effect of multi-representational material on learning—as expressed by the multimedia principle (Fletcher & Tobias, 2005; Mayer, 2001)—is complemented by a set of design principles that deal with the issue, how to overcome problems connected with the presentation of multiple information sources (Mayer, 2001, 2005).

One of these principles is the so-called modality principle: “Students learn better when words in a multimedia message are presented as spoken rather than printed text” (Mayer, 2001, p. 134). The theoretical explanations for this superiority of spoken over written text presentation in multimedia learning basically rest on the limitations of visual processing. If verbal information is added to some visualization (illustration, graph, etc.) in written form, both information sources must be processed by the visual processing channel. As we know from everyday experience, we usually cannot attend simultaneously to spatially distinct visual information sources. Physiologically, visual acuity is restricted to an area of about 1° to 2° of visual angle which on a computer monitor in 80 cm distance roughly corresponds to a circular area with a diameter of 2.5 cm (approximately corresponding to the size of a quarter dollar coin). Thus, in order to extract all information learners are forced to split their visual attention between the information sources. Consequently, before integrating both sources, the source that was attended first must be held active in working memory until the corresponding information in the second source is found and processed. The more information is held active or the more capacity is needed to search for corresponding information the more cognitive resources are occupied, resulting in a higher cognitive load. Presenting spoken rather than written text is supposed to reduce this load by *eliminating* the need to split visual attention between the two sources.

The modality principle is supported by several studies verifying that it is more beneficial for learning if text in simultaneous presentation with visualizations is presented aurally rather than visually (Brünken & Leutner, 2001; Mayer & Moreno, 1998; Moreno & Mayer, 1999; Mousavi, Low, & Sweller, 1995; Schmidt-Weigand, Kohnert, & Glowalla, 2008; Tabbers, 2002; Tindall-Ford, Chandler, & Sweller, 1997; for a review see Ginns, 2005). For example, Moreno and Mayer (1999) used a sequence of 16 animated illustrations depicting the process of lightning. The illustrations dynamically visualized e.g. the motion of cool air that becomes heated or positive charges moving up to the cloud producing a flash light. Illustrations were accompanied by an expository text describing each of the major events. Text was spoken, written inside the illustration frame or written below the illustration frame. Participants performed better on subsequent retention and transfer tests when text was spoken rather than written (modality effect). Within written text conditions, participants performed better when text was written inside rather than below the illustration frame (spatial contiguity effect).

As outlined above, these effects can be explained by differing processing demands due to a visual split attention. However, as Moreno and Mayer (1999) point out “the superiority of concurrent animation and narration over concurrent animation with on-screen text might [also] be caused by students missing part of the visual information while they are reading the on-screen text (or vice versa)” (Moreno & Mayer, 1999, p. 359). Thus, split attention entails a cognitive and a perceptual component. In fact, due to the aforementioned physiological boundaries several theories on visual attention allocation (for an overview, see Allport, 1989) suggest that the eye itself is a limiting factor for information processing. The resources of working memory may or may not be sufficient to process all information gathered by the eye. But the eye itself is surely limited in the amount of information that can be

fixated and gathered in a discrete time interval. Reconsidering the introductory quotation, information may have to be extracted and manipulated in working memory before it can be stored (Paas et al., 2003), but it also must be extracted before it can be manipulated. Tversky, Morrison, and Betrancourt (2002) refer to this notion as the *Apprehension Principle*. The structure and content of the representation must be readily and accurately perceived and comprehended.

In most studies the actual split of a learner's visual attention has mostly been inferred from subsequent learning outcomes or self-ratings of cognitive load. In order to explore, *how* a learner actually splits his or her visual attention between written text and visualizations it appears reasonable, if not necessary, to observe the *process* of allocating visual attention and cognitive resources to split information sources. One method that is commonly associated with visual attention and cognitive processing is the measurement of eye movements. The relationship between visual attention and eye movements has been extensively investigated (cf. Rayner, 1998). In complex information processing such as reading, the link between the two is probably quite tight. For such complex tasks it is commonly assumed that there is a functional relationship between the allocation of visual attention, cognitive processing and eye movements. Before outlining these assumptions it is necessary to shortly consider particularities of eye movements.

Contrary to introspection we do not move our eyes smoothly over some static visual display (e.g. a text or a graphic) but instead make sudden jumps from one location to another. There are periods of 100 to 500 ms, called fixations, in which the eyes come to rest, interspersed with rapid eye movements of 15-40 ms (depending on the size of the eye movement), called saccades (cf. Reichle, Pollatsek, Fisher, & Rayner, 1998). During saccadic movements little visual information is acquired. Instead, the visual information necessary for reading or scene perception is

acquired primarily during the fixations (cf. Just & Carpenter, 1980). Consequently, fixating a discrete area (words, sentences, objects, etc.) is commonly taken as a correlate of attentional and cognitive processes allocated to the inspected area (eye-mind assumption). That is, at the beginning of each new fixation visual attention is assumed to be allocated to the stimulus at the center of fixation. When the information within this area is sufficiently processed attention may be reallocated to a new stimulus in order to program the next saccade while the eye remains fixated. These covert shifts of attention are assumed to occur shortly before the next saccade is executed (Henderson, 1992; Reichle et al., 1998).

For the matter of split attention in multimedia learning two general aspects of a learner's viewing behavior might be of particular interest, (a) the distribution of fixations across the split information sources, and (b) the pattern of saccades from one source to the other. Unfortunately, none of the theories in the field of multimedia learning predicts particular patterns of eye movements yet. However, applying the method of eye tracking may help gaining further insight into how much visual attention is captured by each of multiple visual information sources, how the integration of spatially separated stimuli is visually managed, and which attributes of a learning material moderate the split of visual attention.

EYE MOVEMENTS IN SPLIT ATTENTION CONDITIONS

Although eye movement studies have generated a good understanding of the processes involved in reading and in scene perception (for reviews, see Rayner, 1998; Underwood, 2005) only few experimental eye movement studies have addressed *combinations* of words and pictures in the past. Notable exceptions are studies from Hegarty on the comprehension of mechanical diagrams (Hegarty, 1992a, 1992b; Hegarty &

Just, 1993), Carroll, Young, & Guertin (1992) on the visual analysis of cartoons, d'Ydewalle and colleagues on attention allocation in subtitled television (d'Ydewalle, Praet, Verfaillie, & Van Rensbergen, 1991; d'Ydewalle & Gielen, 1992), Rayner, Rotello, Stewart, Keir, & Duffy (2001) on the integration of text and pictorial information in print advertisements, and more recently Holsanova and colleagues on newspaper reading (Holmqvist, Holsanova, & Holmberg, 2007; Holsanova, Rahm, & Holmqvist, 2006). Meanwhile, a growing number of eye tracking studies have been conducted with multimedia learning material (e.g. Ciernak, Scheiter, & Gerjets, 2007; Faraday & Sutcliffe, 1996; Folker, Ritter, & Sichelschmidt, 2005; Hannus & Hyönä, 1999; Schmidt-Weigand et al., 2008).

A common result among these eye movement studies is that people favor text over pictures. Rayner et al. (2001) investigated the pattern of viewing behavior for people looking at print advertisements. When looking at an advertisement viewers tended to read the large print first, then the smaller print and then they looked at the picture. Although some viewers did an initial cursory scan of the picture, most of them did not alternate fixations between the text and the picture part of the ad. Also the viewing behavior in subtitled television is largely text directed (d'Ydewalle et al., 1991; d'Ydewalle & Gielen, 1992). Clearly, when foreign movies are subtitled in the local language, reading subtitles is more or less obligatory. However, d'Ydewalle and colleagues (1991) found that reading subtitles is preferred even if the movie and the subtitles were both presented in the local language. Since this preference was observed no matter if the participants were familiar (Dutch) or rather unfamiliar (Americans) with subtitled television the authors conclude that either (a) reading subtitles is more efficient in following and understanding a movie or (b) processing of the visual modality is more dominant.

In learning material one may expect illustrations to attract some more visual attention because

of their functions in the learning context. Levie and Lentz (1982) distinguish four general functions: (1) attention guiding, (2) affective, (3) cognitive, and (4) compensatory functions. However, the assumed benefits of illustrations do not seem to be reflected in the learners viewing behavior. Hannus and Hyönä (1999) found that learning from illustrated textbooks is heavily driven by the text. They presented text passages from 4th-year elementary school biology books to elementary school children. The children spent 80% of their learning time on reading the texts. Furthermore, 66% of the time spent inspecting illustrations was devoted to read the figure captions! In accordance with Rayner et al. (2001) there was also little back-and-forth looking between a relevant text segment and a corresponding illustration. This viewing behavior may have been due to some text characteristics. As the authors note, in their text book passages, no reference was made in the text to any illustration.

Folker et al. (2005) used color-coding to make references between text and illustrations more explicit. Twenty students (mean age 24.3 years) read a textbook passage describing the function and the different phases of mitotic cell division. In the color-coding condition, passages of the text corresponding to structures or labels in the pictures were of the same color. Participants in this group were significantly faster in processing the material than participants who had no explicit color reference in the text (control condition). The faster processing, however, was due to fewer fixations on the picture region in the color condition while the time spent reading remained constant across conditions. Unfortunately, Folker et al. (2005) do not report the movement patterns between text and picture region. Thus, we do not know if color coding simply facilitated the processing of the illustration or if it evoked a different visual strategy.

It might well be the case that the textbook illustrations used by Hannus and Hyönä (1999) and Folker et al. (2005) were not sufficiently

helpful or necessary to understand the text. In multimedia learning, however, a special emphasis is given to the *integration* of text and pictures in working memory. Hegarty (1992a, 1992b; Hegarty & Just, 1993) applied diagrams and verbal descriptions of pulley systems in order to examine such integration processes. In a study from Hegarty and Just (1993) participants viewed text and diagrams describing pulley systems. Being instructed to understand how the respective pulley system worked, viewers tended to inspect the diagram at the ends of sentences and clauses. Approximately 80% of the participants' diagram inspections occurred after reading the segment describing that particular aspect of the diagram. Thus, the participants' viewing behavior as they read text accompanied by diagrams suggests that viewers attempted to fully interpret a sentence or clause before inspecting its referent in the diagram. Hegarty (1992b) concluded that the construction of a mental model from the material was largely text directed.

In another study, Hegarty (1992a) further examined the construction process of the mental model by using a sentence-picture verification task. Participants were presented with a static diagram of a pulley system and a sentence describing a dynamic attribute of a component of the pulley system. Participants were asked to respond whether the sentence was true or false of the depicted system. Recording reaction time and inspection time, she found that differences in reaction time were largely due to differences in diagram inspection time. Both, reaction time and inspection time were highly related to the statements' difficulty (number of inferences required to verify a dynamic attribute). Concerning the strategies, participants typically read the sentence before inspecting the diagram in 98.5% of trials, suggesting that the overall strategy was to construct a representation of the text first and then verify this representation against the diagram. However, participants also reread the text during a trial, thus switching back and forth between text and

diagram about three times per trial on average. The number of re-readings was again related to the statements' difficulty, being higher the more inferences were required to verify the sentence. Hegarty interpreted these results in terms of working memory load. The higher the demands of inferring and storing the motion of the pulley system, the earlier the sentence representation decayed and had to be reactivated by re-reading.

In the Hegarty (1992a) study participants had to infer motion from a static diagram of a dynamic pulley system. Exploiting the possibilities of computer-based instruction, processes that are dynamic by nature can be depicted by dynamic rather than static visualizations. In comparison to static visualizations, the cognitive demands to process and integrate written text accompanied by *dynamic* visualizations may be different. Motion does not need to be inferred by the learner but is readily available. This direct access to dynamic information may cause a visual strategy different from the one commonly observed with static visualizations. First, the depicted information does not need to be mentally animated. And second, dynamic visual information is more transient than a static display. Therefore, learners may be inclined to attend to dynamic visualizations earlier in the integration process, being not as much text directed as with static visualizations.

Taken together, the management of split attention during learning appears to be driven by written text. But how is the visual attention to written text influenced by the presence of dynamic compared to static visualizations and/or the presence and degree of time constraints? The following sections describe a series of four experiments in which learners' eye fixations were tracked as they watched a multimedia instruction on the formation of lightning similar to the one used by Moreno and Mayer (1999). Besides eye movements, the experiments applied measures of cognitive load as well as learning outcomes. In order to explore the influence of split attention on cognitive load and learning outcome measures the experiments

also entailed presentation conditions in which text was spoken. The focus, however, will be set on the learners' viewing behavior under split attention conditions.

EFFECTS OF DYNAMIC VS. STATIC VISUALIZATIONS ON SPLIT ATTENTION

The purpose of the first two experiments was to examine whether characteristics of visualizations moderate the effects of split attention on viewing behavior. By comparing dynamic with static visualizations, the experiments ask whether and to what degree the transience of visualizations affects visual attention allocation. How much attention is devoted to dynamic compared to static visualizations? How is visual attention on written text affected by the presence or absence of dynamics in visualizations? And, how do learners estimate the presence or absence of dynamics in visualizations in relation to their split of attention? To answer these questions, the experiments observed view-

ing behavior and collected subjective estimates of students who received one of the following four presentation formats: a multimedia instruction presenting (1) dynamic visualizations together with written text, (2) dynamic visualizations with spoken text, (3) static visualizations with written text, and (4) static visualizations with spoken text. The learning material consisted of a 16-step multimedia instruction on the formation of lightning. The content of the material was based on an animation used by Moreno and Mayer (1999). Visualizations were designed to illustrate the dynamics of the major events (cf. Figure 1).

Both experiments confirmed that split attention during learning from the applied multimedia instruction was largely text directed. The presence of written text led learners to attend to the text before splitting their visual attention by switching back and forth between text and visualization. Overall, participants spent up to twice as much time reading than inspecting visualizations and switched on average 4 times per scene between written text and visualizations. Both, viewing time on text and visualizations as well as the number

Figure 1. Selected frames of the multimedia instruction (scenes 1 – 4)

Note: The expository text is written in German since the experiments were run at Justus Liebig University, Giessen, Germany.

of transitions between both information sources were slightly affected by the presence vs. absence of dynamics within the visualizations. Participants spent some more time on dynamic compared to static visualizations and, thus, less time reading text. Furthermore, experiment 2 revealed that visual attention was captured by dynamic visualizations, indicated by a lower number of transitions between text and visualizations compared to static visualizations. However, the amount of initial reading after a scene change was not affected by the presentation format of the visualizations.

Experiment 2 obtained self-ratings in order to assess cognitive load. These measures allow a more detailed view on the attentional aspects of presentation format. Participants reported a higher difficulty with the learning material for written compared to spoken text presentation (“How easy or difficult was it for you to learn something about lightning from the presentation you just saw?”), confirming the afore mentioned effect of text modality. In addition, participants were asked to give subjective estimates of the following more detailed statements: (1) “I would have preferred to stop the presentation myself at certain points“, (2) “I would have preferred to look at some illustrations again“, (3) “I would have preferred to rewind and repeat parts of the text“, (4) “I missed parts of the textual information“, (5) “I missed parts of the illustrations“, (6) “It was difficult for me to relate textual and pictorial information to each other“, (7) “The illustration distracted me from textual information“, (8) “The textual information distracted me from the illustration“, and (9) “How did you perceive the presentation pace? The pace was ...”. Statements 1 to 8 had to be rated on a 6-point scale from completely false, false, rather false, rather true, true to completely true. Statement 9, concerning the pace of presentation had to be answered on a 7-point scale from very slow, slow, rather slow, optimal, rather fast, fast, to very fast. The internal consistency of the statements was considerably good (Cronbach’s $\alpha = .83$). Correlations between

single statements and overall difficulty with the material range from $r = .25$ to $r = .51$. The highest correlation is reached by statement (3) (repeat parts of the text). This correlation highlights the role of text comprehension in cognitive load.

Furthermore, the initial and constant reliance on written text, as found in numerous eye tracking studies, suggests that learners follow a visual strategy, i.e. voluntarily attending to written text. In contrast to this hypothesis, participants in the experiment reported a significantly higher agreement with statement (8) than with statement (7), i.e. they felt distracted from inspecting visualizations by the presence of written text (and not vice versa), no matter if visualizations were dynamic or static. Thus, initial reading appears to be rather automatic than intended.

Since the presentation time was limited (i.e. once the animation was started it proceeded with a constant pace), the time spent reading was lost for inspecting the visualizations. Consequently, participants rated presentation time as less appropriate in written compared to spoken text conditions (statement (9)), i.e. the split of visual attention was subjectively time consuming. Thus, the effect of split attention can be described as a distraction effect evoked by written text in a time limited presentation condition. Participants felt they needed more time to sufficiently attend to all offered information sources.

Taken together, presenting written rather than spoken text in a multimedia instruction leads to a rather automatic initial reading behavior that is, compared to spoken text presentation, perceived as a time-consuming process. Consequently, one should expect that with longer presentation duration learners devote relatively more time to visualizations than to written text. Once enough time is given to attend and integrate all information sources the harms of split attention should disappear. Furthermore, the visual strategy may change as soon as the learner can control the pace of presentation. The experiments presented in the following section were designed to test these hypotheses.

EFFECTS OF TIME CONSTRAINTS ON SPLIT ATTENTION

The main idea of these two experiments was that pacing is an additional source of cognitive load. If learners have more time to read expository text, the need to split visual attention between written text and visualizations should be less harmful. Moreover, if learning is largely text directed, as indicated by prior studies, split attention should have a larger effect on visual compared to verbal information. Finally, it is an open question how additional time is used in terms of visual attention allocation. We may expect that after reading has been successfully completed relatively more time can be spent viewing visualizations.

The purpose of the first of these experiments was to examine the influence of system-controlled pacing of instruction on effects of split attention and text modality. The learning material consisted of the same multimedia instruction as in the first two studies. Dynamic visualizations on the formation of lightning were accompanied by expository text (visualization format was not varied). The text was either presented in spoken or written format. The variation of pacing was derived in the following manner. In the fast condition, timing was set to a ratio of 120 words per minute resulting in a presentation duration of 140 s. This pace approximates a timing originally applied in Mayer and Moreno (1998) by adjusting the pace of presentation to a normal speaker's rate. Medium and slow paces were obtained by reducing the ratio successively with a factor of 0.75. Thus, the ratio was 90 words per minute for medium pace and 67.5 words per minute for slow pace resulting in durations of 187 s and 249 s respectively. These variations resulted in a 2 (spoken vs. written text) x 3 (fast, medium, and slow pace) factorial design. Results are presented for the split attention conditions, i.e. where text was written.

Overall, learners under split attention conditions showed a comparable viewing behavior at the beginning of each scene, i.e. they started

with a reading sequence. However, the longer the presentation lasted relatively more time was spent inspecting visualizations. As it was expected, the absolute number of transitions between text and visualizations increased with presentation duration. However, also the *relative* number of transitions (i.e. transitions per second) increased with presentation duration. All these changes emerged in the additional time for each scene. Comparing the viewing behavior only in the time intervals of the fastest pace of presentation revealed no differences in the ratio of time spent reading to time spent inspecting visualization or in the number of transitions. Deviating viewing behavior obviously settled in the additional time given by slower pacing.

In accordance with this viewing behavior, the difference between written and spoken text presentation became more evident in a visual memory task compared to a text retention task. This difference was larger the faster the pace of presentation was. In addition, subjective cognitive load revealed that the harms of split attention (i.e. the modality effect) were apparent under serious time constraints. Overall, cognitive load dropped down for longer presentation durations. A modality effect could only be found under fast presentation.

The observed patterns of viewing behavior and its contribution to cognitive load and learning outcome can be understood in terms of particularities of reading. People are known to differ in reading speed (cf. Just & Carpenter, 1987). Reading speed reflects individual abilities (e.g. Jackson & McClelland, 1975, 1979; Just & Carpenter, 1992) but it is also adjusted to characteristics of the text (e.g. Graesser, Hoffman, & Clark, 1980) and task demands (e.g. Hartley, Stojack, Mushaney, Annon, & Lee, 1994). Concerning the specific task of reading to summarize expository text, Hyönä, Lorch, and Kaakinen (2002) identified different types of eye movement patterns. Participants read (and subsequently summarized) two expository texts (approximately 1,000 words each). 75% of their participants followed a linear reading strategy, i.e.

most readers went through the texts from left to right with only few backward saccades to earlier passages, so-called regressions. Such regressions usually do not exceed 10% of the saccades occurring during reading (cf. Rayner, 1998). The linear readers in the Hyönä et al. study could be further divided into “fast linear readers” (mean reading rate: 231 words/minute) and “slow linear readers” (133 words/minute). These results confirm (a) the linear reading behavior consistently found across various reading tasks and (b) the inter-individual differences of the pace of progressing through the text. There was, however, a group of 20% of readers who followed a distinctive strategy, the “topic structure processors”. With a reading rate of 139 words per minute this type of reader was rather slow. Compared to the linear readers the topic structure processors devoted additional visual attention to headings and topic-final sentences as expressed by significantly more and longer reinspective fixations. Most notably, these readers turned out to have the highest working memory span (Danemann & Carpenter, 1980) and to have written the best summaries. The worst summaries were produced by the slow readers. While the comparably slow reading rate of the topic structure processors appears due to deliberate, probably effortful strategies for remembering and summarizing the expository texts, in the case of the slow linear readers this same rate appears to be a rather unsuccessful attempt to compensate for comprehension difficulties.

Individual differences in reading speed may interfere with the learning task in a system paced multimedia instruction for several reasons. First, the faster the pace the more likely some – especially visualized – information is missed or not sufficiently processed due to the general tendency to attend to written text first. Second, a faster pace of presentation especially challenges slow readers probably resulting in even poorer text comprehension. And third, adjusting ones reading speed to a system-controlled pacing may hinder an adjustment to the complexity of the content and

the application of deliberate viewing strategies. Thus, split attention effects might at least partly be caused by a mismatch of system-paced instruction with self-paced reading. These hypotheses gain support from a final study to be reported in this chapter. In this study, learners were under control of the pace of presentation. Each of the 16 scenes lasted until participants hit the space bar to start the next scene. Text was again either written or spoken.

First of all, learning under self-paced presentation did not reveal any differences between written and spoken text presentation in terms of learning outcomes and cognitive load. That is, the learners were able to adjust the pace of presentation to be comparably successful in learning from the animation and to experience a comparable cognitive load. One may expect the higher cognitive load under split attention to be expressed in a longer time on task for written compared to spoken text presentation. Contrary to this hypothesis, the learner-paced presentation durations in written text presentation were almost identical to spoken text presentation in terms of means, variances, and ranges. Overall, the variation of system-paced presentation durations in the former experiment (140, 187, and 249 s, respectively) roughly fitted in with the range of learner-paced presentation durations (132 to 285 s). It is also notable that the average presentation duration in this experiment (183 s) was very close to the medium system-paced presentation duration of 187 s in the former experiment. Due to these similarities on the time dimension, differences in the observed viewing behavior of both experiments can be devoted to the issue of learner control. Figure 2 depicts the amounts of time each participant spent reading and inspecting visualizations under system controlled (left panel) and learner controlled (right panel) presentation. Figure 3 depicts the number of transitions for each participant in both experiments.

As can be seen in the right panel of Figure 2 time on task under learner-controlled presentation is almost exclusively driven by the time learners

Figure 2. Time spent reading (triangles) and time spent inspecting visualizations (circles) for each learner under written text conditions in system controlled (left panel) vs. learner controlled (right panel) presentation

Figure 3. Number of transitions between text and visualizations for written text conditions in system controlled (left panel) vs. learner controlled (right panel) presentation

spent viewing text. That is, while participants in system-paced instruction used additional presentation time in favor of illustrations (Figure 2, left panel) participants in learner-paced instruction used additional presentation time exclusively for reading. Furthermore, transitions in learner-paced instruction did not systematically vary with time on task (Figure 3, right panel) while in system-paced instruction additional presentation time lead to an increase of transitions between text and visualizations (Figure 3, left panel). Taken together, participants in system-paced instruction used additional presentation time in favor of visualizations and switches between text and visualizations while participants in self-paced instruction used additional presentation time mainly for reading. Apart from the time learners spent read-

ing the text, they showed a highly stable fixation pattern in a self-paced instruction. Learners adjusted the pace of presentation to their individual reading speed and engaged in an otherwise systematic viewing behavior.

These results can be interpreted in the following manner. The longer the system-paced presentation duration was the more participants can be assumed to have read the written text. They really had additional time to spend on inspecting visualizations and “to look around”. In learner-paced instruction, the split of visual attention between text and visualizations appears rather systematic and is comparable to the viewing behavior shown by the medium system-paced presentation group. The general strategy was to read (some portion or all of the) text, then switching to inspect the

visualization, re-reading some portion of text and going back to the illustration once more. The inter-individual difference in the time spent reading almost perfectly correlated with the chosen presentation duration. Thus, an optimal fit of presentation pace to task demands in concurrent presentation of text and visualizations is apparently driven by individual reading speed.

THEORETICAL IMPLICATIONS

The findings of the studies reported in this chapter have some implications for theoretical accounts of split attention effects in multimedia learning, namely cognitive load theory (Sweller et al., 1998) and the cognitive theory of multimedia learning (Mayer, 2001). Split attention effects are usually explained in terms of limited cognitive resources. Two further resources were introduced in this chapter that may interact with the cognitive processes associated with split attention: (a) visual perception and (b) learning time. As noted earlier, due to restrictions of visual acuity our eyes have to move in order to gather all information given in a multimedia learning material. In fact, the term “split attention” may rather refer to the common insight that we cannot look at a text and an illustration at the same time. Eye tracking studies revealed that we manage this limitation of our eyes in a fairly consistent way. Learners almost immediately look at written text and usually spend much more time reading than viewing visualizations. Some researchers concluded that text is perceived as the main medium for the acquisition of information. In this view, the observed eye movements indicate a strategic and reasonable decision made by the learners. In fact, expository text is a highly structured information source and people are used to gain much information from reading. Visualizations are usually not self-explaining and are often accompanied by written text. Reading the text first might often have been experienced as being helpful in order

to understand visualized information. In one of the presented studies, however, participants felt distracted from inspecting visualizations by the presence of written text – although they spent most of their time reading! Thus, the observed viewing behavior rather indicate a preconscious attentional capture of written text.

One may conclude that due to the attentional capture of written text visualizations are not sufficiently processed. But the comparably short fixation times on visualizations may also indicate a higher computational efficiency of pictures compared to text. As Larkin and Simon (1987) point out, “sentential representations [i.e. text] are sequential while diagrammatic representations [i.e. visualizations] are indexed by location in a plane. The information displayed by [visualizations] is only implicit in sentential representations and therefore has to be computed, sometimes at great cost, to make it explicit for use” (p. 65). In other words, reading requires word-by-word fixations, lexical access, and syntactic as well as semantic processing while the information depicted by visualizations may be gathered at a glance. In accordance with this interpretation, eye movement studies on scene perception have led to the conclusion that “participants get the gist of a scene very early in the process of looking. [...] The gist of the scene is abstracted on the first couple of fixations, and the remainder of fixations on the scene are used to fill in details” (Rayner, 1998, p. 398). However, whether the ‘gist of a scene’ is sufficient for learning depends on the complexity of the visualization and the complexity of referential connections between the text and the visualization.

A necessary precondition for split attention effects to occur is that one source of visual information cannot be understood without the other (Sweller, 1999), i.e. both sources have to be attended in order to “get the full picture” of what is to be learned. There is evidence that the interdependence between different learning elements moderate effects of split attention, being harder

to handle for learning material of high compared to low “element interactivity” (Tindall-Ford et al., 1997). Element interactivity refers to the extent to which the learning task requires the learner to hold several related chunks of to-be-learned information in working memory simultaneously. As Ginns (2005) notes, there is no objective measure of element interactivity. However, eye movements may be interpreted as an indication of this interplay between text and visualizations. In the studies reviewed in this chapter eye movements varied with the complexity of the material. A picture in an advertisement is almost surely less complex than, for example, the diagram of a pulley system. As a result, participants in the Rayner et al. (2001) study did not look back from the picture of an ad to the text while those re-readings occurred between a pulley diagram and the accompanied text (Hegarty, 1992b). Hegarty (1992a) interpreted the number of switches between the text and the visualization in terms of working memory load. More re-readings occurred when more inferences were required. Concerning the perceptual aspects of split attention there may be less content-specific variables that moderate split attention as well. For example, dynamic visualizations may be considered as less complex than static visualizations since the depicted dynamics are readily perceivable and do not need to be inferred by the learner. Accordingly, in one of the presented studies more alternations occurred between text and static visualizations compared to text with dynamic visualizations.

The presented studies also highlighted the role of learning time for the management of split attention. In contrast to the physiological restrictions of visual perception, learning time is a resource that is either set by the ‘instructor’ or allocated by the learner. If learning time is restricted by a system-controlled pacing of instruction, it is an obvious source of extraneous cognitive load. Consequently, the pacing of instruction moderates effects associated with split attention (cf. Ginns, 2005). In the presented studies learners perceived

multimedia instructions as “faster” when verbal explanations were written rather than spoken, a higher cognitive load only occurred for fast presentation paces, and no effect of text modality occurred at all when learners controlled the pace of presentation. Given the general tendency to attend to written text first, split attention under time constraints especially impairs processing time for the pictorial information. The results of the presented eye tracking studies support this view in showing that especially visual memory proved sensitive to the modality of text presentation. Furthermore, participants spent relatively more time viewing visualizations when the pacing of instruction was slower.

But the influence of time constraints is not restricted to visualizations. Conversely, the comparison of viewing behavior under system-paced and self-paced instruction rather highlights the prominent role of reading for split attention effects once more. The pattern of viewing behavior in self-paced instruction is fundamentally different from the one observable in system-paced instruction. Under self-paced instruction, learners spent a comparable amount of time looking at visualizations while their time on task strongly varied with the time spent reading. In the absence of extraneous load in terms of time constraints, the inter-individual differences in reading time suggest that the main source of cognitive load in the instructional material was the text. In fact, text comprehension is well recognized as a matter of managing working memory load (Graesser & Britton, 1996; Just & Carpenter, 1992). The difference between system-paced and self-paced viewing behavior may indicate a change in cognitive strategies. Reading is an inherently self-paced activity. Individual reading speed does not only reflect text comprehension abilities but also the contribution of deliberate, probably effortful, strategies for remembering expository text (Hartley et al., 1994; Hyönä et al., 2002). While under system-paced presentation reading speed has to be adapted in some way to the pace of presenta-

tion, self-paced presentation allows the learner to engage in a more elaborated processing of verbal explanation. Consequently, written text must be assumed more compatible with self-paced than with system-paced instructions. In this view, under self-paced presentation written text may also be superior to spoken text. Actually, there already exists empirical evidence for such a “reversed” modality effect (Tabbers, 2002).

PRACTICAL IMPLICATIONS

The research presented in this chapter allows suggesting how split attention effects may be overcome. In time-limited presentation, (a) the perceptibility especially for the visualization is decreased, and (b) written text comprehension is disturbed. Consequently, negative influences of split attention on learning can be avoided if both information sources are sufficiently perceptible and/or if the design of a multimedia instruction ensures not to bother a regular reading behavior.

To make sure that all information sources in a multimedia instruction are sufficiently perceptible the instructional designer must consider the split of visual attention that occurs whenever two or more visual information sources are presented concurrently. In fact, current design guidelines already recommend presenting written text near rather than far from visualizations in order to minimize split attention (spatial contiguity principle). Furthermore, guiding visual attention to appropriate referents, e.g. by color-coding, can have positive effect on visual processing (Folker et al., 2005) and cognitive load (Kalyuga, Chandler, & Sweller, 1999). Due to the fact that learners consistently attend to written text first one might be seduced to present text and visualizations sequentially rather than concurrently. Indeed, sequential presentation eliminates visual split attention, which may facilitate text comprehension. But sequential presentation also eliminates the temporal contiguity between the text and the corresponding visualization. A

number of studies have shown that concurrent presentation is superior to sequential presentation of corresponding information sources (‘temporal contiguity principle’, Mayer, 2001; for a review, see Ginns, 2006). In his meta-analysis, Ginns (2006) also identified the complexity of learning materials as a moderator of temporal contiguity effects. Indeed, complexity in terms of referential connections between text and visualizations may require alternations between both information sources. Thus, it is recommendable to present corresponding information sources close together in space *and* time as well as to make referential connections explicit.

Reducing split attention by spatial contiguity or color-coding while the presentation is still system-paced (as it is indeed the case in many of the studied materials) always bears the risk for the learner to miss some information. This risk is probably higher for visualizations than for text and if the material is rather complex. Furthermore, system-paced presentation may interfere with individual differences in (self-paced) reading speed. An easy way to avoid these problems is learner-paced instruction. Instead of specifying a system-controlled pace that may be appropriate for an average learner, this minimal form of user interaction allows each learner to adjust the pace of presentation to his or her individual needs. Doing so, the learner can ensure to capture all information that is displayed. An individually chosen pace allows the learner to follow a regular reading behavior that is susceptible to cognitive strategies. In this view, learner-control is not only recommendable to overcome difficulties with split attention in multimedia learning but learner-paced instructions can even benefit from written text presentation.

CONCLUSION

Two main conclusions can be drawn from the eye tracking studies outlined above. First, viewing

behavior in combinations of text and visualizations follows a fairly stable pattern that can be moderated by design attributes of the instruction. In general, written text drags visual attention away from inspecting visualizations. Thus, visualizations have to “compete” with the text, whenever it is written. The degree of competition is influenced by visual dynamics as well as the presence and degree of time constraints. Learners adapt to these properties of a multimedia instruction by distributing their visual attention between written text and visualizations differently. Furthermore, they are able to adjust the pace of presentation to a regular reading strategy that only varies in the time taken to read text.

Second, under less attentional competition, less time constraints, and learner control of pace, effects of split attention change, decrease, or even disappear. The competition between written text and visualizations was stronger when visualizations were dynamic rather than static and when presentation time was seriously constrained. Especially when learners are relieved from time constraints, the need to split visual attention loses much of its detrimental effects. These differential effects on cognitive load and learning outcome are associated to particularities of the viewing behavior. In general, presenting written text forces the learner to read text. When learners can follow a regular reading strategy by controlling the pace of presentation they do not suffer from written (compared to spoken) text presentation. Thus, the need to read written text may or may not interfere with extracting information from visualizations depending on how seriously reading and viewing visualizations are disturbed by the design of a multimedia instruction.

A theoretical implication of these results is that current explanations of split attention need to incorporate resources of visual perception and learning time in addition to cognitive resources. As a practical consequence, the question for an instructional designer is if the displayed information can be sufficiently extracted by an individual

learner. Understanding the demands of a particular learning material on the learner’s perception and accounting for individual differences by implementing user interaction appears promising to advance the design of multimedia instructions in a learner-supporting fashion.

FUTURE RESEARCH DIRECTIONS

Concerning the limitations of the presented eye tracking studies, the applied learning materials consisted of rather short presentations. A three-minute multimedia instruction on the formation of lightning can be considered to be a prototypical case of an application of dynamic visualizations. For the matter of generality, this research must be extended to broader classes of multimedia learning material. For example, the comparison of viewing behavior under system-paced and self-paced instruction led to the hypothesis that reading strategies play an important role even in split attention. Effects of a strategic behavior may be rather small in an instruction of 3 minutes length. Thus, it appears worth examining if and how visual strategies may change with the amount of content, especially the amount of text.

Visual and temporal dynamics of a multimedia presentation are only two design characteristics that may be expected to affect a learner’s viewing behavior. The patterns of viewing behavior in the presented studies highlighted the role of expository text in split attention. However, one can easily imagine more complex and/or abstract pictorial information, for example electric circuits or statistical graphs that may require more processing resources for visualizations than for written text. Similarly, text difficulty depends on the text structure and the subject matter. Furthermore, multimedia learning material can differ with respect to the referential connections between text and visualizations. It can be assumed that all these characteristics of a learning material affect the learner’s viewing behavior

and, thus, the way split attention is managed. In order to gain a better understanding of split attention effects one direction of further research is to explore the viewing behavior with learning material that systematically varies those aspects. Such research can help estimating the relative contribution of verbal explanations in comparison to visualizations and the contribution of “element interactivity” (Tindall-Ford et al., 1997) between textual and visual information.

Finally, eye tracking offers an extensive database. There are numerous ways in which those data can be analyzed that go way beyond the level of analyses presented in this chapter. For example, in reading research viewing behavior is usually not described in the overall time spent reading a text but in terms of gaze durations or single fixations on words and the saccadic movements between these gazes or fixations (Rayner, 1998). Such analyses are accompanied by theoretical models accounting for eye movements on the same level of description (e.g. Reichle et al., 1998). These fine-grained cognitive process models can be tested by tracing the eye-movement protocol (e.g. Salvucci & Anderson, 2001). So far, there is no such interplay between theories of multimedia learning and observations of viewing behavior, i.e. current models on the integration of verbal and pictorial information do not predict the time course of visually attending to the information sources. However, models develop with the level of observations they have to account for. Further eye tracking studies may stimulate to advance current models in order to allow predictions of fixation paths based on an accurate model of the learning process.

Chapter 4.13

Leveraging Libraries to Support Academic Technology

Heather Jagman

Melissa Koenig

DePaul University, USA

Courtney Greene

DePaul University, USA

ABSTRACT

Through leveraging the relationship between libraries and technology, colleges and universities can make the best use of the skills that librarians bring to the table. At DePaul University, three positions have been created, which report to two campus units: The University Libraries and Instructional Technology Development. The consolidation of both library and instructional technology perspectives to create this first group of blended positions at DePaul has been successful, due in large part to the fact that the primary responsibilities of these positions are in areas of mutual interest: instruction, collection development, and technology support for faculty and students, whether on a consulting basis or at the reference desk. As libraries and librarians become

ever more closely and actively aligned with the teaching mission of the university, universities and colleges can transform librarians' roles within the academy by leveraging their skills to enhance teaching and learning in today's online environment.

INTRODUCTION

As more and more library services and resources are delivered online, libraries and technology become increasingly intertwined. In their article "*Merging Library and Computing Services at Kenyon College: A Progress Report*," Oden Jr. et al. (2001) describe the phenomenon as follows:

...the era when computers largely performed repetitive and otherwise tedious tasks (such as data processing) transformed to an era when computers

DOI: 10.4018/978-1-60960-503-2.ch413

served equally to store, retrieve, and manipulate information. The transformation has meant an increasing overlap between library services and computing services, making an integrated approach seem sensible. (Oden Jr. et al., 2001)

More and more institutions are exploring this model of combined library and IT services in various ways. Ferguson, Spencer, and Metz (2004) give brief descriptions of similar undertakings at Bucknell University, Pacific Lutheran University, and Wheaton College, and note “the need for the library and IT organizations to work together to support today’s scholars and students in a much more seamless fashion.”

Jerry D. Campbell, CIO and Dean of University Libraries at the University of Southern California, Los Angeles, points to initiatives undertaken “within academic libraries in the digital age: providing quality learning spaces; creating metadata; offering virtual reference services; teaching information literacy; choosing resources and managing resource licenses; collecting and digitizing archival materials; and maintaining digital repositories.” (Campbell, 2006) These are just a few examples of how libraries have expanded services and resources using technology. To make the best use of the skills that librarians bring to the table, colleges and universities must continue to explore further avenues to leverage the relationship between libraries and technology.

In some environments as at Kenyon College, described by Oden Jr. et al. (2001), the integration occurs not only at the departmental or administrative level, but also within individual positions, requiring staff with expertise in both arenas. Barth and Cottrell (2002) describe in some depth the Librarian Technology Consultant model adopted at Kenyon College, in which positions serve as liaisons to specific departments and schools. They state, “This type of cross-focus began to build bridges with constituents, notably faculty, to better serve the user by bringing a more holistic approach

to service through focusing on the patrons rather than the collections.”

BLENDING LIBRARY AND INSTRUCTIONAL TECHNOLOGY POSITIONS

Library mission statements generally speak to providing support for the instructional and research programs at a given university. DePaul University’s library mission is no exception to this rule, and states that “as an integral part of the academic function of DePaul University, the libraries’ mission is to support the current and anticipated instructional and research programs of the University by providing collections, services, facilities, and personnel to satisfy the information and research needs of DePaul students, faculty, and staff.” (Brown, 2002)

To serve this mission, the libraries have facilities on all six DePaul campuses, with paper, microform, video, and audio collections as well as extensive electronic collections available 24×7×365 to university affiliates from anywhere in the world via the Internet. Each library facility also has public access computers, and all students, faculty, and staff have electronic access to reference services, document delivery, and course reserves. As libraries increasingly deliver their services online, our patrons begin to expect this type of access, and are beginning to demand the same type of access to their other course materials. Because libraries have led in this area, librarians become natural advocates for electronic access to materials.

According to its mission, the University’s department of Instructional Technology Development (ITD) “advocates for students and collaborates with faculty and university departments in developing a learning environment enriched through effective use of technology in the curriculum.” The compatible missions of ITD and the libraries make these academic support units

natural collaborators. Guan and Morrisett (2006) emphasize the importance of “taking advantage of the long-established trust relationship between librarians and faculty.” As they point out, librarians are already seen as trusted members of the academic community. Faculty are accustomed to asking for assistance in finding library resources for their classes and in acquiring materials for their research, as well as inviting librarians to provide library research instruction for their students. Expanding this role so that librarians show faculty how to integrate library resources entirely into their online course sites, or into course sites complementing in-person instruction, is a natural place to begin the consultation. Leveraging this relationship allows instructional technology departments a way to reach faculty in a non-threatening way.

Librarians also bring an understanding of the organization of information, including experience with indexing and database construction. These skills, along with librarianship’s emphasis on user-centered services, are valuable skills and can be applied in many arenas, from online course organization to assisting with the creation of database-driven Web sites.

At DePaul, the blending of librarian/instructional technology consultant positions began in 2003 with the hiring of a suburban campus coordinator who also served as instructional technology consultant for the suburban campuses. Two additional librarian-consultant positions were developed in summer 2005 and resulted in the changing of job duties for two existing assistant coordinators of library instruction positions. As DePaul increases the numbers of these dual positions, it has become important to look at the personalities and skill sets of the individuals who are either hired or reorganized into them.

Though specific job titles vary widely, this type of position is referred to within the library world as a “hybrid” or “blended” librarian, which Steven J. Bell and John Shank (2004) define as “an academic librarian who combines the traditional

skill set of librarianship with the information technologist’s hardware/software skills, and the instructional or educational designer’s ability to apply technology appropriately in the teaching-learning process.” While the skills themselves are important, of equal if not more importance is the way in which the blended or hybrid librarian executes his or her work—to be able to communicate genuine enthusiasm for the potential uses of technology in the teaching environment. It is the combination of enthusiasm with the library background, subject knowledge, and technical and teaching skills that truly transform and reframe the way faculty perceive the use of technology in their classes.

Librarians who report to both the Libraries and Instructional Technology Development are not only enthusiastic promoters of teaching with technology, but are also able to draw connections between the activities of both units from a unique perspective. At DePaul University these blended librarians have aided in the development of, and participated in, a number of cooperative projects and cross-departmental trainings.

COLLABORATIVE TRAINING: BLACKBOARD

The earliest training collaboration, “*Linking to Resources in Blackboard*,” began as a day-long workshop to teach faculty how to use the Blackboard course management system at the University’s newest and smallest residential campus. In addition to learning the functionality of the Blackboard course management system from an instructional technology consultant (ITC), a librarian instructed faculty in linking to content contained in library databases. In the course of delivering the workshop, it was discovered that faculty could also benefit from a more basic overview of library resources. In time, the combined library and instructional technology development

staff also recognized there was an audience for a more intensive Blackboard training workshop.

The *Blackboard Institute* (BI) evolved as an endeavor to offer brief, intensive training in Blackboard. Existing instructional programs offered by instructional technology development were structured over a five-week period, and many faculty members balked at this extended time commitment. Coordinated by one of the blended librarians, the hands-on workshop is offered over three consecutive days to faculty members interested in building a Blackboard course site to complement classroom instruction. When the inaugural Blackboard Institute filled to capacity within a few days, a second institute was added, which also filled to capacity. Future institutes are planned during academic breaks with two more to follow immediately prior to the fall term. An additional *Advanced Blackboard Institute* is also planned, designed to expand the skills of the initial institute participants.

During the Institute, participants develop and/or upload a course syllabus, structure course information, identify and link to online resources, and create learning activities to engage learners. Hands-on activities are complemented by showcases, discussions, and critiques among the participants. As different instructional technology consultants and librarians present, other staff members are available, roaming to assist faculty members as needed. This helps to build the role of librarian as technology expert.

A presentation on linking to library resources takes place during the morning of the second day. The benefits of the online course reserve system are demonstrated first. Faculty need only to submit citations for items to be put on reserve for their courses. The library determines whether the item may be linked through an existing database subscription, and if not, scans the relevant articles or chapters. Items which cannot be placed on electronic reserves due to limitations of format or of copyright are placed on print reserve and a link is created to the catalog record. Faculty are

also taken through the process of creating stable, persistent links to articles of their choice in the library's online database collection, and are taught how to include those links in their course sites or course Web sites. Faculty appreciate being able to recommend online full-text articles, and provide links to them to at a moment's notice.

In addition to the blended librarians leading the session, librarians representing the subject areas of the participants are invited to the presentation and encouraged to continue the discussion over lunch. The positive outcome of this training endeavor supports Bell's finding that when "library staff is involved in managing the course management system (CMS) or providing training for new users ... [t]hat is a favorable condition for librarians to influence faculty to create links to the library." (Bell, 2002)

Faculty awareness of, and facility with, electronic reserves and linking should lead to inclusion and promotion of resources already purchased by the libraries. These outgrowths can improve student work as well—when faculty know how easy it is to include an article from the day's newspaper, they are more likely to add that link into their course site. In turn, students are more likely to read and access items that are immediately available. Cohen agrees: "Integrating course-management software with the library's digital offerings is essential for getting the maximum value from the institutional investments of both money and expertise." (Cohen, 2002) Gibbons also argues that integrating library resources into course management systems makes students regard them more favorably, and thus increases the likelihood those students would turn to the linked electronic resources provided by the library. (Gibbons, 2005a) Furthermore, according to studies cited by Gibbons, it is the convenience and efficiency of course management systems that appeal most to students. (Gibbons, 2005b) Students rated being able to access syllabi and course readings as the most attractive and useful features.

ADDITIONAL FACULTY TRAINING OPPORTUNITIES

Librarian members of the instructional technology consultant staff also assist with the development and delivery of instructional technology development workshops on using word processing applications, developing presentations, and building Web sites, as well as on homegrown applications such as QuickData, instructional technology development's online survey development tool. Aside from the obvious point-of-service opportunities to promote and recommend related library resources, librarians working with faculty in this capacity increase the possibility that faculty will think of the library when designing their assignments.

Instructional technology development workshops provide an ideal forum for promoting the library's "Just for Faculty" section of the library's Web site. (DePaul University Libraries, n.d.) This page includes information about course reserves, the library's instruction program, suggestions for purchase, and interlibrary loan. It also includes step-by-step directions for linking to library resources and provides a tool that wraps code around each link to enable proxy access for off-campus university affiliates.

TECHNOLOGY COLLABORATIONS: LEARNING CONTENT MANAGEMENT SYSTEM

Several additional outgrowths of the library-ITD collaboration exist, resulting in technical solutions primarily utilized or supported by the library. Ranging across functional units in the libraries and instructional technology development, these applications are critical to the delivery of library services and resources. The successful use by the library of one jointly developed application has led to its adoption by other university units.

The first and most established of these is instruction builder (IB), a learning content manage-

ment system (LCMS). This tool can be used to build interactive lessons by creating and linking together instructional elements such as animations, and assessment elements such as quizzes, tests, and assignments. All of these objects can be shared with other users of the application and used or re-used in multiple contexts. The library's instruction program makes heavy use of IB, currently delivering nine targeted, class-specific workshops to four schools or units across the University. In sum, over 7,000 students have taken at least one of the ten workshops that have been available over the life of the application. Additionally, the University's Office of Institutional Compliance utilized the application to deliver training to all employees.

Instruction Builder 3.0 was released in August 2005, the third version release in the project's five year lifespan. This release of the product was the culmination of a multi-year joint development process between the University Libraries and Instructional Technology Development, undertaken by a cross-functional team of stakeholders, including the library instruction coordinator, the head of library Web services, Instructional Technology Development's lead developer, and three of the Library/Instructional Technology Development joint-report positions, one of whom served as project manager. For the two previous releases, the same collaborative model has been used to generate system requirements, test beta versions, and compile lists of enhancements.

Feedback collected from the development team, librarian graders, and student users of the system has led to a number of changes to the application over its lifespan. In conjunction with the library-driven enhancements in the third release, the project manager worked with the Office of Institutional Compliance within the University, for which a separate instance of the IB application was established to integrate their requirements and feedback. Interface changes, restructuring of user permissions, and enhanced functionality

are a few results of this iterative, collaborative design process.

INSTRUCTION BUILDER: CURRENT STRUCTURE AND FUNCTIONALITY

The instruction builder (IB) system is flexible and allows instructional objects created within it to be linked together into one of two delivery methods:

- Workshops, which are built using a combination of instructional elements and assessment elements, and which are linked to specific DePaul courses via the University's student information system
- Tutorials, which may be freely accessed (i.e., they are not linked to any course) and which are primarily composed of instructional elements, with no required assessments

IB is role-based; display options and permissions are assigned according to role. The three major categories of roles are student, instructor (faculty), and administrator. All three log in to a common interface to access workshops and other data. Students complete workshops at their convenience, and are not required to complete them in one sitting. Once submitted, depending on their content, workshops may be graded automatically by the system or interactively by a faculty member, librarian, or instructional designer.

Instructors may view workshop content and class roster data from their login screen. Additionally, they are provided with a direct URL to each workshop, which they may add to their course within a course management system, or send via e-mail.

Administrative access to the system is managed at several tiers. Most users have access to view published content and to grade submitted workshops. A smaller group of users have the ability to build individual content items, to com-

bine them to form workshops or tutorials, and to "publish" or release them to students and instructors. Higher-level administrative tasks such as activating and deactivating users, assigning user permissions, creating and populating groups, and editing released content, are restricted to only a few select users.

ELECTRONIC RESOURCE MANAGEMENT

The two units also work collaboratively on an application for managing electronic resources. The University initially contracted with a vendor providing aggregated, single-entry access to library electronic subscriptions over five years ago. This vendor also provides a link resolver, which uses the OpenURL protocol to provide more seamless access to electronic full-text content across all library databases and vendors. At the time of inception, the library's Web services department was maintaining its own database of information on library subscriptions to online journals and databases. Over time, the library Web services department worked with the vendor to customize the look and feel of search and results screens so that they blended seamlessly with the library's Web site.

In July 2005, reorganization consolidated several positions with technical or Web site management responsibilities from both the libraries and instructional technology development into a single department, responsible for all systems and development projects for the larger teaching and learning resources unit. At this time, day-to-day maintenance of technical and interface issues for these services is managed by the new, merged systems and applications development department, with assistance from collection development on a case by case basis for subscription/vendor contacts.

FUTURE DIRECTIONS AND POSSIBLE APPLICATIONS

With each year bringing more integration of technology across the whole of higher education, and with the technology landscape constantly changing, it is likely that more and more of the services offered and resources provided by libraries and instructional technology support units will be inextricably intertwined with the online world.

Most important, though, must be the examination of why this effort will prosper. It is already immediately apparent that some of the areas most profoundly impacted by technology include:

- Instruction, whether in-class or online, and whether conducted by faculty or by academic support units such as the libraries or instructional technology development
- Library collections, including online databases and indexes, electronic journals, and books
- Technology support for faculty, staff, and students, as new technologies are adopted and integrated into the curriculum (recent examples include streaming multimedia, podcasting, and blogging)

The consolidation of both library and instructional technology perspectives and responsibilities to create this first group of blended positions at DePaul has been successful, due in large part to the focus of these positions on the areas previously listed. The Institute of Museum and Library Services (IMLS) recent white paper publication, *“The Future of Librarians in the Workforce Project—University Libraries”* confirms this:

Faculty will still expect librarians to understand their intellectual needs and to anticipate those needs in the works they acquire and license (including GIS and other non-traditional resources). More than ever faculty look and will look to librarians to deliver instruction to the community

in the productive use of all manner of resources. (Institute of Museum and Library Services, 2006)

Further, the organizational structure at this institution supports such an arrangement, since both the libraries and instructional technology development are part of the same overarching administrative unit, teaching and learning resources.

In addition, as previously mentioned, the success of these and similar positions is affected by other, less quantifiable factors related to the personal characteristics of the individual filling the position; it is essential that the individual possess appropriate technical skills and discipline background, as well as certain elements of personality (e.g., enthusiasm, self-direction, flexibility, curiosity/interest in technology), which are the most difficult to quantify when developing “hybrid” or “blended” positions.

It is also important to remember that although many of the trends and forces in the current environment indicate a shift toward an environment where more and more “blended” positions exist, the audience for library services and resources remains rich and varied in its interests, needs, and approaches. “Traditional” library services such as reference, cataloging, circulation, archives, and preservation have become neither superfluous nor outmoded, as evidenced by their continued utilization, and they retain their importance to the support of teaching and learning within the academic enterprise. This carryover of skills and values, albeit with new and different methods of delivery, is recognized within the IMLS paper: “... There is also a need to assure that the basics of library work do not change in the electronic age.” (Institute of Museum and Library Services, 2006) In fact, circulation of DePaul’s print collections increased 23% for the 2005 fiscal year, despite yearly increases in e-book and electronic journal subscription access, illustrating the continuing impact of one the library’s most basic resources: books.

Campbell grapples with these issues of transition in his article “*Changing a Cultural Icon: The Academic Library as a Virtual Destination*.” The library is still seen as a cultural icon, but it has become increasingly apparent that the public face of the icon needs to be updated to better reflect the ideals of a new society. If libraries fail to take advantage of opportunities to change their image, their role in the academy may be threatened by the impact of technology and its perceived ease of use. Libraries will always be keepers of information, but their previous service model, primarily passive, will need to shift in order to retain its importance in a society that values desktop- and doorstep-delivery services. He concludes, “Over the next decade, colleges and universities will have to make critically important practical and policy decisions about the future of libraries, about the space devoted to libraries, and about the roles of librarians.” (Campbell, 2006).

It is clear that a crossroads has been reached. We argue that these decisions can be made easier as libraries and librarians become ever more closely and more actively aligned with the teaching mission of the university, and as universities and colleges look at transforming the librarians’ roles within the academy by leveraging their skills to enhance teaching and learning in today’s online environment.

KEY TERMS AND DEFINITIONS

Blended or Hybrid Librarian: A librarian with a skill set consisting of traditional library skills, facility with hardware and educational software, and the ability to communicate the appropriate use of technology in a teaching and learning environment.

Course Management System (CMS): An online learning environment, which bundles teaching and communications tools. These tools can be used to supplement classroom learning or can stand alone as an online learning experience.

Learning Content Management System: A system where instructional designers and other instructional content developers can create, store, reuse, manage, and deliver digital learning content using a central learning object repository.

Link Resolver: A software application that uses the OpenURL protocol to provide more seamless access to electronic full-text content across all databases and vendors for a desired citation.

OpenURL: An ANSI standard (Z39.88) used to transport metadata and/or other identifiers about a source object to a target object. In libraries, this standard is used by link resolvers to connect patrons to resources and services.

Persistent Links: Links provided by a database that allow direct and stable access to a particular document or item.

Reference Services: Service provided by libraries whereby patrons are assisted in the location and retrieval of information relevant to their information needs.

Student Information System: Often part of enterprise solutions that also manage human resources and financial services, student information systems are responsible for maintaining the records of course enrollment, grades, course history, and other data related to a student's academic career.

Chapter 4.14

Student Decision Making in Technology Application

Ali Ahmed

University of Wisconsin - La Crosse, USA

Abdulaziz Elfessi

University of Wisconsin - La Crosse, USA

ABSTRACT

This study investigated factors that influence students' decision-making processes in selecting a classroom or online course, student technology skills and experience, and concerns students have about Internet integration. Students completed a survey questionnaire and Web-based pretests and posttests. A Likert scale instrument was completed by students in both a control group and an experimental group. Independent two-sample t-tests and an analysis of covariance (ANCOVA), using the initial score as the covariate, were conducted. Level of significance (alpha) was set at .05 to achieve statistical significance for all analyses. Both groups in this study were full-time, on-campus students with access to the same tech-

nology resources. Findings reveal that students' perceptions and experiences were quite similar.

INTRODUCTION

Educational reform is exerting pressure on prospective and experienced teachers to model authentic teaching and to demonstrate understanding and knowledge of various instructional techniques and tools. Teachers are being trained or retrained to reduce the lecture-and-listen styles of instruction that have traditionally been used and to enhance their facilitation of appropriate student-centered instructional methods. Technology is one of the new teaching and learning tools that teachers are expected to use. As more schools invest in technology and students increasingly obtain technological sophistication, teachers are

DOI: 10.4018/978-1-60960-503-2.ch414

expected to not only demonstrate technology competency but also be effective at integrating technology into their teaching.

The use of technology as an instructional tool and medium is usually determined by the pedagogical style adapted by the instructor (Shovein, Huston, Fox, & Damazo, 2005). However, during a time when active student participation in the learning process is receiving widespread attention, educators must consider student learning preferences and technology abilities when planning a course delivery format. Various factors determine students' preferences and perceptions about technology application in both classroom and online environments. In this study, the authors studied the factors that influence students' decisions to learn in a classroom vs. an online setting. In addition, the authors also examined students' technology skills and concerns about Internet integration within classrooms.

INSTRUCTIONAL ENVIRONMENT

Participation in Web-enhanced classrooms or online distance learning is influenced by student motivation, technology experience, learning styles, and learning expectations (Shovein et al., 2005). According to Shin and Chan (2004), education level, online learning experience, and Internet skills affect student participation in online learning.

Many institutions of higher education are using Web-based instruction for classroom and distance education (Falvo & Solloway, 2004). Various online course management systems have evolved within the last decade and have been widely adapted by educational institutions. Course management systems such as Blackboard™, WebCT™, and Desire2Learn™ have been used in classrooms to supplement learning and as an online distance education delivery medium. In a comparison study of two online course management systems, Storey, Phillips, Maczewski, and

Wang (2002) revealed that ease of technology use and access to technology are important considerations when deciding whether to use technology. Buzzell, Chamberlain, and Pintauro (2002) stated that both Web-based and classroom learning are effective instructional environments.

Advocates of online learning mention the flexibility that online learning provides. Although online learning offers flexibility, it is not yet regarded by many educators as an appealing replacement of classroom learning; therefore, the significance of flexibility should not override other factors that affect learning such as student learning styles and technology skills. Atan, Rahman, and Idrus (2004) recognized the benefits of Web-based instruction such as increased opportunities for using different instructional strategies, use of multimedia, improved communication and interaction, and easy access to course materials; however, they also argued that the impact of a traditional course delivery system supercedes that of online learning.

Due to the time and technology skills needed to manage online classes and to teach and support students, online learning is more demanding and involved than is generally assumed (Shovein et al., 2005). Atan et al. (2004) observed that, "distance education learners need constant reminders regarding learning strategies, time management skills, motivation, and discipline" (p. 105). Students require online support for successful online learning. Although concerns about the effects of technology on learning and course management are raised when teaching online, the presence of technology in traditional classrooms also calls for a reassessment of classroom management practices. The physical space in classrooms and disruptions of student learning by the Internet require new classroom management styles (Lim, Pek, & Chai, 2005).

Effective integration of the Internet requires careful consideration of individual learner differences and needs. If online learning is to be integrated into campus-based courses because of the potential of the Internet as an effective learn-

ing tool, a mixed-mode delivery format should be adapted to supplement face-to-face learning (Sheard & Lynch, 2003). This view is consistent with the findings of Rovai, Wighting, and Liu (2005) who reported that hybrid learning increases persistence and commitment to online learning.

TECHNOLOGY USE AND PERCEPTION

Educational scholars and practitioners have long reported that students prefer learning in environments in which they are comfortable. As educational institutions and instructors began to integrate the Internet as an instructional tool and delivery medium, students learned and developed the technology skills that became important, if not required, for this new method of learning. However, not all students were fascinated with the use of technology for teaching and learning. A study by Rule, Barrera, Jolene, Dockstader, and Derr (2002) reported that students in a technology-rich environment had higher technology skills than classroom students with limited access to computers. Although Rule et al. found no significant differences in students' attitude toward computers, their study revealed that students who were highly motivated were more likely to use computers than their less motivated counterparts. They further reported that access to computers and technology support are important factors in a student's decision to utilize computers.

When Buchanan, Brown, Casanova, Wolfram, and Xie (2000) contrasted two student groups in online and classroom environments, they found that Web-based students considered technology skills, organization, and personalities more important for learning compared to classroom students. Other studies point out that student choices and decision-making are influenced by personal relationships and technology support. In a survey of student perceptions about Internet use for learning, an overwhelming number of students

stated that an online medium facilitates learning more thoroughly than face-to-face environment (Cottrell & Robinson, 2003). Cottrell and Robinson posited that two potential reasons for these perceptions are the independence of and access to materials that Web-based learning provides. Cottrell et al. further noted that online learning environments individualize learning because students can learn according to their learning preferences, style, and pace. Web-based instruction increases collaboration and mentoring, enhances students' self-confidence, and provides students with alternative learning styles (Chang, 2003). In a comparative study of online and on-campus students, Rovai et al. (2005) discovered that no difference in learning and performance exists as long as students using the online environments have a sense of community and collaboration similar to that found in classroom environments.

In examining the role of student perceptions about the instructional delivery medium, Miller, Rainer, and Corley (2003) found that perceived ease of use and usefulness of a medium encouraged students to enroll in a course utilizing such a medium. Possessing the necessary skills to successfully learn in such an environment creates a positive perception about the instructional medium. Miller et al. further demonstrated that students who exhibit technology anxiety or lack technology skills are less motivated to learn in an online environment.

DESCRIPTION OF THE STUDY

Students enrolled in an introductory educational technology course took part in this study to investigate the various factors that influence student decision making with regard to technology use. The study explored whether differences in student technology experience, skills, or concerns about Internet integration play a role in learning in a classroom or an online environment.

The experiences and perceptions of two groups of students who were either enrolled in classroom or online sections of the same course were compared. Students in the two course sections were full-time, on-campus students with access to similar resources such as computers, printers, university networks, and the Internet. The only difference was that the online group completed the course as distance education students while the classroom students used the Internet as a supplement to face-to-face learning.

DATA COLLECTION

To study student technology experience including learning environment and concerns about technology use, students completed a survey questionnaire and pretests and posttests. To compare and investigate students' perceptions about technology integration, a Web-based pretest was administered to both groups (online and classroom) during the first day of the semester; a Web-based posttest was administered again at the end of the semester. Both tests were executed and scored automatically using an online assessment tool. This study was conducted to answer the following research questions:

1. How do student technology experience and skills determine student preference for online or classroom learning?
2. Are there any significant differences between online and classroom students' decision-making processes in the use of the Internet as an instructional medium?
3. Are there any significant differences in student concerns about the use of the Internet as an instructional tool?

SUBJECTS

Participants consisted of two groups of pre-service teacher education students. Although all students were full-time, on-campus students, one section of the course was taught online as a distance education course. One group of 24 students was enrolled in the classroom section of the course, while the other group of 23 students completed the course online.

Many of the participants were undergraduate students of junior and senior standing. The course is one of the required courses in the education program and is designed to introduce students to the field of educational technology.

INSTRUMENT AND DATA ANALYSIS

The first goal of this study was to compare the level of "computer and Internet technology skills" of students in the two sections. A Likert scale instrument (1 = Expert, ..., 5 = None) was completed by the students in both classes. This was part one of a questionnaire on Web-based educational technology (Tetiawat, 2003) consisting of eight items. Independent two-sample t-tests were conducted to determine the difference in the mean scores between the two groups.

The second purpose of the study was to assess and compare the factors that influenced the students' decisions to use Internet/Web technologies. A Likert scale instrument (1 = Very strong influence, ..., 5 = No influence) was completed by the students at the beginning and the end of the semester. This was part two of a questionnaire on Web-based educational technology consisting of 12 items. Analysis of covariance (ANCOVA), using the initial score as the covariate, was conducted to determine the difference in the mean of the scores for each class at the end of the semester.

The final purpose of this research was to compare the students' levels of concern regarding the use of the Internet in teaching and learning. A

Likert scale instrument (1 = Extremely concerned, ..., 5 = Not concerned) was again completed by the students at the beginning and at the end of the semester. This was part three of a questionnaire on Web-based educational technology consisting of 16 items. ANCOVA, using the initial score as the covariate, was conducted to determine the difference in the mean scores for each class at the end of the semester. The level of significance (alpha) was set at .05 to achieve statistical significance for all analyses.

RESULTS

To examine student decision-making procedures in using technology as a learning tool, this study researched the role of student technology skills, student perceptions about the influence of technology on learning, and student concerns about incorporating technology in learning. Forty-seven students completed the assessment at the beginning and at the end of the semester. The data on sex, age, and degree program are presented in Table 1.

The study assessed students' level of technology skills. Normal probability plots reveal that the normality assumptions were valid. Leven's

test for homogeneity of variance indicated that the assumption for equality of variance was not violated. Independent two-sample t-tests indicated no significant difference ($P\text{-value} > .05$) in the mean scores of level of skills among the two classes for seven of the eight items. The only significant difference ($p < .05$) among the two classes was found for the item, "using the Internet for other communication forms (e.g., chat, discussion forum, listserves, bulletin-board)," (see Table 2) where online students revealed more experience in Internet use for communication compared to the traditional (classroom) group. Most students in both groups ranked their word processing and presentation software skills as advanced or intermediate. Students ranked their skills in developing Web courses as the lowest of the eight skills.

Student responses to several statements were analyzed to examine the factors that affect student decision-making processes. The results from the analysis of covariance (ANCOVA) indicated only a significant difference ($P\text{-value} < .05$) among the two groups in item two (studying performance is improved) regarding the factors that have influenced or would influence their decision to use the Internet/Web (see Table 3).

According to the data (see Table 4), both the online and classroom students were most influenced in their decision-making by the need to communicate with instructors and friends (item 4), their confidence in the value of the Internet (item 11) to improve studying performance (item 2), and the ease of Internet Study (item 3). Conversely, the data reveals that the ability to use technology on a trial basis (item 9) and the availability of other courses on the Internet (item 12) had the least influence on student decision-making process.

In investigating students' levels of concern when deciding whether or not to use Internet/Web technology instruments, ANCOVA indicated a *marginal* significance ($p = .08$) between the two groups for the item "ownership of the Web-based

12. 12. Availability of other courses on the Internet/Web	0.358	0.553

courses." The results from ANCOVA are given in Table 5.

Table 6 shows that students were most concerned about technical problems (item 11), effectiveness of Web-based courses compared to face-to-face learning methods (item 4), keeping up with the speed of technology (item 10), and the possibility of the Internet replacing face-to-face classrooms (item 16). Students seemed to have been less concerned about the ownership of courses, lack of support from their own institution, and the limited use of the Internet in their subject areas.

DISCUSSION

Unlike distance education or classroom learning, the use of technology such as the Internet as an instructional tool and medium requires students to have at least basic technology skills. Students are becoming increasingly familiar with technology application in classroom learning and distance education settings and many have some form of technology experience, regardless of their learning environments and fields of study.

In this study, the findings did not reveal widespread discrepancies in student technology skills and perception about the incorporation of technol-

ogy in instruction. The mean score of classroom (3.18) and online (3.02) students' overall skill levels reveals that students in both groups had some

technology experience. At the very least, both groups of students had intermediate skills in Internet use, presentation applications, and common productivity software, such as word processing. Additionally, many colleges offer workshops that provide training in the aforementioned programs. However, despite the training and the importance that word processing and presentation skills hold, students did not acknowledge any expertise in the programs. Students reported to have fewer competencies in the less commonly used skills of programming and Web site development. In investigating student technology skills, Dexter and Riedel (2003) reported that students only exhibited competency in technology that they found useful to their learning process.

Overall, the only significant difference between the two groups' technological skills was found in the use of the Internet for communication. This is an important factor for students when choosing

course delivery format. In fact, the online students reported to have better Internet communication skills compared to the classroom group. This point is consistent with other studies of online learning because effective use of the Internet for learning and communication requires greater interaction and use of different communication media such as email, online chats, and discussion forums. For successful Web-based instruction and improved learning outcomes, students must engage in asynchronous communication in addition to the real-time, synchronous media during group discussions. Although the Internet is a great communication tool, many students see no need for other tools other than email, and therefore fail to develop skills in other communication media. On the other hand, students who have more skills in various Internet communication technologies are more inclined to use the Internet as a medium of learning.

Communication plays an important role in determining the quality of online learning. Successful online learning requires virtual learning communities and increased peer interaction (Rovai et al., 2005). Frequent and immediate communication leads to increased interaction and improves learning. Because students value peer interaction and support (Falvo et al., 2004), educators must utilize various strategies to complement online discussion in order to have effective communication (Ortiz-Rodriguez, Telg, Irani, Grady Roberts, & Rhoades, 2005). Furthermore, Ortiz-Rodriguez et al. found e-mail to be an effective one-on-one communication tool and online forums to be good for group discussion.

The learning environment and delivery format are important to consider when making decisions about course enrollment. In this study, students were told to identify some technological factors that influenced their decision-making. Overall, students' selection showed the significance of the Internet as a communication tool as the most influential factor, although they had mixed perceptions about the value of the Internet as a learning tool. The mixed perceptions about the instructional value of the Internet could be attributed to past technology experience that involved using technology as a communication tool rather than a learning tool. This experience could have swayed students' perceptions about how the Internet influenced their decision-making.

The fact that most students selected the availability of other courses (item 12) on the Internet as the factor that least influenced decision-making supports studies that report undergraduate students are less inclined to enroll in distance education courses (Rovai et al., 2005). In this study, meeting the maximum enrollment in the online section may have been due to the fact that the classroom section of this course had reached maximum capacity enrollment.

Students in both groups were interested in using the Internet to help in course completion rather than as a tool to help them learn the course

content. The similarities in responses students gave to this issue revealed that regardless of the learning environment (online or classroom), students preferred to use technology as an instructional aid and communication tool.

In examining students' concerns about the use of the Internet in online or classroom learning environments, analysis of the statistical comparison did not show any significant differences in student responses. Widespread access to technology and support in using the technology are however crucial considerations. Respondents in both groups were more concerned about technical problems impeding the use of the technology rather than the effectiveness of the Web to improve academic performance. The data reported that students did not consider an institution's role in a course to be important as long as they were obtaining support and services in completing the course. Students were not very concerned about the institution that owned and delivered the course. This finding is incongruent with the view of Shin et al. (2004), who found that affiliation with a university does affect student online learning outcomes; a strong, student-university connection was found to lead to positive learning outcomes and a more persistent online learning presence.

Students considered technology an add-on to the content that they are required to learn in order to graduate. Students voiced concerns about developing new technology skills because technology evolves quickly. This concern could have contributed to hesitation on the part of some students to adapt to and embrace technology even though they are aware of its potential. Software and hardware are constantly upgraded, and students are required to keep up to pace with the changes. This could have diminished students' abilities to develop competency even in basic technologies such as word processors.

Some people might expect the classroom students to have been more concerned about technology application because of the general belief that online students have better techno-

logical competencies. Though such a premise is understandable, the amount of time students spend online increases the likelihood of technical problems, therefore making online students' levels of concerns identical to classroom students. Also, the Web was used to supplement classroom learning of traditional students and therefore was not much of a concern.

The lack of significant differences in many of the issues raised among the two groups is partly due to the fact that although the online students completed the course online, they were also on-campus students and had access to the same technology resources and facilities as their classroom peers. The course instructor was also available for meetings in case individual online students needed to meet in person.

CONCLUSION

As both groups of students in this study were full-time, on-campus students with access to the same technology resources and support, this study found that students' perceptions and experiences were quite similar. Responses may have differed if the online group completed the course while stationed off campus. The only notable difference between the two groups was that the online group did not meet face-to-face with the instructor in a classroom-learning environment. Significant differences could be found in many of the items in the study that addressed factors that influence student decision-making and their levels of concern if the students do not have access to similar resources. Although the subjects in this study were predominantly undergraduate education students with similar access to technology resources and support, many online distance education students are working adults with diverse experiences and expectations and different levels of technology skills and support, and are enrolled in a course by choice rather than to complete a requirement.

Though the online students liked the constant communication and flexibility Web-based instruction provides, a danger exists that students may lack the discipline and commitment that online distance education requires. Considering that the majority of the students in this study were young, the flexibility of the online course had its complications. For example, students tended to submit assignments late and had difficulty coordinating the online group interactions and activities, especially when such interactions involved real-time communication. Distance education requires more self-discipline and planning compared to a classroom environment, where students rely heavily on instruction from the teacher.

Students' responses revealed that technology use in a course was not a major issue of concern. However, the course in which the students are enrolled can make a difference. Some courses require more technology skills than others. In this study, respondents were enrolled in an instructional technology course that involved the development of technology skills and technology application in curriculum; therefore students' level of concern potentially may have been different compared to if they were enrolled in another course that did not focus on instructional technology. Students in this course were aware of the technology skills and technical support they were to receive.

Although the participants in this study were required to enroll in the online course, many other on-campus students nationwide are enrolling in online distance education courses as a way to graduate more quickly. Completing an online course is no longer complicated or overwhelming because many students develop technology skills much earlier than in the past, more technology training and support is available, and access to online courses delivered by colleges has increased. However, the use of Internet is not limited to online distance education as an increasing number of faculty are also incorporating the Internet in their traditional classrooms. No matter how the technology is applied, the concern is less about

technology skills and availability and more about how to incorporate technology as an effective instructional tool. In considering use of technology, students' decision-making processes will be influenced by a combination of several factors, notably how the Internet can facilitate and enhance learning. Meanwhile, as online learning is increasingly becoming popular among traditional students, more studies need to be conducted to examine how students can concurrently be on-campus and distance education students in a meaningful and effective way.

Chapter 4.15

Transforming a Pediatrics Lecture Series to Online Instruction

Tiffany A. Koszalka
Syracuse University, USA

Bradley Olson
SUNY Upstate Medical University, USA

ABSTRACT

A major issue facing medical education training programs across the USA is the recent advent of universal mandatory duty hour limitations and the time pressure it places on formal face-to-face educational sessions. In response to these mandates and associated issues many medical education programs are exploring the use of online instruction to address issues of accessibility. This chapter describes the instructional development process followed to transform a classroom-based pediatrics residency lecture series into an on-demand, video-enhanced, online instructional environment. An overview of the learning principles and instructional sciences that guided the design process is provided. The phases of the designed solution are then described in the context of en-

hancing the lecture series as it was transformed into online instruction. Implementation logistics are described followed by an overview of the benefits, barriers, and initial project outcomes. Plans for future enhancements and research projects are also discussed.

INTRODUCTION

Designing good instruction is predicated on understanding learning. Effective learning is predicated on accurately defining learning outcomes and providing instructional environments that support the achievement of learning outcomes. Both are essential to successful online instruction (Koszalka, 2007, p. 2).

Principles of learning and the instructional sciences were used to enhance the overall strength of the pediatrics residency curriculum at SUNY

DOI: 10.4018/978-1-60960-503-2.ch415

Upstate Medical University in Syracuse, New York. In response to the recent advent of universal mandatory duty hour limitations and the time pressure it places on formal face-to-face educational sessions, the entire residency curriculum, consisting of a year-long classroom-based lecture series, was transformed into a blended video-based online format supported by application-based classroom experiences. The online lectures component was not a straight conversion where lectures were simply videotaped and offered to the residents through a distance education program, rather the demand for change was used as an opportunity to re-evaluate the design of the lecture series and apply sound learning and instructional design principles to enhance the overall residency instructional process.

Application of learning principles. Learning at its foundation is about change, change in human condition based on experiences. Principles of social learning theories posit that learning is a construction of knowledge based on an individual's observations of, and interactions with, information and people around them. Learning can occur both at surface and deep levels depending on how individuals interact with new information.

Surface learning suggests storage and remembrance of information, facts, concepts, principles, and procedures. It often results in recalling basic information and demonstrating new procedures and behaviors, for example. Deep learning, or critical thinking, suggests activation of higher order thinking. Outcomes of this type of learning include constructing knowledge to evaluate, apply, diagnose, problem solve, debate, critique, and other activities that require successfully addressing complex and ill-structured problems, such as those encountered by medical professionals.

The construction or learning of knowledge at these different levels is supported through different types of interactions (instruction) with content and people that accommodate individual preferences and learning styles of the learner (Akdemir & Koszalka, In-press; Akdemir & Koszalka, 2005;

Kidney, G., & Puckett, 2003). Thus, instruction is thought to be richest and most effective in facilitating deep learning when:

- Learners are *engaged* in solving real-life problems;
- Existing knowledge is *activated* as a foundation to new knowledge;
- New knowledge is *demonstrated* to the learner;
- When new knowledge is *applied* by the learner;
- When new knowledge is *integrated* into the learner's world (Merrill, 2000).

Application of instructional sciences and design processes. The instructional sciences inform how activities can be designed to prompt and facilitate required levels of learning that meet expected outcomes. To design instruction and learning experiences that apply learning principles successfully an instructional system design (ISD) process can be undertaken. The process includes: (A) analyzing the gap in knowledge (what does the learner know and what should they learn), (D) designing an instructional and learning solution, (D) developing the solution based on the design, (I) implementing and testing the solution, and (E) evaluating the results (Dick, Carey, & Carey, 2005; Smith & Ragan, 2005). An ADDIE approach, guided by principles of learning and instruction, is especially important when designing instruction for online applications, as the perceived separation of learner and facilitator can be distracting to the learner or fail to provide information and social learning interactions required by the learner.

Distance education of the past was designed to stand on its own as correspondence courses in which learners received an instructional packet and submitted assignments at their own pace. There was little or no social interaction with peers or an instructor. Distance education today however mostly refers to technology-delivered instruction and learning activities that are designed to provide

informational and instructional elements as well as social learning elements to actively engage learners with content, peers, and the instructor through digital technologies (Grabowski & Small, 1997). The major benefit is posited to be providing instruction to those who have limitations of time or travel (Hawkrige, 1999; Stock-McIssac, 1999).

Incorporating these interaction elements however, comes at a price. Learners in distance education seem to have a wide range of technology skills and content application knowledge (Lamb & Smith, 2000). Thus, addressing the needs of such a wide variety of learners can be a challenge. Designing for such a diverse audience often means incorporating multiple and rich representations of the same information (e.g., lecture, readings, learning aides) and providing learners with multiple ways to interact with content and demonstrate their learning (e.g., discussion boards, online assessment, reflective journaling). Thus, it is critical when converting from classroom-based instruction to online delivery that instructional materials and learning activities be well integrated and aligned with expected learning outcomes, e.g., surface recall or knowledge application in problem solving.

THE PROBLEM WITH THE CURRENT RESIDENCY CLASSROOM-BASED CURRICULUM AT SUNY UPSTATE

Prompted in part by a recent citation for poor resident attendance at the pediatric core conference (classroom lecture) series a curriculum reform effort was undertaken at SUNY Upstate Medical University. As part of this reform an analysis of the formal didactic educational program was undertaken. This analysis revealed that as a result of significant clinical responsibilities the 36 pediatric residents could only attend approximately 30-40% of the offered lectures. This attendance situation has recently been made worse across the country in medical education with the introduction

of mandatory work hour limitations that restrict residents' ability to attend standard face-to-face lectures series (Higgins, 2006). The curriculum analysis that was undertaken also revealed that the offered lecture series did not cover the necessary scope of content as outlined by the American Board of Pediatrics (ABP). As a result of these findings it was decided by Upstate's Pediatrics departmental administration to take advantage of distance education technologies to provide greater access for the residents to 'attend' the lectures and address the above noted challenges. Specifically, there were three gaps the institution has tried to overcome from the traditional formal didactic component of the pediatric residency program:

- Lack of overarching design in the core curriculum to cover a defined scope of content.
- Poor conference attendance due to mandatory duty hour limitations making lectures increasingly inaccessible.
- Lacked meaningful learning objectives and measures of knowledge acquisition in core lecture curriculum.

The previous core face-to-face lecture curriculum consisted of a 50-minutes didactic conference series offered 3 days per week. At the end of the academic year the same series was repeated with the assumption that any missed lectures would be attended the next year by the resident as needed. The 120+ annual lectures in this face to face lecture series were organized and presented monthly according to the identified clinical domains. See Table 1. It is important to note that missing from this list of face-to-face lecture topics are the domains of Dermatology, Genetics, Orthopedics and Pharmacology. Because Upstate has limited access to content experts in these fields robust face-to-face lectures in these content domains could not be delivered. However, with the development of the online curriculum content experts could be recruited to cover these domains so that our online curriculum covers a proper and expected scope of content.

Transforming a Pediatrics Lecture Series to Online Instruction

Table 1. Pediatrics residency curriculum listing clinical domains

Clinical domain	*New Domains	Topics covered in clinical domain
Adolescent Med.		Adolescent History; Adolescent Physical Exam; Eating Disorders; Depression
Cardiology		
Developmental Peds.		Patterns of Development & Disability; Spinal Dysraphism; Disorders of Communication & the Autistic Spectrum Disorders; Disorders of Language, Learning & Cognition; Diagnosis and Treatment of ADHD; Cerebral Palsy; Parent Partners in Health Education: Introduction; Parent Partners in Health Education: Communication; Parent Partners in Health Education: Educational Advocacy
Dermatology	X	Principles of Atopic Dermatitis; Acne; Newborn Skin
Emergency Med.		
Endocrinology		Type 1 Diabetes; Type 2 Diabetes; Diabetic Ketoacidosis (DKA); Hyperthyroidism; Acquired Hypothyroidism; Congenital Hypothyroidism; Short Stature; Delayed Puberty; Precocious Puberty
Gastroenterology		Vomiting; Diarrheal Disorders; Gastroesophageal Reflux Disease (GERD); Jaundice (Part 1); Jaundice (Part 2); Gastrointestinal Bleeding; Malabsorption; Abdominal Mass; Refeeding Syndrome; Celiac Disease
Genetics	X	Prenatal Diagnosis; Newborn Screening & Metabolic Emergencies; Chromosomal Abnormalities; Teratogens; Malformations & Deformations; Common Genetic Syndromes

*Expertise not previously available at Upstate to conduct classroom sessions in these domains

The pediatrics faculty consists of 50 physicians all of who are content experts, but who have varying degrees of expertise in instructional design and no formal training in instructional concepts or designing online instruction. The lectures that they provided were of a similar quality typical of most academic medical institution. The lectures however consistently lacked educational objectives and rarely had measures of knowledge acquisition by which achievement can be assessed.

THE PROPOSED PEDIATRIC ONLINE CORE CURRICULUM

In order to address the issues of accessibility and lack of content scope it was decided by the department's education committee to develop an online core curriculum that covers the full scope of content outlined by the American Board of Pediatrics Blueprint Document (ABP 2006). The ABP outlines the content that is tested by the national board certifying examination.

The Associate Program Director for Resident Education at Upstate took the lead in developing the pediatric online core curriculum. This core curriculum now consists of approximately 130 learning units divided into 20 basic clinical

domains. Figure 1 provides a view of the online table of contents of the clinical domains (menu on the left) that residents see once logged into the course. Refer to table 1 for a complete listing of the clinical domains and topics covered within each.

This online pediatric core curriculum is offered through a commonly used Course Management System (CMS) called Blackboard. Within each domain folder are the basic learning units that comprise the core content of that knowledge domain (figure 2). For example in the Genetic domain topics on prenatal diagnosis, new born screening and metabolic emergencies, chromosomal abnormalities, etc. are accessible. Within each of the topics is access to lectures, supporting slides, reading materials, and short self-assessment quizzes.

By clicking on one of the learning topic folders (e.g., Prenatal Diagnosis) inside the clinical domain (Genetics) the basic architecture of each learning unit is revealed. This structure has been kept intentionally simple and consistent across domains to avoid interface complexity (Grunwald 2006). In designing online learning environments it is desirable to keep the basic architecture simple so that learners will quickly learn to navigate their way around the site without wasting time and effort learning complex linking and

Figure 1. Main menu of pediatric core curriculum at Upstate Medical University

Figure 2. Learning unit architecture and navigation

technology strategies. This way the learner dedicates a majority of his or her cognitive efforts towards learning the content rather than navigating a complex interface. A common mistake often found in the design of online learning environments is to use features of the technology simply because they are available (Gilbert & Moore, 1998; Kidney & Puckett, 2003; Koszalka & Ganesan, 2004). Non-purposive - not explicitly related to a specified learning outcome - use of technical features can inhibit learning (Kersley, 1997; Koszalka & Ganesan, 2004). Thus a consistent and easy to follow technical infrastructure is recommended.

The basic architecture of each learning unit in the pediatric core curriculum consists of four components: a video lecture that highlights the essential points of the learning unit, a printable copy of the lecture slides, a review article that serves as a summary document of the essential material, and a quiz that assesses the learners' acquisition of the content material. The video lecture is integrated with synchronized PowerPoint slides to effectively present of the topic content. See figure 3. This component mimics face-to-face lecture with the exception that learners have the

advantage of being able to start and stop a video lecture at any time. They can also skip forward and backward within a lecture to review points that they recall from a previous viewing, supplemental reading or quizzing materials, or from outside experiences. As mentioned previously the learners may also download the PowerPoint presentations and review them without the video.

The overall design of the online core curriculum provides the residents with flexibility to review required content domains and topics when they have time and access. To help them develop deeper understanding of the content the lectures and presentation notes are supplemented with learning objectives, focused reading materials, and self-check quizzes. Although provided as a self-paced, anytime-anywhere accessible format, the delivery of the content online has also provided opportunities for the university to revise the format of classroom sessions.

The in class session are now more focused on case-based discussions that engage the residents in applying information from the online lectures and activities. Thus, residents are now engaged in surface and deep learning activities during all aspects of the new curriculum with a focus on

Figure 3. Sample video and synchronized PowerPoint topic lecture

discussion, application, and case-based social learning activities during classroom sessions.

IMPLEMENTATION: PROCESS, BENEFITS, CHALLENGES, AND INITIAL RESULTS

The pediatric online core curriculum is the result of a two-year educational reform effort that employed learning theory and the ADDIE model of Instructional development. This model involved the analysis, design, development, implementation, and evaluation of an instructional solution to Upstate's pediatrics residency education program challenges of non-attendance in lecture series, gaps in presented content domains, and weak/non-existent learning assessment approaches. This stepwise systems-based approach for designing and implementing instructional solutions involved analyzing instructional problems followed by designing solution that address identified learning and instructional problems. Once the solution was designed instructional materials were developed and the instruction was implemented and tested. Through out this process both the instructional product and the process were evaluated to verify that the product addressed the problem originally

identified and learners were able to achieve expected outcomes. The following is a description of each of the phases conducted during the development of Upstate's pediatric online residency core curriculum.

Analysis Phase. The initial step in the curriculum reform efforts involved analysis of the curriculum content, learners, and environmental factors to define the instructional problem and scope of this project. As in any system, the educational systems is made up of multiple stakeholders (e.g., administrators, educators and learners) who may have differing opinions of the problem and different ideas of problem causes and what the next steps should be in reforming the current system. Lacking a common understanding of the problem will make it difficult, if not impossible to reach consensus on possible solutions. Thus, the analysis phase is critical in identifying gaps in knowledge and skills, describing the key problems (gap between current knowledge and expected knowledge), articulating causes of the gaps, and suggesting potential instructional and learning solutions.

The steps to perform a gap analysis primarily involve collecting a variety of data from key of stakeholders and the instructional and practice environments. Questions that are addressed to

stakeholders should be designed to elicit information from their perspective on current practices, ideal practices, problems (gaps) faced by the educational organization, potential causes of identified problems, and potential solutions. The data collection methods that Upstate used included the following:

- External review of our educational program by a nationally recognized pediatric educator and leader.
- Telephone interviews of 10 former pediatric residents (5 in practice/5 in fellowship) concerning their perceived strengths and weaknesses after having completed training at our institution.
- Survey of all department chairs about their perceived educational needs within their departments.
- Analysis of an external governing agency's review of our educational program.
- Focus group discussions with current residents, faculty and the education committee about each group's perceptions of the strengths and weaknesses of the educational program.

The results of this data collection method were analyzed in order to clearly define the gaps faced by the educational program from the perspective of the various stakeholders. These gaps were then synthesized into 3 statements that were easily communicated and agreed upon by the entire faculty. The gaps that the Upstate pediatric residency program faced were as follows:

- The face-to-face core lecture series did not cover the full scope of content defined by the American Board of Pediatrics blue print document.
- Lecture attendance was poor (<30-40%) partially because of resident commitments to service obligations and mandatory duty hour limitations.

- There were no clearly defined learning objectives for each of the lectures in the core series and consequently no measure of whether our learners had achieved those objectives.

Once these gaps were clearly defined it was a relatively straightforward process to gain the acceptance of the faculty on an online curriculum that accomplished the following three goals.

- Create a designed curriculum that covers a defined scope (i.e. the *American Board of Pediatrics* blue print document).
- Create a lecture series that is accessible to the residents when and where they need it.
- Develop learning objectives for the core lecture series that covers the scope described above and provides learners with ways to check that they have achieved the objectives.

This proposal was presented to the faculty during a 3-hour workshop dedicated, in large part, to launching the online curriculum. The response of the faculty was overwhelmingly positive to this project proposal as they were able to easily see the gaps and follow the rationale for a proposed solution that would be helpful in closing identified gaps.

Design Phase. The chief step in the design phase is to devise an instructional plan that specifically addresses the gaps outlined in the analysis phase. At Upstate the online curriculum was designed to address the 3 gaps in access, content, and learning assessment outlined above. In response to the gap in the content scope of the face-to-face curriculum the ABP blueprint document was used to define the scope for the new online core lecture curriculum. The ABP document, revised every 3 years, keeps up with the advances in medical knowledge and outlines the material that is covered by the annual certification examination, thus is useful in preparing instruction that readies residents for this exam.

A major decision during curriculum design for delivery with any type of media is to define the scope of the curriculum. Critical to these decisions is defining the boundaries of the core content knowledge that is required within a content domain. This is only possible in consultation with individuals who have sufficient domain expertise to make appropriate decisions as to what novices do and do not need to master within the specific domain. If the choices of what to study are left entirely to the novice scholarly research suggests that their learning will be less efficient and they will develop feelings of being overwhelmed by the volume of the material to cover (Leff, 2006). Thus the ABP was helpful in defining content updates to the lecture series.

Thus, Upstate's approach was to rely on an external source (ABP blueprint document) to define the boundaries of the overall curriculum. The project instructional designer partitioned the ABP document and distributed it to the various pediatric divisions with expertise to serve as the outline for the material that they were responsible for covering in the revised curriculum. This approach aborted any discussions/arguments that may have occurred between various stakeholders in regards to content ownership and facilitated the ultimate timely development of the curriculum material.

In order to address the accessibility gap the solution was to develop the new core curriculum for an online environment. By doing so the material would be accessible to learners anytime and anywhere. It is this accessibility that our learners cited as one of the most appealing aspects about the revised pediatric curriculum.

Finally, in addressing the 3rd gap, lack of learning objectives or measures of achievement, Upstate required each of the faculty to include specific learning objectives in their video presentation and 4-5 multiple choice questions that related specifically to those learning objectives and presented content. Each learning unit was designed with the same architecture of video lecture, followed by core reading material, and ending with self-

test of knowledge acquisition in the form of an online quiz. By requiring the faculty to develop these basic components for each learning unit the development of a more uniform core curriculum focused on the most important aspects of the key curricular topics was fostered.

Development Phase. The chief task of the development phase was to build the instructional materials that were designed in the previous phase. During development of the online curriculum there were two main tasks to achieve. First the 50 faculty members in the department of pediatrics were introduced to models and sample templates of curricular materials in the new instructional medium, BlackBoard. In order to accomplish this, prototype lectures were first prototyped and piloted tested with pediatric residents. Once the pilot series was developed and implemented residents were surveyed to determine their satisfaction with online pilot curriculum, which was overwhelmingly positive. This pilot study provided important feedback that was used to enhance the prototype prior to sharing with the faculty.

After testing the pilot series and obtaining positive feedback a faculty development workshop was scheduled that was dedicated to launching the project to create the online curriculum. During this 3-hour workshop the faculty were introduced to the pilot series and the user results. The response of the faculty to this workshop was quite positive and it proved to be an instrumental step in moving the entire development process forward.

The second step to the development phase was to partition the ABP blueprint document among the 19 divisions within the department of pediatrics. This task was led by the project instructional designer who is also a board certified pediatrician. Once this document was partitioned it was distributed to key faculty members within each division who served as section editors. These individuals partitioned their sections of the ABP blueprint document and distributed it among their individual faculty members to develop their lectures covering the content outlined in their portion

of this document. Each followed the guidelines provided during the faculty development workshop to revise or create their topic curricular materials, e.g., lectures, presentation, reading list, and assessment questions. Once topics were ready a technical development process was conducted to videotape and synchronize the lectures and presentation slides, upload all instructional materials, create online quizzes, and integrate the topic into the BlackBoard interface.

Implementation Phase. The chief step of this phase is to implement the educational materials that were developed in the previous step. At Upstate there were 3 main tasks required to implement the online curriculum. First, it was necessary to set up a project timeline to facilitate communication and logistical management among the 50 faculty members involved in the process of generating over 100 lectures. Project management is critical to using limited project resources in a timely manner, like technical development and support personnel and video editing suites. A commonly used project management tool, a

Gantt chart (see Figure 4.), was developed to show progress toward an agreed upon project timeline. This chart helped to facilitate the coordination of multiple aspects of a project within the timeline and greatly enhanced the communication process with the disparate faculty members involved in the project.

The 2nd step in the implementation phase was to verify that the technical infrastructure (e.g., BlackBoard, video taping and editing suites,) was adequately in place and set up to support the various aspects of constructing the online curriculum. This included obtaining the technology to create video lectures with coordinated PowerPoint slides that could be embedded in the CMS. It also meant designating an individual to serve as the central coordinator in the collection of articles & quiz questions for each of the 100+ lectures.

The 3rd step in the implementation phase was to set up a monitoring process for the learners' progress through the curriculum. Once an online curriculum is designed and developed the in-

Figure 4. Portion of the core curriculum revision project gantt chart

instructional designer must decide how to monitor learners' progress thorough the curriculum. This is largely automated when using a CMS such as BlackBoard. However, decisions on what benchmarks will be followed in order to document a student's completion of a curriculum must still be made. At Upstate the completion of the online quizzes was used as the marker of the learner's completion of an individual learning unit. Benchmarks for the expected number of completed learning units by the end of each year of training were identified, published, and distributed to the residents. One additional part of implementation is to test the instructional program and material before final release. This assures that the materials are accessible and working before the audience begins to engage in the instruction.

Evaluation Phase. The final step of the instructional development process is the evaluation phase. Two basic types of evaluation are common in such projects: process evaluation (formative) and outcome evaluation (summative). Process evaluation asks the questions, "is the project progressing according to plan and what enhancements need to be made before final release?" Outcome evaluation asks the question, "did the instruction address the gaps it was intended to at the outset?"

Process evaluation measures for this project included completion of the total number of lectures which have been placed into the CMS. Commitments were obtained from each of the divisions on the number of lectures that would be provided to cover their respective domains as outlined in the ABP blueprint document. As the curriculum has continued to be constructed over the past year it has been a simple matter of checking off each of the lectures from a master list once they have been completed and uploaded to the online course management system. At the time of this writing 90 of the final 130 lectures are complete and available to our learners through Blackboard.

One other measure examined as part of the formative evaluation was the results of a learner satisfaction survey. The two main areas of interest

were (i) information on overall user satisfaction with the online curriculum and (ii) suggestions that the users had for improving the curriculum. The level of satisfaction questions resulted in >90% of the survey respondents rating the pilot curriculum as outstanding or very good. Several minor suggestions for improvements were provided based on the two following open-ended questions:

- Please describe any technical difficulties that you experienced with the pilot phase of the online lecture series.
- Please suggest any changes to the online lecture series that you would like us to make.

Suggestions in response to these survey questions as well as direct personal feedback from participating residents were used to enhance the final version of the curriculum. Continued data collection of satisfaction with the online curriculum will be solicited and analyzed to continually upgrade the online curriculum throughout its life.

The final (summative) outcome measures were designed to gauge whether the online curriculum effectively addressed the gaps that it was designed to address. We queried:

- Comparison of the scope of the final curriculum to the ABP blueprint document (verifying the final curriculum covers the full scope of content as outlined by ABP)
- The overall use rates of the online curriculum by the residents to verify that we have adequately addressed the issue of accessibility.
- Review of uploaded curricular materials to verify that each learning unit has a statement of the objectives followed by a measurement of the achievement of those objectives

The preliminary results of the review of the scope of the online curriculum compared to the

ABP blueprint document reveal that of the nearly 90 lectures that have been developed to date, approximately 20% are entirely new lectures on material that was not previously covered in our face-to-face curriculum. This is a significant improvement over what our program was previously providing. When the curriculum is complete a final analysis will be performed to see if there are any significant gaps in the scope of content of the online curriculum compared to the ABP blueprint document.

The utilization rate that was expected of the residents and provided to them as a benchmark was a 50% completion by the end of the first year of the online curriculum. Our project team has been actively recording and posting the online lectures for the past 8 months so 90% of the curriculum was accessible. The overall use rate of the curriculum by the residents has been 40%. It is fully anticipated that the final use rate, after completing the first year of development, will meet the 50% threshold for the curriculum.

Finally, the online curriculum was reviewed to verify that each learning unit has learning objectives and accompanying measures of achievement. Nearly 100% of the posted curriculum complies with these criteria. Effective communications of requirements, sample templates, and review processes are credited with the nearly perfect compliance.

Thus, following a systematic process of instructional development, ADDIE, with accompanying project management checks and balances, professional development for faculty that provided rational for and clear steps toward curriculum re-form, technical support, and department buy-in led to the successful development of an enhanced pediatrics online curriculum. The learning and instructional design principles provided a framework that guided the construction of robust and effective instruction that seem to be well accepted by residents, the learners. Certainly enhancements will be necessary in the future as content revisions are suggested and new

technologies emerge. There is also a greater need now to develop a better understanding of what affects this new delivery mechanisms is having on resident learning and practice in the long-term and the relationships between online learning and board scores.

PLANS FOR THE FUTURE: ENHANCEMENTS, RESEARCH, CONCLUSIONS

In moving forward with this project it will be important to measure the future achievement of the learners exposed to this new curriculum on norm referenced examinations like the American Board of Pediatrics' certification examination. The 3 and 5 year running averages will be followed to see how the new online curriculum effectives the performance of the pediatric residents on exams. Other interesting future areas of investigation may be to examine the barriers and affordances that promote and interfere with the use of online curriculum by pediatric residents or the use of new technologies to make the learning engagement more portable and on-demand with new technologies like smartphones. This will be particularly important to examine, as it appears that E-learning and the use of new portable technologies will continue to grow in medical education. The needs of users will need to be clearly understood in order to avoid developing curricula that are ineffective and under utilized.

Following established instructional design processes and considering learning principles becomes even more important as education shifts away from face-to-face modes. This work for the Upstate Medical University pediatrics residency program was deemed successful based on it approach to transforming its classroom lecture series to online instruction using instructional design principles and process.

KEY TERMS AND DEFINITIONS

American Board of Pediatrics (ABP): The governing agency that certifies pediatric practitioners within the United States of America. The certification process involves passing a norm-referenced examination upon completion of pediatric residency training.

American Board of Pediatrics Blueprint Document: This is a 212-page document that outlines the core content of the *American Board of Pediatrics* certification exam that is taken upon completion of pediatric residency training.

Core Curriculum: The core curriculum is the agreed upon scope of material that defines the significant knowledge that is contained within a domain like pediatrics. It encompasses what would be reasonably expected for a practicing pediatrician to know.

Course Management System (CMS): A packaged program that is used for creating, delivering, and managing online instruction. Often course management systems include menu and template based tools to help developers easily build content, communication, testing, and other types of screens that support teaching and learning. These systems often also include management functions that support assignment grading, monitoring learner access, and completing course evaluations. Examples of popular CMS include BlackBoard, WebCT, and ANGEL.

E-Learning: Also referred to as online learning, it is the use of internet technologies to deliver a broad array of educational materials.

Instructional Design: Phase with the instructional systems design process where instruction is planned that is designed to close an instructional gap based on learning theory and instructional design theory.

Instructional Development: Phase with the instructional systems design process where instructional materials and processes are built based on a blue print developed during a design phase.

Instructional Systems Design: Systematic process for designing and developing instruction. Generally includes analysis, design, development, implementation, and evaluation phases.

Interface Complexity: A term that describes the degree of complexity that a user encounters when engaged with a digital medium like a website. With increasing complexity of the interface of a webpage, for example, the user required to dedicate cognitive energy to learning the intricacies of the interface as opposed to the content that is contained within the website.

INTRODUCTION

There are several reasons why university-based researchers and community groups may choose to collaborate together on research projects. Involving the end-users of the research data in the research process often motivates them to integrate the results into new policies, procedures, and education programs. Research outcomes therefore become more relevant to the community members than would be the case using a more traditionalistic approach to research (Morrison & Lilford, 2001; Patton 1997). Community-based partners fully immerse themselves in a collaborative research process as they strive to underpin their interventions with other complementary concepts

or evidence-based theories. They are then better positioned to promote social change.

Furthermore, collaborative projects provide an educational opportunity for partners to develop a collective consciousness in addressing the issues at hand (Gallagher, Easterling, & Lodwick, 2003; Karim, 2001; Minkler & Hancock, 2003). The problem is viewed from multiple perspectives as university-based researchers and community professionals contribute unique strengths and share research-related responsibilities within the social and cultural dynamics of the partnership (Gibbon, 2002). Simultaneously, university-based researchers are able to come to a better understanding of the community of interest and its changing realities. The cultural differences of both groups are acknowledged, and sensitive strategies can be collaboratively developed in which the roles

DOI: 10.4018/978-1-60960-503-2.ch416

and expectations are clearly outlined (Agency for Healthcare Research and Quality, 2003). Full advantage can be taken of the knowledge, experiences, and perspectives of professionals in the community as they provide input on all aspects of the research project. Thus, the research process becomes a collaborative, co-learning, community-building experience.

There are obvious benefits to working in collaboration. However, real collaboration takes time; time to engage in meetings, complete accountability processes, and resolve problems. The delicate balance between democracy and efficiency can be compromised when you have to choose between equal participation and looming deadlines (Stoecker, 2003). Weaver and Cousins (2004) described this dilemma as assessing manageability or having to make a choice between achieving complete diversity on the researcher-community team and the unwieldiness of working with a large committee. Compromise is often necessary.

This article describes our experiences using a collaborative approach involving university-based researchers and community professionals—in this case, long-term care (LTC) managers, administrators, and hospital-based educators and researchers—to create an online dementia care training program.

BACKGROUND

The Sisters of Charity of Ottawa Health Service (SCOHS) is a corporation with a teaching chronic care hospital and two LTC facilities. Community professionals at SCOHS recognized that their healthcare providers were facing challenging behaviours from persons suffering from dementia, which has been known to lead to staff burnout, distress, and high turnover rates. The community professionals felt that this problem could be partially ameliorated with staff education through e-learning. They contacted a professor in the Fac-

ulty of Education at the University of Ottawa who was conducting research on e-learning. Together, they agreed that conducting a project involving frontline workers in LTC facilities that addressed this issue would be mutually beneficial. Additional experts were recruited to join the project, including psychologists as content experts, e-learning course developers and pedagogy experts, and evaluators experienced in online course evaluation. Six pilot LTC facilities were identified, and representatives from each facility were included in the research team.

THE ONLINE DEMENTIA CARE TRAINING PROJECT

The research group used the Demand-Driven Learning Model (DDLM) (MacDonald, Stodel, Farres, Breithaupt, & Gabriel, 2001, see Figure 1) to guide the design, development, delivery, and evaluation of the bilingual dementia care training program. The program was targeted towards frontline healthcare providers (registered and nonregistered) who care for persons experiencing dementia in LTC facilities.

Conducting the Needs Assessment

As advocated in the DDLM, the first step of the project involved identifying the needs of the learners. The university-based researchers conducted three in-depth focus group interviews with seven healthcare providers (prospective learners) and two site coordinators who would serve as the on-site support persons for the learners during the implementation of the program. Through the needs analysis process, community-based stakeholders were able to provide input regarding the design, development, and delivery of the dementia care training program. The results of the needs analysis are published elsewhere (MacDonald, Stodel, & Coulson, 2004).

Figure 1. The demand-driven learning model (MacDonald, Stodel, Farres, Breithaupt, & Gabriel, 2001)

Designing and Developing the Program

The course facilitator, a content expert and psychogeriatric nurse with no e-learning experience, was responsible for putting together the first draft of the program content and learning activities. To ensure the content was authentic to the community experience, as recommended by the DDLM, the course facilitator drew on her experiences working with frontline personnel who provide care to individuals with dementia. Once she developed the content, the pedagogy team reworked it into an appropriate format for e-learning. This was a time-consuming process, but one the academics felt strongly about as they were concerned with respecting online pedagogical principles and the quality of the online course design.

The pedagogy team encountered competing tensions as they developed the content using a collaborative approach. Ensuring the content was comprehensive, another DDLM component, was difficult to achieve due to time limitations. The content had to be chunked into sections that could be completed in 30-minute learning sessions,

which limited the amount of content that could be included. Thus, content experts were advocating for the inclusion of a wide range of content, while other stakeholders wanted to reduce the amount of content, as they were aware of the limited time the learners would have to engage in the program.

Other issues related to time also affected the collaborative process. The pedagogy team had limited time to develop the content and adapt it to an online format, due to deadlines imposed by the funding agency and delays in hiring qualified project staff. Once the content was approved, it was given to the instructional designer to be put online. The instructional designer developed the online program using WebCT, the online course management system adopted by the University of Ottawa. However, the pedagogy team quickly realized that, while having many advantages, this system limited certain aspects of course design and evaluation. Time constraints and the initial decision to work with the University of Ottawa's Centre for E-Learning prevented the research team from exploring alternatives to WebCT.

The instructional designer questioned the efficiency of the collaborative process adopted in

this project. He felt there were too many people trying to reach consensus. He postulated the lack of efficiency was because “the roles of the people involved were not well-defined.” Similarly, not all stakeholders felt they were heard when they contributed expertise. One team member stressed that learners must be honestly informed about the time commitment required to participate in this project, prior to their consent and participation. Another found the program hard to navigate, and suggested changes be made in the online layout. However, despite these warnings, neither the amount of content was reduced to meet the learners’ expectations and needs, nor the navigation improved before the program was offered, and both were identified as weaknesses of the program in the evaluation (MacDonald, Stodel, & Casimiro, 2006). These changes did not occur due to time constraints and/or lack of project ownership. Compromise, rather than consensus, became the decision method of choice, especially as the deadlines loomed closer.

A significant factor in the lack of project ownership was that the principal investigator had to leave the project suddenly at the beginning of the production phase. This temporarily compromised the project’s leadership. Leadership is necessary for the smooth running of a project. This leader should bring expertise in optimizing group functioning, such as defining roles and orienting the group towards action. This person should also ensure equality among members and aim for consensus.

Delivering the Program

The completed program was delivered to 95 learners at six sites in three provinces across Canada. Forty-nine (52%) enrolled in the French language program, and 46 (48%) enrolled in the English language program. Learners were expected to spend two hours each week, at their convenience, reading the content and completing the learning activities and evaluations. Each site

had a coordinator whose role was to support the learners in their learning and with the technology. These site coordinators were an integral part of the pedagogy team.

Throughout the delivery of the program, the site coordinators met with the pedagogy team for 30 minutes each week via teleconference. These meetings enabled site coordinators to keep track of the timelines set out for the learners, and allowed them to provide feedback to the pedagogy team regarding the learners’ experiences and progress with the program. These meetings were instrumental to the success of the program. Because of the regular feedback from the site coordinators, the pedagogy team was able to address problems and concerns that arose in an expedient fashion. For example, when it became apparent that the program required significantly more than two hours a week to complete, and that some of the learners felt frustrated and overwhelmed, the pedagogy team promptly adapted the program by reducing the number of required exercises and extending the deadlines to complete the program. A number of site coordinators attested that the learners immediately felt less pressure once the amount of work was reduced.

Evaluating the Program

One of the reasons the community created a partnership with academics was to help develop strategies for evaluating the program. The university-based researchers had specific knowledge of evaluation and online data collection procedures. Using the DDLM evaluation tool (MacDonald, Breithaupt, Stodel, Farres, & Gabriel, 2002) as a guide, they drafted the evaluation instruments and invited the pedagogy team to provide input. As a result, survey questions were added, deleted, or modified. This collaborative process resulted in the development of relevant evaluation tools tailored to the needs of learners in LTC facilities. Further, the evaluation team conducted in-depth semistructured interviews in order to obtain a rich

description of the stakeholders' experiences with the program, specifically in terms of the DDLM components. Interviews were conducted with ten learners, all six site coordinators, the course facilitator, and the instructional designer. Knowing the importance of management buy-in for this program to be viable in the future, the pedagogy team also interviewed the higher management of the six LTC facilities to gather their impressions of the value of the program for their organizations.

The evaluation team conducted, transcribed, and analyzed all the interviews, compiled and analyzed both the quantitative and qualitative data (French and English), and wrote the final report (MacDonald & Stodel, 2004). The evaluation continued to be a collaborative process as both community professionals and university-based researchers were part of the evaluation team. Moreover, the evaluation team received input from the pedagogy team. This decision making process worked well; the group weighed the importance of outcomes relevant for the learners' practice—a reality best understood by the community—against the outcomes related to the e-learning experience—a reality best understood by the university-based researchers.

Disseminating Findings

The university-based researchers took the lead role in the dissemination activities. However, input received from community members was critical to ensure the quality and relevance of the final products. Input from community members allowed the university-based researchers to create a PowerPoint presentation and two professional posters comprising an overview of the project and its findings that could be used by the community to share details of the project at conferences or in their local healthcare communities. While these individuals may not have had the time or the interest to prepare the presentation material, they were able to actively participate in the dissemination process by using materials created by

the university-based researchers. This highlights another benefit of taking a collaborative approach.

Writing this article involved a collaborative effort between three university-based researchers and one community member. The collaborative approach added to the amount of time necessary to complete the manuscript, yet it added to the quality and accuracy of the article on several fronts. First, both the university- and community-based members' perspectives were reflected. Second, perceptions of the process of running the project were shared and elaborated. Lastly, the workload was shared between the authors. In the end, the process of collaborating in the publication process was a positive experience in which co-learning took place, and a stronger article resulted.

FUTURE TRENDS

The implications and lessons learned from this research are important to consider when conducting future research in this area. Although several of the community members were experienced at and capable of conducting research and disseminating the findings without the assistance of the university-based researchers, they felt a partnership with academics would strengthen their research position in the field of e-learning, and they would gain information on quality e-learning design. In turn, the academics wished to apply their knowledge to the healthcare field, but lacked the intimate knowledge of this group of learners. Consequently, they benefited from the input of the community members and gained valuable knowledge of the content area (dementia care) and healthcare culture. Even though the university-based researchers had much to gain from the partnership, this project was instigated and led by members of the community.

Our experience suggests that taking a collaborative research approach significantly increases the amount of time required to complete a project, though the research team felt it was a worthwhile

trade-off, given the contributions made by each member. We acknowledge that failure, at times, to reach consensus and the pressure of timelines to complete this project by a specific date compromised the quality of the design. From an e-learning perspective, it is critical that the content be developed early in the process. A common fallacy is that once the content is developed, it can be put online quickly.

Stoecker (2003) suggested that it is an unrealistic expectation that those involved in a collaborative project be equal partners in all aspects of the process. His claim appears to be grounded in concerns for the time demands on community members. Indeed, as Israel, Schulz, Parker, Becker, Allen, and Guzman (2003) have suggested, efforts were made to involve community members in the publications resulting from the research process, but few had the time to do so. Sullivan, Chao, Allen, Koné, Pierre-Louie, and Krieger (2003) recommended that communities receive concrete benefits in return for their involvement in research partnerships, noting that without such tangible benefits, the partnership may not be advantageous to the community.

We also realized how important communication is to successful collaboration. Working in a large team means that many relationships need to be developed and maintained. In this project, constructive criticism about the program was sometimes taken as a personal affront by the individual responsible for that aspect of the program, and hard feelings resulted. This point becomes even more poignant when communication between members is conducted via e-mail where tone, emotion, and other nonverbal cues are lost. In the case of this project, misunderstandings in communication caused some minor conflicts, but effective communication also allowed the rifts to be resolved.

Clarification of members' roles at the beginning of the project is also critical. In writing this article, it emerged that the evaluation team was

ill-defined; each of us had a different view of whom the evaluation team comprised. Further, one of the pedagogy team members who had experience in online pedagogy and e-learning applications in healthcare felt that her expertise was not used as much as it could have been. Not only was this a frustrating experience for her, but she also predicted many of the problems reported during program delivery.

In the end, the project resulted in an educational opportunity for all involved (Minkler & Hancock, 2003). The community of program personnel succeeded in offering a generally well received e-learning program to help healthcare providers manage persons with dementia. They also enhanced their skills for designing, developing, delivering, and evaluating a successful e-learning program by using the DDLM. The university-based researchers learned more about healthcare in general, and dementia care specifically, obtained further appreciation for healthcare providers' needs for learning online, and became aware of the values and complexities of collaboration. Further, the university-based researchers also profited by gaining access to data for research purposes.

CONCLUSION

In sum, the adoption of a collaborative research approach with a community of professionals is not only beneficial but also desirable. Collaboration allowed multiple views, attitudes, and experiences to strengthen the program. By describing the complexities involved in this process, we reveal both the challenges and achievements inherent in designing a quality online learning event through collaboration. Moreover, by addressing some of the details involved in this process, we hope that our experiences help others plan collaborative partnerships with community professionals, and develop collaborative e-learning programs for healthcare providers.

KEY TERMS AND DEFINITIONS

Collaborative Research Approach: A research approach that uses the strengths of both researchers and community-based practitioners to increase the quality of the research process and the impact of the research outcomes.

Demand-Driven Learning Model: An e-learning model that is grounded within a constructivist framework and defined by five interrelated dimensions that, in concert, create a high-quality e-learning experience: superior structure; three consumer demands of content, delivery, and service; and learner outcomes.

E-Learning: Learning that takes place via the Internet.

Long-Term Care Facility: A licensed residence for individuals who require personal support and nursing care, and who cannot remain in their family home, because support at home (from family or agencies) is insufficient or unavailable. While funding sources may differ, LTC facilities and nursing homes can be categorized together under this definition.

Instructional Designer: Person who uses technology (media) to design optimised learning events. Instructional design is historically grounded in cognitive and behavioural psychology.

Pedagogy: The profession, art, science, theory, principles, or methods of education, instruction, and teaching.

Psychogeriatric Nurse: A nurse whose practice is focused on older people (usually 65 years of age or older) with mental illness and/or cognitive impairment.

Web Course Tools (WebCT): An e-learning platform and online course management system used extensively in colleges, universities, and other educational institutions. WebCT supports online tools such as discussion forums, e-mail, live chat, and whiteboarding, as well as content in various formats (e.g., html documents, Web pages, and so on). WebCT recently merged with Blackboard, another leading provider of educational software.

Chapter 4.17

Gaming and Simulation: Training, and the Military

Sheila Seitz

Windwalker Corporation, USA

Courtney Uram

James Madison University, USA

ABSTRACT

The purpose of this chapter is to provide a brief summary of the military's use of gaming and simulation to accomplish training. Historically, the military has been a forerunner in the exploration of training techniques that incorporate aspects of games and simulations. Training tools emerge in various gaming formats such as simulations, edutainment, commercial-off-the-shelf games (COTS), and serious games. To develop training in the form of games or simulations, elements of instructional design must be considered to include learning objectives, game play, and feedback. Emerging technologies provide possible solutions to training challenges such as achieving affective

learning domain objectives and the portability of training. The military, as an early adapter of games and simulation, continues to forge the way by integrating gaming and simulation, instructional design, and emerging technologies to achieve the ever growing demands of training.

INTRODUCTION

Gaming and the military have a long tradition together, beginning with the use of toy figures within sandbox representations, progressing to complex board games requiring complex analytical skills, and evolving into current use of sophisticated computer models, gaming engines, and high definition 3-D graphics to create virtual worlds of combat. The military has historically

DOI: 10.4018/978-1-60960-503-2.ch417

used technology to “maximize the efficiency and effectiveness of all their activities, training and education.” (Fletcher, 2009, p. 72). Current training tools include a wide range of application of technologies. Simulators, sophisticated machines relying on computational models to mimic the actual experience of soldiers, assist to train in various tasks such as driving a truck, steering a ship, flying an airplane, or shooting a weapon. Games are created to encourage thought and practice in decision making from simple tasks to more complex work of war planning. When simulation is combined with elements of gaming, opportunities emerge to encourage effective training with the unique audience of learners found in the military.

The military considers each member a life-long learner. This core principle presents many challenges to the development of training and becomes accentuated in the development of games and simulations. Specifically is the challenge of reaching today’s military audience of Soldiers, Sailors, Marines, and Airmen; mostly made up of young adult males. (Watkins & Sherk, 2008). They are members of what is known as the Net Gen, the generation cohort who came of age with the evolution of the internet and exponential growth of technology’s role in society. For this military audience, “Learning is participatory; knowing depends on practice and participation. Digital resources enable experiential learning—something in tune with Net Gen preferences. Rather than being told, Net Geners would rather construct their own learning, assembling information, tools, and frameworks from a variety of sources.” (Oblinger & Oblinger, 2005). The military has responded with various methodologies to include games and simulations, serious games, commercial-off-the-shelf (COTS) computer games, and Massive Multiplayer Online Games (MMOG). This chapter discusses the success and challenges of these methodologies, identifies critical aspects of instructional design when developing games for military training, and suggests emerging technologies be examined as new methodologies in the military training field.

History of Gaming in the Military

Roberts (1976) noted that gaming as training was “often used to train military officers” (p. 3). Games found in the military took many forms and emerged as effective methods for training. Chessboards acted as terrain maps and chessmen as soldiers. Sand tables with miniature models to represent armies gave leaders the ability to visualize battles and play out possible scenarios. The Prussians instituted the practice of wargaming around 1824, with the American military adapting wargaming for training later that century. William McCarty Little admired the value of wargaming and ensured that it became a significant part of the curriculum at the newly established U.S. Naval War College in Rhode Island. (Gray, 1995).

Eventually, terrain maps and wooden blocks replaced chessboards and chessmen as civilization progressed. By World War II, wargaming marked an immense turning point for training and development. War games were something used by all super powers (Roberts). The simulation that occurred during the game process was treated as a training technique and evolved into paper based exercises that integrated mathematical algorithms to model elements of warfare such as movement and attrition (Smith, n.d.).

During the 1950’s the Rand Corporation used ideas that emerged during the evolution of simulation training and war gaming to create a board game. Building upon their research and the ideas of Clark Roberts, the project resulted in:

“the formalization of the playing board with a gridded overlay to manage movement and engagements; the use of a Combat Results Table to formalize the results of the battle; the incorporation of terrain types that influence combat activities; a turn-based play mechanism; and the use of dice to add random outcomes to the battle” (Smith, n.d.).

With the onset of the computer age, the abilities of wargaming as training grew exponentially.

A presentation by Hilton G. Weiner at the 35th National Meeting of the Operations Research Society of America in 1969 (Weiner, 1969), examined the trends of the time in regards to military gaming. He likened the games with “confrontational analysis” (p. 1) and identified the ability of computers to advance the technique. Specifically, he noted that computers allowed greater detail in simulation and provided accelerated bookkeeping skills. These advancements furthered abilities of time-sharing, multi-agency and standardization. However, he felt that while phenomena of warfare such as machines and munitions could be captured in the war games, much work was needed to capture the other phenomena of motivation, morale, and miscalculation (p. 5). He called for further research in the improvement of understanding the phenomena and increasing the ability to model them.

The use of wargaming in training continued to evolve throughout the 1970s and at the beginning of the 1980’s, an emphasis was placed on combining the best features of war gaming and analytic modeling to build strategic analysis for existing threats of nuclear warfare. Building upon RAND’s expertise in these areas, the US Defense Department supported the efforts of the Rand Strategy Assessment Center (RASC) which guided much of the research and advancement in the area of training and war gaming throughout the decade. (Davis & Winnefeld, 1983). Davis (1986) called for the need to create computer programs that were transparent yet able to explain the decision that occurred during the simulations of wargaming. While much advancement was made with the now familiar Red and Blue Agents programs (Schwabe & Wilson, 1990), the end of the decade and the Cold War would bring new demands to the field.

Throughout the 1990’s, investigators of wargaming as a training technique recognized in numerous studies the need to advance the models driving the artificial intelligence with the computer programs and increase the ability to share data across those institutions engaged in the field.

(Bennett, 1993, Hillestad, Bennett, & Moore, 1996, and Davis, Bigelow, & McEver 2001). As mentioned by Bankes (1991), many of the models did not adequately reflect the new requirements of warfare, a shift from the force on force of the Cold War to more of contingency based operations known as Military Operations Other Than War (MOOTW) (Joint Publication 3-07, 1995). Yet, the focus of wargaming as a training technique remained that of increasing understanding as opposed to outcome based performance, i.e. winning the war. (Schwabe, 1994).

Today, games and simulations function as military recruiting tools (Zyda, 2005), educational learning tools (Gredler, 2004; Gee 2003), and corporate training tools to foster learning in professional, corporate, or adult education. As for the military specifically, games and simulations are teaching tools at all levels of education (Babus, Hodges, & Kjonnerod, 1997). Collective and individual training designs benefit from the critical thinking and flexibility encouraged by games and simulations. These learning tools address many objectives: rehearsing behaviors, teaching skills to troops, and assisting policy makers in evaluating, identifying, and improving protocol.

Current regulations within the military identify distributed learning as a key to facilitating continuing education programs (AR 370-1, 2007). Included within distributed learning are various forms of gaming and simulation described as interactive multimedia instruction, computer aided instruction, simulation, and interactive training technology (including stand-alone and on-line games.) Training commands are encouraged to leverage “distributed-learning concepts, when cost efficient and effective training will result.” (p.15)

The military possesses a rich history of training and education to draw upon as it continues to develop and implement games and simulations as viable training tools. Central to this effort is the ability to consider the learner, more specifically the range of learners that exist in the military, when designing games and simulations for training.

As noted by Klopfer, Osterweil, & Salen (2009): “Lastly, it is important to acknowledge that games and learning has a history that predates the advent of modern video games... This history has taught us several important things, not the least of which is that players determine how they learn.” (p.8).

Range of Gaming within Training

The study of gaming within the military is somewhat confounded by the wide range of definitions that exist to explain what is and is not considered a game. As noted by Klopfer, Osterweil, and Salen (2009), “...perceptions of what games are (are or aren’t) continue to cast a heavy shadow over the games and learning space.” (p.7). The range of games considered for training, to include occurrences within the military, are games, simulations, serious games, COTS games, and massive multiplayer online games (MMOGs). Perhaps the best approach in examining games within military training is suggested by Caspian Learning (2008), “...it is more useful to look at the general literature placing these terms in their cultural context.” (p. 14).

Games and Simulations

Games and simulations have unique characteristics that differentiate them from each other (Kirkley & Kirkley, 2004; Prensky, 2001; Ricci, Salas, & Cannon-Bowers, 1996). Games are defined by Gredler (2004) as “competitive exercises in which the objective is to win and players must apply subject matter or other relevant knowledge” (p. 571). Simulations conversely are “open-ended evolving situations with many interacting variables” (p. 571). Understanding games paves the pathway for recognizing the structures, standards, and techniques found in simulations (Aldrich, 2004). Mike Zyda, a professor of gaming at the University of Southern California and a key contributor to the successful game, *America’s Army*, explains that, “The definition of games is story, art and

software.” (Federation of American Scientists, 2006; Zyda, 2005). The primary difference, when considering military applications, may be found in the purpose or application of the game.

While it is important to understand that games and simulations differ in many aspects; they often share an important commonality. Each works to foster experiential learning (Gredler, 1996). Within this model of learning, elements such as reflection and debriefing are significant (Thatcher, 1990; Kriz, 2003). If the context of the game or simulation is primarily to construct a story whose intent for learning is to encourage game play for entertainment, it remains a game albeit with learning requirements. The game may employ experiential learning as an element, perhaps a motivator. However, the game would not be classified as an “instructional game”. According to Tennyson and Jorczak (2009), “Instructional games have specific learning outcomes as primary goals.” (p. 5).

A helpful comparison of games and simulation within the military is found with *America’s Army* and *DARWARS Ambush*. *America’s Army* is a game that was developed specifically for the purpose of recruiting new soldiers by the U.S. Army. The game takes the form of a first person shooting perspective and role plays the life of a soldier. While some military units have used the game for training, its primary purpose and design is to attract young men who enjoy gaming and may gain an interest in the U.S. Army while playing. *DARWARS Ambush* is a simulation game that simulates a vehicular movement (patrol) within a combat environment. The purpose of simulation is to train multiple people within an immersive environment how to react to possible ambushes when part of a vehicular patrol. While *DARWARS Ambush* evolved from a stand-alone, single player simulation to the current version of an immersive environment that changes based on lessons from the actual combat environment and involves multiple players, its primary training purpose persists.

The military's success with games and simulations may be found in the wide variety and continuous adaptations that are applied as training needs increase and diversify. At the National Defense University, gaming and simulation have been combined to create learning environments which foster analytic skills and enable the process of concept validation leading to doctrine development. (Joint Forces Quarterly, 2009). To do so, one must consider that, "useful analytical environment in which to identify and weigh policy options and needs is the goal of good game design. (McCown, 2005). Flexibility and adaptability can be found in projects such as the development of various leadership games noted in the work of Iuppa and Borst (2007). During these projects, developers experimented with the balance of computer modeling for simulation and the interplay of human actors with virtual avatars to achieve training objectives. Over time, they found what worked and did not work was based on its appropriateness toward implementing the training objective.

Challenges with games and simulations are most exemplified in selection of the appropriate instructional delivery to meet the training objective. Choosing an advanced technological tool simply because it is available does not guarantee effective training. Investigations into simulators (computer generated environments to replicate the actual skill which the learner must perform) supports this; as Yardley (2003) states that in training, one must consider if the technology is, "... appropriate for increasing the use of simulation and strategies for purchasing and implementing simulators." This finding emerged as he studied the Navy's desire to balance training which normally occurred at sea with the possibilities of what could be done while ships are in port.

DARWARS and America's Army are motivating examples of the diverse goals which can be achieved through games and simulation. The military continues to lead the way in developing the possibilities both within training goals and

outside of the goals, such as analytical analysis, recruiting, and doctrine development. However, more research is needed to determine what learning outcomes can be systematically achieved by the use of individual and multiplayer games to train adult participants in acquiring knowledge and skills while sustaining the ability of games to provide intense and engaging experiences (O'Neil & Perez, 2009).

Serious Games

When applied in a non-entertainment realm, gaming and simulation technology results in serious games (Zyda, 2005). According to Susi, Johansson, and Backlund (2007), the term serious games have been defined, but no true definition of what it actually is exists. Taken as a whole, Susi, Johansson, and Backlund's (2007) interpretation of serious games from present research is defined as "digital games used for purposes other than mere entertainment" (p. 2). Serious games emerged from research within the military training field. Observing great potential for other occupational training, the Woodrow Wilson Foundation funded the Serious Games Initiative (www.seriousgames.com). Serious Games "...are characterized by their specificity and applicability for particular work-related purposes." (Klopfer, Osterweil, & Salen, 2009, p.21).

The 1980's decade marked the time when serious games, which often take the form of simulations and games in electronic formats, were used throughout the military (BinSubaih, Maddock & Romano, 2009). As described earlier, these electronic wargaming formats would use computer modeling and data capabilities to create simulation centers where soldiers would gather to analyze and fight wars against the computer. The goal was a performance oriented outcome where the decisions were analyzed and evaluated rather than simply trying to "beat" the computer. As computing ability grew, so did the complex-

ity and effectiveness of these serious games to achieve training.

Not until 2002 were serious games recognized by other organizations. The Serious Games Initiative furthered interest in serious games beyond the military. This form of gaming was distinguished by its purpose “to train people for tasks in particular job”. (Klopfer, Osterweil, & Salen, 2009) The serious game industry, described as flexible and adaptable, has developed into a \$20 million dollar market (Van Eck, 2006). The military invests most heavily in the serious games market. (BinSubaih, Maddock & Romano, 2009).

Serious games cover a wide range of training opportunities for the military. These include: tactical experience, ambush, rifle range, foreign language and culture, leadership, post traumatic stress disorder and obstacle courses (BinSubaih, Maddock & Romano, 2009). Sawyer and Smith (2008) created a taxonomy to capture the range and application of current serious games development efforts. Within the taxonomy, military training is identified as “defense” and examples such as games for health (rehabilitation and wellness) and games for training (soldier support) are recognized.

One example of a serious game endeavor by the military that models the type of electronic games commercial and civilian entities are interested in is that of games developed for dismounted infantry leaders. (Beal, 2006). The project included three games to teach leadership skills at different organizational levels experienced by infantry leaders. Successes of these serious games included the ability to represent realism and fidelity to the actual combat environment due in large part to the involvement of subject matter experts early on and throughout the development of the games. The learners also valued the opportunity to learn desired leadership skills; the findings found this factor to be more important than ensuring the games were fun and entertaining.

Challenges in implementing these serious games involved capturing feedback for a high level of required cognitive skills in an artificial

intelligence model. The participants expressed the need for feedback from a human instructor vital to their learning. Continuing to improve models and consolidative representation, especially in such a dynamic combat situation, is one goal of the Modeling and Simulation Center Information Analysis Center (Henninger, 2009).

Also of interest was the finding that although the participants were of the digital native generation, not all found the technology to be intuitive or familiar. (Beal, 2006). Ensuring a serious game is navigable without interfering with learning is an important task of the developer. As pointed out throughout this chapter, stating clear training objectives for the games was critical.

Given the high cost of creating in-person training to address the skills at the center of serious games objectives, makes this genre of game a center piece for further research and investigation. As computing ability allows the fidelity of the experience to increase, it cannot be considered a panacea for all training. However, its effectiveness and potential justify development to continue, especially as training budgets are high visible targets both in military and corporate budget scenarios. The military’s contribution to serious games is significant; yet the influence of the military within body of research for serious games and training must be acknowledged and addressed. National education and workforce development goals may differ, generating more varied requirements from research. (Federation of American Scientists, 2006).

Commercial-Off-The-Shelf (COTS) Games

Current markets of COTS games include a plethora of titles that carry a military theme. A small sample of these games include: *Call of Duty*, *Close Combat: First to Fight*, and *Full Spectrum Warrior*. Because these titles are COTS, it is safe to assume the primary purpose of their development was not training but rather entertainment. However,

the military's National Simulation Center at Fort Leavenworth, Kansas, endorses the use of these games as training tools, validating their potential in preparing soldiers for combat situations. In their publication, *Commander's Guide to Games for Training*, (2006), it is noted, "Games can provide an alternative training environment at a lower cost. The tradeoff is a reduction in fidelity." (p.5).

The success of COTS development can be partially attributed to the investment of the entertainment industry in the wargame genre. As noted by Macedonia (2000), "The military cannot afford to ignore advances in industry, where the graphics systems for game consoles and personal computers have nearly doubled their performance every nine months for the last five years." While the fidelity, which is the ability of training to recreate the actual environment where the task must be performed such as the war zone for the military, is decreased by moving from a realistic environment to a virtual world, the savings in terms of both fiscal and time cannot be ignored.

Another element contributing to the success of COTS in military training is that of providing a training environment familiar to the target audience. (Ford, Barlow & Lewis, n.d.). Many soldiers today grew up alongside the internet and are quite comfortable using the technology for the purpose of learning. COTS provide a motivating environment through its natural design of engagement. If soldiers are aware of the training purposes with COTS, they may overcome the outcome based orientation (play to win) and focus on the feedback given by the game to grow in understanding of their personal skill development.

The primary challenge in using COTS as a training tool is achieving the goals of training. "COTS gaming systems do not generally have the assessment components that are critical for effective training." Hussain and Ferguson, (2005). This finding is shared by O'Neill and Perez (2009), "There is general consensus in our community that learning with interactive environments, such as games and simulations, is not effective when

no effective instructional measure or support is added." The communities these authors refer to are the developers of games and simulation for training and adult education purposes. While few would dispute that learning occurs while gaming, the challenge for adapting COTS for military training is in achieving the specificity of the learning goal and the requirement to measure training effects to justify critical resources. Other challenges such as licensing fees and use of appropriate technologies to achieve training also exist.

To balance the evident worthiness of COTS for training with the need to ensure the targeted learning is achieved within training, it would be helpful for future training developers to provide policy and guidelines in this area, "Subject to the evaluation and trialing of games, the policies and practices for the effective use of games must be produced." (Ford, Barlow & Lewis, n.d.)

Massive Multiplayer Online Games (MMOGs)

Massive multiplayer online games (MMOGs) are another type of gaming medium the military is exploring. MMOGs offer collaboration and sharing of knowledge, skills, and values with other players both inside and outside of the game (Gee, 2003). MMOGs encourage individuals to think as a team and "make soldiers to think critically about their surroundings and enhance their situational awareness" (Curtis, Thomas & Ritter, 2008).

In their attempt to create elements of military training that address changing tactics of asymmetric threats, Fu and et.al (2007) investigated the use of MMOGs in developing and distributing training demonstrations. While training demonstrations exist in many forms to address different objectives, Fu, et.al, focused on 2-D animated representations with the intent to achieve procedural knowledge objectives. They used MMOG in the development of the demonstration, seeking synchronous feedback from soldiers currently implementing tactics in the war zone who pro-

vided current and relative data. The format of a 2-D animated representation provided a familiar training format for the target audience of soldiers. While the training demonstration did not attempt to achieve all training requirements, it proved worthy of development to provide one type of training tool within a toolkit of training sources.

Challenges with MMOGs and use in military training include security, cost, synchronous participation and connectivity of the technology. Because applications of MMOGs involve real time interactions between avatars driven by actual soldiers, knowledge exchanged should be shielded from possible enemy actors. This requires similar security measures used with existing military networks; the unique requirement of 2-D virtual world representations further implicates current challenges in this area. (Axe, 2008). While significant cost savings can be realized with MMOGs by reducing the logistical requirements of bringing soldiers and equipment together to train, the cost to develop realistic virtual representations must be carefully managed. The success of using MMOGs in the development of the training demonstration relied on synchronous participation of soldiers. Saving logistical costs in moving soldiers to a central place to train and away from the war zone is one advantage of MMOGs application; however, bandwidth and connectivity have persisted throughout the current decade as challenges for the military. The advantage of MMOGs may be lost to the lack of connectivity and bandwidth required.

Despite these challenges, the benefits of MMOGs and the possibilities in developing future training remain worthwhile. As noted in a research study of wargaming and distributed learning (Van der Hulst, Muller, & Roos, 2008), "...decision making can only be mastered by repeating the task as many times as possible in a controlled yet relevant reality, combined with intensive reflection upon one's own performance." MMOGs demonstrate promise in providing training avenues of relevant reality and the ability to access reflection and feedback.

Key Factors when Implementing Games as Training

Objectives

The first task in designing games for training is to ask, "What task(s) do I want the learner to perform after completing this training?" This is especially relevant for military training: "Clearly defined training objectives are critical to training effectiveness. Training game developers should define specific training objectives before software development begins." (Beal, 2006).

In their study of military training, Fletcher and Chatalier (2000) clarify the role of objectives:

"Training objectives are most often expressed in terms of what students can do (skills), what they must know (knowledge), and/or the attitudes they must possess after they finish the instruction. In training, the objectives can be derived directly from the skills and knowledge required to perform a job. In the absence of these objectives, relevant, systematic design, development, implementation, and evaluation of the instruction is unlikely". (p.14).

By nature, objectives must be measurable. Within a gaming context, determining if low level cognitive skills such as knowledge or comprehension are achieved is a simple task. Multiple gaming elements have been created to move game play along by requiring the measurement of learning and provide designers many options. While developed for game play, these elements prove useful in evaluating learning. Simulation training designers have developed strategies allowing the measurement of higher level cognitive skills such as analysis and synthesis.

However, measuring affective skills such as motivation and attitudinal change is much more difficult. One strategy is to integrate decision points within the training and record the action of the learner. Choices are aligned to objectives and measure whether the desired outcome is met. Yet, this is only one strategy; if more games are

to be developed for training purposes, designers will need multiple approaches to achieve any affective behavioral goals. Writing measurable, sound objectives to attain affective performance learning goals continues to be a significant factor to creating successful training tools.

Game Play

A key characteristic of games is often referred to as “game play”. Rollings and Adams (2003) define game play as, “one or more causally linked series of challenges in a simulated environment.” Associated with this description are terms such as: competition, story, and reward. Game play provides a strong link between games and learning. “The promise of games is that we can harness the spirit of play to enable players to build new cognitive structures and ideas of substance.” (Klopfer, Osterweil,& Salen, 2009).

Yet, the goal to build cognitive structures is not always the game developer’s goal. This is where design goals for games that are to be used in military training differ from those of commercial game developers. Commercial games are primarily concerned with game play and interweave learning and game play to motivate the user to continue. A fine balance between failure, which is expected, and advancing forward, which is desired, is often described as key to a successful commercial game:

“The secret of a videogame as a teaching machine isn’t its immersive 3-D graphics, but its underlying architecture. Each level dances around the outer limits of the player’s abilities, seeking at every point to be hard enough to be just doable. In cognitive science, this is referred to as the regime of competence principle, which results in a feeling of simultaneous pleasure and frustration--a sensation as familiar to gamers as sore thumbs.” Gee (2008, p.67).

Games designed for military training may engage in the interweaving of learning and game play, however, the primary purpose of training drives design not game play. As mentioned with

serious games, most applications of games and simulations within the military motivate the user by providing the expected training within the experience of playing the game. While studying cadets who played a COTS game for training purposes, researchers reported that, “We found that leaders who are serious about using games for training want to use them to learn leader tasks and skills; they are less motivated to use them for fun.” (Beal, 2006, p.8).

The challenge for developers of military training games becomes in implementing game play within instructional design of a game whose purpose is training. If successfully accomplished, this can increase learner motivation with a positive effect in meeting performance outcomes. The developer’s challenge is to work with instructional designers to integrate elements of game play that create desired effects of motivation without interfering or distracting from the training goals of the game.

Iuppa and Borst (2007), in developing story based simulation for the military, identified elements of game play that can assist in achieving training goals. These include: navigation (allowing the learner to move around within the game and create a “sense of agency”); purpose (if the learner understands purpose of game play then becomes motivated to participate in the simulation); and competition (which can be with other people or factors such as a clock). The authors also state that narratives “afford the opportunity for learners to acquire tacit knowledge and leadership skills through anecdotes.” (p.60)

Feedback

In order to achieve the balance of game play (failure and success); the game design must be able to prevent the player from experiencing too much failure. Various types of feedback exist for this function, the most predominant tool being game hints or clues. While these tools occur in a subtle manner (between scene transitions or as an

optional navigational button), they become critical in assisting the player to advance within the game. The player thus learns through feedback.

Instructional design principles for adults state the importance of feedback within effective training. Lieb (1991) noted that adult learners often require specific knowledge, or feedback, regarding their learning to meet training objectives. The most common form of feedback is to provide correct answers to exam questions. Other techniques include visual clues that represent the correct information and compare against the information the learner generated. In analyzing the feedback, the learner comes to understand the knowledge and can apply it within the training task.

Many leaders in the military find that a key to the success of military training is the inclusion of feedback to the soldiers during and after a training event. The feedback is provided in a formal process known as the After Action Review (AAR). Unique to this process is that the soldiers generate the critique of the learning themselves, facilitated by the instructor or observer as opposed to the instructor or observer solely providing comments. Research has documented the difficulty in integrating feedback, “Modeling the human cognitive skills required for effective feedback during mission execution and critical thinking during after-action reviews has proven very difficult...to incorporate into stand-alone training games.” (Beal, 2006, p.8)

Since many games and simulations are implemented without instructors or facilitators, it is important design the game or simulation to include AARs. According to software developers, Virtual Heroes (2008):

“These data points (AAR) accomplish several critical goals. First, they ensure congruity between instructional and game design; learning objectives are now measurable outcomes. Second, AARs translates to clear return on investment for organizations who select learning based game products. Third and arguably most importantly, in

this virtual world, objectives translate to behavioral goals.” (p.5).

To link these critical elements of objectives and feedback, a variety of game play tools have been created to target specific aspects of learning. Developers at Virtual Heroes are focusing on integrating biofeedback data to learners while they engage in a simulation (2008). This technique is similar to an athlete that might monitor their heart rate while exercising, adjusting their actions in accordance with their goals. Another technique found in the simulations that Iuppa and Borst (2007) describe simply provides text based feedback to the player based on the decision they made during the game play. The feedback includes whether the decision was correct or not, a review of the decision made, and an explanation of how the decision is related to the desired training objective. These examples model the spectrum of technology within games that can be implemented to provide feedback, an essential element of effective training.

Emerging Technologies and Military Training

As the military continues to develop the use of games and simulations to meet their training mission, challenges continue to arise. Two specific challenges that appear to persist are: (1) achieving affective domain objectives and (2) portability. In searching for solutions, an examination of emerging technologies is useful.

Achieving Affective Domain Objectives

One key to effective training mentioned in this chapter is to identify measurable objectives, to include those for the affective domain. Traditionally these objectives would measure learners’ motivation, attitude, values, and other affective descriptors with instruments such as questionnaires, surveys, or indicator instruments. Training that centers around affective domain objectives may rely on intangible actions such as the informal

learning that occurs when learners communicate with each other regarding the training content. To achieve these objectives can be challenging; emerging technologies may offer some solutions.

While emerging technologies encompasses hardware and software products, this discussion of affective domain objectives is focused on specific Web 2.0 tools. Web 2.0 internet technologies, such as social networking tools, blogging and virtual worlds are emerging as parallel opportunities for learning in addition to serious games and simulations. Moreover, the technologies are proving to be particularly effective training tools for the military.

Social networking sites, such as *MySpace*, *Facebook* and *LinkedIn* provide a location on the web where people can interact with each other to form and support relationships. These sites include e-mail and instant messaging and encourage the user to generate their own content to display and share. The U.S. Army has incorporated this concept to some extent with its *Army Knowledge Online* (AKO) program. AKO is a central location on the World Wide Web for soldiers to utilize many services, among them the ability to dialogue with each other through the use of discussion forums. Topics on these discussion forums are generated by soldiers and by moderators, chosen for their subject matter expertise.

Considering social networks for integration with games in designing training programs reveals much potential. "Social networks themselves may also be powerful learning tools. . . . social networking application supports the game, but is not a game itself." (Klopfer, Osterweil, & Salen, 2009, p.14). Utilizing a social networking tool within a training program with affective domain objectives has many advantages, including the ability to support soldiers with communication tools that are familiar and appealing, especially when they are isolated by their mission or location. Social networking tools can also facilitate the dialogue required for successful implementation of this type of training.

The challenges of implementing such a social network include the ability to mitigate the risk of soldiers' confidentiality and maintaining high quality moderators who facilitate dialogue and ensure program integrity. Developer's must also consider how to create game play that calls for social networking tools while remaining focused on learning objectives. However, the ability of social networking tools to assist in achieving affective domain objectives cause them to be worthy of further investigation and experimentation within training programs.

Blogs are web-based platforms for hosting discussions around specific topics. These types of dialogues have long existed in electronic platforms, primarily within e-mail exchanges or on discussion forum boards. However, the structure of blogs has emerged as the preferred form by users of electronic communication methods (Brogan, 2008). Blogs often adapt guidelines such as e-mail policies to avoid abuse of the tool. Among the many advantages of blogs are that they increase trust while building a collaborative environment. Since blog postings are permanent, they build a wealth of collective knowledge. Participants tend to avoid posting information that is false because of the audience's ability to question and hold authors accountable. Promoting blogs may send a message to soldiers that they are trusted to share; censorship becomes the exception rather than the rule.

The military has had mixed experience with blogs. Many soldiers have posted their own experiences within a blog format for the world to read. Due to concerns of compromised information unintentionally reaching the enemy, policies were established to mitigate the risk. Soldiers continue to share their stories online in blogs; however, content must be screened by leadership to ensure that sensitive information is not being compromised. The military as an enterprise hosts public affairs (PA) sponsored blogs which are considered a tool in the PA mission. Discussion

forums continue to be the primary dialogue tool within training realms.

By adding blogs as a tool within a training program that is primarily dealing with affective domain objectives, developers expand the program's ability to reach a variety of learners. Also, learners' can gain a sense of ownership not only of their learning, but as part of the training program itself. Combining these aspects with a gaming format may prove to be powerful strategies to achieve challenging training goals.

Virtual world is a term often used to describe a 3-D computer simulated environment where people interact via an avatar. The extent to which content is mostly generated by the users is unique to virtual worlds. (Rezed.org, 2008). Virtual worlds are an example of a term described by Dede (2007) as a MUE, an acronym for Multiuser Virtual Environment. In his research, Dede explores MUEs as a possible format for schools in the future. Virtual worlds and MUEs are relatively new (*Second Life* began in 2003). They share many attributes of serious gaming formats, yet little data exists regarding these formats as a viable training tool. Many large corporations and universities are exploring the potential of MUEs and virtual worlds for educational purposes.

The military is exploring the use of virtual worlds. The U.S. Army teamed with commercial entities to launch five pilot projects in 2008. (U.S. Army, 2008) The pilots focus on various training venues to include information models for wounded soldiers, collaboration between representatives of several different federal agencies, and preparation of new recruits with virtual drill sergeants and recruiters. Forterra Inc., a commercial creator of virtual worlds, supported the U.S. Army in an endeavor to fill training gaps existing for deploying units (McCaskill, 2005). Testing of a prototype demonstrated that virtual worlds can support a wide range of military training audiences with relevant experiences based upon current combat conditions at multiple levels of warfare.

For the military, virtual worlds can enable those soldiers who share a common interest in the subject matter of the training to dialogue and extend learning beyond the training content presented in a standalone version. Osmotic conversation is that information which flows in the background hearing of members so that they may pick up relevant bits as though by osmosis. (Merriam-Webster, 2008). It is a tool that may assist in achieving affect domain objectives. In *Second Life*, members have the ability to be in a large group, yet eaves drop on the conversations which are occurring in the background. The informal nature of osmotic communication can be realized within the virtual world format. *Second Life* uses a tool called "spatial audio" defined as the moving of an avatar away from another avatar that allows side conversations, which is impossible within traditional telephone conferences. While the military is exploring the use of virtual worlds in many aspects such as recruiting, conferencing and training based on primarily cognitive domains, it may also consider expanding exploration of virtual technology to affective domain centered training.

A model for utilizing gaming as an integrator of formal and informal learning emerged during an attempt to create a conceptual plan to deliver an alcohol and substance abuse prevention training model grounded in persuasion theories for the military. The current face-to-face training relies on the instructor's ability to manage active resistance by the students, facilitate respectful collaboration and move students toward personal behavioral change. The model is structured around a series of activities that provide formal learning (dissemination of information) and informal learning (students sharing their personal experiences, views and perceptions). Often it is interactions and conversations that occur between the students participating in the training that becomes the most influential component in moving students toward change.

Traditional models of e-learning typically begin with an underlying structure for disseminat-

ing information. Layers of interactivity are added throughout the training to engage and motivate the learner thus improving their retention, comprehension and ability to apply the information presented. Elements of the alcohol and substance abuse prevention training easily converted to this format; however, lost in the translation were the affective elements, such as the student interactions and conversations which are necessary in applying persuasion theories. Web 2.0 internet technologies demonstrate the potential to achieve the affective elements. The challenge is how to integrate e-learning and Web 2.0 technologies to create an effective training model; and a possible solution may be gaming. Through gaming, the core element of the training model is able to deliver information while simultaneously engaging the affective domains with Web 2.0 internet technology components.

Current efforts in the realms of military training reveal a model shift from traditional instructor-led training to more diverse, multiple-delivery type systems centered on the student. Included in these systems are gaming platforms such as simulations and scenario-based gaming. By positioning the game as a central platform for the alcohol and substance abuse prevention training, the student is afforded the opportunity to control the learning situation and become motivated to achieve the objectives set forth in the training tasks. The model described is currently in development; it remains to be seen whether developers will create a training program with the ability to achieve affective domain objectives.

Portability

The military approach to training is to define objectives for student outcomes and the requirements for the training program, then devise alternative approaches to satisfy them. (Fletcher & Chatelier, 2000). The military's focus on distributed learning evolved from multiple goals; however, a significant factor is the ability to deliver individual

training that is effective, yet saves money and time – limited resources of the military.

Emerging technologies such as streaming video, virtual worlds, file compression, and various communication tools advance the ability of the military in meeting its distributed learning goals. Most games retain the trait of portability; they can be delivered to the learner in almost any location via electronic methods. This feature has become critical as the military continues long-term combat operations in remote locations.

Web 2.0 applications provide the military with scalable and sustainable tools that are adaptable when delivering the program anywhere, anytime, for anyone. A technological advantage of current virtual worlds such as *Second Life*, is the small memory space on a computer that is needed; most of the program is streamed via internet to avoid cumbersome updates and large data requirements.

Designing training that combines gaming and simulation with emerging technologies takes advantage of tools to meet affective domain objectives and utilizes applications that meet distributed learning goals of portability while possibly reducing costs and time requirements. Reflected in research is the ability of distributed learning to conserve resources (Prensky, 2001). Future investigations should focus on the ability to measure effectiveness of these programs with learners and ensure that training design focuses on its primary purpose to assist the learner in building and developing skills.

CONCLUSION

“Games can play a number of roles in learning, but they are most effective as learning environments when they have well-integrated instructional guidance and/or instructional support.” (Munro, 2009) This is a fact the military not only recognizes but embraces as they attempt to expand their ability to deliver training anywhere, anytime for anyone. The varieties of games that exist provide multiple

opportunities for learning, but it is important to identify what the games were designed for (learning versus entertainment) before establishing expectations for the game player. Developers of military training must understand the desired outcomes and ensure that sound instructional design is incorporated. The key factor for selecting training tools should focus on appropriateness rather than technological features or efficiently priced deliveries. Emerging technologies appear promising when creating games that require a blend of informal and formal learning and are primarily focused on affective domain objectives. Technological issues such as portability become more significant to a military engaged in persistent high operational tempos.

Fletcher (2003) suggests that those concerned with military training change the paradigm within current development arenas; "We should start building -- design drives science more than science drives design." Designing training environments that may employ technologies yet to be developed may inform the direction and future of distributed learning, both for the military and the fields of training and education.

ABSTRACT

Electronic games have the potential to support learning by doing and enhance student motivation. However, there is little guidance in the literature on how to leverage the affordances of electronic games to design effective instruction. This chapter is our effort to start to accumulate knowledge to guide the design of electronic educational games. We present a case study describing how the unique components of electronic games enabled the design of Conquest of Coastlands, a learning environment delivered as an electronic game. We describe how our team synthesized two sets of

design principles from the literature on electronic games, instructional design, and intrinsic motivation and how these principles informed the design of Conquest of Coastlands. The principles and the related case study may inform the design of future electronic educational games and generate research questions to be investigated in empirical research.

INTRODUCTION

The Federation of American Scientists (FAS) released a report in October 2006, proposing digital games as a solution to reshape education (2006). The report lists a series of research and

DOI: 10.4018/978-1-60960-503-2.ch418

development challenges. One main area of challenges focuses on the design of games for learning. How can we design games that contribute to instructional goals? To answer this question, we need to understand the affordances (Gibson, 1977) of the electronic games, the potential and possibilities that the media may offer to enable effective learning.

Electronic games have two affordances for impacting learning: the promise to support learning by doing (Kirriemuir & McFarlane, 2003) and the motivational effects of games. Supporters of electronic educational games emphasize the potential of electronic games in providing simulated real world experiences. Squire (2006) considers game playing as designed experience, in which students learn through participating and performing in the game world. Gee (2007) states that the games that he is interested in “are digital simulations of worlds that are ‘played’ in the sense that a player has a surrogate or surrogates through which the player can act within and on the simulation” (p. 1). These are epistemic games (Shaffer & Gee, in press) in which learners play the role of professionals such as engineers, urban planners, journalists, or lawyers in authentic simulations of a society. It is argued that these games help learners develop ways of thinking and knowing valued by respective professions.

Advocates of electronic educational games often cite the work on intrinsic motivation to support the use of games in education. Psychologists (Lepper & Malone, 1987; Malone, 1981) analyzed computer games and identified a list of elements that are motivating, including challenge, curiosity, fantasy, and control. Flow (Csikszentmihalyi, 1991) is another theory related to motivation. It describes a sense of control, deep engagement, and exhilaration when one is involved in an optimal experience. Research shows that intrinsic motivation and flow positively contribute to learning (Cordova & Lepper, 1996; Csikszentmihalyi, 1991; Hektner & Csikszentmihalyi, 1996).

These views provide valuable insights on the effective dimensions of electronic games in education. However, how do instructional designers transform the two affordances of electronic games to enhance motivation and simulated experience into effective design of instruction? How should elements of electronic games be designed to meet instructional goals? This chapter explores these questions by presenting a case study of how the unique components of electronic games enabled the design of *Conquest of Coastlands*, a learning environment delivered as an electronic game.

This chapter starts with a theoretical framework that identifies the components of electronic games and describes two instructional design models and a motivation theory, all of which are guiding the design of our learning environment. Then, it presents an overview of the game and the quest that we are developing. Next, it describes the instructional elements identified for the quest and discusses how we leverage two affordances of the game to support effective instructional design.

THEORETICAL FRAMEWORK

Components of Electronic Games

Electronic games usually have two components: story and game play. Although some game designers argue that story is not a necessary element in all games, we consider it a key element in electronic educational games (Williams, Ma, Prejean, & Richard, in press). A story in an electronic game consists of characters, settings (context), and events (plots) (Stapleton & Hughes, 2006). Characters act to pursue the object of their desire or motivation. This action constitutes the plot. In the course of their pursuit or quest, characters encounter obstacles or problems that interfere with their achieving of the goal. This is the source of conflict, which is the essence of drama. Characters seek solutions to problems and take action to overcome obstacles. The drama consists of the ongoing friction between the characters’ motives,

the obstacles they confront, and the choices they make in confronting them.

Game play describes “what the player does” in the game. It can be broken down into the constituent game mechanics, including goals, rules, tools, cause, effect, and consequence (Stapleton & Hughes, 2006). It describes how the player follows the rules and uses the tools and resources to achieve the goals of the game and how the game responds to the player’s action based on certain cause-effect-consequence rules.

Four-Component Instructional Design (4C/ID) Model

The four-component instructional design (4C/ID) model (van Merriënboer, 1997) is a model for teaching an integrated set of knowledge and skills required for solving complex problems and completing complex tasks. There are four inter-related components in the 4C/ID model: learning tasks, supportive information, part-task practice, and just-in-time (JIT) information.

Learning tasks. Learning tasks are the concrete, authentic whole-task experiences similar to complex real-world problems. Repeated practice of learning tasks allows learners to generate abstract schemata from concrete experiences. Learning tasks are categorized into simple-to-complex classes. The order of the task classes and the specific instances of the tasks define the overall sequencing of the instructional content.

Supportive information. Supportive information is provided to assist with the non-recurrent aspects of the learning tasks. It includes mental models, cognitive strategies, and cognitive feedback related to reasoning and problem solving. Inductive-inquisitory and inductive-expository strategies are appropriate for teaching supportive information.

Part-task practice. Although learning tasks may provide enough practice for the recurrent skills, part-task practice may be needed to reach a high level of automaticity for these skills. Part-

task practice is a “divide-and-conquer” approach in which the learner practices constituent skills required to complete the whole task. The 4C/ID model advocates teaching the whole task at the beginning of the instructional program and embedding part-task practice in the context of the whole task.

Just-in-time (JIT) information. JIT information provides the step-by-step knowledge needed for part-task practice. JIT information is offered when it is relevant; it fades away when the learner acquires more expertise.

The strengths of the 4C/ID-model lie in its strong theoretical base. We concur with Merrill (1999) that this model has synthesized the best from existing instructional design models and incorporated theories derived from current cognitive psychology research. The 4C/ID model is not only influenced by the classic works on instructional design (Gagne, 1985; Merrill, 1983; Reigeluth, 1983), which are based on behavioral and cognitive psychology; it has also integrated components from more recent constructivist instructional design theories and models (Collins, Brown, & Holum, 1991; Spiro, Feltovich, & Jacobson, 1991). The integration of instructivist and constructivist approaches are made possible in this model because of the influence of cognitive load theory (Sweller, van Merriënboer, & Pass, 1998). The impact of the cognitive load theory is best reflected in the concept of “reflective expertise” (van Merriënboer, 1997) discussed in the model. Reflective expertise is the ability of a learner to generalize learning using two transfer mechanisms: domain-specific automated process to address familiar aspects of problems; and heuristics operating on cognitive schemata to solve unfamiliar aspects of problems. With such expertise, when presented with a problem, a learner can quickly solve the familiar aspects of the problem by automatically applying the rules, thus freeing up working memory to deal with unfamiliar aspects of the problem using heuristics and cognitive schemata induced from previous experiences

and examples. The learning tasks and supportive information are primarily designed to promote schema-based transfer. Constructivist strategies such as cognitive apprenticeship (Collins et al., 1991) play an important role in achieving this transfer. Part-task practice and JIT information may enable rule-based transfer. Instructivist strategies (Gagne, 1985) that take a “divide-and-conquer” and “drill-and-practice” approaches can be of value to facilitate rule-based transfer.

The 4C/ID-model not only has a solid theoretical foundation, but also features a strong research base. Empirical evidence of the model has been demonstrated in a series of studies. Research has been conducted with regard to the training of fault management (Jelsma & Bijlstra, 1990; Morris & Rouse, 1985), computer programming (van Merriënboer & De Croock, 1992), and statistical analysis (Pass & van Merriënboer, cited in van Merriënboer, 1997). The studies demonstrate that strategies based on the 4C/ID-model tend to provide better transfer than the conventional strategies (van Merriënboer, 1992). The 4C/ID-model informed the design of ADAPT^{IT}, a computer-based training design tool that helps professionals to design training courses for complex cognitive skills (The ADAPT^{IT} Consortium, 2003). Analysis of evaluation data indicates that this tool has met the expectations for efficiency and effectiveness.

Cognitive Apprenticeship

Cognitive apprenticeship (Collins et al., 1991) is an instructional design model built on traditional apprenticeship. In traditional apprenticeship adults teach children skills such as speaking, farming, and sewing by showing them how to complete the tasks and helping them when it is their turn to try. In cognitive apprenticeship teachers help learners acquire transferrable cognitive skills by demonstrating the thought process for completing certain tasks and guiding the learners as they work on the tasks themselves.

Cognitive apprenticeship advocates six instructional strategies: modeling, coaching, scaffolding, articulation, reflection, and exploration. Modeling, coaching, and scaffolding strategies help students acquire knowledge and skills through observation and guided practice.

Modeling. Cognitive apprenticeship typically starts with modeling, which provides students with an opportunity to observe expert performance of a task in order to build a conceptual model of the processes for completing the task. Jonassen (1999) categorizes modeling into two types, including “behavioral modeling of the overt performance and cognitive modeling of the covert cognitive processes” (p. 231). After students observe the expert performance, they are engaged in the completion of the task themselves.

Coaching and scaffolding. Coaching and scaffolding strategies provide the support students need to accomplish the task and to bring students’ performance closer to expert performance. Coaching involves observing students’ performance and providing hints, feedback, further modeling, reminders, and new tasks to address specific issues in students’ performance. Scaffolding can be provided by offering suggestions, help, cue cards; the teacher can even perform parts of the task that are beyond students’ ability. Coaching and scaffolding should gradually fade as students become more competent in performing the tasks.

Articulation and reflection. Articulation and reflection strategies enable students to gain access to and control over their own thinking. Articulation refers to requiring students to articulate their knowledge, reasoning, and problem-solving processes. Teachers can encourage students to articulate their thinking by asking for explanations and elaborations, or requiring them to explain their ideas to peers in cooperative groups. Reflection involves helping students compare their own problem-solving processes with those of the experts, thus making it possible for them to modify their processes. Techniques to enhance reflection focus on reproducing or replaying both expert

and students' performance to offer opportunities for comparison.

Exploration. After students become competent in solving the problems with no support, exploration should occur. Exploration involves pushing students to find and solve problems on their own. Students may be given general goals (e.g., exploring why the stock market crashed in 1929) and they can focus on specific sub-goals of interest to them. The purpose of exploration is to encourage students to become automatic in setting problem goals and solving the problems.

The 4C/ID model and cognitive apprenticeship are the two main instructional design models that inform the design of Conquest of the Coastlands. To conceptualize the complementary role of these two models, we identified two categories of instructional elements: problem and support (Table 1). These are the main elements in instructional design models that emphasize the role of authentic experience in learning (e.g., Hannafin, Land, & Oliver, 1999; Jonassen, 1999; Schank, 1999). In these learning environments, the student is presented with a problem, a project, or a task in a rich context. A variety of resources and tools are available to support the learner. From the perspective of this framework, the learning task in the 4C/ID model is the problem to be solved. Supportive information, JIT information, and part-task practice offer support for accomplishing the whole task. Cognitive apprenticeship offers additional support to guide student learning through observation and guided practice.

Table 1. Instructional elements based on 4C/ID and cognitive apprenticeship

Instructional Elements	
Problem/Project/Task	Learning task
Support	Supportive information
	JIT information
	Part-task practice
	Cognitive apprenticeship strategies

Intrinsic Motivation

Malone and Lepper (Lepper & Malone, 1987; Malone, 1981) developed a theory of intrinsic motivation after analyzing related literature and conducting experiments on electronic games. They identified four categories of design features that enhance intrinsic motivation, including challenge, curiosity, fantasy, and control. The first category of features focuses on developing an optimal level of challenge for the learner. Performance goals should be personally meaningful and the attainment of the goals should be uncertain. However, the sense of uncertainty should not be to the extent that it damages the learner's self-esteem; instead, the completion of the challenging goals should contribute to enhanced feelings of self esteem. To achieve this, there should be goals of varying difficulty so that the learner can work at a level appropriate for their ability. Hidden information and randomness may also enhance the uncertainty of the goals.

The purpose of the second category of design features is to enhance curiosity, including sensory curiosity and cognitive curiosity. Sensory curiosity can be facilitated with the use of perceptual stimuli such as light, music, animation, graphics, and video and audio effects. However, the enhancement of sensory curiosity should not distract the learner from instructional tasks. "Cognitive curiosity is evoked by the prospect of modifying higher level cognitive structures" (Malone, 1981, p. 363). It is the desire of the learner to better organize one's knowledge. The key to evoke the desire is to create a cognitive dissonance (Festinger & Carlsmith, 1959) by highlighting the incompleteness, inconsistency, or a lack of parsimony in the learner's understanding.

The third category of design features is concerned with giving the learner a sense of personal control by providing choices and personalization opportunities. For example, the learner can be given the choices concerning the characters, names, fantasies, icons, and other bells and

whistles irrelevant to the instructional aspects of the activities. Information and feedback is personalized based on these choices.

The last category of design features relates to fantasy. Malone defines fantasy-inducing environments as those that evoke “mental images of things not present to the senses or within the actual experience of the person involved” (American Heritage Dictionary, cited in Malone, 1981). Fantasy is appealing because of its cognitive and emotional impact. The cognitive benefits of fantasies lie in that fantasies provide analogies and metaphors that enable the learner to use existing knowledge to make sense of the new information. Fantasies have emotional appeal in that they arouse strong emotions through stories related to conflict and war, competition, and interpersonal relationships. There are two types of fantasies: endogenous and exogenous. In endogenous fantasies, there are inherent connections between the fantasy and the content and the goals of the fantasies match the instructional goals. For example, *Civilization* is an endogenous game for teaching history. In this game, the player builds civilizations and ensures its growth by balancing issues related to infrastructure, resources, diplomacy and trading, technological advancement, city management, and military. The fantasy advances as the civilizations evolve. Social studies can be taught by using this game. On one hand, the player needs the historical knowledge to succeed in the fantasy. On the other hand, the player needs the fantasy as a context to understand historical knowledge. In exogenous fantasies, the connections between the fantasy and the content are superficial; the same fantasy can be used as “sugar-coating” for a variety of content. For example, a *Speedway* game in which the students’ race cars move at the same speed as they correctly answer arithmetic questions is considered an exogenous game. In reality, arithmetic skills are not required for car racing; it is an artificial connection. The same game can be attached to any other content. Researchers argue that endogenous games are more interesting and

more instructionally effective than exogenous fantasies because of the inherent relationship between the fantasy and the content.

CONQUEST OF THE COASTLANDS AND THE GLIM QUEST

Conquest of the Coastlands is a role-playing electronic educational game with a science fiction/fantasy setting. Pursuing larger strategic objectives, the player character will be challenged with a variety of problem solving “quests,” which form the main plotlines of the interactive narrative and will provide the immediate motivations for player-character activities in the game. Each quest is designed to achieve specific learning goals.

The game takes place amid an ancient conflict between two sentient species and their struggle for dominance on a planet in another solar system. While not technologically sophisticated, the planet’s two rival sentient species have reached a turning point in their evolutionary history where it is likely that one—the Mruk-ma—will likely drive the other—the Sheft-ma—into extinction.

The Mruk-ma are aggressive, sea-faring species, while the Sheft-ma are city-builders who make their home in “The Coastlands,” along the marshy seashores and river valleys of Mertis’ lone continent. For the vulnerable Sheft-ma, the strategic key to their self-defense is a deteriorating system of fortifications built in the coastal wetlands surrounding their cities. But these wetlands are mysteriously disappearing at an alarming rate, and the threat of invasion by Mruk-ma fleets is growing.

A decisive change comes when the survey ship of an advanced alien race crash-lands in the oceans of Mertis. Arriving in escape pods from their doomed spaceship, the strangers, called Cilati, are scattered around the planet. Now hopelessly stranded on Mertis, some of the alien crew manages to make their way to The Coastlands, where they are warmly welcomed by the Sheft-ma. The Cilati survey team brings with them precious

scientific knowledge, technology, and methods that could dramatically shift the balance of power in the conflict between the two rival species. The survival of the Sheft-ma will depend on whether they can effectively utilize the science and tools of the Cilati to rebuild their crumbling forts and defend their disappearing coastlines.

The Cilatis are a highly advanced race of space-faring explorers. Extremely long-lived, they traverse the galaxy in pursuit of knowledge about other planets and other life forms. Cilati ships have visited countless worlds, quietly observing the species that inhabit them. Generally, they never interfere in the cultures they study, and they seldom even make their presence known.

However, it quickly becomes apparent that the Mruk-ma have adopted a radically new strategy in their struggle with the Sheft-ma: ecological warfare. By attacking the delicate environment on which their peaceful rivals depend, the Mruk-ma hope to wreck the Sheft-ma civilization and eliminate their species.

Our team is currently developing the *glim* quest in Conquest of the Coastlands. It is a four-week life science and environmental science curriculum for children ages 11-13. The curriculum consists of approximately 10 hours of electronic-game activities followed by approximately 10 class periods of hands-on, classroom-based activities. The primary goal of this curriculum is to teach an integrated set of knowledge and skills that allow students to address environmental issues. For professionals, such expertise may take years of education and experience to develop. Our four-week curriculum will focus on relatively simple but still complex and authentic problems.

INSTRUCTIONAL COMPONENTS OF THE GLIM QUEST

The 4C/ID model provides an overall framework to structure the instructional aspect of the game. This section describes the four instructional components of the *glim* quest: learning tasks,

supportive information, part-task practice, and just-in-time information.

Learning Tasks

In this curriculum, the learning tasks involve addressing environmental issues similar to those found in the real world. The tasks are organized in a simple-to-complex order. The electronic game addresses problems that have less variables/factors at play, followed by classroom activities which present more complex problems. Much support is provided in the game because students have little experience dealing with these issues. Performance constraints and modeling examples are offered to reduce the cognitive load.

The central problem presented in the *glim* quest focuses on exploring a drastic reduction on the harvesting of *glim*, a fish found in the coastal regions, which is a key staple of the Sheft-ma diet. The game provides an opportunity for the learner to explore an ecosystem that has been disturbed by an invasive species and other biotic and abiotic factors. Performance constraints are provided; learners are required to follow a set of scientific inquiry heuristics to approach the problem. At the beginning of the inquiry process, they are asked to create a data collection plan; during the process, they write a progress report from time to time; toward the end of the process, they develop a final report in order to draw conclusions and discuss findings. A modeling example is available to illustrate how scientists follow the inquiry process and develop various plans and reports to solve an environmental problem related to acid rain.

Supportive Information

Supportive information, including the mental model of the balance of the ecosystem, scientific inquiry skills, and cognitive feedback, is provided to assist with the non-recurrent aspects of the learning tasks. They are related to two primary learning outcomes: scientific inquiry and the bal-

ance of the ecosystem. Students are expected to acquire knowledge and skills needed to understand and conduct scientific inquiry, including “asking questions, planning and conducting investigations, using appropriate tools and techniques to gather data, thinking critically and logically about relationships between evidence and explanations, constructing and analyzing alternative explanations, and communicating scientific arguments” (National Research Council, 1996, p. 105). Students should also obtain an improved mental model of the interdependence and balance of the ecosystem components.

We employ both inductive-inquisitory and inductive-expository strategies to design the instruction for supportive information. For example, the inductive-expository strategy is used to help the learner understand how various factors lead to the imbalance of the ecosystem and related consequences. We present several case studies of coastal issues and then draw out the relationship among various factors such as farm run-off, construction of levees, and the introduction of invasive species. We use the inductive-inquisitory strategy to teach complex relationships among organisms as well as between organisms and the environment. For example, a principle that we want the students to learn is that an invasive species can disrupt the balance of an ecosystem; the change in the ecosystem caused by the invasive species may impact a native species directly or indirectly. To teach this principle using the inductive-inquisitory strategy, we provide an analogical encoding (Gentner & Markman, 1997) tool, which presents two examples illustrating the impact of invasive species and the learner is guided to identify the common principle underlying both examples. Research shows that analogical encoding is more effective than the pure discovery approach. For more information on the analogical encoding tool, see the work of Williams, Ma, Feist, Richard, and Prejean (2007).

Part-Task Practice

The learning task of the game involves recurrent skills such as interpreting graphs of fish catch data and water quality data. These are the secondary learning outcomes of the curriculum. Part-task practice provides opportunities for the learner to acquire these skills. To give the learner a sense of context, part-task practice should be embedded in the game rather than as a prerequisite for playing the game. More part-task practice is available in the associated classroom activities.

JIT Information

JIT information provides the step-by-step knowledge needed for the learner to perform the recurrent aspects of the learning tasks. For example, for the learner to practice reading and interpreting graphs, a tutorial is available to teach the knowledge and skills necessary for the practice. The tutorial presents concepts and principles related to graph interpretation, gives examples, and provides corrective feedback to the practice.

LEVERAGING THE AFFORDANCES OF THE GAME To Promote Learning By Doing

Components of electronic games can be leveraged to support the instructional elements. Table 2 shows how the instructional elements in Table 1 are mapped with the components of the electronic game to guide the design of instruction. For example, two components of electronic games, story and game play may serve as devices to situate the problem and the context. The story describes the characters, the settings, and the events related to the problem. The game play presents the goals for the learner and defines the rules and tools for achieving the goals. To provide support to the learner, characters in the story and tools in the game play may deliver supportive and JIT information

Table 2. Instructional elements and components of the electronic game

Instructional Elements		Components of the Electronic Game
Problem/Project/Task	Learning task	Designing the story and the gameplay to present the learning task
Support	Supportive information	Delivering supportive information, part-task practice, and JIT information by characters in the story and tools in the game
	JIT information	
	Part-task practice	
	Cognitive apprenticeship strategies	Implementing cognitive apprenticeship strategies via characters in the story and/or tools in the game

as well as facilitate part-task practice and enable cognitive apprenticeship strategies.

Designing the Story and the Gameplay to Present the Learning Task

Presenting the learning task in the context of story and game play may enhance a sense of authentic experience. In contrast with traditional methods of knowledge representation, games provide a rich description of situations and tasks which are more meaningful to students. They allow the players to identify fully with a character, act on the plot, and experience the cause-and-effect of their actions. This is important because contemporary learning and instructional theories (Jonassen, 1999; Schank, 1999; Spiro et al., 1991), including the 4C/ID model (van Merriënboer, 1997), all emphasizes the role of an authentic context in facilitating learning by doing.

Presentation of the *glim quest* learning task is primarily through three elements: the game cinematic that introduces the back-story of the entire game, an interactive cut scene that focuses on the specific challenge in the quest, and several interactions between the learner and non-player characters. The following aspects of story and game play design have a critical role in developing a rich context for the learning task.

Setting. A compelling story begins with a rich setting. In our game, the opening cinematic introduces the learner to the setting: a fictitious planet where two opposing species are in conflict. Each

quest has its own detailed setting that contributes to the overall game story.

Characters. Characters add to the richness and authenticity of the learning task. For example, the learners first come to know details about their own character's motivations and other key figures in the opening cinematic. The player character's main motivation in the game is to preserve and restore the Sheft-ma's fragile coastal ecosystem. The cinematic also provides a glimpse of the dreaded Mruk-ma scouts who are spying on the Sheft-ma coastlands. As the player character begins each quest, characters facilitate presenting the goals and details of each learning task. For example, in the interactive cut scene for the *glim quest*, the learner takes on the role of the player character, a talented and courageous young apprentice who is given a task to investigate a fish depletion problem that is threatening the survival of the Sheft-ma.

Events/plots. The opening cinematic and the interactive cut scenes depict the back-story of the game and quests and provide a context for each learning task. During the interactions with non-player characters, task goals are clarified and needed details are provided. As the plot unfolds, the player character encounters obstacles such as determining what data to gather and how to interpret the data.

Goal. Providing the player with clear goals, consistent with those in the game narrative, is essential to effective game play and further facilitates presentation of the learning task. The goal of the *glim quest* matches the player character's

motivation to preserve and restore the coastlands, and is clearly presented to the player character.

Rules. Rules help clarify the end goal of the learning tasks. There are two sets of rules that define the winning of the *glim quest*. The first set of rules concerns whether the player character follows the instructions of the mentors to successfully complete the scientific inquiry process. The second set of rules is related to Sheft-ma values, including knowledge, stewardship, practice, and critical thinking. The player character may gain more points if s/he adheres to these values. These rules are presented during the interactions between the player character and the non-player characters.

Tools. The presentation of the learning task is coupled by an introduction of tools that the player character has available to complete the task. During the interaction between the Cilati mentor and the player character prior to his/her departure on the quest, the mentor provides the player character with a personal digital assistant (PDA), a versatile device based on the Cilati's advanced technology. This serves as the primary tool for the player character to complete the quest. Other tools common to electronic games, such as a map tool and an inventory, are also available to the player character.

Delivering Supportive Information, Part-Task Practice, and JIT Information by Characters and Tools

Providing support by characters and tools as the story and game play unfold adds to the authenticity of the experience. As the plots evolve, the opportunities for providing support naturally occur when the player character encounters obstacles. In the pursuit of the goal, the player character confronts the problems with the support provided by characters and tools in the game.

In the *glim quest*, the learner is mentored by two non-player characters, a Cilati and a learned Sheft-ma elder. The Cilati provides support and guidance to the player in conducting research. The

Sheft-ma elder is learned in many disciplines possessing a folk understanding of the forces at play in the natural world. To help the learner with the quest, the Sheft-ma elder discusses his hypotheses based on his own experience and folk knowledge. The Cilati mentor guides the learner through the scientific inquiry process, introducing conceptual information needed to complete the inquiry and taking into consideration of the Sheft-ma elder's folk understanding.

The PDA is a main tool that provides support to the learner. It facilitates communication between the learner and the Cilati mentor, allows data collection and analysis, and enables presentation of case studies and related information. Case studies are used extensively to provide the supportive information. The cases are stored in the case library in the PDA and the analogical encoding scaffold is also embedded in the case library. Part-task practice and JIT information on how to interpret graphs is facilitated by a tutorial embedded in the PDA.

Implementing Cognitive Apprenticeship Strategies via Characters and Tools

The story elements in the electronic games can easily support cognitive apprenticeship strategies. In stories, the hero usually has a mentor (Campbell, 1949) who provides tools and advice to support the adventure. Meeting with the mentor not only advances the plot in the story but also offers an opportunity to use cognitive apprenticeship strategies.

A more interesting example of how the characters and tools in this game support cognitive apprenticeship strategies involves the interaction supported in the PDA *sketch tool*. The tool allows the learner to work as a forensic sketch artist to determine the key characteristics and classification of the invasive species. Near the start of the quest, a non-player character shares a strange skull with the player character. The skull is not

of any creature with which the local Sheft-ma are familiar. In order to determine what the organism is, the Cilati asks a series of questions concerning the organism's characteristics. For example, the Cilati begins by discussing the teeth embedded in the skull, explaining that examining these can provide hints on the types of food they eat, which is a key factor for determining where the organism fits in the classification taxonomy. The *sketch tool*, appearing to be under the control of the Cilati, displays teeth of herbivores, carnivores, and omnivores found on Earth, and asks the learner to select the ones that most closely resemble those found in the skull. The Cilati confirms or rejects the learner's selection, eventually guiding the learner to understand that the invasive species is an herbivore, and concludes the interaction by drawing the teeth in the *sketch tool*. The Cilati goes on to guide the player through examining the other features of the skull. The *sketch tool* interaction allows the Cilati to model the cognitive processes involved in identifying the features of an organism.

The next two cognitive apprenticeship strategies, coaching and scaffolding, are facilitated through the interaction between the learner and the Cilati. For example, the Cilati asks the learner to follow the scientific inquiry process to investigate the fish depletion problem. Scaffolding is provided by requiring the learner to use a set of scientific inquiry heuristics. A particular noteworthy aspect of the game is its affordance to facilitate coaching via the non-player characters and within the context of the story. The learner develops and submits a progress report to the Cilati, who reviews the report and provides individualized feedback. In reality, it is the teacher who provides the feedback. However, the game allows the teacher to deliver the feedback assuming the role of the Cilati, thus maintaining the authenticity of the story and keeping the learner immersed in the context.

The game also enables the implementation of articulation and reflection. The learners are encouraged to articulate and reflect on their scientific

inquiry process in several communication reports they submit to the Cilati: the data collection plan, the progress report, and the final report. These reports are supported by the PDA.

The final strategy of cognitive apprenticeship, exploration, is not implemented in this version of the game. However, it is supported by the classroom activities. The learners are given open-ended, broad research issues, and they work in teams to generate research question and conduct investigations to answer the questions.

LEVERAGING THE AFFORDANCES OF THE GAME TO ENHANCE MOTIVATION

From the theory on intrinsic motivation, we identified four principles to inform the design of the *glim quest*. The following describes how our effort in applying these principles.

Developing a Meaningful Challenge with Optimal Levels of Difficulty

Our first effort to enhance intrinsic motivation (Lepper & Malone, 1987; Malone, 1981) focuses on developing a meaningful challenge with an optimal level of difficulty. In our game, the challenge is for the learner to identify why fish catches decline dramatically for Sheft-ma fishermen. This challenge is meaningful because: (a) it is a problem in a rich context with a potentially devastating impact on the well-being of the Sheft-ma, and (b) it resembles authentic environmental problems on Earth. To ensure that the performance goals are challenging but attainable, we provide various types of support described earlier in the chapter. We have not implemented other strategies that may provide the optimal level of difficulty, such as designing performance goals at variable difficulty levels and adding hidden information and increasing randomness. We will explore these strategies in the future development of the game.

Enhancing Sensory and Cognitive Curiosity

Commercial electronic games enhance sensory curiosity with the design of three dimensional (3-D) environments, cinematics, as well as stirring audio effects and music. Styled after the commercial games in terms of the interface design, Conquest of Coastlands integrates these state-of-the-art media with the design of the story, the game play, and the instruction. The game is also designed to augment cognitive curiosity by evoking cognitive dissonance in the learner. We adopted Socratic method (Collins & Stevens, cited in Malone & Lepper, 1987) as a means to trigger a sense of cognitive dissonance through dialogs between the Cilati mentor and the learner. The mentor asks questions and provides feedback in order to reveal problems in the learner's thinking and therefore to generate interests in learning.

Providing Choices and Personalization Opportunities

In Conquest of Coastlands, we give the learner a sense of control by providing opportunities for choosing names and gender, customizing the clothing, and selecting a secret code. These elements are irrelevant to the instruction, but they provide a sense of control that is motivating to the learner. In addition, we also personalize some of the feedback. The teacher, responding in character as the Cilati, provides personalized feedback on the reports submitted by the learner. We expect this feature to be both motivating and instructionally valuable. It is costly to design elements for personalization and choices, so we have limited these features in the current quest. We will further explore and evaluate these strategies in the future.

Developing an Endogenous Fantasy that is Emotionally Appealing

To develop an endogenous fantasy, we align the goals of the story and the game with instructional goals. In Conquest of Coastlands, the goal of the story and the game is to address an environmental issue. This goal also serves as the instructional goal.

Different fantasy context appeals to different people because learners have different emotional needs and different fantasies address different needs. To attract diverse learners, we try to address a variety of human emotional needs such as fear, love, hope, trust, faith, and fortitude. For example, in Conquest of Coastlands, we use vivid 3-D and 2-D arts as well as cinematics to depict Mruk-ma as dreadful creatures that perform deadly attacks on Sheft-ma villages. Drastically declining fish catches may soon lead to famine in the Sheft-ma city state; the learner is driven by the love for his or her country to investigate the problem.

CONCLUSIONS AND IMPLICATIONS

In spite of the growing interest in developing electronic educational games, there is little guidance in the literature on how to design effective electronic educational games. Educators have little experience in designing electronic educational games and the computer game industry lacks expertise in integrating effective pedagogy into game design. This chapter is an effort to start to accumulate knowledge to guide the design of electronic educational games. It presents a case study of our experience in leveraging the affordances of the electronic game to design a learning environment delivered as an electronic game. It describes how we synthesized two sets of principles from the electronic games, instructional design, and intrinsic motivation literature and how these principles informed the design of Conquest of Coastlands. The first set of principles describes how we align components of the electronic game

with instructional elements to meet instructional goals. The second set of principles presents our effort to leverage the affordances of Conquest of Coastlands to enhance motivation.

This chapter may be beneficial to both game developers and researchers. For developers of electronic educational games, the principles and related examples presented in the chapter may inform the design of their games. Although some of the principles are specifically related to the 4C/ID model and cognitive apprenticeship model, they should be relevant to developers who choose any design models that emphasize student-centered learning and learning by doing, because these design models (e.g., Hannafin et al., 1999; Jonassen, 1999; Schank, 1999) all underscore the roles of authentic problems, supporting resources, and scaffolds in learning. These models share similar instructional strategies with the 4C/ID model and cognitive apprenticeship.

For researchers, this chapter presents a list of theory-based principles that need to be examined in empirical research. Research questions may be generated from these principles. For example, one principle concerns implementing cognitive apprenticeship strategies through characters or tools in the game. Coaching and scaffolding require the mentor to provide individualized feedback and customize the learner's tasks on the fly. Currently, we are building a Web interface for the teacher to access the documents that the learner submits and to facilitate providing feedback, in character as the Cilati. We are yet to evaluate the effectiveness of this strategy. The main drawback of this approach is that feedback from teachers may be time-consuming; students may not be able to continue to play the game until feedback is provided. Research is needed to evaluate and develop technologies that facilitate more efficient and effective coaching and scaffolding. For example, natural language processing technologies such as latent semantic analysis (LSA) (Landauer & Dumais, 1997) may be promising technologies for implementing coaching and scaffolding strategies.

Another example relates to design principles that may enhance motivation. The implementation of these principles (e.g., the enhancement of sensory curiosity) with the cutting-edge technology is expensive. Although theoretically these strategies may enhance motivation, the motivational gains may not be significant enough to justify the cost. Future research is needed to address this issue.

KEY TERMS AND DEFINITIONS

Affordances of Instructional Media: The potential and possibilities that instructional media offer to enable effective learning

Endogenous Fantasy: In endogenous fantasies, there are inherent connections between the fantasy and the content and the goals of the fantasies match the instructional goals.

Flow: Flow is a theory on motivation (Csikszentmihalyi, 1991). It describes a sense of control, deep engagement, and exhilaration when one is involved in an optimal experience.

Game Play: It describes “what the player does” in the game. It can be broken down into the constituent game mechanics, including goals, rules, tools, cause, effect, and consequence (Stapleton & Hughes, 2006). It describes how the player fol-

lows the rules and uses the tools and resources to achieve the goals of the game and how the game responds to the player's action based on certain cause-effect-consequence rules.

Just-In-Time (JIT) Information: JIT information provides the step-by-step knowledge needed for the learner to perform the recurrent aspects of the learning tasks.

Learning Task: Learning tasks are the concrete, authentic whole-task experiences similar to complex real-world problems.

Part-Task Practice: Part-task practice is a “divide-and-conquer” approach to teach one or a limited number of constituent skills at a time in order for the learner to reach a high level of automaticity for these skills.

Supportive Information: Supportive information includes mental models, cognitive strategies, and cognitive feedback related to reasoning and problem solving. It is provided to assist with the non-recurrent aspects of the learning tasks.

Chapter 4.19

A Video Game, a Chinese Otaku, and Her Deep Learning of a Language

Kim Feldmesser
University of Brighton, UK

ABSTRACT

It is a buyer's market for employers in today's global village, where having another language under your belt could make the difference at an interview between employment or the dole queue (unemployment line). Learning additional languages rapidly has been the goal of immersion schools, and their approaches are effective in many respects because they make use of situated learning experiences in communities of practice. Such experiences present their own challenges however, as living in the country of the chosen language for a considerable period of time may not be possible. Migrant workers too may be shunned by native speakers, particularly if they have little or no knowledge of the native language, reducing learning opportunities to en-

gage in discourse. Video games may be one way to address these challenges. In order to do this, however, more must be understood about the ways in which games support these theories, the way individuals learning a second language interact with them, and what researchers and developers of serious games must know to support this use of games. This chapter will outline the relevant theories for second language learning, describe how they operate in games, and present guidelines for research and development of serious games and second language acquisition.

INTRODUCTION

*Tell Me and I Will Forget
 Show Me and I May Remember
 Involve Me and I Will Understand
 - Confucius 430BC*

DOI: 10.4018/978-1-60960-503-2.ch419

This is a longitudinal qualitative study of how a ‘virtual world’ of commercial off-the-shelf (COTS) video games was providing a safe space for an intermediate-level second language learner. The study investigates her ability to develop *deep learning* of English by engaging in extensive video game-play in the target language. Drawing on Vygotskian principles of research, which focus on the process and not the outcome of development, this small-scale research project explored, through interview, the process of learning to play *Deus Ex*TM.

I chose the title of this project having read Tobin’s (1999) experiences with his son entitled *An American Otaku*. As the computer miniaturizes into ‘must-have’ fashion accessories such as mobile phones and handheld gaming devices, a new generation is buying into the cyber age. Tobin (1999) used it to describe his son’s fanaticism with the role-playing game *Warhammer*TM and his immersion into cyberculture at the beginning of the millennium. As a father of a teenager, he asks himself pertinent questions about the possible ramifications of using this new technology—such questions as whether a life on the Net can be satisfying, and whether his son’s self-confidence and the interpersonal skills he is developing through e-mail communications can translate into real life? Will he have ‘real’ (face-to-face) friends? Do otaku grow up to be happy, normal adults? The fixation on new technology that stigmatized otaku a decade ago is now in common use among teenagers growing up in technologically advanced societies that are rapidly being changed by the technology of the integrated circuit and the Internet. The title reflects how the subject, Zoe, a mainland-Chinese English Language student, was drawn in to extensive video game-play by effective game design despite the barrier of the second language. Like an otaku, she would spend many hours alone playing the video game *Deus Ex* on her laptop in the host family bedroom.

The Research

For the sake of brevity, the background to how the research was initially set up has not been included; the details of how the subject Zoe was found, the year-long platonic relationship of the author with the subject as a support tutor in her curriculum studies, and how, through many conversations about learning styles, she agreed to participate in this study have also been left out. Similarly, the ethical considerations that were taken into account prior to, during, and after the study have been edited, only including those areas which may impact on future research.

The Subject

‘Zoe’ is from China and in her early twenties. She has been studying in England for nearly three years. She remained with the same host family for this time. She came to the UK having completed her Chinese (full board) high school studies with the intention of improving her English sufficiently, so as to enter a UK university. She was preparing applications to universities during the time of this study. She proudly announced her Communist roots to me—that her father was a prominent member of the Party in her city and that she would need to undergo a re-education program on her return to China (in order to reintegrate with Chinese society), having completed her studies in the West. She was keen to study Japanese culture on her degree course (citing that “you should know your enemy better than your closest friend”) and looked forward to living as an exchange student with a Japanese host family for a year.

Preparatory Measures

Participant exposure to gore, violence, and death through the playing of *Deus Ex* was addressed and procedures put in place whereby the subject could contact the researcher directly should any concerns arise from video game-play. Also, an

agreement was reached whereby the researcher could terminate the study if evidence of video game-play was having detrimental effects on the subject's health, her studies, or her social life. Communication lines to the subject's course tutors and host family were established and maintained throughout the study and for some time afterwards. Despite these safeguards, Zoe decided not to play *Deus Ex* for at least three weeks of her own volition before informing me or asking me for help with the game for the first time. The first interview starts at this point, after Zoe had had possession of the game for six weeks. I told Zoe she could keep the games until she intended to return to China (in six months time) so that she did not feel the study had disrupted our relationship, as I felt that if I had removed the games after the interviews, she may have felt rejected and used by the research process. Addiction such as befits the title otaku is well documented, and many gamers would admit to spending more time playing video games than watching television. Zoe clearly fits into this category. I also presented her with a good bilingual dictionary as a present which she was very pleased to receive, explaining that she could tell her parents she had been given the dictionary "in order to help in research" and that it would act as a lessening blow if she admitted to having played hours of video games. She indicated during the second interview that her mother did not object to her playing *Civilization III* (another game I lent her) if it was helping her with her studies.

594: Zoe: yeah, in the last few minutes...also last week I told my Mum I play this game and I say how useful it is...(Kim: *What does she say?*) She say "Alright, if you think it's useful." (Kim: *So she was quite happy to...*) because I tell her this game just helped me to understand more and understand well during my Maths, Religious Studies, and World Development...nearly every single subject so this is very helpful.

This piece of information was most reassuring as I had concerns about parental approval despite Zoe's maturity. Zoe's concerns about causing upset

or disappointment to her parents by her actions surfaced during tutor support on a number of occasions throughout my year as her personal tutor.

Research Material

The video game focused on in this chapter is the first-person shooter/role-play game *Deus Ex* made by Eidos Interactive (n.d.). The reasons for using *Deus Ex* are pedagogic in that it provides a thorough training session at the start of play in order to develop the player's skills. Additionally, the vast narrative script is dual-coded, with all dialogue subtitled and a copy of all conversations stored and easily accessed in *Denton's* (your character's name) databank, giving another form of backup to aid the learner. The game-play is paused and is not jeopardized while accessing the databank for facts or while reviewing a conversation. The game is designed to stretch the player into new *zones of proximal development*, not in a hack and slash way often used in inferior video game design, but in a thought-provoking way, demanding the player/learner step beyond their *regime of competence* (Gee, 2003, p. 71) in order to advance skills ready for more challenges later in the game. *Deus Ex* makes you question allegiance and commitment to government agencies fighting terrorism, develops leadership skills, and hones survival skills in hostile environments. It cannot be played half-heartedly, demanding weeks of regular play in order to reach its natural conclusion. The commitment is rewarded through a virtual world that is both compelling and, as Gee (2003, p. 5) described it, "life-enhancing."

SOCIOCULTURAL THEORIES OF LEARNING

The Zone of Proximal Development

How we learn language, and particularly how we learn a second or other language, has been

researched by many disciplines. Second Language Acquisition (SLA) is a relatively new field of investigation and as such has generated numerous theories. Pica (1998) comments on the theory-less but theory-laden field of SLA:

Theory-less in that, as most major textbooks remind us, there has yet to emerge a single, coherent theory that can describe, explain and predict second-language learning. Yet it is theory-laden in that there are at least forty claims, arguments, theories, and perspectives that attempt to describe and explain the learning process and predict its outcomes. (Pica, 1998, p. 9, cited in Beatty, 2003, p. 79)

SLA research is informed by the psychological research into behaviorism and cognitive theories of memory and learning (Bartlett, 1932; Skinner, 1957; Chomsky, 1965; Krashen & Terrell 1983; Swain, 1983; Gass, 1988; Skehan, 1989; Schmidt, 1994; Gupta & MacWhinney, 1997; Shimizu, Tang, Rampon, & Tsien, 2000; Churchland, 2002; Fauconnier & Turner, 2002), theories of human and child development (Bruner, Goodnow, & Austin, 1957; Subrahmanyam, Greenfield, Kraut, & Gross, 2001), first language acquisition and socialization studies (Slobin, 1985; Watson-Gegeo 2001), and cognitive anthropology (Lave & Wenger, 1991; Chaiklin & Lave, 1996). More recently the field of sociocultural theory, based on research by Vygotsky (1978), Bakhtin (1981), and Luria (1982) among others, has been included in the SLA research arsenal.

The theory of the zone of proximal development is part of the Social Development Theory proposed by Vygotsky (1978).

Aljaafreh and Lantolf (1994, cited in Dunn & Lantolf, 1998) describe the zone of proximal development as:

...the framework, par excellence, which brings all of the pieces of the learning setting together—the teacher, the learner, their social and cultural

history, their goals and motives, as well as the resources available to them, including those that are dialogically constructed together. (cited in Dunn & Lantolf, 1998, p. 415)

Research by Aljaafreh and Lantolf (1994) revealed that the potential level of development of the learner could be ascertained by the degree of assistance required in order to carry out an activity and also “the visible ability of the learner to utilize forms of external assistance” (Lantolf & Thorne, 2006, p. 277). That assistance could be supplied by a teacher or more knowledgeable peer, from a book such as a dictionary definition or from contextual clues provided by the environment such as learning to say “bless you” when someone sneezes, for example.

Aljaafreh and Lantolf (1994) define development in the language acquisition context as:

the study of how mediational means are appropriated by the individual as a result of dialogic interaction with other individuals.... The potential level of development of the learner is suggested by the kinds of assistance needed to carry out the activity and the visible ability of the learner to utilise forms of external assistance... assistance should be graduated—with no more help provided than is necessary, for the assumption is that over-assistance decreases the student's agentive capacity. At the same time, a minimum level of guidance must be given so that the novice can successfully carry out the action at hand. Related to this is that help should be contingent on actual need and similarly removed when the person demonstrates the capacity to function independently. Graduation and contingency are critical elements of developmentally productive joint activity. This process is dialogic and entails continuous assessment of the learner's ZPD and subsequent tailoring of help to best facilitate progression from other-regulation to self-regulation. (Lantolf & Thorne, 2006, p. 277)

Vygotsky's research showed that at a given time, an individual's development was afforded and constrained by his or her ZPD. The individual's capacity to respond to and benefit from certain kinds of interaction such as prompts, body language, or verbal remarks that would allow him or her to carry out an activity he or she would otherwise be unable to perform provided Vygotsky not with a *capacity of ability* as so many tests reveal, but the *potential growth* or proximal development to be expected from the subject. This 'provoked development' he referred to as the *experimental-development method* and at other times the *instrumental method*. Vygotsky elaborates thus:

The [ZPD] defines those functions that have not yet matured but are in the process of maturation, functions that will mature tomorrow but are currently in an embryonic state. These functions could be termed 'buds' or 'flowers' of development rather than the 'fruits' of development. The actual developmental level characterizes mental development retrospectively, while the [ZPD] characterizes mental development prospectively... the [ZPD] permits us to delineate the child's immediate future and his dynamic developmental state, allowing not only for what already has been achieved developmentally but also for what is in the course of maturing. (Vygotsky, 1978, cited in Lantolf & Thorne, 2006, p, 267; author's emphasis)

Vygotsky had already formed the key principle of the ZPD concept—the difference between the actual level of development already obtained and the cognitive functions comprising the proximal next stage. It was this that is attractive to educators, as it gives a yardstick to understanding aspects of students' emerging capacities and could be used for effective diagnosis of future development. Over the period of time Zoe was playing *Deus Ex*, observable changes had occurred. These changes would signal maturation of her ability to process

the gaming environment—to be in control of the various elements—and therefore demonstrate learning within her own ZPD. The additional factor of having to play in an L_2 environment suggests that in order to make these advances in game-play, Zoe would have had to decode the language along the way. This would be indicative of language learning. Transformation over time is at the heart of this method. The process of decoding and reusing the language as 'one's own' demonstrates the use of higher-order skills and L_2 development within the ZPD. This would demonstrate *deep learning* had occurred.

Deep Learning

Deep learning is important in this study because it shows that the language has been acquired and can be used as an instrument or artifact of language rather than a memorized semiotic 'out-of-context' symbol. An example of the latter would be testing student memory by showing the students a set of flash cards of target language, waiting a few minutes, and then asking them to write down as many as they could remember. Although some of the target language may be part of the subject's own lexical set, the test does not impinge on the subject's understanding of meaning. They could memorize the letter shapes for example and have no relationship to the semiotic association with the words presented. Just as a toddler blurts out an expletive (if exposed to them) without understanding the semiotic meaning but relishing the reaction it generates, learning can be a veneer on the surface without any engagement with meaning. Deep learning involves the learner in complete understanding. Weigel (2001) defines deep learning succinctly:

Deep learning leads to understanding and long-term retention of information through the critical analysis of new ideas and may be defined as 'learning that promotes the development of condi-

tionalized knowledge and metacognition through communities of inquiry’. (Weigel, 2001, p. 5)

Conditionalized knowledge here is defined as knowledge that specifies the contexts in which it can be useful. This requires the learner to think about how the knowledge can be applied in a particular circumstance. It requires engagement with the meaning to provide some form of concrete example in order to create an artifact that can be used in the mind of the learner. The interviews revealed some of the above characteristics of Zoe’s development of conditionalized knowledge within her ZPD, as the excerpts from the interview demonstrate.

Flow

Regular video game players will engage with a well-crafted video game for a number of hours at a time. I wondered if this intense focus of attention was the same as ‘flow’, as posited by Csikszentmihalyi (1988, cited in Arnold, 1999, p. 15). Arnold describes flow as “a state of optimal experience—effortless movement of psychic energy.” Goleman (1995) emphasizes the importance of the presence of this state for learning to take place:

Flow represents perhaps the ultimate in harnessing the emotions in the service of performance and learning. In flow the emotions are not just contained and channeled, but positive, energized and aligned with the task at hand. (Goleman, 1995, cited in Arnold, 1999, p. 15)

A gamer may experience the sensation of flow as they become more adept at a game. We could liken it to spectating a professional sports event where we almost feel the movements of the players which can be observed as the involuntary muscle twitches in the leg as a goal is scored because we are so in tune with the event. Perhaps it is the way we are sometimes so engrossed by a

musical performance that we lose our sense of our surroundings. Gamers twitch or involuntarily jerk as something happens in the game environment for example. Goleman adds:

Because flow feels so good, it is intrinsically rewarding. It is a state in which people become utterly absorbed in what they are doing, paying undivided attention to the task, their awareness merged with their actions. (Goleman, 1995, pp. 90-91)

Although flow has been cited in a number of research articles, there is little empirical research into what flow actually is. Csikszentmihalyi defined the flow response as a “holistic response” or an “optimal state of experience in which there is order in consciousness... This happens when psychic energy, or attention, is invested in realistic goals, and when skills match the opportunity for action” (1990 cited in Marr, 2000). Marr (2000) highlights the fact that there has been no experimental investigation into the nature of the somatic states that parallel flow; specifically, the “visceral and musculoskeletal concomitants to flow have never been examined.” Whether flow is self-generated by increased dopamine levels in preparation for the anticipated task as Marr suggests, or a form of meditative state is reached where certain perception channels are elevated causing others to be diminished has yet to be fully researched. Nevertheless, good video games do produce a state of flow where attention is fully directed at the task presented. I chose the video game *Deus Ex* because of its compelling storyline and almost flawless linking of game-play and feedback mechanisms, such as *Denton’s databank*, which make it not only an exciting game to play but also a thought-provoking one.

We start the interview evaluation with Zoe’s experiences playing the first-person shooter *Deus Ex*, a dystopian, cyberpunk world set in the 2050s where a mysterious pandemic is rapidly spreading across the globe. Terrorist organizations flourish

as government agencies attempt to maintain order and stability. You, the player, are about to be trained as a special agent, and all that you know is you are ‘nano-augmented’ and the second agent to be so endowed. Nanotechnology by this time has become sufficiently advanced that ‘nanites’, small robotic organisms the size of a human cell, can be injected into the body and give the player superhuman powers. In *Deus Ex* you and your brother *Paul*, who is already working as an agent in the field, are nano-augmented. There are 11 skills used by *JC* as a special agent: computers, electronics, environmental training, lock picking, medicine, swimming, and skills with weapons from low-tech, melee weapons such as knives and mini-crossbow, pistols and rifles, to heavy weapons such as rocket launchers and explosive devices. Each of these skills has four levels of mastery (untrained, trained, advanced, and master) that can be increased by earning additional points as you play the game. You start the game with a nominal set of points, which you can use to develop your character skills. Deciding how to upgrade your skills creates a unique character every time you play the game, and overdeveloping one skill at the expense of another could leave you with fewer choices of how to solve problems or puzzles within the game or may enhance a particular style of play you favor. Wise decisions need to be made because once made they cannot be undone. You may be a player who avoids confrontations and decide to develop your character’s spy skills—lockpicking, hacking, and bypassing security systems for example. *Deus Ex* is said to be among one of the few role-play games (RPGs) on the market that can be played without resorting to violence (except for one unavoidable confrontation), which makes it unique in providing many alternative styles of game-play to reach the same objective.

The Interview

The interview was conducted at Zoe’s host family home, upon her request for assistance to proceed

with the game. She called me first of all to let me know she had stopped playing *Deus Ex* as she did not want to “kill any more *Chinese policemen* in the game.” She sounded a little upset and I was concerned because my experience of game-play did not involve having to attack these characters. We start the interview with Zoe describing her initial reactions to playing *Deus Ex*.¹

131. Zoe: (*sitting in front of her laptop*) the lucky thing is...when I show some medicine or kind of weapon I can see the shape...I can know what exactly it is...this is the only thing...I know.

Zoe is using visual clues to find out what items in the virtual environment are used for. In the next utterance she indicates the game is difficult to understand. She has not accessed the databank to find out her mission objectives, but is awaiting aural instruction (from the very effective game prompts acting as a form of *other-regulation* when the player strays away from the game’s mission objectives). She has accessed the map provided and may have used the compass provided by the HUD (heads-up display) to work out directions within the environment. Zoe is finding out about the design of the game, which Gee (2003) calls the design principle.²

133. Zoe: when I’m playing this *Deus Ex* because...but I’m quite understand because they give me map...that will tell me where you should go...when they go there...actually I don’t know what I need to do...so when I face to the enemy I just know I got to shoot them to protect myself and I just walk anywhere until the ‘contactor’ just tell me...‘ah’...you need to do something else...which means I arrive to the right place so I need to carry on next mission.

It took her two weeks of play to begin to feel confident within the environment, where she was able to develop strategies in order to survive. This is not dissimilar to the orientation of a tourist arriving in a foreign city. Also, the ‘contactor’ Zoe refers to is a character at the *UNATCO headquarters* who has access to *Denton* via a *neural infolink*—the game design effectively has a coach guiding you

around the first level. The explicit information on-demand and just-in-time principle ensures the player is given relevant help just when it is needed. As the player becomes more competent, the guidance offered is reduced until it is no longer necessary. This reflects the other-regulation to self-regulation used in Vygotsky's (1978) genetic method stated earlier.

135. Zoe: Yes! Really funny but...yes the first week...I'm just like this kind of confused...and in the second week I'm just improved...I can understand more...play more martially.

She has developed a "save-game" strategy in order to replay unsuccessful parts in order to "get them right." This reflects Erickson's (1956) moratorium principle and Gee's (2003) *practice principle*. The psychosocial moratorium principle (Gee, 2003, p. 67) enables learners to take risks in the game environment because real-world consequences are lowered. Freedom to experiment without direct real-world consequences permits the learner to develop game (and laterally, real-world) concepts about life through trial and error. Begg, Dewhurst, and Macleod (2005) comment on the value of this principle in the training of medical doctors, who can make mistakes with their *virtual patients* without real-world consequences, meanwhile learning and improving their performance. Good COTS video games constantly juxtapose real and virtual realities so that your *projected identity* (i.e., the character you portray in the game—see Tripartite identities and knowing yourself) is forever being questioned and molded throughout the game. The concept of *play* has been at the center of many theories of learning, as it could easily be observed in action through children's daily activities as they learned about their environment and their social and emotional world with peers and adults. Piaget (1962), Bruner (1983), Vygotsky (1978), and Luria (1982), among others, sought to identify how play functioned in the cognitive processes of child development, and later as maturation takes place. Sociocultural theories of play have identified the

many ways in which play may affect children's cognitive development, but also their social and emotional development. Vygotsky (1978, cited in Lantolf & Thorne, 2006, p. 185) believed that play embodied imagination and that it contained all the developmental levels in a condensed form. Through make-believe play, children were able to extend themselves beyond their own cognitive abilities and therefore present themselves with the next appropriate ZPD through a process of self-reflection and metacognitive thinking. Gee (2003, p. 67) refers to the self-knowledge principle, which states that the virtual world is constructed in such a way as to make learners think about themselves and their current and potential capacities as well as the game domain they are playing in. The game environment acts upon the player by provoking development within their ZPD. The somewhat hostile environment of *Deus Ex* forced Zoe to make numerous game-saves or lose the progress she had made if her character suddenly died.

137. **Zoe:** I save many times...because sometimes I will make a mistake.

Kim: you go back and play a different part of the game 🐼

Zoe: Yes.

Kim: so you could actually be at the beginning of the game playing it at one time and then you could be later, playing a different part of the mission 🐼

Zoe: actually, I don't do that...I just continuing... but I'm worry about I will done something wrong so I always save.

Good COTS video games tap into our innate sense of survival and self-preservation, and encourage us to project this onto the character we are becoming in the game. Zoe had become emotionally involved with her virtual identity as *JC Denton, UNATCO agent*. Her desire to show me the part of the game where she dispatched *Anna Navarre*, another top agent at *UNATCO*, would demonstrate her competence as a player.

Anna's augmentation utilized older robotics technology, and her destruction brought about by *Denton* may be symbolic of the technological race for supremacy where outmoded ways must make way for the new. *Anna Navarre* is one of the few game characters that has to be 'terminated' in order to progress through the game—stealth and avoiding conflict both work effectively as strategies otherwise. However, at line 193 Zoe remarks that *Anna* just "explode herself." The reason is based on Zoe having found two parts of a code word that act as a 'killswitch' or detonation device when spoken to *Anna Navarre*, a way for the *government agencies* to ultimately control their creations should they get out of hand. Zoe had accessed this code through hacking computers in the *UNATCO headquarters*. Once the two clues had been found, it was only a matter of repeating them in sequence during a conversation with *Anna* for the kill switch to take effect. Zoe was taken by surprise (193: *I just be injured*) as the blast from *Anna's* mechanized body detonating caused her to lose health points.

194: **Kim:** She...you didn't have to do anything... you attacked her or?

Zoe: No just talking to me and suddenly she explode herself.

Kim: Oh, that's interesting, how did that happen? Have you got that saved?

Zoe: I don't think so because I don't like that part...perhaps I delete already (*pause*)... Yes I delete it.

Kim: Are you deleting it because...I mean...why are you deleting parts of games that you've saved before?

Zoe: something I think is not that important because I can save some (*tape ends*).

It appears that Zoe unwittingly terminated *Anna* without fully realizing what she was doing. She also erased games that she claims were unimportant or because she required space for her college work (523). It made no sense to me that

Zoe would want to delete the record of achievement of destroying a powerful enemy, and so perhaps this particular scene was too shocking to Zoe and deleting it may have been cathartic for her. However, she remembers all the details quite clearly.

145. **Zoe:** (*showing Kim earlier save where Anna is still alive*) this lady...I kill her...you tell me I've got several chance to kill her....

Kim: there's different ways actually...yeah.

Zoe: but I kill her in aeroplane.

Kim: you did?

Zoe: Yes.

Kim: alright...erm...interestingly if you do that the game immediately presumes that you're the enemy...is that right?

151. **Zoe:** No, no yet! I'm very lucky because that communicator, the contactor, and then he says 'oh you shouldn't kill her' but he say you did anyway...he says...because at this time only me and you know you kill her so I will help you to cover up this thing.

Zoe returns to her *boss's office* and has to select a response—which she does (emboldened below). She, as the projected identity *JC Denton*, has now effectively lied to *her boss*. Zoe has already started to form a *virtual identity*, which she is prepared to protect in the game environment by fabricating the truth.

Excerpt from *Deus Ex Script*³

JC DENTON: I have some bad news about Agent Navarre.

MANDERLEY: No shit. What the hell happened in there?

JC DENTON: Lebedev. A surprise attack.

MANDERLEY: I find that hard to believe. You're digging your own grave if you cover up for your brother.

JC DENTON: Yes, sir. I'm not covering up for Paul, sir.

MANDERLEY: Because he's gone, JC. I hope you'll understand this. The Coalition has shut down his augmentations and activated the killswitch.

JC DENTON: Activated...what?

MANDERLEY: Some very important officials have become nervous, nervous about Paul but also about you.

JC DENTON: I think I've proved myself. Can they really kill him—by pressing a button?

MANDERLEY: Yes—and you, too. So take these orders seriously. They're sending you to Hong Kong.

The above dialogue highlights the threat of a *killswitch* implanted in all nano-augmented *UNATCO* agents, which Zoe did not quite grasp as a concept. She had some concept of her own character exploding uncontrollably once she was in *Hong Kong* (248). She may have spent considerable time playing the game with it ending abruptly because she had not addressed the need to deactivate the *killswitch*.

The earlier comment on game deletion is interesting to note because in line 202, Zoe is recalling the scene where she gets arrested and imprisoned at the *UNATCO headquarters*, having been on the run from *UNATCO* for *Anna Navarre's* murder.

202: **Zoe:** Yes, very...what can I say...just the whole situation been changed...because before I'm the member of *UNATCO* and suddenly I'm be arrest and they will take all my weapons and medicine and any kind of things and they throw me into a kind of little room.

...

208: **Zoe:** because before I never played this game and you never told me he will face this situation and suddenly (*Kim: (laughing) sorry...*) and all the people...because...can you remember...at the first few missions when I complete them I back to *UNATCO* center I see many many soldiers and they

say '*Oh yeah great...you're such a hero and you done many many things*' something like that and '*I wish I can go with you to carry on this mission*' something like that...and I just think...they just like my brother or er, we have very good partnership...I have very good relationship with all these soldiers...feel very comfortable and I'm be free to go into the *UNATCO* or go out...I'm very free to go around that location...but suddenly...I'm being arrest and I'm thrown into security prison and all these people...they're not my friends at all...suddenly I feel it's a trap...just like trap and....

Kim: so you needed to delete that part of the game? yeah?

210: **Zoe:** Yeah, such a very erm...depress memories...it's not a good memory which depress me.

What is apparent from the above quotes is that deleting the game saves from the computer has not deleted the emotional trauma associated with the loss of status, position, power, and camaraderie she had initially with the *UNATCO* characters in the game. More noteworthy are how the comments made by the AI (artificial intelligence—non-player characters that respond to your character to create the illusion of reality) are memorized almost verbatim by Zoe, expressions that to a native-speaker playing the game would be considered 'throw-away' lines in the game-play scenario. Zoe has adopted a strategy of clicking on every AI character until no more useful information is forthcoming and the phrases presented are superfluous to the plot. Here is an example:

GUARD 1

If you need help, talk to one of the receptionists. You do not require a security pass to visit the first three levels of offices.

Late night....

My feet are killing me.

Hope you find who you are looking for.

The last three phrases are padding, but for a language learner they can be informative colloquial expressions in the L_2 . Zoe has been accessing these (for each and every character) throughout the game. More significantly, she is able to recall the expressions easily from their embodiment within the video game storyline. *Deus Ex* provides the player with a “memory bank” of past conversations, written word-for-word. This gives the learner an opportunity to access the language both aurally and visually. This reflects the dual-coding theory research of Paivio (1990, 1991) and Clark and Paivio (1991, cited in Rieber et al., 1996, p. 2). Within *Deus Ex*, *referential processing* opportunities occur at cinematic cuts or when a player clicks on an in-game character in order to obtain information. Referential processing is particularly important because dual coding theory predicts that learning will be enhanced when information is encoded in both systems (i.e., dually coded). Information that is dually coded has twice the chance to be retrieved and used (Kobayashi, 1986). There is no limit to the number of times a learner accesses this information, which enables them to repeat and create representational structures undisturbed by other elements of the game. Although there is no appropriate grading of the language in COTS games, given the opportunity to employ study skills, a learner can access a much richer use of the L_2 than may be possible within immersion classrooms for example, where pedagogic principles of “comprehensible input” and “caretaker talk” (Ellis, 1994, pp. 248-267) limit teachers’ use of the language as they guard learners against unnecessary exposure to certain (grammatical and pragmatic) forms of language and monitor the quantity of content delivered so as to avoid cognitive overload. COTS video games were never designed with language learners in mind, so none of the above restraints are present during game-play. In fact, they have been created to be richly immersive environments for a *native* speaker. The language learner receives exposure to the L_2 as it was originally intended. Clearly,

Zoe had made associations in order to understand the context of her character *JC Denton* within the gaming environment and was also able to emotionally identify closely with the character as *Denton* becomes hunted as an enemy of *UNATCO*. Gee (2003, p. 209) makes reference to three more key principles that enabled Zoe to learn within the game’s environment. The first two are the situated meaning principle and the text principle, where signs and signifiers are understood because of their embodiment in the context of the game, and where moving back and forth between text and embodied experience permits growth within this learner’s own ZPD:

To understand or produce any word, symbol, image or artifact in a given semiotic domain, a person must be able to situate the meaning of that word, symbol, image or artifact within embodied experiences of action, interaction, or dialogue in or about the domain. (Gee, 2003, p. 24)

A language learner must have access to the situation where that word or symbol, image or artifact was taken from in order to create meaning—an embodied experience of action, interaction, or dialogue. This is defined as *active learning* or *situated learning*. The richly immersive world of video games can supply highly detailed embodied experiences. Gee (2003) highlights the need for the player to be able to participate in ‘affinity groups’ or ‘groups’ within the semiotic domain. This is the third principle alluded to above, the semiotic domains principle. Zoe was clearly proud to be a part of *UNATCO*, but her *affinity group* no longer regarded her as a friend. Zoe has trouble accepting this loss and creating a new affinity group in *Hong Kong*. The metalevel thinking about semiotic domains principle focuses on the ability of the learner to apply critical thinking (i.e., not passive thinking) about the relationships of semiotic domains being learned to other semiotic domains. Zoe’s awareness of her *imminent death* by activation of the *killswitch* clearly worried her,

having seen its effect on *Anna Navarre*. Now she is on the receiving end. Her inability to locate *Tracer Tong* in *Hong Kong* may have led her to seek external assistance from this researcher in order to preserve her *virtual self as successful agent*, although as you will see later, other events were preventing Zoe from forming her new identity with the affinity group in *Hong Kong*.

Zoe had put in many hours of game-play in order to develop *Denton's* skills—the achievement principle states that there must be sufficient rewards offered at each level of the game to allow the learner to continue towards mastery and sufficient signposting given for the learner to recognize when he or she has been rewarded. In *Deus Ex* those rewards are improvements to your core skills or your weapon accuracy or upgrading of your augmentations. However, Zoe appears more taken by the AI comments of her being an effective agent in the field (see 208 above).

The intertextual principle could be seen as having a more global understanding of certain categories of text, through exposure to a number of embodied experiences within a number of domains. Zoe travels to *Hong Kong* where she will meet a 'terrorist leader' that was supporting *Paul*, her character's brother, another nano-augmented agent who has been terminated by *UNATCO* for his involvement with *Tong* and his cohorts. Zoe will have no choice but to drop the identity she created at *UNATCO* and start to build a new one using the embodied experiences the game presents her with. Her ability to cast off the old and adopt the new will also be a guide as to her ability to recognize the intertextual 'genre' of building a personal identity and will be a measure of how she has developed within her ZPD as the game provokes her towards this goal. Sadly, Zoe is reluctant to identify herself with *Chinese terrorists*, although *UNATCO* regards her as a common criminal now and the memories of this depress her (210). Despite this, she continued to play—in game-play terms she would have had to play for a considerable time in order to exit the *UNATCO*

headquarters and find *Tracer Tong* in *Hong Kong* which reinforces Gee's (2003, p. 67) committed learning principle, concerning commitment to the virtual character within a compelling virtual world.

Tripartite Identities

Gee (2003) argues from a sociocultural perspective that learning as deep, critical learning will come about only if the learner has made the commitment to take on the *identity* of "a person who can learn, use and value the new semiotic domain" (Gee, 2003, p. 59). In other words, unless the learner has decided that the new domain is accessible to them as a *member of this new community*, they cannot participate in it because they do not consider themselves eligible or even capable members of this new group. Zoe's reluctance to associate with the *terrorists in Hong Kong* may have hindered her ability to progress any further or resolve the pressing issue of the *killswitch*, the *terrorists* being the only ones with the technology to deactivate it. Perhaps the semiotic label 'terrorist' had powerful, negative associations for Zoe to the extent that she did not want to associate with them. To develop her *virtual identity*, Zoe must perceive herself as "a person who can learn, use and value the new semiotic domain" (Gee, 2003, p. 59). Zoe would need to forge links from her primary *real-world identity* (the multitude of identities she portrays to others in society) to her secondary *virtual identity* (the way she perceives herself as a character in this game). Our *real-world identity* is what helps us understand who we are, and includes our moral, cultural, and political viewpoints too. In the third identity, the *projected identity*, the learner builds through projecting their own wishes, goals, aspirations, and personality onto the *virtual identity* and is a combination of the other two. It is through this process of juxtaposition of real-world and virtual world identities that we achieve deep learning via our projected identities (Gee, 2003, p. 66).

There is nothing to stop Zoe from restarting the game or mission and playing the character *JC*

Denton in quite a different way. This is a common strategy among gamers as they learn from the experience of failure in the game as to what works and what does not within the confines of the game. It also enables you as the player to direct your game-play according to the desired combination of real-world and virtual-world identities (the multiple routes principle). If Zoe had simply played the game without participating in the game domain—that is, as an external observer—her description of *her arrest* would be vague and non-committal. However, she was highly emotionally charged, even after not having played for three weeks. She was also not happy to enter the game environment again during the interview, describing it as scary.

Interview Continued: Provoking Zoe's ZPD

The emotional bonds Zoe had created demonstrated a strong virtual identity had been developed, along with her projected identity as a good team player within the *UNATCO* staff and soldiers. Losing this bond was quite painful for her. I would argue that Zoe's projected identity as an important member of the group within the game was formed by her virtual self becoming an integral part of the community of practice (Lave & Wenger, 1991) that consisted of agents working for *UNATCO*. Zoe had put herself on the virtual payroll at *UN-ATCO*! Once she had lost this identity (through the intentional game design of terminating *agent Navarre*), the loss may have been such that her motivation to continue had all but stopped. Nevertheless, she found the game so compelling she eventually asked for my help. At this stage in the game-play, Zoe, as *JC Denton*, is unsure of her character's *real identity and background*, though she has some certainties.

218: **Zoe:** yeah, I think so...but at the time I'm definitely sure that *UNATCO* is my enemy... because I know that they are the organization

who killed my *parents* and caused...I lost my *brother*...and I'm going to find out the truth in *Hong Kong* and I need to find out the people who is called...strange Chinese name...*Tang Sing Tong* or something like this.

As a player Zoe appears more confident and aware of the goals she needs to achieve at this stage of the game now that I have provoked her ZPD, and she starts to self-regulate her thoughts again.

242: **Zoe:** I feel quite weird because...when I arrived *Hong Kong*...I got so many thing I need to do...first...and then second.

Kim: (*laughs*) can you remember them...after 3 weeks?

244: **Zoe:** I remember he said I need to find this guy...what's his name?

Kim: *Tracer Tong*.

246: **Zoe:** yeah, *Tracer Tong* (this guy).

Kim: yeah, why do you need to find *Tong*?

248: **Zoe:** because he said I need, I must to contact these people because he's a friend of my *brother* and then I can get more details from this guy. I think he's the leader of terrorists in *Hong Kong*. [So I have to.] And another thing is my *brother* and I...we are no natural people we are been...what can I say...our body is been modify...can I say that...with part of some...just like...robot...some systems which is in our body...my *brother* already die...this is why I need to...when I...in *UNATCO*, I need to send some details from his dead body and the people...I'm quite confused because they say something like...I'm quite special and quite unusual...I'm different compared with my *brother* because I didn't...(what can I say) very strange...I don't understand this part...just that...I didn't...oh! very strange but at least I am sure when I arrive in *Hong Kong* they said my body will be explode or something...over...my life will be over...

so I only got 12 hours to a life...I need to find out *Tracer Tong* to sort out this problem.

249: **Kim:** okay, so *Tracer Tong* knows the answer to stop your body exploding.

Zoe: yeah, something like that.

In line 248 Zoe is summarizing her goals on an ‘actions to do’ level, while on a metalevel she is recreating her *virtual identity* and her character’s reason for existence. She is aware that her *brother Paul* is dead and that *UNATCO* is to blame, is the enemy (218), and is also responsible for *JC’s parents’* death. Notice too how Zoe has resigned herself to accepting the need to associate with the affinity group of *terrorists* in *Hong Kong*, almost under her breath, as private speech (so I have to).

Zoe had called me to help her at this stage of the game as she seemed overwhelmed with the complexities that were unfolding within the game narrative. I decided to clarify the urgency of canceling the killswitch as a priority (249). I direct her to an important conversation with *Jock*, the helicopter pilot, an ally.

256: **Zoe:** Hmm (*reading*). Twelve hours. Killswitch.

Kim: yeah, I think that’s the keyword here.

Zoe: Yeah.

Kim: that they’re talking about the killswitch... in other words...

Zoe: so I will be...

261: **Kim:** dead (*Zoe: dead*) so that’s what happened to your *brother*...so *UNATCO* can switch this thing on...(Zoe: off) well basically, once they start the switch...it’s like they press the switch, 12 hours later you’re dead.

262: **Zoe:** yeah, I remember this...oh yes...when I stay in *UNATCO* center...when I met my former boss...when he talk with that guy (*Kim: Walter Simons*) yeah...and then the guy who in the *Walter Simon* he saw me and he said ‘*We will kill you. You won’t alive in next 24 hours*’...something like this...

but I’m still alive...but the thing is...in my *brother* and I...inside of our bodies there is something what *UNATCO* gave us...and something like killswitch...I think it is a kind of explosion system.

Kim: it’s a time bomb.

264: **Zoe:** yeah, which will...when they are turn... switch on the key and then we will explode ourselves...something like that.

In line 261 Zoe hesitates to say ‘dead’—perhaps she still does not accept that her character will die soon, without any enemy confrontation occurring, if she does not act fast. By line 264 I have provoked understanding of certainty of death unless she takes action to locate *Tong*. I locate the *Primary Goals* screen and ensure Zoe understands these (265) and the location of *Max Chen*, another potential ally and link to *Tong’s* whereabouts. She recalls a scene vividly from inside *Chen’s Lucky Money Club* (282), which she used as a refuge from *MJ12 commando units* (*super-robots that are created to up the stakes of the in-game demands on the player*).

282: **Zoe:** because I get some details from *Max Chen* I think...and another strange thing is, when I get into *Lucky Money* and that *Max Chen* and then somebody follow me, actually...they get into the *Lucky Money* and shoot us...and *Max Chen* has lots and lots of bodyguards that in battle with these guys...and then the both of them...many people die...when the battle finish...and then I just go to the...what can I say...go to the front room of *Lucky Money*...many many people lay on the ground...I saw the people who follow me...they are like kind of policemen but I don’t think they are... they looks quite...they not natural people because they’re wearing kind of machines, something...

Kim: do they move like people, or you haven’t seen them move yet...they’re just dead.

284: **Zoe:** I think I saw one...they are very very powerful...really hard to kill. Yeah. So I didn't join the battle! Too hard!...I thought 'Oh my God!' (*Kim: (laughs) okay...probably wise!*) Yeah, when I saw they are follow me I just ran into the *Max Chen's room* and I closed the door...when they finish I open and go out.

This rich description of a massacre and the power these new characters wield appear to have frightened Zoe into a state of inaction. I decided to investigate her use of augmentations, as she would need these to survive the next stages of the game. I discovered she was poorly equipped as a player in this department (289) and that she considered the augmentations practically useless.

292: **Zoe:** I don't use that actually...I think they're useless! Perhaps because I didn't upgrade them...so they only comes out very slightly...result...so they are not that helpful.

Kim: but you upgraded your strength, yeah?↗

294: **Zoe:** it's not that helpful...i think if I can up to four...level four then might be very useful.

295: **Kim:** so your actual augmentations...you don't really switch them on then when you go into a battle or...(Zoe: no) when you're trying to avoid people or...

296: **Zoe:** I even try once but...it's not that helpful.

Interestingly she seems reluctant to experiment with using the augmentations in any aspect of the game. Even the built-in augmentation of a light is not used. There appear to be technical reasons.

393: **Kim:** do you ever use your light?↘

394: **Zoe:** this is why I'm want to talk about with you...I don't know why this game...they...it takes a long time to...when I press F12 and then it switch on the light but you have to wait a long time to start to move.

395: **Kim:**(to start to move?) show me...right you've got a light.

396: **Zoe:** I can go into here, but when I...strange...I don't know...(giggles) perhaps because you're here!

Kim: because I'm sitting here it suddenly works! (*laughs*)

398: **Zoe:** you're lying, you're cheating!

Kim: what was happening before?↘

400: **Zoe:** before when I press this kind of keys (*the F keys along the top of the keyboard*) the game would suddenly just be...stopped.

Nevertheless, they worked when I used them, which Zoe was pleased to observe. Returning to (300) indicates why there may have been problems with the augmentations.

Kim: let's take a look at your health now.

300: **Zoe:** I'm always being very healthy...and I already...

Kim: you've got 253 (*normal game supply is four or five per mission!*)...now is that from picking them up in the game↗ or (Zoe: No↗) have you used 'cheats'↘?

302: **Zoe:** of course used 'cheats'.

Kim: okay↘ tell me.

304: **Zoe:** because in the game.

Kim: tell me about using 'cheats'...how many 'cheats' have you used↘?

306: **Zoe:** erm, just several times...one I changed this medicine number...number of this medicine box and er, number of ammos...I had lots and lots of weapons but...most useful one I think is this one...(points to *sniper rifle*) 2006 ammo because it's very...you can see the details with this one...first the maxi range is very good and you have silencer...very very quiet...I think 'maxi' range is the most important thing...it's very high...I can shoot very far away and then...without people knowing.

Zoe has resorted to using cheats to gain unlimited health, unlimited ammunition, and advance all her physical skills. She was also distancing herself

from potential enemies and picking them off like a sniper—an effective strategy. Her off-hand manner with regard to the use of cheats (302) indicates she considers this to be an expected compromise by gamers and not at all unusual. She either decided that augmentation is not helping her achieve her goals or she felt the need to supplant the dearth of *augmentation canisters* with other (unlimited) options. Two questions come to mind: Is augmentation considered to be akin to ‘defiling the body’, which is considered unacceptable in some cultures, and does that hold true for the Chinese culture; and is Zoe using cheats to compensate for her unwillingness to use the augmentations? Using cheats is certainly an accepted part of gamer strategy to continue playing, despite the real-world inabilities of the gamer (Gee, 2003, p. 187). Good COTS video games allow for degrees of autism among its players, and cheat codes permit players to overcome particular weaknesses that would otherwise prevent their continuing or participating in the game. Despite giving herself endless *health kits* and unlimited *ammunition*, Zoe came to realize she is no match for the demands being made on her character in the virtual world and so retired from play for three weeks. Nevertheless, the game was so compelling that Zoe was unwilling to return the CD-ROM to me even though I had offered to take it back during one tutorial session; instead she was determined to solve the issues that were still vividly active in her mind three weeks later. She had already discussed the lack of strategies (41) at the beginning of the game and was now confronted by the need to provide another set of strategies at a much higher level. She had advanced-level skills using the cheats so she was effectively playing as a ‘grand master’, but without augmentation, she was mortal. Augmentation leads to possession of god-like powers, as the initial cinematic introduction and the title of the game itself indicates. Zoe had reached the limits of her ZPD. Her strategies were now useless to her. In fact, she was still using a *New York UNATCO* ‘shoot on sight’ strategy in *Hong Kong*

which was inappropriate because there were no threats initially, as the *military police* were friendly towards her character *JC Denton*. However, Zoe decided she needed to get some information from the *police headquarters* in the *marketplace*. The character *Maggie Chow* offers to help *JC*, but she is merely using him as a pawn in her own game to incite a feud between the two *triad* gangs. She gives the code for a secret vault in the *police HQ* to *JC*, but the answers he is looking for are not there—the first double cross the player experiences in the game. This action resulted in Zoe shooting at least one *Chinese military policeman*. (There may have been two more in the station—I decided not to look as I believed Zoe was deeply embarrassed at committing such acts, and this may have been the reason for such a long delay before informing me of the difficulties she was experiencing). A number of possible solutions could have been available to her, but she did not seem to have considered them—using a *riot prod* to render AI unconscious or wearing a *camo suit* (345 below) were not being considered by Zoe, neither to avoid detection when snooping around nor as a strategy to escape when under attack—both very effective strategies. What was more surprising was the disdain she held for the objects discarded as rubbish (*Zoe: I’ve already threw them over 5 already*). I decided to provoke her ZPD on this issue.

340: **Zoe:** (reading from *Denton’s databank*) computing system...they can render an agent invincible to...

Kim: is that ‘invincible’? 🐢?

342: **Zoe:** ‘invisible’ (Kim: Ohh! 🐢🐢; Zoe laughs) to both humans or bots by dynamically...

Kim: etcetera etcetera yeah...a bit of technical English there...(reading) dynamically refracting light and radar waves...so, basically it makes you *invisible*.

344: **Zoe:** but they are not very 🐢useful 🐢.

There is still reluctance to use this equipment for some reason. I decide to provoke another area altogether—her culture.

345: **Kim:** it's like a magic cloak (*Zoe: hmm→*). well, you've got one so let's see how you could possibly use it... (*Zoe: I've already threw them over 5 already.*) I'm sure you could find some more. What's interesting about this is that at the moment you are saying you can't play any further because you keep getting shot by Chinese police.

Zoe 'complained' to me that she could not play *Deus Ex* any further without "having to shoot *Chinese military police*." I now discover she has disposed of at least five opportunities to become invisible while investigating situations and places, thereby remaining undetected and avoiding bloodshed.

346: **Zoe:** ㊦ it's not only like that... I'm not pleased to play foreign game which (*inaudible* 'when they travel?') China because I think Western people they always misunderstand Chinese culture and people and life... they always criticize them, they always blame something which they don't agree.

347: **Kim:** I'm sorry... who disagrees ㊦?

348: **Zoe:** Western people.

There seems to be considerable bottled-up emotion. I persist.

349: **Kim:** about what? ㊦

350: **Zoe:** about anything I think because for Western people China is too foreign, too foreign and many cultures can blame many issues... can bring up many issues and many things people don't accept and they disagree with.

351: **Kim:** but my issue here is that you're playing the game, you're in China, your Chinese, naturally by birth... so...

352: **Zoe:** yeah, it's Chinese people's fault... I think until today, Chinese people's minds haven't been independent, haven't been... (*pause*) rescued... you can say... we are still in limited opinion... just like can you remember why, the past hundred years why China been ruined by Western people... because the last Chinese dynasty we closed our market... we closed Chinese land... we don't allow our residents go out to trade with another country. (*Kim: right.*) We are no interest in outside world.

Zoe has been reflecting deeply on Western and Chinese cultural differences and is heavy with emotion about Chinese people being misunderstood in the West. Her comments about Chinese people's minds not having been independent, and not having been rescued provokes questions in my own mind about whether they are independent and rescued now. Does Zoe consider they are? I provoke further.

353: **Kim:** okay, so how does that...

354: **Zoe:** We're proud of our civilization. So until today is same thing happen. Even we open our market we are pleased people to... foreign people trade with us... to do some commercial thing.

355: **Kim:** my point is, here you are in this game but you won't go any further... why is that? ㊦

356: **Zoe:** This is what I'm talking about.

357: **Kim:** okay, explain again 'cos I can't.

358: **Zoe:** my feeling!

I understand her argument to be that Western minds do not understand Chinese culture because China has been "closed to the West for so long." What I don't understand is how a Chinese player, playing an American secret agent, still finds it okay to kill a *Chinese military policeman* without any justification (other than needing to get into the *police station* in order to continue her mission).

The proof must be in the game itself, so I decide to investigate.

359: **Kim:** just go into the game, show me where you are in the *market*.

Zoe: (looking at *Saved Games*) *Lucky Money*... no I get out from there.

Kim: so what's happened...have you met *Max Chen* at this point (*Zoe: yes*) and have you been into the *Versalife* building? 🗡

Zoe: no yet because I cannot.

Kim: okay, so it's locked to you.

Zoe: (perhaps I will meet some enemy) I'm just scared play this game sometimes!

Zoe claims to be quite frightened by the game environment, but retains her composure while we look around the market.

371: **Kim:** okay, so you've looked at *data cubes* and what do you do when you read that? If you just click on it...that's the free *map*, okay...so you've picked up the *map*...erm, so have you been involved in any gun fights or anything in the *market* at all...or are you just walking through the *market*...you're not actually shooting anybody in the *market*.

Zoe: I'm not, because when I arrived there at first time...I think the *policemen* they move by themselves...but before there's another *policeman* sitting...standing in there...he was standing there and I talking to him and he said '*no one can show their gun in this market*' so I always just take my empty hand go into there. If I pick up any weapons from my pockets and then I think the policemen will start to shoot me...something like this because when this *residents* saw me take a gun people will terrified and will run away.

Kim: what, you've done that? 🗡

Zoe: I didn't 🗡 (*Kim: oh you haven't then*) but I suggest it will happened and there is a warning bell..(*Kim: yeah yeah*) yeah, if I

pick up something people will run there to rung bell. (*Kim: sure.*)

Zoe has not experimented or if she has, she has forgotten as it is quite possible to walk around the *market* with a drawn weapon without encountering any opposition. It is the discharging of weapons that causes the alarms to activate. She has taken the word of a *Chinese policeman* AI character as 'law to be obeyed' and she obeyed it. Interestingly, the real-world law (within Zoe's domain as a Chinese national) appears to be stronger than the *virtual game law* at this stage. The real-world semiotics have powerful representations in the virtual world until such time as the player wishes to break those codes, as Zoe does by shooting a *policeman*, protected by the psychosocial moratorium principle. Zoe may have spent many hours of game-play trying to find answers to *Tong's* whereabouts, fully knowing her *virtual life* was coming towards an end. In an act of desperation, I believe she resorted to violence against the *military police* in an effort to try to uncover mission-critical facts, unaware that this was a 'red herring' in the game design. The game does not just spoon-feed the player with facts and information—the player must tease it out of the game environment, which is hard work. Gee (2003, p. 90) calls this the probing principle. For example Zoe:

1. Probes the virtual world to gather data,
2. Creates some hypothesis based on this data,
3. Reprobes the world by applying the hypothesis to see the effects, and
4. Responds to the feedback.

This principle could be seen as cyclic for every independent action the player carries out in the game, and a player may need to juggle a number of these separate cycles depending on the complexity of the storyline. Gee (2003, p. 90) comments that without this strategy in place, a player would not get very far in a video game. Clearly, Zoe had tried everything in her power to progress through the

game. She had reached the limits of her ZPD as far as the game domain was concerned. I provoke her development at this critical stage, but first notice something strange about the way she holds her fingers over the keyboard of her laptop. I ‘drive’ for a moment to see what the problem is.

375: **Kim:** let’s just go down this road...how do you...(keyboard configuration to control character movement does not work for Kim)...oh, you use different patterns altogether to go forward...(Zoe: *there’s a robot in there*) and the robot’s ‘green’ (*friendly*) at the moment, okay.

Zoe has changed the key bindings, which control movement and bring up information screens and call up weapons and other devices from her inventory. I did not clarify what changes she had made so as not to interrupt the flow of her description of the current situation. Watching the contortions she had to put her fingers through to carry out simple movements was revealing as she had positioned many keys in close proximity—nevertheless she still seemed unsure of which keys did what. This could have been what was causing her such difficulties in fending off opponents earlier in the game and now presented a problem of control at a higher level of play. Additionally, laptop keyboards are much more compact and do not offer the raked profile of a large keyboard, but lie flat, which could be presenting Zoe with more physical control issues. I return the laptop control to Zoe.

376: **Zoe:** (*aside: you see this, I kill this*).

Kim: who’s that?

378: **Zoe:** *Chinese Military Police (smiles)*.

Kim: so you did shoot him?☹

380: **Zoe:** ☹☹ yes.

Kim: okay→ um...why did you shoot him?☹

382: **Zoe:** because I need to get into there (*indicates police station*) yeah...when I picked this, opened this (*Kim: that’s the police station is it?*) Yes. When I get into there but I’m no allow in.

Kim: okay, so you feel you need to go in there for some reason?☹

384: **Zoe:** because inside have first a *TV control system* I can, when I go there I can switch off. Then I can go to many place.

Kim: why do you need to switch that off?→

386: **Zoe:** I dunno—sometimes I think it’s important (*giggles*).

In 376 Zoe refers to a *Chinese policeman* who she has shot dead. She mentions the act but refers to the character as *this* (not him). Unless she means to utter the phrase “I kill(ed) this man,” but in her next breath she identifies him by using the job title ‘*Chinese military police*’ but does not add gender (*policeman*). I wondered if this was a strategy to lessen the act and divorce herself from it by remaining gender-neutral or genderless. Her argument for having to enter the *police HQ* using violence demonstrates her overarching aim to meet the game goals even if it meant killing a *Chinese authority* figure. In contrast to her concerned voice on the phone when she called to tell me about not wanting to kill any more Chinese characters in the game, Zoe seems quite calm now. It is as if, having shown me the deed, she has been absolved of the crime. I decide to retrace my steps and ensure she understands all the basic elements of the storyline.

405: **Kim:** how do you feel about the two games...i mean...do you think you’ll carry on with *Deus Ex*?

Zoe: perhaps not...really...if I will play again...perhaps I will start in the middle or from the beginning start because...as now I’m in Hong Kong...I feel is...the story of this game is getting deeper and more complex.

Kim: it gets even more complex...i assure you.

Zoe: Yes, of course...because in the beginning I’m a member of *UNATCO*...and at the end I’m joined to terrorism group...and then become enemy of *UNATCO*...and *UNATCO* is a fake...is not right...is work

for money...is no work for government...
no work for the residents...this is...which is
disappoint me...a lot and shock me...and...
on the other hand....

She seems keen to start over with the new information, although there is reluctance too and she has not come to terms with the concept of working outside of a government framework in the *Hong Kong* environment, which I suggest is to do with her Communist Party upbringing and her unwillingness to associate with *terrorists*, even in a virtual world. I check her comprehension of the plot.

409: Kim: did you understand the plot with the Grey Death...this sort of plague and the vaccine that you're trying to find...did you understand that part of the story...you know you had to find those big green canisters...sort of bubbling liquid?

Zoe: Yes.

411: Kim: do you know what they were...part of the story?

Zoe: before I don't know...because I remember the contactor he always tell me 'you need to find these...there is three bottles of this green water, or something...green liquid...i don't know what's it for but anyway I found this...these three bottles.

413: Kim: can I tell you what they are?↗

I started to go into an explanation of the plot instead of 'concept checking'. I was starting to feel tired after nearly three hours of interview. Zoe stopped me and wanted to explain her understanding, which seemed a better idea. She seems to be very alert still—perhaps because she can sense that solutions to her game-play will be provided soon.

414: Zoe: no...before you tell me I tell you...and then when they said 'good you've found out these three bottles and then we will send a group of military to cover up...to find out...

to take these things away'...and I think it's alright...but...the second time...i mean...after I achieve this goal...after I complete this mission...the next time when I see this thing is...they are just next to *my brother's* dead body...well...i dunno...i think something wrong about those things...which is not right.

Kim: but you'd learnt to recover them...what and then *UNATCO* own them...*UNATCO* have them.

416: Zoe: I think they have them just for...it's an important element to support their secret testing...or something...do you think so?↗

I was surprised that Zoe had not grasped the special significance of these objects. She had a photo and description of one in her data files and had risked *her virtual life* on a number of dangerous missions in order to secure them for *UNATCO*. The whole narrative of *Deus Ex* is based on their very existence, but Zoe seems to have missed the point: *Ambrosia* is a vaccine against the *Grey Death*, is manufactured by *Versalife*, and is in short supply, hence the importance of *UNATCO* preventing it from getting into anyone else's hands. I explain a little more of the plot, and concept check vaccine and antidote with a dictionary. Zoe makes the association with Bird Flu and then corrects herself to mean the cure, not the disease. She realizes that *Ambrosia* is a positive thing, so must have thought that it was for negative uses, such as poison. I cannot see why she made this assumption at the beginning of the game, but decided not to ask her so as not to embarrass her. I refer to a bilingual dictionary to define 'vaccine'.

426. Zoe: its like this...(shows dictionary).

Kim: like an antidote...okay...is there another word that you know?↗ What does a doctor give you to stop you getting the disease?↘

428. Zoe: cure↗? Medicine.

Kim: yeah what sort of medicine...I'll give you another word...do you know the word 'vaccine'?↗

430. **Zoe:** hmm...oh yes...like bird flu!⁴

Kim: yes↗ okay.

432. **Zoe:** or another normal flus...so...hmm...to protect you before you get this thing.

Kim: so those green bottles you were looking for in *Deus Ex*...they are a vaccine.

434. **Zoe:** ahhh↗??? But it's a positive thing...i thought they are....

Kim: they're a positive thing, no, they're a good thing...but there is a limited supply of the vaccine...just like with the bird flu...they can only make so much of it...so who do they give it to?↘

436. **Zoe:** I think...of course...because the vaccine is limited we can't give every single person in the world so we...

Kim: so who decides who gets the vaccine?↘

438. **Zoe:** government.

Kim: hmmm↗...who does the government give the vaccine to?↗

440. **Zoe:** the most important people first...the wealthy people or like this country (Britain) it's the Royal Family first and another famous celebrity like...celebrity of sport...or singers...this kind of...businessmen...this kind of people...poor people especially...for example in America like black people like New Orleans...these⁵ people will be abandoned...because they are useless...they are no valuable to the government.

Kim: so that's really what the story of *Deus Ex* is about...you start off working for UNATCO and you start off getting this...the first raid you do...when you go up into the Statue of Liberty Island...you have to tell the NSF boss...you arrest him at the top of the building (*Zoe: yes yes*) and he has one of the canisters...or you were trying to stop them because they were taking the canisters...so really the NSF were stealing these vaccines from UNATCO...or from the government.

442. **Zoe:** they want to survive more people.

Kim: exactly...they're trying to protect their own people...so when you realize that that's why you join NSF...because you realize they're trying to protect the ordinary people.

444. **Zoe:** the government want to abandon useless people.

In 442 (*they want to survive more people*), Zoe now sees the reason the NSF wanted to capture the *Ambrosia* shipments from UNATCO—in order to save ordinary people. She may have a concept of the NSF as 'freedom fighters' now. Initially, *Denton* as a UNATCO agent is fighting the NSF, a supposedly *terrorist organization*. The plot of *Deus Ex* plays with the concept of "one man's terrorist is another man's freedom fighter"—a quote spoken by a character in the novel *Harry's Game* by Gerald Seymour, constantly making the player consider whose side he or she is on. Zoe's provoked ZPD leads to her self-regulating her mission goals and purposes as *Denton*:

444. **Zoe:** the government want to abandon useless people.

Kim: and let them die of this death...but it also turns out...the more you look at the story you find out that the Grey Death was created by...

Zoe: UNATCO...government!↘

Kim: well by...some government agency...to kill people so the government could take control...that's what happens in the next part...when you go into *Versalife* you'll find out a bit more information!↘

Zoe: so who I am!↘?

Kim: sorry...how do you end or who do you become...↗ well you'll have to find out! If you're interested enough.

Zoe: I don't understand!↘ If my parent's could die, which means they're nat(ural?)...normal person so why my *brother and I* we're half machine...we are half robots...we no not natural people any more... (*Kim: that's*

something you'll need to discover) ...ourselves have been modified...why?🔪👊 ... and why chose me?🔪👊

Kim: these are questions that the game will answer (*chuckles*).

Zoe: why they chose me...and no choose anybody else?🔪👊 how special I am.👊

Zoe seems excited to discover the answers to these questions now. I need to check whether she still feels unable to use the augmentations.

435: **Kim:** but I'd recommend that if you do want to play on and find those answers you also will find you need to start using those unnatural (*Zoe: super powers*) super powers in order to...well obviously progress through the game.

Zoe has used the word 'super powers', not in the sense of great nations, but as a noun phrase to describe what being augmented is like. This may have resonances in fantasy figures like Superman™, where god-like skills are used for good, not evil.

Zoe: I feel very slowly to update these skills... because I need to find that bottle (*upgrade canister* or *augmentation canister*).

Kim: yeah those...you will find once you get into *Versalife*...there's four more upgrades that you do in *Versalife*...probably you have to go in there a second time.

Zoe asks about *Versalife*—she is interested in finding out about this company as it is the next stage of the game.

456: **Zoe:** What does *Versalife* mean?

Kim: *Versalife* is a company in *Hong Kong*...and obviously you're going to go in there and find out what they're doing but you'll soon find out they're doing a lot more than what you think they're doing...(laughs).

Zoe: is it illegal thing? (*Kim: Oh yes! Laughs.*) Something bloody👊 ...something darkness👊...or it's something good for people...good for residents...

Kim: ummmm...

Zoe's final question still demands to know if the Chinese government is being slandered in any way, but I assure her that it is only the *American government* that receives criticism, but I play this down.

463: **Kim:** no🔪👊...there are no...there is no criticism of any known government in this game so as far as that game is concerned it's a politically correct game except for maybe a connection between the *American government* and who they're controlling.

Zoe: I think so because the first location is the *Liberous Island* so...

Kim: but I think that is just because there...obviously the number of people who will play the game are probably Americans...that's probably they're bigger.

Zoe: Yes, because George Bush everyday talking about anti...

Kim: ...terrorism.

The tape ended at this point. Although we started to have a discussion about terrorism and American and British policy, I cannot include this data as it was not recorded. Nevertheless, the interview process brought to mind many unanswered questions Zoe had about international terrorism and police states.

CONCLUSION

Despite not having grasped the global pandemic storyline initially, my attempts at provoking development of her ZPD provided Zoe with increased determinism to continue with the game from a more informed position.

Zoe was able to complete 12 missions, albeit using cheats, up to the interview. This is quite an achievement in itself, as Zoe did not demonstrate the skills of a seasoned first-person shooter gamer, and the game's virtual character, being male, may have been difficult for Zoe to relate to. Self-regulation to such a degree in an L_1 environment, without L_2 dialogic support—that is, relying on her own study skills to mediate for her without reference to communities of enquiry exterior to the game—clearly demonstrates the effectiveness of the gaming environment to supply this dialogue. Given that the project ran over a number of months, Zoe must have engaged in many hours of play to reach this level as an intermediate learner of English. This seems to indicate that she had fully identified with the virtual character *JC Denton*, and until the cultural issues arose about playing in *Hong Kong*, she was making good progress. This disturbance to her play/learning is indicative of her feelings towards the game's cultural stereotyping of Chinese and may have been sufficient to cause her to withdraw from the game. There is also the possibility that the complexity of the storyline was overreaching her ZPD so flow was disturbed and only sporadic learning was occurring. It would be interesting to discover how she acquired the cheat codes for the games, whether off the Internet or by asking friends at college. The study could not ascertain whether any external help was given to Zoe throughout the period of play and is a weakness of the study. I base my assumption of minimum peer/expert support based on reports from the host mother who commented that Zoe rarely left her bedroom after returning home from college (implying she did not have an active 'social life' with other students), and also my personal observations of her in the learning resources center at the college and seeing her walking home from college where she was always alone. She would have had to engage with the plot in *Deus Ex* to be able to give such detailed descriptions during the interview, and there are indications of deep learning with regard to this.

The strongest evidence is the emotional upset she displayed when describing her capture and imprisonment by *UNATCO*. Her ability to make the domain shift from the in-game conspiracy of a *government* destroying its own people in order to gain control over the population, to the reported appalling lack of government response given to the victims of Hurricane Katrina in August 2005, allegedly based on the victim's social class and race, demonstrates Zoe's understanding of real-world parallels within the semiotic devices of the game.

Understanding the processes that lie behind the metacognitive shifting of domains is under-researched partly because the processes are so immediate and therefore difficult to measure when they occur, and partly because they remain for the most part invisible and unconscious to the learner. I would argue that Zoe has made strong virtual identities within the video games that have demanded her to utilize the target language in order to reach a certain stage in the games she has been playing. She has not had opportunities to develop her "gaming skills" through communities of enquiry, but has provided evidence of her deep learning of real-world issues through exposure to the game and has demonstrated competence at shifting domains within her inter-language competences, which constitutes a higher-order skill. Zoe has certainly been provided with new ways of viewing such topics as conspiracy, terrorism, and allegiance, and it would be interesting to follow up the research to see if, one year later, she is able to recall any of the issues she discussed in detail as that would certainly demonstrate long-term retention of information, and more significantly, whether her ZPD had expanded in these topic areas. She could certainly recall in minute detail after her three-week abstention from playing the game, which supports the argument that video games can provide effective situated learning environments. What COTS video games often do not do is provide the pedagogic intervention required. As the researcher, and as a member of a community of enquiry, I had to engage in provok-

ing Zoe's ZPD in order for her to understand the detailed plot of *Deus Ex*. Whether this was due to her need for more refined study skills or more likely her need to be part of a real-world community of enquiry would be worth researching further. The question is, do COTS video games teach language as a standalone product, or does there need to be intervention and dialogic intercourse with an expert from a community of enquiry? There were sufficient affinity groups within the communities of practice in *Deus Ex* to enable Zoe to feel part of the game and to contribute to its 'development'. Further research will need to be carried out to ascertain how effective these communities are in providing the learner with language skills in the L_2 .

There is little doubt that good COTS video games are engaging and provide dynamic and compelling entertainment. What cutting-edge educators desire is for the rich virtual worlds within video games to be harnessed for the presentation of learning material.

Video Games in Educational Use

van Eck (2006) is clearly optimistic about "serious games" that are in development,⁶ where the lessons learned from manufacturers of COTS games have been applied to "edutainment" products so that the game-play element has not been overshadowed or lost through overzealous pedagogy. This particular process of production of digital game-based learning (DGBL) as "one-off edutainment" is expensive, as it is time consuming and requires a great deal of input in terms of man-hours, which companies are reluctant to invest in for fear of "revisiting their unprofitable past" (van Eck, 2006, p. 20). van Eck (2006, p. 18) reminds us of the dangers of "academizing" games and quotes Papert (1998) who refers to edutainment software of the last decade, which instead of harnessing the power of games for learning resulted in "shavian reversals"—the offspring that inherits the worst characteristics of both parents—where the game

element is boring and the learning is just "drill and kill." He argues that we must ensure we do not put too much emphasis in the other direction either, where games are fun to play but "hit and miss when it comes to educational goals and outcomes" (van Eck, 2006, p. 18). By finding the synergy between effective game-like engagement with the software and effective pedagogy, van Eck claims that COTS digital game-based learning is possible in the classroom.

There are a number of organizations that classify games according to guidelines agreed upon within the video games industry to inform parents and teachers of game content and suitability for young players. The Entertainment Software Rating Board (2007) and the Pan-European Game Information (n.d.) age rating system established in 2003 provide an informative censorship of game content by giving a range of suggested ages the games are suitable for, as well as iconic representations of game content, such as bad language, sex, drug use, violence, gambling, and fear, as well as racial and other forms of discrimination. This rating system is similar to that used by the film industry, but has a much lower threshold for age suitability, starting its ratings at 3+, then advancing to 7+, 12+, 16+, and 18+ for adult games. These ratings are a useful tool for teachers and educators when selecting material suitable for certain age groups and cultural backgrounds.

The data provided by this study for the use of COTS video games to teach second or other languages can be considered inconclusive. Nevertheless, further research into COTS video games should attempt to assess how much change is occurring within a learner's ZPD while accessing the L_2 environment. Studies that assess all four skills (listening, speaking, reading, and writing) through provoking the individual learner's ZPD would provide valuable data as to how rapidly the L_2 was being acquired. Access to diagnostic equipment used by games manufacturers on subjects for beta testing new games would provide a richer source of data about how the player accesses the

L₂ within the game environment. Attention could be given to where the game needs to supply the dialogic interaction, which would otherwise have been supplied by a teacher or more knowledgeable peer within a community of enquiry.

Video Games in Employment

Just as Zoe felt comfortable in the *UNATCO headquarters*, I suggest that video games themselves can create communities of enquiry within the game world where the domain knowledge of a field of enquiry is accessible, in stages appropriate for the learner on the periphery of his or her chosen subject. I do not envisage this as a static “body of knowledge,” but as an organic database of simulated experiences that accurately reflect the real-world domain as it is updated and renewed.

“In communities of practice, knowledge, skills, identities, and values are shaped by a particular way of thinking into a coherent epistemic frame” (Shaffer, Squire, Halverson, & Gee, 2004). This concept of providing epistemic frames is based on the epistemology of that domain, the working knowledge of how certain professional groups think. Doctors speak about medical issues in the language they all know, as do teachers, scientists, lawyers, and childminders. Within those frames lie the language and concepts of that domain’s culture and practice. Video games would be able to act as examples of good practice within these epistemic frames and provide that group with learning environments for future employees.

I am not suggesting either that *all* forms of learning should be accessible only as a video game. What video games do, and do well, is provide a rich immersive environment containing virtual identities that act as powerful learning tools, and this could be integrated into current e-learning programs where scenario-like engagement is required by the learner, for assessment purposes for example. This is already practiced in jobs where there is a high risk factor such as air-traffic control or training tactical military operations, or

where simulation is an effective substitute during training where equipment used has a high replacement cost such as fighter jets or oil rigs and where novices require specialized training before being presented with the real-world scenario.

Video Games in Life

When a player identifies with a character in a video game, he or she is projecting his or her own self into the game and giving birth to a new identity that they will eventually accept as a real-world identity. This may sound like fantastical science fiction, but the evidence is already available, as this powerful communication and learning device is being used for both good and evil. Gee (2003, p. 151) highlights the fact that racist organizations have produced their own video games in order to teach their perspectives on reality. He argues that video games are no more powerful than books or films in that we take from them what we choose to, but also suggests that playing such a game would inform the player of why such an organization hates the way that it does and makes the player want to “redouble their efforts to work for world peace, diversity and tolerance” (Gee, 2003, p. 199). I would argue that minds can be changed by dialogue, and that learning is dependent on what you bring to the video game as your real-world identity. There are a myriad of facets that make up each and every life. The games design for the language learner to experience deep learning of the target language includes the learning of that language’s culture and what binds it together as a society. Video games used as powerful learning devices would make it possible to create virtual identities that enable learners to share in the effective social practices, powerful identities, shared values, and ways of thinking of important communities of practice. Shaffer et al. (2005) direct us to the provision of epistemic frames for learners, where finding out about the ways of thinking, doing, and knowing within different communities of

practice, such as different professions, leads to a “thickly authentic” context in which to learn where

activities are simultaneously aligned with the interests of the learners, the structure of a domain of knowledge, valued practices in the world, and the modes of assessment used (Shaffer, 2005).

By engaging the language learner in virtual communities of practice that they desire to be part of, they are more able to acquire the target language while developing their projected identity as a member of that community. Video games are fun too:

In play, we participate in a simulation of a world we want to inhabit, and epistemic play is participation in a thickly authentic simulation that gives learners access to the epistemic frame of a community of practice. When it succeeds, it is fun, not because fun is the immediate goal, but because interest—linked to identity, understanding, and practice—is an essential part of an epistemic frame, and thus of an epistemic game. (Shaffer et al., 2004).

I do not call for the abandonment of hard-won effective practices in English Language Teaching (ELT), which have produced and will continue to produce results in providing learners with the opportunities and abilities that ownership of another language can bring them. I do call for the adoption of any and all technologies that will make the task easier to produce those results by engaging the learner. Prensky (2001) highlights the differences that these technologies are already having on the way young people think and act in the society (Prensky, 2001). Learning styles are changing and the pedagogic processes must adapt to address this change. The technology is now ripe for deploying into educational settings such as language learning. The idea is not new. Titles such as *Who is Oscar Lake?* (Language Publications Interactive) and the *Carmen San*

Diego series (Brøderbund) launched over a decade ago were brave pioneering examples of what was then considered cutting-edge language learning products. Perhaps the video game industry could take the “moral high ground” by spearheading the development of video games for learning in all communities of practice. Our schools and universities would greatly benefit from being able to provide our students with rich, deep learning environments. And as regards examining learners, just sit the examinee in front of the video game of their chosen domain and see how well they survive in it!

KEY TERMS AND DEFINITIONS(FROM THE 36 LEARNING PRINCIPLES PROPOSED BY GEE, 2003)

Committed Learning Principle: Learners participate in an extended engagement (a lot of effort and practice) as extensions of their real-world identities in relation to a virtual identity to which they feel some commitment and a virtual world that they find compelling.

Design Principle: Learning about and coming to appreciate design and design principles is core to the learning experience.

Identity Principle: Learning involves taking on and playing with identities in such a way that the learner has real choices (in developing the virtual identity) and ample opportunity to meditate on the relationship between new identities and old ones. There is a tripartite play of identities as learners relate and reflect on their multiple real-world identities, a virtual identity, and a projective identity.

Intertextual Principle: The learner understands texts as a family (genre) of related texts and understands any one such text in relation to others in the family, but only after having achieved embodied understandings of some texts. Understanding a group of texts as a family (genre) of texts is a large part of what helps the learner make sense of such texts.

Multiple Routes Principle: There are multiple ways to make progress or move ahead. This allows learners to make choices, rely on their own strengths and styles of learning and problem solving, while also exploring alternative styles.

Practice Principle: Learners get a lot of practice in a context where the practice is not boring (i.e., in a virtual world that is compelling to learners on their own terms and where the learners experience ongoing success). They spend a lot of time on task.

Probing Principle: Learning is a cycle of probing the world (doing something); reflecting

in and on this action and, on this basis, forming a hypothesis; reprobing the world to test this hypothesis; and then accepting or rethinking the hypothesis.

Psychosocial Moratorium Principle: Learners can take risks in a space where real-world consequences are lowered.

Regime of Competence Principle: The learner gets ample opportunity to operate within, but at the outer edge of, his or her resources, so that at those points things are felt as challenging but not “undoable.”

Self-Knowledge Principle: The virtual world is constructed in such a way that learners learn not only about the domain, but about themselves and their current and potential capacities.

Semiotic Domains Principle: Learning involves active and critical thinking about the relationships of the semiotic domain being learned to other semiotic domains.

Semiotic Principle: Learning about and coming to appreciate interrelations within and across multiple sign systems (images, words, actions, symbols, artifacts, etc.), as a complex system is core to the learning experience.

Situated Meaning Principle: The meaning of signs (images, words, actions, symbols, artifacts, etc.) are situated in embodied experience. Meanings are not general or decontextualized. Whatever generality meanings come to have is discovered bottom up via embodied experiences.

Text Principle: Texts are not understood purely verbally (i.e., only in terms of the definitions of the words in the text and their text-internal relationships to each other), but are understood in terms of embodied experiences. Learners move back and forth between texts and embodied experiences. More purely verbal understanding (reading texts apart from embodied action) comes only when learners have had enough embodied experience in the domain and ample experiences with similar texts.

ENDNOTES

- ¹ The excerpts have been transcribed from audiotape recordings between Zoe and the researcher. Pronunciation, grammar, and syntax errors have been left unaltered and an indication of intonation direction given by arrows at the end of a line. Italics indicate characters, locations, or fictional places within the game environments, so *Hong Kong* indicates the city as represented in the game environment, not the real-world city. Where discussion involves real-world locations, these have been left in normal font. Where Zoe uses the first person singular to refer to herself as a character in the game, 'I' remains in normal font.
- ² Gee's excellent book on *What Video Games Have to Teach Us About Learning and Literacy* has been referenced throughout Zoe's interview to highlight the key principles built into good COTS video games.
- ³ Full © script for *Deus Ex* prepared by Luke Kowalski: http://db.gamefaqs.com/computer/doswin/file/deus_ex_script.txt. Description of the game *DeusEx* with hyperlinks are from Wikipedia: http://en.wikipedia.org/wiki/Deus_Ex
- ⁴ A topical subject for China—SARS and now Bird Flu (H5N1 avian influenza).
- ⁵ Zoe refers to the almost complete lack of response by the Federal Emergency Management Agency (FEMA) in the United States before, during, and after Hurricane Katrina hit New Orleans (taken from Wikipedia, September 5, 2005; available at http://en.wikinews.org/wiki/Federal_response_to_Katrina_a_%27National_Disgrace%27).
- ⁶ *Environmental Detectives* developed by Education Arcade, *Hazmat Hotzone* from Entertainment Technology Centre, *Virtual U* developed by Professor W.F. Massey, and *River City* by Professor C. Dede.

ABSTRACT

This chapter explores the challenge of balancing narrative development and instructional design in the creation of an electronic game-based learning environment. Narrative is a key factor in successful commercial games. The hero's journey is explained and proposed as a model narrative structure for developing educational role-playing games and informing instructional design. Opportunities to embed various instructional strategies within the hero's journey structure are presented.

DOI: 10.4018/978-1-60960-503-2.ch420

INTRODUCTION

With annual proceeds that exceed the movie industry, the popularity of entertainment video games is stunning. In January 2007, Blizzard Entertainment announced that their massively multi-player online role-playing game (MMORPG), *World of Warcraft*, had more than 8 million subscribers (Blizzard Entertainment, 2007). The result has been a call by many, including the Federation of American Scientists (2006), to explore digital games as a viable approach for teaching in K-12 and higher education.

An increasing number of game-based learning environments are currently under development or have recently been released in which the learner is placed in virtual worlds and asked to engage in various tasks. For example, *River City*, for children ages 11-14, is a multi-player virtual environment emphasizing player tasks designed to develop higher order thinking skills and content knowledge in biology and ecology (Ketelhut, Dede, Clarke, & Nelson, 2006). *Quest Atlantis*, for children ages 9-12, immerses children in a virtual world with an emphasis on developing social responsibility (Barab, Thomas, Dodge, Carteaux, & Tuzun, 2005). *PeaceMaker* provides opportunities for a player to develop an understanding of the Israeli-Palestinian conflict through an engaging simulation (Impact Games, 2007). With this heightened interest in digital game-based learning, comes a need to explore methods and models for designing effective educational games.

One of the key issues in the design of electronic game-based learning environment involves aligning the requirements of multiple components of a game, such as narrative, gameplay, and instruction, to create a game that is both engaging from the narrative and gameplay perspectives and effective from the instructional design perspective. For many game genres, a compelling narrative context is essential to engage players fully and provide them with an appealing range of options and outcomes in creating their own stories. In developing electronic game-based learning environments, balancing the development of a compelling game narrative with instructional design needs can be challenging. There is little guidance in the literature on how to create stories that meet instructional goals and how to develop educational content in the context of stories. The purpose of this chapter is to share our own experience in aligning the demands of good interactive storytelling on the one hand with sound instructional design on the other, in the creation of a role-playing game for teaching life science and scientific inquiry for children ages 11-13. The

implications for design outlined in this chapter will likely inform instructional designers of how narrative can be effectively utilized in educational game-based learning environments.

LITERATURE REVIEW

The Art of Narrative

One only has to look into the face of a child as she listens to a story to realize the power of this medium to entertain and to educate. On a daily basis, we engage in storytelling with those around us. The use of stories to pass on knowledge is common in all cultures. Storytellers seek to expand one's conceptual understanding of a topic or share relevant experiences that others have had (Burke, 1993). Parents often share stories with their children in order to teach some lesson. Grandparents may pass on family knowledge in the form of stories. Stories, in some form, are an essential part of everyday life. Stories can provide a meaningful context for learning through the description in rich detail, engaging characters, and illustration of knowledge in context. In contrast with typical methods of knowledge representation, stories provide a rich description of situations which are more meaningful to students.

By and large, the conventions of Western narrative are founded on aesthetic principles advanced by Aristotle, who argued that, at its best, narrative has the capacity to be both entertaining and edifying. The most lasting influences of Aristotle's *Poetics* on Western narrative are found in the conventions of *character* and *plot* (Aristotle, trans. 1997). Character may be understood broadly to refer to the personal forces at work in a story, shaping—and shaped by—the plot. Plot is the unfolding of action and the arrangement of incident in the story. For the reader or audience, characters provide the point of access, so to speak, for understanding and appreciating that unfolding action.

Reduced to its most basic components, the Aristotelian model of narrative operates such that: characters have a given motivation or desire; characters pursue the object of their desire (i.e., often presented as a quest); they encounter antagonists or obstacles that interfere with attaining their goal, resulting in a source of conflict; characters seek solutions and take action to overcome these problems, resulting in a progress toward the object of desire or motivation. Ordinarily, these struggles create a sense of rising action, described as narrative tension, which leads to a climax or series of climaxes, resolving that tension. As much for us today as for Aristotle and the Greek dramas he analyzed, the appeal of any narrative is rooted in observing the relationship between the actions a character chooses and the problem he or she confronts.

Therefore, in one sense, narrative can be defined as a record of the choices and problem-solving efforts of characters in pursuit of their goals. The dynamic described previously can be easily identified at work in virtually any Western narrative, from the simplest of stories, like “Cinderella”, to the most complex of dramas, like *Hamlet* (Shakespeare, 2003).

The latter provides us with a familiar illustration. Hamlet’s moral code pre-disposes him to seek revenge when he was told that his father was murdered by his uncle. Thus the motivated Hamlet sets about to take action against his uncle. However, in the course of that pursuit, he is confronted by a series of obstacles—specifically, doubts about whether his uncle is actually guilty of the crime. Hamlet’s moral code also requires that, before he can act and carry out his plan, he must be absolutely certain that his uncle did indeed murder his father. Hamlet is therefore faced with difficult choices: Should he obey the commands of his father’s ghost and kill his uncle, despite his uncertainties? Or should he allow his uncle to live and therefore continue to suffer the haunting of the ghost? Hamlet chooses to investigate his father’s murder further and seek answers to his doubts, so

he devises a series of tests to determine whether his uncle is genuinely guilty of the crime. With each successive test comes renewed motivation as well as new doubts and new obstacles for Hamlet to overcome in his pursuit of the truth and of justice for his father’s murder. So it is that *Hamlet* is loved by audiences as a great detective drama as well as a probing psychological study.

From its most primitive beginnings, narrative dramas have served ritual and didactic roles in the societies that produce them. Plays were meant, in part at least, to instruct audiences and to edify them. Aristotle described the most desirable outcome for the dramas of his time as *catharsis*. Aristotle also observed that the instructive value of plays was organically bound to their capacity to entertain: Audiences sitting in the amphitheatre must be made to sympathize with King Oedipus and his motives, for example, in order to invest emotionally and cognitively in the problem-solving exercises of the characters on the stage below.

This touches the central problem for conventional narrative: audiences are simply spectators to the drama, passively observing the motives, decision-making, and actions of characters on-stage. Spectators are distinct from the characters they are observing. *So, traditionally, the chief challenge for narrative artists has been to find ways to distract the spectator from that distinction; to immerse their audiences ever more deeply in the characters they create and to engage them more fully in the action of the plot.* Addressing this challenge is the primary objective of interactive narrative.

Role of Interactive Drama in Electronic Games

For the most part, interactive drama emerges from the very same traditions as conventional drama and operates according to the same root principles. Interactive drama relies on fundamental assumptions about character, motivation, and plot; about characters’ will and capacity to act; about

obstacles, conflict, and the role of choice-making in pursuit of desired ends. What distinguishes interactive drama from conventional drama is erasing the distinction between spectator and character. In effective drama, the spectator will understand and even empathize with a character. But when the spectator identifies fully with a character, the narrative ceases to be a traditional *drama* and instead becomes an interactive drama (Crawford, 2004; Mates, 2004; Murray, 1997) or a *game*.

Murray (1997) suggests that interactive drama can be analyzed from three aspects: immersion, agency, and transformation. Immersion is the feeling of identification with the protagonist and being present in the place depicted in the drama. It is the goal of both traditional drama and interactive drama to provide the audience or player a willing suspension of disbelief. Agency is a sense of control and empowerment experienced by the players when they take actions based on their own intention and when their actions have an effect on the world where the interactive drama takes place. Transformation has three meanings. The first involves having the audience and the player take on the role of someone else. The second refers to transformation as variety, meaning that the interactive drama provides variations of game experiences to the player depending on the choices made and actions taken by the player. The third meaning is the personal transformation of the player in the game. Immersion and some aspects of transformation already exist in the traditional drama (Mates, 2004).

We argue that what distinguish the interactive drama from Aristotelian drama are two related elements identified by Murray (1997): agency and transformation as variety. In a conventional narrative drama, the audience passively observes the characters without the opportunity to act on their own motives. In interactive drama, however, the players have a sense of agency. They take action based on their own intentions. In conventional narrative drama, characters face a limited array of possible options when confronting a problem.

The plot then moves in linear fashion to trace the cause-and-effect outcomes of the single option that the character selects from that array. This can be termed a “fixed-structure” drama. In interactive drama or game, to enable player agency and to allow for the player’s free choice in pursuing his motives, all of the cause-and-effect outcomes for all of the options must be calculated to provide transformation as variety, that is, variations of experience on a theme. Therefore, unlike a conventional drama which follows a single, fixed-structure plot-line, an interactive drama or game must be structured for a large (but limited) number of possible plot-lines; that is, a “flexible-structure” story.

Although “flexible-structure” stories may allow player choices and provide a sense of agency, there has been a debate among two camps of players, developers, and scholars: those who favor narrative and those who focus on player agency and game interactivity. To the root of the debate is the conflict between player agency and narrative. Narrative is driven by the direction planned by the writer; whereas interactivity and learner agency depend on the motives of the players. In an effort to reconcile the conflict, Henry Jenkins develops a persuasive argument for viewing games “less as stories than as spaces ripe with narrative possibilities” (2004, p. 119). Game developers such as Will Wright strive to create a compelling space of narrative possibilities in which players can “define their own story arc” (Perlin, 2004, p. 13). For example, in his strategy games such as *SimCity* and *The Sims*, there are no specific goals or objectives. The players make decisions as to which cities or characters they wish to create and what goals they want to achieve.

Clearly, by allowing the spectator to become a participant in the fiction, computer games have the potential to engage audiences in the conventions of character and plot in much richer, deeper ways than conventional dramas. Aristotle would remind us, however, that there may be much more to this than just increased exhilaration for

audiences. If we attend to the Aristotelian premise that drama has the capacity to be both entertaining and edifying, then we must acknowledge that the interactive form of this medium has special virtues over its conventional antecedents. It is in the design of the narrative possibilities of the game space that one must also integrate the “educational possibilities”. The design of the narrative must be such to support player quests and tasks that provide opportunities for construction of desired knowledge and understanding.

Importance of Narrative in Game Genres

Narrative plays a role in most game genres, though its importance varies. Action games, such as platformers, shooters, and racing games, often have story elements, though story is less important than the play experience (Dickey, 2006). In platformers, such as *Super Mario Brothers*, the story is simplistic. The player takes on the role of Mario (or Luigi) avoiding obstacles, or King Bowser (the villain) and his henchmen in order to rescue Princess Peach. Story, in the form of text, is displayed at the beginning of each level. The story creates valuable context for the game, but, in of itself, is less important than other factors such as game play to the overall game experience. First-person shooters (FPS) and third-person shooters (TPS), such as *Halo* and *Doom*, often utilize brief cinematics to provide some measure of background information on the player character, setting, and overall goal. In these types of games, narrative plays a greater role than in platformers. But designers must approach this greater role

cautiously in shooters, never allowing narrative to get in the way of game play and its immediacy.

In adventure games (e.g., *Myst*) and action-adventure games (e.g., *Tomb Raider*), narrative is important in order to create a rich space for the player to explore. Often these games rely on intriguing story to propel the player to explore the world. Both of these genres provide rich worlds for exploration, conundrums, and obstacles that integrate with a compelling storyline.

Role-playing games (e.g., *World of Warcraft*, *Guild Wars*) provide rich worlds in which players can experience their own characters' growth in ability and strength as they seek to complete tasks. A richly developed narrative is essential to role-playing games because they are slower paced, providing more time for the player to experience and reflect on the story. Extensive back-story, varied non-player character types with complex motivations, and plot twists are critical to compelling role-playing games. The importance and complexity of narrative grows greater as we move through platformers, shooters, adventure, and role-playing games (see Figure 1).

Role-playing games (RPG) are a genre that may be well suited for the development of educational games that target higher order educational goals such as those that fall into the following categories in Bloom's cognitive learning domain: application, analysis, synthesis, and evaluation. Rich virtual worlds found in RPGs provide opportunities for students to be immersed in contexts that allow them to satisfy their curiosity and need to explore. Woven from narrative, audio, 3D graphics, and interactivity, these rich contexts are rife with educational possibilities.

Figure 1. Importance and complexity of narrative in game genres

Player characters are able to follow their own interests as they learn more of the world through experience. Many contemporary theories on learning environments emphasize the role of experience in a rich context (e.g., Barrows, 1996; Jonassen, 1999; Schank, Fano, Bell, & Jona, 1994; Spiro & Jehng, 1990). A second beneficial characteristic of RPGs is that they tend to be slower paced than platformers or FPSs. The emphasis in RPGs is *not* placed on high intensity action (e.g., killing and destroying as in FPS) but on reflective action driven by intellectual deliberation. The gradual uncovering of the story, the unfolding of a mystery, the increasing grasp of a problem—these complex narrative features of RPGs create fertile conditions for motivating students.

Another compelling characteristic of RPGs is the chance for players to experience the growth of their character over time. An educational RPG provides a means for students to experience their own intellectual growth, directly represented in their player character. The characteristics made explicit and emphasized in the player and non-player characters provide opportunities to model those characteristics we desire in our students.

Finally, the structure of role-playing games, a sequence of progressively more difficult challenges, is consistent with how instructional experiences are organized as a progression of increasingly difficult educational experiences (van Merriënboer, 1997). Table 1 summarizes role-playing game characteristics that may lend themselves to educational games.

Narrative Structure

In its simplest form, stories have three acts: beginning, middle, and end. At the beginning of the story we try to capture the attention of the audience and place the protagonist in a situation where they are faced with some challenge or problem. This creates an imbalance that compels the protagonist to take action in order to restore equilibrium. During the “middle” of the story, the protagonist continues to face obstacles, make choices, and experience the consequences of those choices. It is these experiences that result in the character growth needed to ultimately overcome the overarching problem. The story ends when the character’s “world” has been restored to balance by solving the problem and achieving the goal.

In his work, Joseph Campbell explored the power of myth through comparative analysis, drawing out certain universal truths that transcend culture and history. His work, *The Hero with a Thousand Faces*, draws forth a common story structure, which he calls a monomyth, which underlies many of the world’s most compelling myths and legends (Campbell, 1949). This “hero’s journey” is a model story structure that fits well with the development of role-playing games and has been used in cinema and commercial game development. For example, the structure of movies such as *Star Wars* (Burns, 2007) and the *Lion King* were openly derived from the hero’s journey structure outlined by Campbell. Indeed, with books like Christopher Vogler’s (1998) *The Writer’s Journey: Mythic Structure for Writers*, the

Table 1. Role-playing game characteristics that lend themselves to educational games

Role-Playing Game Characteristic	Benefit for Educational Game
Rich Worlds for Exploration	Compelling learning contexts
Slower Pace for Experiencing Story and Reflection	Facilitates reflective action driven by intellectual deliberation
Character Growth in Ability and Strength	Players can experience their own intellectual growth explicitly represented in their player character; game characters can model desirable characteristics
Series of Challenges	Supports progression of educational

monomyth has now become a virtual normative for writers working in popular entertainment media.

The hero's journey has three main stages that correspond with the three-act story structure: departure, initiation, and return (Campbell, 1949).

- **Departure:**
 - **Call to Adventure:** The story begins with the hero in their “ordinary” world. The hero receives a call to adventure; a call to leave the comfort of his or her everyday existence.
 - **Refusal of the Call:** Often times the hero refuses the call hoping the problem will go away or that another “more worthy” will take up the call. The resistance to accept the call is often based on a sentiment we all share in common; a fear of the unknown. Eventually the hero accepts the call, though with trepidation.
 - **Mentor:** A wise mentor provides encouragement, guidance and support to the hero as she prepares for the journey.
 - **Crossing the Threshold:** The hero embarks on the journey, crossing from the familiar to the unknown.
- **Initiation:**
 - **Road of Trials:** The hero is confronted by a series of obstacles; help is provided. These trials prepare the hero for the ultimate battle to come.
 - **Ultimate Trial:** The hero must face and defeat the ultimate evil. In myths highlighted by Campbell, these trials often involve reconciling a disconnect between truth and ones' own beliefs, or reconciling the good and bad characteristics of a father figure in order to better understand oneself.
 - **The Prize:** After passing through the trial, the hero is able to obtain the prize he sought; the object or understanding that will benefit the place she left behind.

- **Return:**
 - **The Journey Home:** The hero may initially refuse to return home having grown to love the new world and abilities. But eventually he is compelled to return home in order to help those that he left behind.
 - **Bestows the Prize:** At the conclusion of the journey, the hero arrives home with the object that was sought. The object or knowledge restores equilibrium to the world.

In addition to effective story structure, a number of storytelling devices can enhance the quality of a narrative. Noteworthy are character design, creation of conflict, and plot twists.

Character development is a crucial part of good story design. Compelling game-based narratives are often written from the player character's point of view. Action in the game narrative is driven by player character decisions as she faces obstacles and choices in pursuing a goal. The conflict the character experiences results in growth. Designers can bring to bear various character types commonly found in conventional storytelling. Vogler (1998) defined seven archetypes in his popularization of the hero's journey. The *hero* (protagonist) is the main character typically promoting the action in the story. The *shadow* is usually the main opponent often the cause of the hero's problems. *Mentor* characters play a larger role in helping the player along their journey. *Shapeshifters* are characters whose real intentions are hidden from the main character. *Guardian* characters are those that block the path of the hero. Some games employ guardian characters which the player must defeat to move to the next level. The *trickster* distracts the hero from his quest. The *herald* brings news to the hero.

Conflict is an essential ingredient to a compelling narrative. Conflict propels the narrative forward and facilitates effective game play. As in narrative development, we must infuse conflict

into the game in order to cause the character to act thereby propelling the story forward. One can create conflict through a *unity of opposites*: two characters desire to possess the same object. A *ticking clock*, or “time-lock,” is another example of a conventional narrative mechanism that can facilitate conflict.

Plot twists are yet another device that designers can employ to enhance the narrative. Plots twists include “red herrings” (i.e., providing clues in order to mislead the player character) and reversals (i.e., a story that moves predictably down a path suddenly turns in an unexpected direction).

CONQUEST OF THE COASTLANDS

Our team is currently developing a role-playing game that features intriguing storylines, immersive 3-D representation of context and quests (problems), simulations, tools and resources that support quest completion, choice of roles and tasks, levels of play, record keeping, as well as real time interaction and feedback. Quests in the virtual environment are supplemented by classroom-based activities, which address students’ knowledge gaps revealed during game play and extend problem solving from the virtual and fictitious world to similar problems in the local community.

Styled after highly successful commercial products like *World of Warcraft* and *Everquest*, the role-playing game features a science fiction/fantasy setting. Pursuing larger strategic objectives, the player character is challenged with a variety of “quests” that is, player-characters must pose questions and seek answers, investigate mysteries, formulate hypotheses, gather evidence and information, use appropriate tools and techniques, and ultimately take action to solve problems presented within quests. These quests form the main plotlines of the interactive narrative and provide the immediate motivations for player-character activities in the game. Each quest is designed to achieve specific learning goals.

The game takes place amid an ancient conflict between two sentient species and their struggle for dominance on a planet called *Mertis* in another solar system. It is a warm, wet world of stormy oceans, dotted with countless islands and a single small continental landmass. While not technologically sophisticated, the planet’s two rival sentient species have reached a turning point in their evolutionary history where it is likely that one—the *Mruk-ma*—will likely drive the other—the *Sheft-ma*—into extinction.

The Mruk-ma are an aggressive, sea-faring species, while the Sheft-ma are city-builders who make their home in “The Coastlands,” along the marshy seashores and river valleys of Mertis’ lone continent. For the vulnerable Sheft-ma, the strategic key to their self-defense is a deteriorating system of fortifications built in the coastal wetlands surrounding their cities. But these wetlands are mysteriously disappearing at an alarming rate, and the threat of invasion by Mruk-ma fleets is growing.

A decisive change comes when the survey ship of an advanced alien race crash-lands in the oceans of Mertis. Arriving in escape pods from their doomed spaceship, the strangers, called *Cilati*, are scattered around the planet. Now hopelessly stranded on Mertis, some of the alien crew manage to make their way to The Coastlands, where they are warmly welcomed by the Sheft-ma. The Cilati survey team brings with them precious scientific knowledge, technology, and methods that could dramatically shift the balance of power in the conflict between the two rival species. The survival of the Sheft-ma will depend on whether they can effectively utilize the science and tools of the Cilati to rebuild their crumbling forts and defend their disappearing coastlines.

The Cilati are a highly advanced race of space-faring explorers. Extremely long-lived, they traverse the galaxy in pursuit of knowledge about other planets and other life forms. Cilati ships have visited countless worlds, quietly observing the species that inhabit them. Generally,

they never interfere in the cultures they study, and they seldom even make their presence known.

It quickly becomes apparent that the Mruk-ma have adopted a radically new strategy in their struggle with the Sheft-ma: ecological warfare. By attacking the delicate environment on which their peaceful rivals depend, the Mruk-ma hope to wreck the Sheft-ma civilization and eliminate their species.

The future of their civilization now depends on whether the Sheft-ma will be able to master the mysterious science of their alien allies, the Cilati. To put it in the epic terms that are conventional to RPGs of this genre, it is only amid desperate circumstances like these that heroes emerge... Heroes who know that understanding the world around them is the first step in controlling it... Heroes who recognize that well-armed fleets and fortresses alone will not be enough... Heroes who foresee that the secrets of science will be the key to Conquest of the Coastlands.

INTEGRATION OF NARRATIVE DEVELOPMENT AND INSTRUCTIONAL DESIGN

In our development process we view story development and instructional design as intricately interdependent. We began our process by developing a story concept. Effective storytelling often relies on conventional story structure. We adopted the traditional three-act story structure and the “hero’s journey” as frameworks to guide our story development. The hero’s journey is a model framework for not only guiding the development of a compelling story, but an equally effective framework for thinking about instructional design.

Employing Episodes

In the development of *Conquest* we found it useful to think of the game narrative as a series of episodes (i.e., quests) with each having its own story with a beginning, middle, and end. These

quests have their own plot, usually utilizing the hero’s journey, which contributes to an overarching story for the entire game. In each quest the player completes some learning tasks. For example, in one *Coastlands* quest, the *glim quest*, the player character, the hero, is called upon to research a devastating threat to the Sheft-ma’s food supply: a more than 70% reduction in harvests of a fish, called the *glim*, which is a primary food source for the Sheft-ma. This quest begins with the player character being called to appear before the council and tasked with learning all they can. As the quest story unfolds, the player learns the cause of the fish depletion, but also gains valuable information about the overall plotline. That is, what are the root causes of the devastating deterioration of The Coastlands. The *glim quest* has a clear story arc with outcomes that not only satisfy its own story but also contribute important information to the overall story of the game.

Hero’s Journey: Call to Adventure/Refusal of the Call

The hero’s journey begins with a call to adventure. Just as the hero desires to escape the ordinary but often fears the unknown of the quest, we often desire to embark on adventure yet fear that we may not be up to the task. This theme is an integral part of human nature and one to which many students can relate. Students are naturally curious and desire to learn yet must be drawn into the adventure of learning. This aspect of the hero’s journey provides a way to dispel some of the inertia that may hold a student back from fully engaging in the learning process.

Gaining students attention and engaging them in an intellectually challenging task is a key aspect of many instructional models. For example, Robert Gagne’s “events of instruction” begins with gaining the learner’s attention (Gagne, 1985). Madeline Hunter (1982) argued for the anticipatory set in order to “hook” the learner. Keller (1983) advocated gaining attention

through perceptual arousal and inquiry arousal. In *Conquest of the Coastlands* we utilize an opening cinematic to gain the student's interest in the overarching game storyline in a call for the player to engage in the adventure. The game cinematic provides the player important back-story that will serve them later in the adventure. Similarly, as we present each quest, we utilize interactive cut scenes in order to set up the problem and gain the student's interest in accomplishing the goal. For example, in the *glim quest*, the cut scene opens with the player character being called before the High Council. As the scene unfolds, the player character expresses eagerness to help her species and an innate curiosity to know and understand. Yet she also shows fear in accepting the task. Ultimately, she overcomes the reluctance to take on the quest and commits fully to the adventure.

Hero's Journey: Mentor Provides Support

In the hero's journey, the mentor often motivates the character to accept the call and provides needed support for the journey. The development of the mentor concept in our game was not only informed by the hero's journey, but also the cognitive apprenticeship model, an instructional design model that emphasizes the role of mentors in supporting learning (Collins, Brown, & Holum, 1991). In our game, we provide mentors to aid the player character. The first mentor is Ikiru, the player character's elderly uncle, who is learned in many disciplines, possessing a folk understanding of the forces at play in the natural world. The player is first introduced to Ikiru in the opening cinematic where learned that Ikiru has a growing concern about the changes he sees in The Coastlands. As the player character prepares for the journey, Ikiru provides encouragement and help. For example, in the *glim quest*, Ikiru provides the player a list of potential hypothesis, based on his folk understanding, as to what may be causing the reduced catches. As the quest unfolds, the player meets

with the Cilati, the other mentor, who having unique expertise as an accomplished scientist, facilitates the recasting of the folk hypotheses into viable scientific hypotheses thereby scaffolding the player. The Cilati also provides technology, a personal digital assistant (PDA) that has tools and resources to aid the player in the investigation.

Hero's Journey: Crossing the Threshold

As in a hero's journey, we strive to create learning environments where the student is truly committed to the quest of "making the material their own". Just as the hero fears to accept the call to adventure, students have fears that prevent them from fully engaging in an activity. If we have done well in gaining their attention with a compelling adventure, we hope to see engagement. In *Conquest of the Coastlands*, the player character shows hesitancy to accept the call to explore the *glim quest* yet ultimately confronts her fears and commits to the task.

Hero's Journey: Road of Trials

In the hero's journey, the road of trials is a series of challenges, often placed by the antagonist, that help prepare the hero for the ultimate test to follow. These increasingly difficult challenges help the hero grow in strength and wisdom. Similarly, instructional models advocate a sequence of increasingly challenging problems and content. For example, the instructional design model adopted by our team, the four-component instructional design (4C/ID) model, advocates a sequencing of task classes from simple-to-complex (van Merriënboer, 1997). The 4C/ID model consists of four inter-related components: learning tasks, supportive information, part-task practice, and just-in-time (JIT) information. Learning tasks, most relevant to this discussion, are the concrete, authentic whole-task experiences similar to complex real-world problems. These learning tasks are categorized

into simple-to-complex classes. The order of the task classes and the specific instances of the tasks define the overall sequencing of the instructional content. In *Conquest of the Coastlands*, we follow a progression from simple-to-complex for the game (i.e., quests are progressively more challenging) and within each quest (i.e., tasks within each quest are progressively more challenging). For example, earlier quests in the game have the player engage in partial scientific inquiry whereby some of the inquiry task are already completed (e.g., problem statement defined, hypothesis developed). Later quests in the game will have students engaging in full inquiry and open inquiry. Similarly, a quest such as the *glim quest* begins with simple tasks (e.g., summarizing data provided by non-player) shifting to more complex tasks (e.g., analyzing and interpreting water quality data).

Hero's Journey: Ultimate Trial

The ultimate trial of the hero's journey is a climactic moment where the hero, after much personal growth as a result of confronting obstacles, faces, and overcomes a great challenge. In this stage of the journey, the emphasis is on the hero's transformation. Similarly, we strive for the design of educational experiences that are transformative. Many of us have experienced a master teacher or mentor who provided us a challenging task that truly transformed our thinking about a concept or topic resulting in a new found understanding. As in a story where the hero "faces death" in the ultimate trial and survives, the learner works at the edge of their ability to accomplish a challenging task and thereby is transformed. So too should this ultimate learning experience be for the player character. In our game, we are striving to provide a sequence of quests that culminates in an ultimate trial. For example, in earlier quests the player character engages in supported inquiry. As the player progresses, we increase the difficulty of the challenges presented and fade the scaffolding provided. At the conclusion of the game, the

player character engages in independent scientific inquiry; demonstrating, we hope, a new found depth and breadth of knowledge. Similarly, within a quest, the sequence of tasks can progress toward an ultimate trial.

Hero's Journey: The Prize

In this stage of the hero's journey, the hero is rewarded by gaining the object of their desire. This sort of narrative device provides a clear motivation for the character thereby driving the story forward. In the framework of the hero's journey, the prize is the object or elixir that initially propelled the hero to begin his or her journey. This plot device helps focus the player character on a clear goal. Similarly, from an educational perspective, the goal or prize should drive the educational activities. Wiggins and McTighe (2001) suggest we begin with the end in mind. In instructional approaches such as goal-based scenarios (Schank, Fano, Bell, & Jona, 1994) and problem-based learning (Barrows, 1996), the goal or problem becomes the organizing focus of the activity. The goal should be interesting and motivating to the player and should result in the development of knowledge and skills desired. In the development of *Conquest of the Coastlands*, we strived to create clear story goals in the game (e.g., learn why the *glim* are dying in order to avert famine) that corresponded to clear learning goals (e.g., with guidance, learners are able to articulate the question or problem at hand, design an investigation, gather data, draw conclusions, and communicate the results and research process, National Science Content Standard A).

Hero's Journey: The Journey Home

As the hero begins the journey home, there are still challenges to overcome. These challenges further motivate the player as they continue their quest.

Hero's Journey: Bestowing the Prize

At the conclusion of the hero's journey, the protagonist returns home triumphantly, and bestows the prize, elixir, or wisdom upon those that she left behind. This mechanism provides a way for the learner to synthesize the key aspects of what was accomplished and learned in the quest providing a beneficial learning activity for the player and a valuable artifact for evaluation. Two strategies from the cognitive apprenticeship model (Collins, Brown, & Holum, 1991), reflection and articulation, provide insight into the benefits of this final stage of the journey. Articulation refers to requiring students to articulate their knowledge, reasoning, and problem-solving processes. These explanations and elaborations require the student to make their thinking explicit providing opportunities for feedback from others and serving as a source for their own reflection. Reflection involves helping students compare their own problem-solving processes with those of experts, thus making it possible for them to modify their processes. This final stage of the journey provides an opportunity for players to articulate their thinking and then reflect upon it. In *Conquest of the Coastlands*, a key element of Sheft-ma culture is the manner in which the Sheft-ma preserves and communicates knowledge. At the conclusion of each quest, the player character returns to the Chief Cantor, a key figure whose role in this fictional society is to document what is learned in the hero's various adventures and provide a synthesis of the learning. These quest summaries are noted in scrolls, and the learning acquired through heroic questing is then shared with the rest of the society, delivered in song by the Chief Cantor in order to entertain and educate the populace. The hero's journey is thus completed with the bestowal of the prize.

Story Devices

In addition to effective story structure, a number of storytelling devices can enhance the quality

of a narrative and facilitate instructional design. Noteworthy are character design, creation of conflict, and plot twists.

Character development is a crucial part of good story design. Compelling game-based narratives are often written from the player character's point of view. Action in the game narrative is driven by player character decisions as she faces obstacles and choices in pursuing a goal. The conflict the character experiences results in growth. Designers can bring to bear various character types commonly found in conventional storytelling. The *hero* (protagonist) is the main character typically promoting the action in the story. The *shadow* is usually the main opponent often the cause of the hero's problems. *Mentor* characters play a larger role in helping the player along their journey. *Helpers* are characters that provide other types of support to the main character. *Guardian* characters are those that block the path of the hero. Some games employ guardian type characters the player must defeat to move to the next level. The *trickster* distracts the hero from his quest. The *herald* brings news to the hero. In our own development, we utilize various character types such as player character as hero, Murak-ma as shadow or antagonist, and mentor characters in the form of Uncle Ikiru and the Cilati.

Conflict is an essential ingredient to a compelling narrative. Conflict propels the narrative forward and facilitates effective gameplay. As in narrative development, we must infuse conflict into the game in order to cause the character to act thereby propelling the story forward. One can create conflict through a *unity of opposites*: two characters desire to possess the same object. For example, in *Conquest of the Coastlands*, a unity of opposites is created whereby the Sheft-ma (i.e., player character species) are directly competing with the Murak-ma non-player character species to locate and retrieve Cilati escape pods scattered about the planet. The escape pods have important technology that may help one species overcome the other. In this example, the task of

finding escape pods provides a clear goal for the player (facilitates gameplay) and creates conflict that is motivational. The escape pods provide a fun way to introduce technology that is needed for the student to achieve the curricular goals. A *ticking clock*, or “time-lock,” is another example of a conventional narrative mechanism that can facilitate conflict. In *Conquest of the Coastlands* the player character learns that the escape pods are made of a material that causes them to disintegrate within a limited time when exposed to the elements.

Plot twists are yet another device that designers can employ to enhance the narrative. Plots twists include “red herrings” (i.e., providing clues in order to mislead the player character) and reversals (i.e., a story that moves predictably down a path suddenly turns in an unexpected direction). For example, in our game, there is a rumor that fish depletion is caused by an alien monster, a ferocious predator that eats both fish and fishermen. In reality, the monster is an invasive herbivore. It disrupts the coastal environment by consuming a large amount of marsh grass. Fish depletion is caused by the environmental change triggered by the monster. The rumor serves as a “red herring” that not only enriches the story and but also provides an opportunity to challenge the player to think critically and to distinguish superstition from science.

IMPLICATIONS

The literature review and our experience in designing an educational role-playing game has led to the identification of several principles that may provide instructional designers guidance in the creation of educational role-playing games.

Conceptualize Game Narrative in Quests

Design the game narrative as a series of quests with each having its own story with a beginning,

middle, and end. These quests have their own plot, utilizing the hero’s journey, which contributes to an overarching story for the entire game. Additionally, each quest consists of a series of tasks that support quest learning goals and contribute to the overarching learning goals for the entire game.

Begin Quests with a Call to Adventure

The hero’s journey call to adventure provides a mechanism for gaining the students attention and engaging them in an intellectually challenging task. Children can relate to a character that has fear of embarking on an adventure, but ultimately commits to the task at hand. An opening cinematic or an in-game cut scene can facilitate gaining the students attention and facilitating full engagement in the learning task.

Develop Non-Player Characters that Act as Mentors

A common element of narratives that employ the hero’s journey is the mentor who motivates and supports the hero throughout the quest. Non-player characters can be modeled after the mentor figure in the hero’s journey and can also be informed by the cognitive apprenticeship model. These non-player characters can assist by assigning quests, providing needed clues, and implementing cognitive apprenticeship strategies (e.g., modeling, coaching, articulation, reflection).

Provide for a Series of Challenges/Ultimate Challenge

The hero’s journey and instructional design models advocate for a series of challenges that prepare the hero/learner for the ultimate test to follow. Provision of concrete authentic experiences of increasing difficulty provides for compelling learning opportunities. As the series of challenges

increase in difficulty and the player gains skill and confidence, scaffolding can be faded.

Utilize Plot Device to Drive Narrative Forward and Focus Player on Clear Goals

In the hero's journey, the protagonist's desire or need for an object provides a clear motivation for the character thereby driving the story forward. Utilizing this plot device helps focus the player character on a clear goal. Similarly, from an educational perspective, the goal or prize should drive the educational activities. The goal or problem becomes the organizing focus of the activity.

Design Narrative to Provide Opportunities for Reflection and Articulation

At the conclusion of the hero's journey, the protagonist returns home triumphantly, and bestows the prize upon those left behind in the hero's ordinary world. This narrative element can provide a way for engaging the learner in synthesizing the key aspects of what was accomplished and learned in the quest. This narrative element can facilitate opportunities for students to articulate their knowledge, reasoning, and problem-solving processes. Articulation provides a source for students to compare their own problem-solving processes with those of experts.

CONCLUSION

Electronic games provide unique opportunities for utilizing interactive narrative to create compelling learning environments where students are engaged in shaping a narrative; a narrative that is not only entertaining but also results in new knowledge and skills. This chapter shares our experience in balancing narrative development with instructional design. The hero's journey emerged as a model

narrative structure for developing interactive narrative and informing instructional design. It provides opportunities to embed various instructional strategies, such as gaining attention at the beginning of instruction, mentoring, sequencing learning tasks from simple to complex, clarifying the learning goal, and articulation and reflection of learning.

The hero's journal may serve as a narrative structure for game developers to align narrative development and instructional development in the process of creating effective electronic game-based learning environments. It is our hope that this chapter may guide developers of electronic game-based learning environments and will begin a dialog as to the importance and strategies for aligning interactive narrative development with educational game development.

KEY TERMS AND DEFINITIONS

Backstory: The history of events that precedes the start of a narrative.

First-Person Shooter: A computer game genre where the player character has a first-person perspective.

Interactive Narrative: Narrative in which the spectator is able to make choices that guide the outcomes.

Monomyth: A common story structure which underlies many of the world's most compelling myths and legends.

Platformer: A genre of computer game where the player navigates among platforms while avoiding obstacles.

Role-Playing Game: A game where the player takes on the role of a character.

Unity of Opposites: A narrative device whereby two characters desire to possess the same object.

Chapter 4.21

Teacher Gamers vs. Teacher Non-Gamers

Christopher L. James

Russellville City Schools, USA

Vivian H. Wright

University of Alabama, USA

ABSTRACT

The purpose of this study was to identify secondary teachers with video game-play experience and determine if perceived levels of comfort in regard to completing job-related technology tasks, amounts of instructional technology usage, and amounts of participation in innovative teaching strategies are affected by experience or lack of experience with video games. Although significant differences were not found between teachers identified as gamers and those identified as non-gamers, researchers may choose to investigate specific areas where mean differences were found. For example, gamers were more comfortable using presentation software for demonstrating concepts in class, communicating electronically with colleagues and students, us-

ing the Internet for instructional purposes, and presenting information using various delivery modes. In comparison to gamers, non-gamers indicated a tendency to communicate electronically with parents more often, encourage students to use electronic tutorials outside of class more often, and allow students to use word processors to complete assignments more frequently. This study can be used as a reference point for future research into teachers and video game-play in regard to teaching practices and job-related tasks.

INTRODUCTION

Video games have become a part of the daily lives of many individuals, regardless of age or gender. In fact, the video game industry has grown to rival the motion picture industry and each of the major television networks in terms of revenues

DOI: 10.4018/978-1-60960-503-2.ch421

and profits. Despite the size of the industry, more research is needed on the potential benefits of video game-play and learning (Shaffer, Squire, Halverson, & Gee, 2004).

In an exert entitled, "From Video Games, Learning About Learning," from his book, *What Video Games Have to Teach Us About Learning and Literacy*, Gee (2003) describes video games as being long, hard, and challenging. Gee indicates if a game has good learning principles in its design, the learning can be translated in positive ways. In his opinion, the theory of learning behind good video games closely resembles learning theories from the cognitive sciences.

Cognitive science is the study of the mind and includes processes such as thinking, reasoning, language, perception, learning, and remembering. Cognitive science crosses several disciplines including computer science, linguistics, philosophy, and psychology (Rapaport, 1996). Research within this area suggests human interaction within an environment and perception are related in creating memory (Glenberg, 1997).

Video games create environments and allow interaction within these environments. According to cognitive science principles, this should create memory. Good games are challenging, give information in context, allow players to create, build problem-solving skills, are motivating, and offer opportunities for individuals to work together (Gee, 2003).

Characteristics of gamers, such as willingness to volunteer, creativity, and reading to gain knowledge, have been used to describe innovative teachers (Cumming & Owen, 2001; Thomas, 1993). Also, similar to video games, innovation requires creating, persistence, action, teamwork, and risk taking (Ballantyne, McLean, & Macpherson, 2003).

Based on the premise that learning takes place in video games and many characteristics of game players and innovators are similar, the researchers designed this study to determine the effects video game experience may or may not have on

perceptions of teachers and their comfort levels when completing job-related computing tasks, amount of instructional technology usage, and participation in innovative teaching practices. If video game experience allows individuals to gain certain knowledge and skills applicable to basic computing skills and instructional technology, teachers may have higher comfort and participation levels in each area. Also, many of the characteristics of game players reflect the same qualities found in innovative teachers.

This study is important to the field of education and gaming because certain aspects of gaming such as problem solving, teamwork, communication, and knowledge of technology may be increased by the playing of video games. Intuitively, if knowledge of technology is increased, comfort levels with various technologies may also be increased. Also, motivation (Rosas et al., 2003) and self-confidence (Carstens & Beck, 2005) have both been enhanced by video game-play. Each of these aspects or traits are important to the field of education as teachers are facing ever-increasing pressure to raise scores on various standardized tests and teachers are expected to perform at high levels in the classroom.

BACKGROUND

Computer games and video games are two terms that are often used synonymously to describe games played on personal computers, handheld systems, consoles, or arcade machines (Wikipedia, 2005). A game is a form of art that requires decision making, opposition, the management of resources, the attainment of tokens, and a sufficient amount of information. Games are often strengthened by diplomacy, simulation, variety, character identification, role-playing, and socialization (Costikyan, 1994). Games are complete systems with explicit rules, with fantasy playing a major role in various situations (Crawford, 1982). Gee described a game as a world in a box allowing a player to create an

identity they really want and the ability to gain experiences that were not available before (cited in Foreman, 2004).

Most people consider games to be for younger members of society or for males only, but the statistics within the industry tell a different story. In May 2005, the Entertainment Software Association released the results of a consumer survey that indicated game players were an average age of 30, with 35% under the age of 18 and 43% between the ages of 18 and 49. Nineteen percent of game players were over the age of 50, and 55% were male.

Previous research has shown gamers to enjoy such activities as exercising, sports, volunteering, religious activities, creative undertakings, and reading. In fact, the Entertainment Software Association (2005) reported that gamers spend over three times the amount of time on activities such as these when compared to playing video games. Also, characteristics of gamers, such as being risk takers (Beck & Wade, 2004), showing a willingness to volunteer, having creativity, and reading to gain knowledge, have been used to describe innovative teachers (Cumming & Owen, 2001; Thomas, 1993).

Research indicates girls prefer games that allow them to play with other players, have high-quality graphics and multimedia components, and allow for communication between participants during game-play (Agosto, 2004). Males tend to enjoy games with a lot of action and fighting with weapons, but both genders believe realism is an important aspect in game design (Media Analysis Laboratory, 1998).

Many educators and parents do not believe video games are a viable component of a curriculum and have issues with the educational software that is available (Virvou, Katsionis, & Manos, 2005). Leaders within the area of gaming and learning argue that video games may change the way we learn and can effectively engage learners (Squire & Jenkins, 2003). A vast amount of information and resources are available to individuals at the

click of a button, but classrooms have not adapted. While games are often complex and difficult, people work through them and the difficulty often provides motivation. Further, Shaffer et al. (2004) indicated that video games allow players to participate in communities and develop thinking and organization skills, but they also noted the field is absent of sufficient research concerning learning theory. One sign this may be changing occurred in March 2004, when the first Serious Games Summit was held at the Game Developers Conference. The summit brought together educational researchers, game developers, and trainers to share experiences in hopes of developing new markets and better products (Corbit, 2005). Another positive sign for the industry is the fact that more colleges and universities are offering courses, and in some instances, degrees related to video game design. Prestigious universities, such as The Massachusetts Institute of Technology, Stanford, Carnegie Mellon, and Southern California, are leading the way in this area (Mangan, 2005).

Until recently, little research existed concerning the potential benefits of video game-play even though many children and adults spent a large amount of time playing games. Now, more researchers are looking at possible benefits of game-play and have found that they may improve social skills, encourage teamwork, increase knowledge pertaining to technology, develop math and reading skills, and improve problem solving (Media Awareness Network, n.d.).

It is evident from the literature that video games have become a part of our culture and have gained a tremendous amount of popularity. For several years, the majority of research on video game-play focused solely on negative aspects, but the trend is beginning to change. Pillay, Brownlee, and Wilss (2003) indicated recreational game players engage in cognitive processing while playing, and many of these processes are very valuable in educational settings. Gamers display the ability to digest explicit and implicit information, reason inductively and deductively, make inferences,

and solve problems. Whether it be in the role of teacher or student, each of these processes lend themselves well to an environment implementing instructional technology.

Instructional technology is changing the way we learn. Exposure to different types of video games aids in developing schema that may be used in completing future tasks and solving problems in technology-rich settings (Pillay, 2003). Structural knowledge may be gained from games, allowing individuals to function in similar environments with instructional technology. According to Gros (2003), video games are often the first access young people have to the world of technology, and they help create a positive outlook towards technology. It is the hypothesis of Gros that children acquire digital literacy through play, and video games are the most interactive multimedia available today. Many games require players to reach some type of goal, and innovative teachers have been described as having a vision for the future and strategies for reaching this vision (Cumming & Owen, 2001).

Innovation is the introduction of something new—a new idea, method, or device (Merriam-Webster Online, 2005). While the formal definition of innovation is rather straightforward, defining innovative teaching practices is much more difficult. Several of the skills learned from video games mirror characteristics of innovative teachers identified by Cumming and Owen (2001), Thomas (1993), and Ballantyne et al. (2003). Each of these studies acknowledged innovative teachers as having the ability to work with others, possessing strong social skills, a sound knowledge base, and a desire to succeed.

After an exhaustive search, the researchers were unable to locate any previous research on teachers who play or once played video games. Rather, most studies focused on such areas as increased motivation, problem-solving skills, aggression, and addiction (Amory, Naicker, Vincent, & Adams, 1999; Bensley & van Eenwyk, 2001; Hauge & Gentile, 2003; Rosas et al., 2002).

Merriam-Webster Online (2006) defines experience as “the fact or state of having been affected by or gained knowledge through direct observation or participation.” If experience playing video games allows teachers to become more comfortable with job-related technology, more readily accept instructional technology, and more readily participate in innovative teaching practices, perhaps the educational community will adopt gaming as a viable component of effective teaching practices at both the postsecondary and K-12 levels. College education departments may add gaming to their pre-service teaching programs, and professional development content for teachers and administrators may be delivered through similar means.

The following research questions guided this study:

1. Who are the teachers with experience playing video games?
2. Are teachers with experience playing video games more comfortable completing job-related technology tasks?
3. Do teachers with experience playing video games use instructional technology more often than those without experience playing video games?
4. Do teachers with experience playing video games participate in more innovative teaching strategies?

METHODOLOGY

Population

The researchers designed this study to determine the effects video game experience may or may not have on perceptions of teachers and their comfort levels when completing job-related computing tasks, amount of instructional technology usage, and participation in innovative teaching practices. In determining the sample for this study, the

researchers had specific criteria for selecting the schools. Specifically, each school needed to be at a secondary level to obtain a better ratio of male to female teachers. The researchers also wanted the schools to include various socioeconomic levels, which were determined by the free or reduced lunch percentage. Based on these criteria, seven secondary schools in North Alabama were selected. For this study, all classroom teachers serving grades 6 through 12 were given the opportunity to complete the survey instrument. By including each classroom teacher, the researchers hoped to reduce the amount of bias when generalizing to the population.

The population was divided into two groups: those with video game-play experience and those without. For this study, a teacher is considered to have video game-play experience if he or she has enjoyed playing video games weekly as a hobby anytime in the past or present. Each respondent was questioned regarding their perceptions of comfort using technology to complete basic job-related tasks, amounts of instructional technology usage in the classroom, and amounts of participation in innovative instructional practices. The researchers then determined if a significant difference existed in comfort levels and amounts of usage between each group in relation to basic job-related computing tasks, instructional technology, and participative levels in innovative teaching methods.

A survey was designed by the researchers to collect information from respondents through a traditional paper option. Each classroom teacher received the paper survey, along with a cover letter, explaining the purpose of the study and directions for completing the survey.

Administrators at four schools chose to have the surveys completed in a faculty meeting and returned at the conclusion of the meeting resulting in return rates of 75%, 75%, 100%, and 94%, respectively. One school chose to distribute the surveys at a faculty meeting and have the surveys returned in a sealed envelope to a designated location, resulting in a return rate of 25.7%. Two

schools chose to have the surveys placed in teacher mailboxes and returned in a sealed envelope to a designated location, resulting in return rates of 70% and 78%. Overall, 258 faculty members were given the opportunity to complete the surveys and 184 surveys were submitted for analysis, resulting in a return rate of 71%.

Survey Design

The survey instrument (see Appendix) was developed by reviewing several instructional technology surveys administered in higher education and a video game survey administered by the Beckman Institute (n.d.), reviewing the National Education Technology Standards for Teachers (ISTE, 2000), focusing on the best practices for using instructional technology established by the University of Texas at Austin (n.d.), and researching a study on innovative teaching (Cumming & Owen, 2001). Questions related to gaming practices were developed by the researchers to garner specific statistics from the participants. The survey contained five sections to gather information regarding and to assess:

1. Demographic information from questions 1-6
2. Game-play experience from questions 7-11
3. Perceptions of teacher comfort levels when completing job-related computing tasks from questions 12-17
4. Amounts of instructional technology use by the teachers from questions 18-30
5. Amounts of implementation of innovative teaching practices from questions 31-41

A four-point Likert scale was used to rate each item from section three ('strongly agree', 'agree', 'disagree', 'strongly disagree'), section four ('frequently', 'sometimes', 'rarely', 'never'), and section five ('frequently', 'sometimes', 'rarely', 'never'). Validation of the survey was obtained by having the survey reviewed by a panel of experts.

Reliability was tested through a pilot application of the survey and testing the internal consistency of the questions using Cronbach's alpha. One question was removed from the original survey to reach an acceptable level of .894 for section three, .839 for section four, and .863 for section five.

Data Analysis

Descriptive statistics were used to analyze items on the survey. Three separate independent samples t-tests were conducted to determine if a significant difference existed between each group regarding comfort levels with job-related technology tasks, amounts of instructional technology usage, and implementations of innovative teaching practices.

Demographics

The first section of the survey instrument included six questions that gathered demographic information from the participants. Percentages were rounded to the nearest whole number for discussion. The first question asked the participants to choose a range in which their age fell. Table 1 displays the frequencies and percentages for this item. The data revealed that 17% of the population fell between the ages of 20 and 29, 26% fell between the ages of 30 and 39, 22% fell between the ages of 40, and 49 and the remaining 35% of the population was 50 or older.

The second question identified the gender of the respondents. The data in Table 2 indicate the participation of 58 males and 126 females in the study, resulting in percentage levels of 32 and 69 respectively.

Table 1. Age of participants

Age	Frequency	Percent
20-29	32	17
30-39	48	26
40-49	40	22
50+	64	35

Question 3 asked the participants to specify their highest level of education. Of the total population, 30% indicated a bachelor's degree as the highest degree earned, while 60% revealed having a master's degree. Also, 9% were identified as having an education specialist degree, and 1% had earned a doctoral degree. Table 3 displays the frequencies and percentages for this item.

Question 4 attempted to gather information regarding the years of teaching for each individual in the study. Frequencies and percents from each range of years are listed in Table 4. Out of the population, 23% identified themselves as having 6-10 years of teaching experience, followed closely by the 0-5 years experience group at 21%. Next was the 11-15 years group at 19%, followed by the group with 25 or more years at 16%. The smallest groups represented included the 16-20 years experience and the 20-25 years experience groups at 10%.

Table 2. Gender of participants

Gender	Frequency	Percent
Male	58	32
Female	126	68

Table 3. Highest level of education

Degree	Frequency	Percent
Bachelor's	55	30
Master's	111	60
Education Specialist	17	9
Doctoral	1	1

Table 4. Years of teaching experience

Years	Frequency	Percent
0-5	39	21
6-10	43	23
11-15	34	19
16-20	19	10
20-25	19	10
25+	30	16

Question 5 gathered data concerning the subject areas taught by the participants. The subject area of math was represented at the highest rate at 19%, followed by English at 17%, history at 16%, science at 12%, special education at 10%, other areas at 10%, vocational at 9%, and physical education at 7%. Frequencies and percents for this question are found in Table 5.

Gaming Experience

The second section of the survey collected participant data specific to video game experience. Question 6 identified each participant as a game player or non-game player during the present or any time in the past. Out of 184 respondents, 66 (36%) identified themselves as a gamer (as having game playing experience) and 64% classified themselves as not having game playing experience.

When asked about playing video games on personal computers, only 18% chose ‘frequently’. The majority, 41%, chose ‘seldom’. When asked about playing video games on consoles, 59% chose ‘seldom’. Within the game-playing population, 48% reported playing Web-based games ‘sometimes’ or ‘frequently’. In an average week, 64% of game players reported playing games less than one hour per week, 27% played from one to three hours per week, and 9% played from three to seven hours per week. No respondents reported playing more than seven hours per week.

Question 11 from the survey asked the participants to list an approximate age at which they

began playing video games. Almost 20% indicated they began playing games at the age of 10, and 17% indicated they began playing games at the age of 12.

Research Question 1

Who are the teachers with experience playing video games? When looking at the game players, 32% of the population was from the 30-39 age group. This percentage was followed closely by the 40-49 age group at 27%. While this study did not account for anyone under the age of 20, these percentages resembled statistics released from the Entertainment Software Association in 2005, where the mean age of game players was found to be around 30.

Among the total male population surveyed, 52% were labeled as a gamer, while only 29% of the total female population carried the same label. Even though the female population had a lower percentage within their own gender, they made up 55% of the game-playing population due to their higher total population in this study.

Each of the groups with years of experience from 0 to 5, 6 to 10, 11 to 15, and 16 to 20 had at least 35% of the group identified as gamers, with the 6 to 10 years experience group leading the way at almost 50%. History teachers and teachers from the group “other” classified themselves as gamers at a rate equal to or greater than 60%. Science, math, and English followed at percentage levels of 32%, 31%, and 41% respectively.

Research Question 2

Are teachers with experience playing video games more comfortable completing job-related technology tasks? Total scores for gamers and non-gamers were computed and analyzed by an independent samples t-test to explore this research question. The effect of video game-play experience was not significant, $t(182) = .983, p = .189$, at an alpha level of .05. Sufficient evidence existed to con-

Table 5. Subject area

Subject	Frequency	Percent
Math	35	19
English	32	17
Science	22	12
History	30	16
Physical Education	12	7
Vocational	16	9
Special Education	19	10
Other	18	10

clude that there is no significant difference among teacher gamers and teacher non-gamers in regard to comfort levels with job-related technology. The mean total score for game players in this section was 20.33 and the mean total score for non-game players was 19.99.

This section of the survey contained six questions. Even though no significant difference was found between the groups for total scores for these questions, the gamers had higher mean scores on five questions, and one question had equal means. Of the five questions with differing means, the question regarding the use of basic computer applications had a very small difference of .01, leaving four other questions with mean differences of at least .10.

The questions with mean differences of at least .10 between each group included perceived comfort levels of using software to demonstrate concepts in class, communicating electronically with colleagues and students, using the Internet for instructional purposes, and presenting information using a variety of delivery modes including audio, video, and text. These differences may be explained by studies such as Mitchell and Savill-Smith (2004), where computer games were found being used to teach a variety of basic and complex skills supporting several areas and disciplines. Also, video games are often times the first access individuals have to technology and may create a more positive outlook towards technology (Gros, 2003).

Each question reflected positive confidence levels for both groups, except in regard to comfort levels creating and updating Web pages. On a four-point Likert scale, this question had a mean score of 2.58 for each group. In fact, 44% of game players and 50% of non-game players chose 'strongly disagree' or 'disagree' in response to this item. In contrast, all of the other questions in this section had mean scores above 3.23, with most hovering around 3.50. Hopefully, each group will become more comfortable working with Web pages as technology advances and becomes more

user friendly, but each group will need sufficient professional development to see great improvement. For example, blogs can replace the often tedious and time-consuming class Web page, but many educators are skeptical in regard to new types of technology.

Research Question 3

Do teachers with experience playing video games use instructional technology more often than those without experience playing video games? After total scores were computed for each group for the survey questions related to this research question, an independent samples t-test was conducted to determine if a significant difference existed between the gamers and non-gamers in regard to their amounts of instructional technology usage. The effect of video game-play experience was not significant, $t(159.273) = -.318, p = .751$, between the two groups at an alpha level of .05. The mean total score for game players in this section was 31.38 and the mean total score for non-game players was 31.73.

There were 13 items answered by the respondents for this section. Six of the questions had more positive results for gamers, and six of the questions had more positive responses for non-gamers. One question had equal means from each group. Even though 12 questions had different means for each group, several questions had similar means, and only three of the questions had differences greater than .10. Of these three, all had higher mean scores for the non-gamers, indicating non-gamers communicate electronically with parents more frequently, encourage students to use electronic tutorials outside of class more frequently, and allow students to use word processors to complete assignments more frequently. In relation to communicating electronically with parents, gamers scoring at a slightly lower level resemble the results from Lawry et. al. (1995), where no clear relationship was found between anti-social behavior and gaming. Also, non-gamers allowing students to

use word processors and electronic tutorials more often may be attributed to computers becoming more prevalent in teacher education programs. Teacher education programs are offering more opportunities for students to learn with various types of instructional technology, and many are requiring introductory computer courses (Betrus & Molinda, 2002).

A few of the items in this section had mean scores below 2.0 on a four-point Likert scale. The choices on this section were 'never', 'rarely', 'sometimes', and 'frequently'. This would indicate an average result somewhere between 'never' and 'rarely' on these items. Neither group exhibited positive results in regard to allowing students to communicate with teachers, students, or experts via blogs. The negative results associated with blogs could be attributed to the new emergence of this type of communicative technology. Blogs are attractive because of their ease of use (Downes, 2004), but many teachers may not be familiar with them. Also, both groups reacted negatively to how often they allow students to use spreadsheets to complete assignments. Game players also had an average below 2.0 in response to allowing students to use databases to complete assignments.

Research Question 4

Do teachers with experience playing video games participate in more innovative teaching strategies?

An independent samples t-test was conducted to determine if a significant difference existed between the gamers and non-gamers in regard to their participation in innovative teaching strategies. The effect of video game-play experience was not significant, $t(182) = .336, p = .737$, between the two groups at an alpha level of .05. The mean total score for game players in this section was 35.71 and the mean total score for non-game players was 35.49.

There were 11 items on this section of the survey. The choices on this section were 'never', 'rarely', 'sometimes', and 'frequently'. When a

closer look is taken at each individual statement, the means are extremely close for each item for both groups, with differences less than .08 for all questions except one. The only item with a greater difference was in regard to how often the individual takes risks with instruction by trying something new. The game players group reported taking risks more often, but the difference between each group was only .10. The slight difference in the amounts of risks taken could be explained by Beck and Wade (2004) when they found gamers to have the ability to implement bold but measured risk-taking strategies in the business world. Beck and Wade (2004) also described gaming as a possible training ground for critical business skills.

Items reported with lower means from each group included using alternative assessments such as digital rubrics and portfolios, and incorporating creative writing activities into daily lessons. Each of the other items in this section represented more positive results, with both groups reporting very high means on reflecting upon and assessing their own teaching and ensuring that all students are experiencing some type of learning success in their classroom.

IMPLICATIONS

Implications of this research may prompt further study and also an evaluation of one's thoughts concerning the potential benefits of gaming. It is hoped that this study and other studies centered on gaming and education will further inform both policymakers and practitioners about the characteristics of game players and the potential benefits of gaming in education.

Is Education Willing to Keep Pace?

Even though this study did not find any significant differences between gamers and non-gamers concerning specific teaching behaviors, there is little doubt the field of education can learn from the gaming community (Gee, 2004). The youth

of today are growing up in technology-rich environments with almost daily advancements in the Internet, video games, and computer games.

Educators are facing a very tough challenge in keeping the attention of their students in a fast-paced, technology-rich society. Students have entertainment at the touch of a button whether it is via MP3 player, computer, cell phone, game console, or remote control. Many students are losing interest in the classroom because of the lack of engagement in this setting. While entertainment should never take the place of quality information within the classroom, student engagement should always be a high priority. Policymakers and practitioners have often been slow to adapt or to accept change. A balance might be beneficial. For example, most secondary students are familiar with podcasting; podcasting has tremendous potential in the classroom. Through a computer or a digital audio device, students can download audio/video broadcasts related to classroom topics, providing another alternative to content presentation other than the traditional classroom lecture and text.

Are College and Professional Development Programs Making Progress Preparing Teachers?

When the data were analyzed, all of the questions and statements received favorable results for both groups except for three questions. These three questions were related to advanced computing skills including updating Web pages, implementing blogs, and using databases. Since these were the only questions or statements receiving low scores, it may suggest that college programs and professional development activities are making progress preparing teachers to complete job-related computing tasks and implement instructional technology. Most colleges and universities are requiring students in the field of education to complete at least one class related to computing skills, and more emphasis is being placed on meaningful professional development at the school level.

CONCLUSION

This study was limited to public schools at the secondary level in North Alabama. With the increase in sales within the video game market and the continual growth of the video game player population, a similar study may benefit from a larger and more dispersed population.

Although significant differences were not found between gamers and non-gamers when t-tests were conducted for each research question, researchers may choose to investigate specific areas where mean differences were found. For example, gamers were more comfortable using presentation software for demonstrating concepts in class, communicating electronically with colleagues and students, using the Internet for instructional purposes, and presenting information using various delivery modes. In comparison to gamers, non-gamers indicated a tendency to communicate electronically with parents more often, encourage students to use electronic tutorials outside of class more often, and allow students to use word processors to complete assignments more frequently. Future research may address issues of experience with technologies such as online banking, scrapbooking, and online shopping. Some respondents may have experience with items such as these, but may not be gamers. This could be a clue why significant differences were not found in relation to job-related technology tasks. Also, researchers may choose to explore a possible link between teachers' private use of computer technology and their willingness to implement instructional technology into the classroom.

In this study, teachers were identified as gamers or non-gamers by age, gender, education level, years of experience, and subject area. Future studies could involve comparisons within gaming teachers concerning teaching behaviors. Factors that may contribute to specific behaviors include average hours of game-play per week, preferred types of game genre, and type of preferred platform. Also, another study may benefit

by exploring the attitudes of each group towards technology and the reasons they use or do not use certain types of technology.

Future researchers could develop a scale or matrix to rate levels of game-play-based on specific characteristics or set criteria. Some game players prefer online gaming in communities, others prefer playing alone on consoles or handheld devices, and some prefer playing simple games on personal computers. As far as time spent playing games, individuals play at all different levels. Some play for less than one hour per week and others may play for several hours in the same week. Also, multiple genres are readily available for free or at varying prices. When studying video game players, there are multiple characteristics and criteria that can be studied. Future studies on teacher gamers would benefit by taking these characteristics into account, and significant differences are more likely to be found in practice.

The video game industry continues to grow at a rapid pace, and more individuals are playing video games than ever before. Many people are spending significant time playing video games, and video games have become part of our culture. While this study did not find any significant differences between those teachers identified as gamers and those as non-gamers, specifically in perceived levels of comfort in regard to completing job-related technology tasks, amounts of instructional technology usage, and amounts of participation in innovative teaching strategies, the potential of video games in education should not and cannot be ignored. It is hoped that this study will be used as a reference point for further study with teachers and the effect of video game-play on teaching practices and job-related tasks.

KEY TERMS AND DEFINITIONS

Blog: Short for Weblog; considered to be an online personal diary/journal that may be updated easily and quickly online.

Innovative Teaching: Demonstrating characteristics that include, but is not limited to, creativity, possessing problem-solving skills, having good social skills, using technology, and having a desire to succeed in teaching and learning.

Instructional Technology: Any type of technology implementation based on learning theories and that takes a systems approach to helping individuals solve problems.

Podcasting: The delivery of digital content over the Internet available for playback on a personal computer or portable media player.

Schema: A mental object, structure, or organizational pattern created by an individual to aid in future understanding.

Teacher Gamer: A teacher is considered to have video game-play experience if he or she has enjoyed playing video games weekly as a hobby anytime in the past or present.

Video Games: The terms ‘computer games’ and ‘video games’ were used interchangeably throughout this study. These games often require problem solving, teamwork, opposition, and character identification in order to attain a goal. These types of games are played on computers, consoles, arcade machines, and handheld devices.

APPENDIX

Survey

This instrument is designed to obtain information to aid in determining the impact playing video games may have on the use of instructional technology and participation in innovative teaching practices.

Please use the following definition in considering your response: A video game is considered to be any game that is played on a personal computer, handheld system, console, or in an arcade.

Directions: Please answer all items. There are no incorrect answers. Responses to the items will be coded and used in a statistical analysis. All answers will be confidential.

1. **Age:** 20-29 30-39 40-49 50+

2. **Gender:** Male Female

3. **Highest level of education:**

Bachelor's Degree Master's Degree Education Specialist Degree Doctoral Degree

4. **Years of teaching:** 0-5 6-10 11-15 16-20 20-25 25+

5. **Subject Area Taught (Majority of Day):**

Math

English

Science

History

Physical Education

Vocational

Special Education

Other: Please Specify _____

6. Do you consider yourself to be a full-time or part-time video game player now or any time in the past?

Yes

No

If you answered no to the previous question, skip to question #12. If you answered yes, proceed to the next question.

7. How often have you played a video game on a personal computer?

Never

Seldom

Sometimes

Frequently

8. How often have you played a video game on a console (e.g., PlayStation, X-Box, GameCube, etc.)?

Never

Seldom

Sometimes

Frequently

Teacher Gamers vs. Teacher Non-Gamers

9. How often have you played a Web-based game (e.g., cards, puzzles, role-playing, etc. on the Internet)?
Never Seldom Sometimes Frequently

10. In an average week, how many hours do you spend playing video games?
Less than 1 1-3 3-5 5-7 More than 7

11. At what approximate age did you begin playing video games? _____

For the following questions, rate how much you agree with each statement using the following scale:

1 – Strongly Disagree

2 – Disagree

3 – Agree

4 – Strongly Agree

12. I am comfortable using basic computer applications.
1 2 3 4

13. I am comfortable using presentation software for demonstrating concepts in class.
1 2 3 4

14. I am comfortable communicating electronically with colleagues and students.
1 2 3 4

15. I am comfortable using the Internet for instructional purposes.
1 2 3 4

16. I am comfortable creating and updating class Web pages.
1 2 3 4

17. I am comfortable presenting information using various delivery modes (e.g., audio, video, text).
1 2 3 4

18. How often do you use computer applications to present lesson content in class?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely (a few times per semester)
Never

19. How often do you use audio/visual equipment to display materials in class?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely (a few times per semester)
Never

20. How often do you communicate electronically with parents?
- Frequently (more than once a week)
 - Sometimes (more than once a month)
 - Rarely (a few times per semester)
 - Never
21. How often do you encourage or allow students to communicate electronically with you, other students, or experts via discussion boards?
- Frequently (more than once a week)
 - Sometimes (more than once a month)
 - Rarely (a few times per semester)
 - Never
22. How often do you encourage or allow students to communicate electronically with you, other students, or experts via blogs?
- Frequently (more than once a week)
 - Sometimes (more than once a month)
 - Rarely (a few times per semester)
 - Never
23. How often do you encourage students to use Web pages outside of class?
- Frequently (more than once a week)
 - Sometimes (more than once a month)
 - Rarely (a few times per semester)
 - Never
24. How often do you encourage students to use Web pages in class?
- Frequently (more than once a week)
 - Sometimes (more than once a month)
 - Rarely (a few times per semester)
 - Never
25. How often do you encourage students to use electronic tutorials outside of class?
- Frequently (more than once a week)
 - Sometimes (more than once a month)
 - Rarely (a few times per semester)
 - Never
26. How often do you encourage students to use electronic tutorials in class?
- Frequently (more than once a week)
 - Sometimes (more than once a month)
 - Rarely (a few times per semester)
 - Never

Teacher Gamers vs. Teacher Non-Gamers

27. How often do your students use word processors to complete assignments?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely (a few times per semester)
Never
28. How often do your students use spreadsheets to complete assignments?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely(a few times per semester)
Never
29. How often do your students use databases to complete assignments?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely (a few times per semester)
Never
30. How often do your students use presentation software to complete assignments?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely (a few times per semester)
Never
31. How often do you take risks with your instruction by trying something new?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely (a few times per semester)
Never
32. How often do you search for new ideas or products to enhance your lessons?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely (a few times per semester)
Never
33. How often do you use alternative assessments such as digital rubrics and digital portfolios?
Frequently (more than once a week)
Sometimes (more than once a month)
Rarely (a few times per semester)
Never

34. How often do you provide individual feedback to students promoting high standards and providing motivation?

- Frequently (more than once a week)
- Sometimes (more than once a month)
- Rarely (a few times per semester)
- Never

35. How often do you reflect upon and assess you own teaching?

- Frequently (more than once a week)
- Sometimes (more than once a month)
- Rarely (a few times per semester)
- Never

36. How often do you coordinate activities within your classroom with out of classroom experiences?

- Frequently (more than once a week)
- Sometimes (more than once a month)
- Rarely (a few times per semester)
- Never

37. How often do you foster student learning by connecting difficult concepts from the curriculum with real-world applications?

- Frequently (more than once a week)
- Sometimes (more than once a month)
- Rarely (a few times per semester)
- Never

38. How often do you incorporate creative writing activities into daily lessons?

- Frequently (more than once a week)
- Sometimes (more than once a month)
- Rarely (a few times per semester)
- Never

39. How often do you promote teamwork within the classroom and the school?

- Frequently (more than once a week)
- Sometimes (more than once a month)
- Rarely (a few times per semester)
- Never

40. How often do you share your knowledge, skills, expertise, and resources with colleagues?

- Frequently (more than once a week)
- Sometimes (more than once a month)
- Rarely (a few times per semester)
- Never

Teacher Gamers vs. Teacher Non-Gamers

41. How often do you ensure that all students are experiencing some type of learning success in your classroom?

- Frequently (more than once a week)
- Sometimes (more than once a month)
- Rarely (a few times per semester)
- Never

Chapter 4.22

Dance Dance Education and Rites of Passage

Brock Dubbels

*Center for Cognitive Sciences, Literacy Education, University of Minnesota, Department of
Curriculum & Instruction, USA*

ABSTRACT

The experience of a successful adolescent learner will be described from the student's perspective about learning the video game Dance Dance Revolution (DDR) through selected passages from a phenomenological interview. The question driving this investigation is, "Why did she sustain engagement in learning?" The importance of this question came out of the need for background on how to create an afterschool program that was to use DDR as an after school activity that might engage adolescents and tweens to become more physically active and reduce the risk of adult obesity, and to increase bone density for these developing young people through playing the

game over time. The difficulty of creating this program was the risk that the students would not sustain engagement in the activity, and thus we would not have a viable sample for the bone density adolescent obesity study. Implications of this study include understanding the potential construction of learning environments that motivate and sustain engagement in learning and the importance of identity construction for teachers to motivate and engage their students. In addition to the analysis of sustained engagement through the four socio- and cultural-cognitive theories, four major principals were extracted from the operationalized themes into a framework for instructional design techniques and theory for engaging learners for game design, training, and in classroom learning.

INTRODUCTION

This article seeks to understand what engages young people in learning, and what sustains their interest to continue. It explores the elements that inform the lived experience of a chosen play activity and the possible social learning theories that might inform it. Four theories were chosen and operationalized for coding the transcript of the phenomenological interview because of their focus on motivation, social learning, and identity construction: Communities of Practice (Wenger, 1998), Affinity Groups (Gee, 2001), Social Interdependence (Johnson & Johnson, 1994, 2009), and Self-Determination theory (Deci & Ryan, 2002).

All of these theories seek to explain the motivation behind learning as socially constructed and distributed phenomena; all seek to describe the process of identity construction as an impetus for situated learning. The assumption in this study was that it is through the process of identity construction that engagement is sustained and supported through the process of group affiliation and is distributed through apprenticeship, modeling, group interaction, interdependence, and situated in space.

IDENTITY CONSTRUCTION RITUALS AND RITES OF PASSAGE

Traditionally, communities gather to provide ceremony for initiation and status transition for such things as the celebration of status change, where a child becomes an adult, and initiation, where single people become married couple. Although there may be many more transitions and rituals in today's society because of the great variety of cultural subgroups (i.e., churches, car clubs, self-help groups like Alcoholic Anonymous, and hobby groups like The Peoples' Revolutionary Knitting Circle, etc.), many of these groups traditionally necessitated face-to-face interaction. But with the Internet and today's computing power,

these relations can be mediated digitally through portals like Facebook, Xbox Live, *Second Life*, and other social networking tools—as well as expert systems that provide feedback based on performance, such as a video games like Dance Dance Revolution (DDR).

The DDR game club might be represented as a ritual rite of passage to understand how and why people build identities around their play, and sustain engagement to ultimately develop expertise. Central to the rite of passage is the initiation ritual (Van Gennep, 1960), where new roles and status are conferred through public performance where play (Geertz, 1973), the subjunctive mood (Turner, 1969), situates the activity, so that rules, roles, and consequences are suspended and participants can explore new identities, associated activities, and their semiotic domains and thus develop new status.

With this in mind, well-designed video games and their fan bases may represent and express new forms of the rite of passage and initiation ritual. Like a rite of passage, games are structured activities that are valued by certain cultural subgroups, depend on play as a subjunctive mood, represent expert systems that resemble apprenticeship activities, and involve performance initiation. The subjunctive mood observed in games and ritual are said to decontextualize the action and provide a suspension of rules, roles, and consequences found in ordinary life to allow for the exploration of new identities, rules, roles, actions, and social affiliations and status in a safe space. Games can do this well.

The ritual and process of identity construction may be an organizing principle in understanding motivation and engagement. The four social learning theories presented for discourse analysis seek to provide the impetus for motivation and engagement and how to structure it, and rely upon aspects of identity construction; these theories do not present themselves as descriptions of the identity construction process. Each theory has a different focus and seeks to describe aspects of

identity and focus on an element that informs identity construction: Community (Wenger, 1998), Activity (Gee, 2001), how individuals interact with each other (Johnson & Johnson, 1994, 1999), and needs of the individual (Deci & Ryan, 2002). For the purposes of this study, these theories were operationalized to provide insight for designing instructional environments that will motivate and sustain the engagement of the learner.

PURPOSE OF STUDY

This interview was to inform design features to develop a program for pre-adolescent exercise with DDR for the study of obesity reduction and increasing bone density. The study was also intended to get a sense of why a young woman sustained engagement with DDR over 3 years to develop expertise, and how educators might replicate that kind of commitment to learning and practice. This study may be especially pertinent to designing instructional contexts, exergaming, and structuring interaction and professional development.

BACKGROUND OF THE STUDY

Health care professionals have observed an increase in levels of childhood obesity. This increase has been attributed in large part to physical inactivity. Physical inactivity can lead to obesity and poor cardiovascular health, and it can also have negative effects on bone health. Bones function to support a mechanical load (a force exerted by body weight, muscle, growth, or activity). Bone is constantly formed and reabsorbed throughout life in a generally balanced way. However, in a three- to four-year window during puberty, bone formation is accelerated. In that period, as much bone material is deposited as will be lost during a person's entire adult life. During these pivotal years of bone development, physical activity is

important for optimizing bone health, as it has been shown to reduce the incidence of fractures later in life.

Because it is difficult to motivate children to participate in the type of cardiovascular activities that adults engage in (running, cycling, aerobics), new strategies must be developed, and these may demand elements that motivate the learner to sustain engagement over a longer period of time in order to promote and sustain life habits for physical conditioning.

DANCE DANCE REVOLUTION IS NOT YOUR TYPICAL VIDEO GAME

DDR is a game that you set up with mats, a TV, a game console and a game disk, and up to four people can play simultaneously (Figure 1). To play DDR, a participant responds to a series of directional arrows (see Figure 2), displayed on a video or TV screen to perform choreographed dance steps or hops synchronized to music. Song tempo and degree of difficulty increase as the player successfully progresses in the game. Because of the game's popularity and its cardiovascular exercise and jumping (bone-building) components, it could represent an appealing model for reducing physical inactivity in children.

DDR may be a possible solution to increasing activity and mechanical load because of the amount of jumping activity, but the young person must be motivated to start, and engagement must be sustained for the activity to produce valid and reliable measures of obesity and bone density.

The issue under investigation was how to help young people start an activity and sustain it; the simple answer to this was, seemingly, to make it fun—to make it a high-interest activity—but many toys, games, and activities are often tried once and then put aside. What came out of the interview was:

Figure 1. Dance Dance Revolution set up

- the importance of aligning the outcomes with a desirable activity,
- autonomy-supporting environments,

- the importance of group and environment to the construction of status and identity that makes belonging to a group desirable along with the sustenance of a common activity,
- the importance of status and relation for reinforcement,
- the centrality of group performance,
- the role of play as a subjunctive mood and portal to engagement,
- and again, the importance of identity construction for transformation to instantiate sustained engagement conveyed through affiliation, apprenticeship, positive interdependence, and expertise. The big idea here is that perception leads to transformation.

INTERVIEW-EE/INFORMANT

To explore this, we recruited Ellen as a DDR expert and possible employee to lead an after-school program at one of our sites at the Minneapolis Public Schools. We posted a hiring description for DDR experts and had a number of responses. One respondent, Charles, shared that he had a lot of

Figure 2. Screen shot and description of DDR

The arrows moving up the screen from the bottom need to match the arrows at the top. When they match, you need to step on the corresponding arrow on the mat. Good players do this in time to the music showing their rhythm & flow—maybe doing spins and hand slaps on the mat.

In this instance, the next move would involve the bottom arrow and the right arrow being stepped upon simultaneously.

friends who were really good at DDR, and Ellen was listed as one of those people. Ellen came into the lab to show us her DDR play, and we were impressed with her expertise.

What was interesting about Ellen was that she was not from a subversive or reactionary subculture. Ellen is part of one of the least studied cultural subgroup in schools (Buckingham, 2007)—an urban, middle-class teen that is successful in school, is respectful to teachers, has a part-time job, plays varsity soccer, in traveling band, is part of the International Baccalaureate Program, and has a satisfying home life.

These elements of her identity were surprising. We usually assume that video game players are a disenfranchised fringe group at school who do not engage with the typical academic fare. Ellen was able to balance not only her academics and music instruction, work a part-time job, but also play sports and have friendships. These elements of balance were enticing and we wanted to know how she was doing it so that we might try and replicate not only the physical health benefits in our bone density study, but also some of the psycho-social and affective elements necessary for sustaining engagement (Chapman, 2003). She seemed like a great role model for creating a curriculum that would rely heavily on identity development and she was an intriguing informant to help us understand how play identities might lead to work habits that help form healthy minds and bodies.

METHODOLOGY AND REVIEW OF LITERATURE

The question driving this investigation is, “Why did she sustain engagement in learning?”

According to Chapman (2003), engagement is more than behavioral time on task. When looking to measure growth or change, or even to understand whether a learner has truly engaged, an educator should also look for evidence of commitment

and positive attitudes related to the activity and subject matter.

- Engagement is not just doing the work, it is a connection and an affinity to an activity supported from the affective domains (Chapman, 2003).
- Skinner and Belmont (1993, p. 572) report that engaged learners show sustained behavioral involvement in learning activities accompanied by a positive emotional tone, select tasks at the border of their competencies, initiate action when given the opportunity, and exert intense effort and concentration.
- Pintrich and De Groot (1990) see engagement as having observable cognitive components that can be seen or elicited through exploring the learner’s use of strategy, metacognition, and self-regulatory behavior to monitor and guide the learning processes.

These attributes do not appear in an activity because a student is told that it is good for them, and that they should commit to their betterment. Least likely is that they do an activity because we threaten, or just because we want them to.

A student must make a choice to commit to an activity and have that commitment reaffirmed over time to sustain engagement. True engagement in an activity is in some sense transformative and resembles identity construction, in that it changes who one is through cognitive, affective, and behavioral elements. It seems likely that without positive reinforcement (Skinner, 1938) the behavior may result in extinction and the game becomes another resident on the island of misfit toys. We look at social learning theories to explore issues of sustaining engagement through socially distributed reinforcement.

DDR is considered a high interest activity for many young people, and it does have a reward system that gives real-time feedback on perfor-

mance with rewards for successful play. But, without aligning those rewards and achievement with social capital, they lack meaning and status, and the reinforcement system remains a token economy (Ferster & Skinner, 1957) whose tokens are unredeemable except as social capital.

The work of Buckingham on identity development may provide some insight for connecting identity with purpose, motivation, and sustained engagement. Buckingham (2008, p. 3) states that Identity is developed by the individual, but it has to be recognized and confirmed by others. Adolescence is also a period in which young people negotiate their separation from their family, and develop independent social competence (for example, through participation in “cliques” and larger “crowds” of peers, who exert different kinds of influence).

Identity and status were traditionally conferred through rites of passage, and there may have been many culturally-specific instances of these rites for different groups and related activities. Video games may represent a new wrinkle in the way that we enact and view rites of passage. They may offer a form of guided, ritualized behavior for identity construction and group affiliation as an autonomy-supporting environment (Ryan & Deci, 1999), Affinity Group (Gee, 2001), Social Interdependence (Johnson & Johnson, 1994, 1999) or Community of Practice (Wenger, 1998).

A rite of passage does not need to resemble the tribal practices that led to vision quests, ritual markings, or exodus. A rite of passage may be organized in three forms: the process of separation, transition, and integration, (Van Gennep, 1960), but all three of these rites may also be presented as single rite (Barnard & Spencer, 1996). What was important for Van Gennep was the idea of Liminality, or the threshold. The threshold in an initiation represents a portal—a representative movement from the status of one social space to another, where ritualistically, the individual or group makes a transition by passing through a

metaphorical or literal portal to represent a change in social status and position.

In the context of Liminality, the activity space may be far removed from reality, and roles, rules, tools, values, and status may be situated in the flux of play as if a hybrid or interstitial space (Turner, 1969). This concept of the threshold and liminality seems to validate Geertz (1973) and his description of the “Center Bet” in describing the ritual of Balinese Cockfighting and Benthams’ concept of Deep Play. According to Turner (1969), there may be many rites of passage in a person’s life through sub-cultural affiliation (Cock Fighting, DDR, First Job) where identity and entitlement are inculcated through desire to become a respected and acknowledged group member, where the individual can share in and contribute to group activity, participate in group spaces, and publicly renew and further their status.

For Wenger (1998), identity is central to human learning; identity construction and learning are distributed through community and relations; learning is socially constructed; and motivation is based on a desire for sharing and participatory culture. The work of Wenger shares many attributes with Gee’s work, but the focus for Wenger was on socially distributed cognition and learning as social participation. Earlier work (Lave & Wenger, 1991) explored the role of learning in apprenticeship, where newcomers would enter into a space where learning was situated and contextualized, and goals and purpose were evident due to entering the space. One entered the space to gain apprenticeship and attempt to acquire and learn the sociocultural practices of the community. Thus, the individual is drawn to the group and begins to engage and learn by finding their role in a distributed, networked, cultural-cognitive process with the purpose of the individual as an active participant in the practices of a social community and become an acknowledged member with skills, knowledge, and the requisite values. This participation leads to the construction of his/her identity through these communities. From

this understanding develops the concept of the Community of Practice: a group of individuals participating in communal activity, creating their shared identity through engaging in and contributing to the practices of their communities.

The difficulty with this theory is that group membership is hard to define. A person may want to be part of group and claim group membership, but not have the identifiable characteristics that define the membership.

Since identity is conferred from others, there are factors that can identify a person as a group member and as having identity markings. For Gee (2001), the activity is primary and provides the motivation and engagement, the source of group membership and the identity markings; for Gee the community and relations are ancillary and stem from the interaction related to the activity. He states that these communities and spaces are hard to identify without knowing exactly why people are there. Whether a person actually claims group membership or is acknowledged can be difficult.

For Gee, whether group membership is acknowledged—claimed or not—attributes can still be observed. The role of Gee's work is central to operationalizing identity and group membership through offering observable sociocultural markers that come from semiotic domains central to the activity as evidence of group membership.

A semiotic domain recruits one or more modalities (e.g., oral or written language, images, equations, symbols, sounds, gestures, graphs, artifacts, and so forth) to communicate distinctive types of messages. By the word "fluent" I mean that the learner achieves some degree of mastery, not just rote knowledge ... Semiotic domains are, of course, human creations. As such, each and every one of them is associated with a group of people who have differentially mastered the domain, but who share norms, values, and knowledge about what constitutes degrees of mastery in the domain and what sorts of people are, more or less, "insiders" or "outsiders." Such a group

of people share a set of practices, a set of common goals or endeavors, and a set of values and norms, however much each of the individuals in the group may also have their own individual styles and goals, as well as other affiliations.
~Gee (2001, p. 2)

This work allows for certain attributes of group membership to be observable rather than subjective. A young person may have grown up participating in an activity with parents and young friends, but during the puberty years, may reject that affiliation based upon new goals for group membership and status. A new group may be more desirable than a current group, and the young person may cast off markings that identify them with the old group such as a hat from a uniform, ways of speaking, values, etc. This does not mean that markings of prior group membership with parents, family, and childhood affiliations are not still observable—an accent or mannerism may indicate origins or influence. For Gee (2001), it is the activities and the group practices that provide evidence of social learning and group membership from semiotic domains, and it is activity that is central to identity construction.

For Deci and Ryan (2002), the focus comes from work on motivation with a focus on Autonomy, possibly built from early work by White (1959), where organisms have an innate need to experience competence and agency and experience joy and pleasure with the new behaviors when they assert competence over the environment—what White called effectance motivation.

For Deci and Ryan, motivation is based on the degree that an activity or value has been internalized, and this is based upon the degree to which the behavior has meaning within the context of the arena of performance.

In order to sustain engagement for Deci and Ryan, motivation must be internalized—the external contingency must be “swallowed whole.” The learner identifies the value of the new behavior with other values that are part of the self. This

process of engagement is the transformation of an extrinsic motive, one that is reinforced from outside the learner's values, into an activity that is assimilated and internalized by the learner as an intrinsic value that becomes part of their personal identity. This process involves constructing values aligned with the group and environment, and thus assimilates behavioral norms that were originally external as part of a new identity. Based on the degree of control exerted by external factors, levels of extrinsic motivation can be aligned along a continuum. (Figure 3)

- External regulation: doing something for the sake of achieving a reward or avoiding a punishment.
- Introjected regulation: partial internalization of extrinsic motives.
- Identified regulation: doing an activity because the individual identifies with the values and accepts it as his own.

Identified regulation is autonomous and not merely controlled by external factors. It is motivation for an activity that has been integrated as part of the learner's values, and refers to identification with the values and meanings of the activity to the extent that it becomes fully internalized and autonomous (Ryan & Deci, 2000).

Social Interdependence describes what informs students' goal attainments (Johnson & Johnson, 1994, 1999). According to Johnson and Johnson (1999)

Students' learning goals may be structured to promote cooperative, competitive, or individual-

istic efforts. In contrast to cooperative situations, competitive situations are ones in which students work against each other to achieve a goal that only one or a few can attain. In competition there is a negative interdependence among goal achievements; students perceive that they can obtain their goals if, and only if, the other students in the class fail to obtain their goals

In cooperative situations, students work with Positive Interdependence, where group members perceive that they are linked with each other, and that the success of each member is linked to the success of the others.

Twelve themes from these theories of identity construction, ritual and rites of passage, engagement, motivation, and social learning were taken to code the interview transcript to inform analysis and make decisions on what factors might be important for the construction our after-school program for tracking design efficacy and measure performance.

THEMES FOR CODING

Of these twelve themes, there seemed to be four major themes, and the rest seemed to be interdependent sub-levels that were common across all of the theories. With this in mind, the major themes are:

- Play as Subjunctive Mood
- Activity Space
- Desirable Social Grouping, and
- Desirable Activity.

Figure 3.

Table 1. Themes for coding

Play Subjunctive Mood	Activity Space	Desirable Social Grouping
Ritual Rites of Passage Initiation, separation, integration	Positive Interdependence	Belonging/ Relatedness
Desirable Activity	Identified regulation	Apprenticeship
Affective Commitment	Autonomy/ Competence	Cognitive Theories of Action

These themes were the most common descriptions of “why” when Ellen described her DDR play. These three themes also represent an aggregation of each theory, but with emphasis on activity, space, and groups, as well as the mood that needed to be present in those themes to be attractive.

DATA COLLECTION

The phenomenological interview methodology (van Manen, 1997) was used to try to elicit responses beyond descriptions of rationale to gather “thick descriptions” (Geertz, 1973) of affective, social, corporeal, and cognitive behaviors behind the activity and experience of playing DDR. And, also to encourage descriptions that were thick enough that the researcher might be able to identify instances of learning and engagement situated and distributed across networks of time and space, mediated through shared activity, and perhaps to see if there were evidence indicating what elements in the identity construction process inform motivation and engagement.

DATA ANALYSIS

The critical discourse methods as espoused by Gee (1999) and Fairclough (2003) not only provide methodologies that are fundamental to qualitative analysis, but are also fundamental to the study of “the scaffolding of human affiliation within cultures and social groups and institutions,” Gee

(1999, p. 1) and “how do existing societies provide people with the possibilities and resources for rich and fulfilling lives,” Fairclough (2003, p. 202). It was for this reason that these methods were used to explore and code the phenomenological interview transcript. Although a sample of one participant is not very robust for generalization, it provided a starting point for more focused theory testing, as well as to provide insights for us as designers, theorists, and education practitioners.

INTERVIEW

This first excerpt from the interview begins to describe the motivation to learn to play Dance Dance Revolution. Ellen and I met on a nice spring day in the Whittier neighborhood near the Minneapolis Institute of Arts at a coffee shop called Spy House. When I asked her about her experience of playing DDR, she said:

The first time I ever played Dance Dance Revolution was with my friends Tyler and Ben. They had it at Devon's house and everyone was playing this game. Really, I wanted to hang out with them, I wanted to participate and so that's when I started learning. Then it was after playing with those guys for so long that I really started to enjoy the game. I actually didn't have a play station before that, so I went out and bought a play station just so I could play DDR, yeah ... yeah, I didn't want to be left out of it. Games are fun and I just wanted to spend time with my friends and this is something that they were all doing.

The basis for Ellen's learning was Belonging/Relatedness to a Desirable Group. This idea of relatedness and Belonging were fundamental in her development of skills and collection of resources to develop as a player. However, she did not have the feeling of connectedness until she was really able to engage in the activity as a participating member—Autonomy/Competence. This indicated introjected regulation, and Identified Regulation seems to require the performance and seems to require some external indication of having internalized the values of the group that are expressed through public performance in the group and a commitment to practice that showed her effort toward group success as an indication of Positive Interdependence.

Surprisingly, the activity was not initially a Desirable Activity, "I wanted to participate and so that's when I started learning." After some time participating, she found enjoyment along with her sense of Belonging to a Desirable Group. This phenomenon suggests precedence of Belonging to a Desirable Group for Ellen over engaging in a Desirable Activity, and also suggests that an individual can develop interest in activity that might not have been initially motivating due to a desire to belong. Speculatively, there may be some indication for the importance of Play as a Subjunctive Mood for developing affinity for an activity. It was clear that she had already identified with the people, but, based on the next excerpt, she had not identified or been identified with the activity. The descriptions she offers indicate that the activities need to be playful and not so serious, and that the activity should offer success for assured status. There must be an entry point for a public performance, and perhaps since this game was new, she could enter without the loss of status that would come from being new and unskilled while the skilled players watched her and perhaps lost interest in her performance, and possibly in her.

I was excited because this was something I could participate in. I've played Halo and I'm not that good at it and everyone was starting out on this for the first time, so I thought I could be one of those good people at it and get respect from people. I was really excited. They have this huge TV at Devon's house and everyone's around you. I was kind of nervous too because you have to do this in front of people. Well, we were all kind of sitting on the couch watching the men and I was like I want to try it. I mean, some of them were interested in seeing me probably because they knew I never played before and they made me where I was probably going to fail, but then I actually really wanted to do it, so I was like, I want to do it next! I thought I was going to be better at the game than I thought I was because I'm thinking, oh these guys they don't have any coordination. This'll be easy for me. I'm kind of in shape, so I was thinking it would be pretty easy and then I do some of these songs and I was like oh, I need to go down a level! I thought I caught on fairly quickly.

What was clear from this passage was the importance of the activity and her feeling that she could be successful participating and "be one of those good people at it and get respect from people." There are several parts to this that are especially interesting:

1. Belief in her ability to succeed was essential in her willingness to perform publicly. Research on adolescents' engagement in literacy, for example, has found that adolescent perceptions of their competence and ability to succeed may be a more important predictor of whether they will engage, than their past performance. (Alvermann, 2001; Anderman et al., 2001; Bean, 2000; Guthrie & Wigfield, 2000). Studies of adolescents have also found that they prefer to perform where they know they will have success

- (Csikzentmihaly, Rathunde, & Whalen, 1996).
2. The fear of performing in front of the group with Autonomy/Competence, but that since people were just starting out, she might have a chance to be good at it and to be respected. This may have played an even larger role because she was one of the girls who watch from the sofa, not one of “the men” who play the games and perform.
 3. The importance of the Activity Space and its affordances as well as the possible change in atmosphere with this new game, where there may have been more emphasis on Play as the Subjunctive Mood.
 4. The role of Belonging/Relatedness seemed to be an important component in her participating in the activity and her feeling of becoming an acknowledged group member. The structure of the activity, according to the next excerpt indicated that DDR, as compared to other games, offered more of an Apprenticeship situation, where others were willing to teach and share; raising the level of success and fun through Positive Interdependence.

This makes a case for the importance of Affective Commitment, Belonging, and Competence, as well as a Cognitive Theory of Action. Although these seem to be sublevels of Desirable Activity and Desirable Group, that inform and reinforce action, they are important factors that indicate engagement and are likely fundamental to its sustenance, and also seem to indicate a form of reinforcement as socially distributed affect and cognition.

Ellen had created a Cognitive Theory of Action and knew that it was essential for her to perform to be acknowledged and claim membership—another indication of Chapman’s (2003) description of engagement, and evidence of Identifiable Regulation. To claim Belonging to this Desirable Social Group, she realized whether implicitly or

not, that she needed to participate through performance (Autonomy/Competence) to Belong. This supports Deci and Ryan’s position that Autonomy, Belonging, and Competence are basic needs that underlie motivation and engagement and satisfy Skinner and Belmont’s (1993) assertion of affective involvement. What is central to these needs are the Activity Space where these young people could interact as a community through the game; the subjunctive mood of play that may have allowed for the desirability and beliefs in success; and the game itself, which seems to be structured to promote Positive Interdependence and can create Identified Regulation through structuring relations through space and activity.

Ellen had already aligned her values internally as Introjected Regulation, but she had not found an opportunity with a Desirable Activity where she might have success in the Activity Space and feel confident that she would succeed and enjoy the activity, “I could be one of those good people at it and get respect from people.”

Halo and *Counterstrike* she described as work (Sutton-Smith, 1997), which has consequences for failure—the desirable group may have been much more advanced in their performance in *Halo* and *Counterstrike*, and perhaps took playing the game much more seriously and raised the stakes of the performance.

Games and play are often about choices without life-threatening consequences, but that does not mean that games are not taken seriously. They can be performance tests (Autonomy/Competence) and Ritual/Rites of Passage that allow for the development and affirmation of a place within a group, establishment of pecking orders, and through this, community status and entitlement; it is possible that the experience of being positioned to perform and possibly fail was some sort of initiation, a form of deep play (Geertz, 1973).

This act of bettering oneself in public can be risky situation—and it really must occur in public for a person to be seen as Competent/Autonomous and as an acknowledged group member (Belong-

ing). This Ritualistic phenomenon was described by Geertz as the “Center Bet” in “Deep Play,” (1973) and based on Ellen’s description, it may be that as competence and expertise evolve, the play gets more serious and the stakes and status of the performance (Ritual) change, the fear of failure increases with the perceived change in subjunctive mood from play to work ethos.

THE PERFORMANCE/INITIATION

Previously, Ellen may have wanted to be part of the group, but Ellen stated that the games they were playing did not provide her with much interest to play, even though she wanted to belong to the group and participate in their space. Because of this, she may not have been considered as part of the group, but maybe more of a tourist or poser because belonging seemed contingent on being able to “do.”

I have a lot of friends who play Counterstrike and a lot of... almost every guy I know plays Halo. You can enjoy watching those games. I don't enjoy it as much. Like I said, it's just way more serious. They get more serious. Well, it's like everyone is more quiet and focused, like they really get into trying to hunt these people down and kill them before they are hunted down and killed. DDR, you are playing against someone but then with Halo and Counterstrike you're against all these people and you have to be, like, watching your back all the time. Even the people watching, they zone out and just watch it. For me it's not as fun. As for DDR, it's more like people jumping around and are less serious, but it's still a lot of fun.

Prior to Ellen’s embrace of the game, she was a groupie. She could talk about how Devon did, but not about her own experience. This came, in part, as being recognized as a player by her community, but it was also a confidence that came of public performance (Autonomy/ Competence);

sustaining engagement with the practice; and working hard to develop status and identity related to the group and the activity and the freedoms and responsibilities that accompany them.

So, what followed was me just trying to find where I could go to play. Then I kind of got eventually frustrated with it—well, not frustrated, but I wanted to play more, so I decided to buy it for myself.

Yeah.

You play by yourself to get better to play with other people. I mean, it's always fun to play by yourself and unlock new songs and things like that.

I got it for Christmas from my parents, so I didn't have to buy it, but I had to persuade them and make sure they got me what I wanted. They didn't really understand but they felt okay about it because it wasn't something violent or anything like that.

Then I was, like, look what I can do! They watched me. They thought it was kind of interesting. This was with my family on Christmas. Then my uncles and my little cousin, who was maybe like seven, they all got really interested by it. So my fifty-year-old uncles are trying it and they're getting really excited. My little cousin, she's getting excited too. She doesn't even really understand what's happening on the screen but she's like jumping around on the pad.

In the DDR trial, Ellen was tested to see how she would respond to public failure: she could have quit and gone home, or she could have laughed it off and found the fun in learning and worked towards acceptance. Ellen found that there were others who were beginners that she could improve with, and more experienced players who were actually helpful and willing (Apprenticeship/ Positive Interdependence) to teach. She, also, found that there is no substitute for experience, and that in order to become a part of the group, she had to go

through the rites of practice and public initiation. According to Van Gennep (1960) this ritualized process is common to many societies where an individual passes from one stage of life to another, and it can involve separation from childhood environment, transition, and incorporation with new status. For Turner (1969), this game may not be as monumental as rites celebrating marriage or death, but it still represents a moment of social transition and eventual change in status. The importance of this is the public acknowledgement of Competence. This seems to be essential to identity construction and acceptance as a member of a group through the activity that is structured in a way that resembles positive interdependence, and may be the reinforcement for sustaining engagement.

It was through the activity that Ellen was conferred status and identity as member not only by her new friends, but through her family and the community, that had the power to convey her status and acceptance. She became a “gamer girl.” This conferred new identity and acceptance allowed her to become that gamer beyond her normal relations and to extend her community network and develop new relations and status:

Because we shared this thing, so it would be, like, oh, so whose house are we going to go to tonight to play DDR? Okay. Well, my friend Devon, his house was the main DDR house just because he had a great room for it and everything. And his parents didn't really care how much noise we made or how late we stayed there, so his house is generally the DDR house. Tyler, who was my friend prior, we would get together and practice a lot. Michael, he bought DDR around the time that I did and we were basically kind of on the same level, and I got to know him better that way just by spending time with all these people. Nick, all these other guys, I had kind of known beforehand, but now we spent all this time together. So, it was basically we all met at Devon's house and that's what we would do for weekend-after-weekend-after weekend.

If we can draw from these Activity Spaces and domains and inspire the learner to feel a connection and affinity to traditional academic fare like engineering, literature, mathematics, and so forth as Desirable Activities, we may provide a portal to embracing academic learning. The challenge seems to be embedding the learning outcomes in a high-interest activity with a reinforcement network to sustain the activity and continue to validate the identity.

As Ellen's ability with the game progressed, she was being recognized as a DDR “gamer girl,” and this conferred upon her a new identity and status. She began to find new connections through familiar school activities. Her familiar conversations changed to unexpected connections in school and at her job; as more people learned about her new status as a gamer girl, the more she began to meet others with an interest in DDR and to connect with the gamer culture. She had begun to move beyond her former status as an International Baccalaureate student (Academic), varsity soccer player (Jock/Athlete), Band Member (Musician/band geek) into a more generalized, pop-culture status, where she was seen as not so serious and more approachable. It may have been important to Ellen to branch out and change people's perceptions. Perception seems to be essential to transformation. We can work to create an identity, but it must still be acknowledged to have status. This may have been her first activity that was run by her contemporaries—autonomous and not overseen by adults.

Perhaps all her work in academics, sports, and band had made her appear to be too serious, and easily influenced by adults—a follower. She may have also felt constrained by all of her commitments and wanted to break out to meet new, fun people, “Really, I wanted to hang out with them ... games are fun.” The proposition that might follow as if a syllogism is that: Gamers are fun, and I want to be fun too.

It is only conjecture and anecdotal, and she did not abandon her commitment to band, sports, or

academics—she graduated with an International Baccalaureate diploma—but as can be imagined, all her work in those areas may have made it important to her to find friends who had interests beyond her everyday world, and that being a gamer would allow her to step away from conversations about the team, assignments, practicing certain pieces of music, and set her apart. Playing the game and being part of that community allowed her the ability to decontextualize and detach from work and become perceived as fun.

Developing these relations may be more than fun; it may be an apprenticeship to develop a coping tool. The importance of play, according to Vygotsky (1978), is decontextualization, where an individual can gain gratification and pleasure even in the midst of unresolved issues and larger, and time-consuming projects. The role of pretense and imagination can bring about pleasure and gratification in the face of uncontrollable circumstances; this can provide some relief through affective reward and pleasure. Perhaps the gaming provided an opportunity to decompress and laugh in the midst of all that responsibility and preparation. But, it was seemingly more than that. It was also a way to connect and extend her status by initiating new players and drawing on the interest and social capital, for example, in a hotel room on a band trip—another autonomy supporting activity space where the identity could be reinforced with status from new participants.

Yeah, it was a school band trip. So, a lot of us went and it turned out that a whole bunch of people knew what DDR was. It was interesting to see them play. Tyler and I, we kind of felt cool because our group that we had played with had progressed better than these other people that we were seeing play. They were like, oh man, this kid is so good and we play with him all the time. Tyler and I played against these people. Yeah, we beat them pretty bad.

In this instance, the game activity did extend beyond the familiar Activity Spaces like Devon's basement; it even seemed to provide an activity

that would make others see her as representative of a Desirable Group. The game and her new status seem to have supplanted the importance of being part of the gamer group in Devon's basement. The activity became a means for extending her friend identity reinforcement network as an Affinity Group (Gee, 2001), where people affiliate because of an affinity for an activity, maybe to be part of the fun—to play. As the activity began to change for the group members, relationships started to change, and the emphasis on the game, itself, diminished.

Well, a lot of the guys that I started playing it with, they moved on to other games because that's what they do. They focus in on something for a really long time and then they'll find something else will be just released and everybody else will just be playing that, so they'll jump into that. Then there was always the people who have it, like Tyler and I, who will still play it. We didn't get bored with it; it's just then there were other things. No. I don't play it as much as I do anymore and my friendships through that have become different. I mean, we're all still friends. DDR was just like this common thing that we had to, like, start us talking and then after that we talked about normal things. I became pretty good friends with a lot of people. I dated one of the guys that I met for awhile. I don't know, it wasn't, like, any different than like you meet people playing for a sports team. You have something in common and that's what you're coming together to do, and then you talk about other stuff because we're not just focused on DDR. Well, at my work it's kind of similar too. We're all stuck working together and so then we get talking. Soccer and sports a lot. Any kind of group that you all come together and you have something to talk about and then we just eventually expand on that and that's how we became friends.

The DDR game did facilitate relationships in ways that other games and activities did not,

but in the end, the initial motivation may need to come from a purpose that only the individual can develop. But, play can facilitate this and may make the entrance to a group, the practice, and eventual mastery of knowledge, activity space, and activity more likely to be enticing, and possibly provide for sustained engagement and eventual mastery. This makes a case for Play as a Subjunctive Mood and the importance of Positive Interdependence.

Playgroups, and the activities that support them, provide a common ground for interaction. There is definitely a pecking order that comes from demonstrable competence and evidence of knowledge from the semiotic domains from the game. Games are built upon play, pretense, and decontextualization, but once these activities no longer provide pleasure and gratification, the activity may quickly end and the relationships and spaces that contextualize and support them may change in the way that Ellen's DDR group cooled off: "and my friendships though have become different. I mean, we're all still friends."

Games are structured forms of play, Dubbels (2008) that provide rules and roles that are defined to help members to decontextualize from the ordinary world where they have responsibility, deadlines, and environments that they cannot control. These same rules and roles also help them to know their status in the game, share common, spontaneous, and authentic experience without going too deeply into personal motives, negative feelings, and Freudian melt-downs. Corsaro (1985) called this play group phenomenon the Actors Dilemma. According to Corsaro, the Freudian meltdown, or over-sharing, is one of the most common causes of playgroup breakup. Perhaps play is the coping mechanism that allows for detachment and the ability to constructively work on what can be changed and separating out that which cannot be changed. Game roles may also allow for exploration of other peoples' values and experience in a safe space without getting too deep or real, which represents an opportunity to

try on and project different emotions, and build comfort and trust through a common experience.

In terms of identity construction, the game may take a form of a Ritual/ Rite of Passage: The Activity Space is no longer like the ordinary world. The rules and roles in a game are different and even changed for the sake of experimentation with social norms. Interpersonal boundaries can be tested without endangering status and relationships—it is a trial, a testing. As with Ritual/ Rites of Passage, when Play acts as the Subjunctive Mood, different parts of person can emerge and people can try on different personae without recrimination, because they are only playing.

CONCLUSION

In answering the original question, "Why did she sustain engagement?" it became evident that her motivation to sustain engagement over time changed. She was attracted to the activity because she wanted to be friends with the kids who hung out at Devon's basement—she wanted to be an acknowledged member of the group, not part of the fan club. To do this she had to perform and risk ridicule and a possible reduction in status. Geertz (1973) described this spatially in that the further away one is from the "Center Bet," or the central public performance, the lower your status and importance to the main event and performers.

To be part of this group, she needed to perform, but she was hesitant to try because the games being played did not mesh with her sense of play and fun. Perhaps because the play of these group members with these games (*Halo*, *Counterstrike*) was already too far advanced for them to tolerate a "newb" (new player) at the controller, and might create a break-down of the activity. In this case, the challenge is learning how to improve performance through the activity of playing better players than oneself.

Ellen decided that it might be better not impose her learning during prime-time play and risk the

ridicule or contempt of poor performance. The lesson seems to be readying oneself to play in the “Center Bet,” which she did with DDR. If one is not contributing to the play, learning, and/or status of the group, perhaps spectators understand their place on the periphery, and that perception is the key to transformation, and this is mediated through play as subjunctive mood.

This ability to detach and decontextualize through play can be a very valuable trait when dealing with pressures of studying for exams, working, and other responsibilities that cannot offer immediate gratification. This inability to decontextualize and detach is one of the central behaviors inherent in Play Deprivation (Brown, 1999), a diagnosis used to make sense of the incredible violence of Charles Whitmore and his shooting spree from the bell tower at Texas A&M University. It was found that Whitmore was raised in a very rigid environment where he was not allowed friends or play. He experienced a life that looked very successful on the surface. But, in 1966 he committed what was the largest mass murder in the history of the USA. According to the National Institute for Play (1), Brown, who was a psychiatrist at Baylor College of Medicine at the time, collected behavioral data for a team of expert researchers, appointed by the Texas governor, to understand what led to Whitmore’s mass murder. What was found through interview, diary, and reconstructing is that Whitmore had been under extreme, unrelenting, stress. After many unsuccessful efforts to resolve the stress, he ultimately succumbed to a sense of powerlessness; he felt no option was left other than the homicidal-suicidal ... Whitman had been raised in a tyrannical, abusive household. From birth through age 18, Whitman’s natural playfulness had been systematically and dramatically suppressed by an overbearing father. A lifelong lack of play deprived him of opportunities to view life with optimism, test alternatives, or learn the social skills that, as part of spontaneous play, prepare individuals to cope with life stress. The committee concluded

that lack of play was a key factor in Whitman’s homicidal actions – if he had experienced regular moments of spontaneous play during his life, they believed he would have developed the skill, flexibility, and strength to cope with the stressful situations without violence.

Brown continued exploring Play Deprivation as a construct and found similar patterns in other violent offenders, and even traffic deaths related to aggression and chemical issues. The role of play cannot be underestimated for its ability to decontextualize and reframe experience. Play therapy currently is a treatment in child psychology for helping children talk about and understand forces beyond their control.

RELEVANCE OF ANALYSIS

The utility of this analysis comes from these recalled phenomena as a pattern for planning instruction and understanding why people learn. We learn to become. We create and engage to gain new experience and entitlement and gain status without danger in our social network, as well as to learn from others, whether it is a workplace competency, gaining social skills, or as a means of adapting to stress.

The role of Play as a Subjunctive Mood in these Activity Spaces and Desirable Groups may be the organizing principle that makes these groups and activities desirable as part of identity construction, as well as the means for identity construction and reinforcement to sustain engagement. For a person to facilitate and construct an identity, they may need to play, just as children play as doctors, fire-fighters, teachers, mothers, and even animals and dinosaurs in games. It is through pretense that we are able to imagine and create cognitive theories of action and circumstance, and it is through play that we develop this capacity.

If we want to sustain engagement, we need to help students develop the capacity for Identified Regulation, where they may turn their play into

meaningful performance when asked to perform in activities that begin to resemble rites of initiation and deep play. This process creates a subtle transition where the initial play activity becomes serious and is approached with the focus of work. Like what Ellen experienced watching advanced players of *Halo* and *Counterstrike*, and eventually what she experienced in practicing in addition to school, homework, and lessons, to prepare for DDR at Devon's.

IMPLICATIONS AND LESSONS FOR DESIGNING INSTRUCTIONAL ENVIRONMENTS

This transcript from Ellen's experience makes a case for developing instructional environments that allow for playful, autonomous group interaction structured as a game to allow for play in much the same way that ritual demands play. The group and space "Re-Place" and the rite offers "Re-Creation."

The use of play as the basis for designing instruction should not be underestimated. Often we forget that play is our natural approach to learning. When working with very young people, such as infants, toddlers, and small children, we align instruction with their interests, and allow objects to help direct inquiry. It is through the use of toys and exaggerated actions and emphasis in modeling target behavior that we allow for failure to be an inherent and necessary part of learning. The hesitation many educators express with this approach is that we have much to do, and little time to do it. It begins to sound like the white rabbit in Alice's Adventures in Wonderland running worriedly and anxiously "we're late, we're late!"

Stress pressure and anxiety are a natural part of learning, just as play is a natural part of learning, however, fear and threat scenarios are not often great motivators, in addition, fear and stress eventually take their toll on the body, mind, and spirit. Play may be the correct context for sustain-

ing engagement and creating the initial portal for engaging learners in focused approaches to work and delay of immediate gratification for the kind of rewards that rigor and sacrifice deliver.

I have used these principles on several occasions to explore games and play as effective methods for aligning content and process with resistant and reluctant learners. I have used it to create games for reading instruction, literature instruction, engineering, mathematics, leadership, and organizational change. To demonstrate how this can be done, I created a game called *Dry Dock* to teach engineering that I will use to demonstrate the four major instructional design principles for play.

PRINCIPLE 1: PLAY AS A SUBJUNCTIVE MODE

Engineering can be a very fun class, but the curriculum I was supposed to teach was very un-fun. In fact the curriculum was the source of the *dysfunction*. I was being asked to start class by presenting standards, why the standards were important, and tell the students why they were learning what they were learning. I found that this was much more for the benefit of observers evaluating the quality of my teaching than it was to motivate and engage the students.

I use standards, and I feel it is important to share the larger scheme of things behind activities and what they might be preparing for, but I do it with Play as the Subjunctive Mood. The first thing I did was to quit thinking that these kids would commit to a curriculum just because it was posted up on the wall. It is not enough to tell students how they are going to fulfill standards and a rubric.

For most, fear of failure was not an issue. Many of them were accustomed to it. They had checked out as an act of integrity, and in doing so, had found that they could dictate terms to teachers because of their disruptive behavior. Although my departure from the scripted curriculum of having

students redesign coffee mugs and the “do it or fail” curriculum did not always sit well with the administrators; it did result in engagement from my students (who did not drink coffee).

I told the students that we were going to be having a boat race, and that I would be bringing in my wading pool from home, and that we would be making sail boats out of Styrofoam to race across the pool. I structured all of the engineering, statistics, and technical writing so that they were embodied in the task, and that through experience, they could discover them. What was essential in this case was not so much joining a desirable group, but in participating in a desirable activity where their group could interact in the activity space semi-independently, and that the task was one where they believed that they would have early and instant success.

In addition to this, I also tried an experiment where I used a different approach to creation of subjunctive mood in the activity: Work as subjunctive mood: I told the students that we were really behind in our work and that we would have to work hard and be rigorous in our approach to these boats. I stressed that it was incumbent upon us to learn terms like resistance, surface area, momentum, and force and apply them into our hull designs. I was talking, but they were ignoring me, tuning me out. When I asked them what they were supposed to do, many of them did not know, and many of them expressed that they did not care.

To test this I introduced the activity where Play was the subjunctive mood: I told the class that we had a fun activity where we were going to be building boats and that we were going to have four kinds of races: speed, weight bearing, stability, and general purpose. I told them that I was going to be showing them examples of boat hulls and that they should play with them a bit to decide what style of boat they were going to make for the races they were going to participate in. I found that kids had listened, knew what to do, and really wanted to start. All of the same principles and terms were still present in the unit,

but they now had permission to be playful and perhaps fail. Play implies failure, recovery and experimentation. Many of the kids made crazy boats that would never work, but they were fairly successful in using the terms to justify their design for each race. It is not always what you do, or whom you do it with—it is how you do it, and that you do it at all.

PRINCIPLE 2: DESIRABLE ACTIVITIES

One of the key issues in creating sustained engagement and identified regulation is in creating activities that align with the goals and purposes of the learner, or exposing the learner to something they think is really cool and they want to do. Making boats was not what many teens would consider a “cool” activity, but it did hold attraction for them when I showed them the tools, the materials, and gave a brief overview of what they would have to do. Getting kids to engage may just be a matter of creating some fun, and showing that they can have early and instant success; that they can work with some autonomy in a space where there is wiggle room for them to be expressive; and that they can make adjustments if they make mistakes. There must be time allowed to go deeply into learning to allow for the student to commit to the *expression of self* into their work. This might mean going off task and making red sails even though it has nothing to do with learning the Bernoulli Effect, the competition, or the embedded learning outcomes.

The opportunity to make aesthetic and seemingly inconsequential changes allowed them investment in the activity through personal expression and to eventually invest in a cognitive theory of the activity, and also allow for a belief in their future success. Add to this the opportunity to work cooperatively and learn from the work of other class members—some call this copying, I call it modeling and apprenticeship—then they can make a start (often full of errors and mistakes)

and adjust for excellence as they work with others and begin to better understand the project/activity. In this way we enable the spontaneous neutral experience that can be useful for beginning the learning process and also building relationships and belonging, and autonomy and competence through the activity.

The key to this principle is in embedding the learning in the activity so that learners can discover the learning principles in the process of the activity through performance and reflection, where they compare what they have done with the work of others, and the instructor can provide encouragement to scaffold further development—this is an apprenticeship model with roles, rules, and positive interdependence. Oddly, this is often also the process of inquiry, discovery, and failure recovery, although time consuming, is often the process through which scientific principles were discovered before they were concentrated into abstractions in textbooks for memorization and testing-- they were tripped over by the scientists and then operationalized into methodology. This can be done when we think of instruction as games and learning as structured forms of play. Some important elements for designing instruction as play are offered in this framework of play for instructional design modified from Dubbels' (2008) Taxonomy of Play:

- Cognitive Theories of Action: we capture the imagination and build cognitive theories of action through imagery/ visualization (mental modeling).
 - A key word for the instruction should be “IMAGINE”.

This first category in the taxonomy provides a basis for testing comprehension. It is important to be able to create mental model and theory of the action. The key attributes are visualization and imaginatively creating mental models and segmenting process and attributes for indexing in memory. If learners index and visualize well,

they will likely have fine grain memory of the experience to draw upon for future use. Thus, creating these mental images is very important for creating the motivation to engage, belief in future success, and a cognitive theory of action.

- Desirable Groups: provide roles and identities they can try on and play with and offer the ability to change roles and play with the identities.
 - A key word for instruction should be “TOGETHER”

Working with others: A great draw because it allows for interaction. Many students need to be able to copy other students until they are able to IMAGINE and create a cognitive theory of action. Some learners do not learn well from instructors. They need to watch another learner translate the experience. Through this, they not only learn how to start the assignment, but also how to create a cognitive theory of action on which they can improvise and express themselves through and commit to the activity. I cannot tell you how many times I have seen resistant learners get into a groove and not want to stop the project once they finally get started!

- Roles: In the case of the boat project, they became Naval Architects and Marine Engineers; just learning about what these folks do as a profession, and, that these professions exist opened a lot of student eyes and created schema for the semiotic domains of each role. They also had Learning and Functional roles (see Appendix B).
- Structuring group work: The creation of roles in cooperative learning as Johnson and Johnson suggest (1994) is very powerful and also what we see in early childhood play, as well as more advanced game experience for video games, teaching empathy, and modeling interaction for professional development. In structuring the work

through roles, each group member has role specific tasks. One can play Return to Castle Wolfenstein or look at game-specific roles (character classes) in Appendix A and Appendix B, and imagine how these roles would culminate in teamwork for a mission. Each character class has several unique abilities and these come with different learning roles and functional roles.

- Identity/Semiotic Domains/Epistemic Frames: Provide rules, roles, values, language, actions, and tools associated with the roles and identities (semiotic domains) that they can work with, and act on that which is inherent to the task, where the performance is the assessment. The role of the Naval Architect is to design a marine vessel for specific activities. The elements that define this role are the tools, activities, language, values, and outcomes associated with the role, and ultimately, the boat floats or it doesn't. This embodiment is informative assessment, where the action provides immediate feedback through complete or partial mastery, or failure and the role provides for measure of progress and schema development based on knowledge of the semiotic domains.
- Create choices and branching decision network: It is important here that the learners explain their cognitive theories of action and are asked to utilize and explain the identity tool box to support their choices and why they did what they did, and what might be next.
- Contingency/Probability: This comes about when we consider the possible contingencies that might come from an action through prediction and hypothesis testing. Examples of this are

resource management; awareness of likelihood of an action based on knowledge of the game and instructional environment, and attempted quantification and probability of failure or success.

This structure for instructional design comes from A Taxonomy for Play and is aligned with a scale for levels of cognitive theories of action in Dubbels (2008). This triarchical model, the third leg being reading comprehension, has been the basis for a number of successful curriculum units as well as digital games, allowing for direct linkage to learning and comprehension metrics and is also available at <http://www.vgalt.com>.

PRINCIPLE 3: SPACES

Spaces are where we can offer activity, autonomy, interaction, and relationships. By creating spaces where learners can self-govern to an extent, we make them desirable, especially if there are desirable tools and resources as affordances. What I did with the boat unit was to create a rite of passage to get from one learning space to another. The students were told that to use the tools and start on their hull designs, that they had to use the hull examples and sketch a hull design, and then explain why and how the hull would perform well in specific race conditions (speed, weight-bearing, stability, general purpose)—then they were to go and test their design and hypotheses.

I was able to create different work spaces by offering tools and independent construction of their boats with a number of hot-wire cutting tools (for the Styrofoam) if they were able to sketch and explain their design based upon the hull exemplars and key vocabulary I had postered around the classroom walls; this was also where I had placed the wading pool for the races, and where students could make test runs of their constructed boats.

In a sense, I had created a threshold or Liminality into my classroom space, much like a game allows one to level up, or passing a rank elevates a soldier. It was a rite of passage of one space to another. The new space allowing more autonomy and less controlled interaction through a verbal examination and demonstration of applied knowledge and competence—a knowledge act (Dubbels, 2008).

PRINCIPAL 4: DESIRABLE GROUPS

This was mentioned in the Desirable Activities, but this deserves its own principal. The role of Desirable Groups was primary for Ellen as a motivator for her to become a DDR expert. What makes it especially relevant is the role of socially desirable groups and the influence they hold in conferring identity, the entitlement, and status that go with it. The role of groups cannot be underestimated for identity construction and the rituals that convey it. If Wenger (1998) is correct, and identity is central to human learning, and as Buckingham states, that identity is developed by the individual, but must be recognized and conferred through community through some type of performance or ritual, then the structuring of ritualized activities for status and competency construction may be immensely important for not only creating engaging activities, but to sustain them and make them life habits.

The studies operationalized in this analysis provide several key features, that when brought together provide a very powerful tool kit for instructional design:

- Communities of practice, which represent the established pathway into community, status, and entitlement. This model aids in our understanding of the distribution of knowledge through webs and networks of sharing, modeling, and instruction through status, identity, community ritual, and affiliation

- Affinity Groups, which explicate the importance of the activity in conveying group membership and status through evidence from the semiotic domains, which are signs, signals, and markings acquired and bestowed through experience in communities of practice and apprenticeship experiences.
- Self-Determination Theory provides the elements that lead to internalization of these activities, values, language, relations, and spaces for the actualization and internalized regulation of motivation and engagement into activities and habits that provide a source of satisfaction beyond the external, or extrinsic rewards that into activity that is self-satisfying and self-fulfilling for enjoyment and effectance, so that engagement is sustained and informs the individual's identity and status.
- Social Interdependence and Cooperative Learning, which provide insights into how to structure learning contexts and positive interdependence for learning, relations, and alignment of identity with valued cultural norms through Instructional design.

These are all brought together with the awareness that play may be the foundation for the construction and development of these descriptions—a portal to work, where we learn that play is the initiation, as well as the rite—and through ritualized behavior, activity, and representation, with allowance for learning and failure recovery we grow, evolve, and make meaning through mental models and prediction-- and thus innovation and deep seated cognitive theories of action due to the inherent process of reflection and do-overs in play and games to heighten public performance and status.

Play seems to be the subjunctive mood that mediates entry into work and competence, and possibly to expertise. As play becomes more competitive through more complex cooperation

and trust, play and learning deepens into effort, application, and work.

In addition, play is the foundation for ritual and representation, and central to creating the context and subjunctive mood for performance that supports apprenticeship, culture, and social learning. Play is fundamentally important for building life habits such as fitness, reading, and even simple things such as manners and cooperative behavior. In his treatise on play, *Homo Ludens*, Johan Huizinga (1938) posited that play was the basis of culture, and Lewis Mumford (1945) reasserted this in his treatise *The Myth of the Machine*—stating that it was imitation (mimesis), role play, the creation of miniature environments, and the symbolic fields of play where every function of life were modeled as a game to develop competency and advance what was known and yet to be known.

Dubbels (2008), in the spirit of Vygotsky, (1978), furthered this by stating that play and representation are the factory of our conceptual abilities, and if play involves the creation of abstractions and models of the world, then sharing play necessitates complex communication as well as a means for innovation and production, and perhaps the basis for cognitive theories of action, mental models, hypothesis creation, and ultimately comprehension.

With play central to our approach, we may find that motivation and engagement increase with little need for threat because of the inherent pleasure of learning without the dangers of repercussion or loss of status through failure. Failure is an inherent part of play, but a gentle entry with play and the promise of early and instant success (as in sail painting) can provide the portal to more profound success through failure recovery, modification, continuous improvement, and iterative design. In a game, there is often a loser, and in order to get better, we assume that we must fail to get better, as we must seek better players and more difficult conditions to improve, develop, and even transform.

Games are structured forms of play (Dubbels, 2008) that can provide the portal to complex social and cultural cognitive enhancement and progression. They represent new forms of ritual and safe contexts for contest and accomplishment through challenging apprenticeships in expert systems, where an expert might not have been available in the past. Games may be the new rite of passage and rituals, or as Vygotsky (1978) called toys “pivots,” where a banana can become a phone in a child’s play, where play is a transitional stage that is the beginning of separating the meaning of an object from literal to figurative. Games may be an elaborate pivot for accomplishment, status, and entitlement through modern day social and cultural networks in virtual and real space, and these may be the elements that motivate and sustain engagement and provide real answers for designing learning contexts and sustaining engagement and creating the kinds of identities that engender habits of lifelong learning and activity.

APPENDIX A. CHARACTER CLASSES

Typical character classes and game roles from a video game can be used as a model for designing classroom instruction for learning roles (see Appendix B also). In this case from the game *Return to Castle Wolfenstein*. Each character class has different skills and fit what Shaffer (2006) calls an Epistemic Frame: the ways of knowing, of deciding what is worth knowing, and of adding to the collective body of knowledge and understanding of a community of practice, where by playing the medic and learning the opportunities and constraints, one begins to create a cognitive framework, or schema for a content domain of identity, knowledge, competence, language, values, and activity. Roles like these can be structured into instruction, just as they are reinforced in communities of practice and the hegemony of social practice and institution.

From Wikipedia:

Soldier: The soldier is the only class that can use heavy weapons. They are: mortar, portable machine gun (MG42), flamethrower, and bazooka/Panzerfaust. On the No-Quarter mod the Venom machine-gun and the BAR (Allies) or StG44 (Axis) have been added as well. Leveling up gives the Soldier benefits such as the ability to run with heavy weapons (instead of being slowed down).

Medic: The medic has the unique ability to drop health packs, as well as revive fallen players with a syringe. They also regenerate health at a constant rate, and have a higher base health than any other class, which makes them the most common class for close-in combat. When a player has achieved skill level 4 in medic, they get Self Adrenaline, which enables them to sprint for, longer and take less damage for a certain amount of time. Some of the medics act as Rambo Medics. Their emphasis is on killing rather than healing or reviving.

Engineer: The engineer is the only class which comes equipped with pliers, which can be used to repair vehicles, to arm/defuse (dynamite or land mines), or to construct (command posts, machine-gun nests, and barriers). As most missions require some amount of construction and/or blowing up of the enemy's construction to win the objective, and as defusing dynamite can be very useful, engineers are often invaluable, and one of the most commonly chosen classes. The engineer is also the only class capable of using rifle muzzle grenades.

Field ops: The field ops is a support class which has the ability to drop ammo packs for other players, as well as call air strikes (by throwing a colored smoke-grenade at the target) and artillery strikes (by looking through the binoculars and choosing where they want the artillery support fired). This class has low initial health, but makes up for having an unlimited supply of ammunition.

Covert ops: The covert ops is the only class which can use the scoped FG42 automatic rifle, the silenced Sten submachine gun (or MP-34 on some Mods), and a silenced, scoped rifle (M1 Garand for Allies, K43 Mauser for Axis). The covert ops has the ability to wear a fallen enemy soldier's clothes to go about disguised, throw smoke-grenades to reduce visibility temporarily, and place and remotely detonate explosive satchels. By looking through a pair of binoculars, the covert ops can spot enemy landmines, bringing them up on their team-map. The covert ops also show enemy soldiers on the team-map. Medic, Engineer, This creates a fluid transition to the next category.

APPENDIX B. LEARNING AND FUNCTIONAL ROLES FOR DESIGNING STRUCTURED INTERACTION AND POSITIVE INTERDEPENDENCE

Functional Roles—Adopted from <http://www.myread.org/organisation.htm>

ENCOURAGER and COP

- Reads instructions and directs participation
- Read the instructions
- Call for speakers
- Organize turn-taking
- Call for votes
- Count votes
- State agreed position

ENCOURAGER and SPY

- Summarizes findings and trades ideas with other groups
- Check up on other groups
- Trade ideas with other groups

*Allowed to leave your place when directed by the teacher

ENCOURAGER and SCRIBE

- Writes and reports groups ideas; is not a gatekeeper.
- Record all ideas
- Don't block
- Seek clarification

ENCOURAGER and STORE KEEPER

Locates, collects and distributes resources including informational resources like web pages and encyclopedia entries

- Get all the materials for the entire group
- Collect worksheets from the teacher
- Sharpen pencils
- Tidy up

*Allowed to leave your place without teacher permission

LEARNING ROLE for LITERACY

Freebody (1992) and Freebody and Luke (1990) identify the roles literate people take on that can be used in a classroom for activities that involve reading or the study of literacies that involves narratives and cultural phenomenon.

CODE BREAKER

How do I crack this code?

What words are interesting, difficult or tricky? How did you work them out?

What words have unusual spelling?

What words have the same sound or letter pattern or number of syllables?

What words have the same base word or prefix or suffix?

What words mean the same (synonyms)?

What smaller word can you find in this word to help you work it out?

What words are tricky to pronounce?

How is this word used in this context?

What different reading strategies did you use to decode this text?

Are the pictures close ups, mid or long shots?

Are the pictures high angle or low angle?

Were there any word pictures, eg similes and metaphors? How did you work them out?

USER

What do I do with this text?

What sort of text is this? (Information, story/narrative) How do you know?

Is it fact or opinion? How do you know?

How can you find information in this text?

How did the author start this text? Did it suit its purpose?

Who would read a text like this? Why?

If you wrote a text like this what words and phrases would you use?

How is the language the same/ different from other similar texts you have read?

Could the text help solve a real life problem?

If you were going to put this text on a web page, how would it be different to the print version?

What is the purpose of this text?

Could you use these ideas in a poem, story, play, advertisement, report, brochure or poster?

How would the language, structure and change?

PARTICIPANT (EXPERT)

What does this text mean to me?

Does the text remind you of something that has happened to you or to someone else you know?

What does the title/cover suggest that the text is about?

What might happen next? What words or phrases give you this idea?

What are the characters thinking and feeling? How do you know?

What message is the author presenting?

What are the main ideas presented?

What do the pictures (graphs, diagrams, tables, captions, illustrations) tell us?

Do they fit in with the text and do they provide more information?

What did you feel as you read this part?

Describe or draw a picture of a character, event or scene from the text.

ANALYST (INVESTIGATOR)

What does this text do to me?

Is the text fair?

What would the text be like if the main characters were girls rather than boys and vice versa?

Consider different race and cultural backgrounds too.

How would the text be different if told from another point of view?

How would the text be different if told in another time or place, eg 1900 or 2100?

Why do you think the author chose this title?

Think about why the author chose particular words and phrases.

Are there stereotypes in the text?

Who does the text favor or represent?

Who does the text reject or silence?

How does this text claim authority? (Consider language, structure and content)

Who is allowed to speak? Who is quoted?

This work was previously published in International Journal of Gaming and Computer-Mediated Simulations (IJGCMS), Volume 1, Issue 4, edited by Richard E. Ferdig, pp. 63-89, copyright 2009 by IGI Publishing (an imprint of IGI Global).

Section V

Organizational and Social Implications

This section includes a spacious range of inquiry and research pertaining to the behavioral, emotional, social and organizational impact of instructional design around the world. From case studies in Africa to studies of gaming on developmentally disabled and learning disabled children to plagiarism and community collaboration, this section compels the humanities, education, and IT scholar all. Section 5 also focuses on hesitance in some faculty members' integration with instructional design, a growing issue among those involved with education who are already forced to "wear many hats" at the higher education level. With more than 20 chapters, the discussions on hand in this section detail current and suggest future research into the integration of global instructional design as well as implementation of ethical considerations for all organizations. Overall, these chapters present a detailed investigation of the complex relationship between individuals, organizations and instructional design.

Chapter 5.1

Culturally Negotiating the Meanings of Technology Use

Deepak Prem Subramony
Utah State University, USA

ABSTRACT

This chapter explores how the “meanings” of technology use are being culturally negotiated between Western educators and native Iñupiat Eskimo learners at schools across the Alaskan Arctic region, as part of a wider examination of the impact of the Western product and process technologies embodied by these schools upon the socio-cultural consciousness of the non-Western learners whose educational needs they seek to serve. There are two distinct aspects to this intercultural negotiation between educators and learners: (1) attempts of the former to reconcile their practices with the latter’s values, standards, and expectations; and (2) efforts of the latter to culturally appropriate the non-indigenous technologies being made available to them. It is expected that professionals work-

ing in a range of organizational contexts within our field may be able to gain insight from the remarkably universal nature of the problems and solutions involved in this extreme and instructive situation of socio-cultural tension.

INTRODUCTION

Our field has, in recent decades, witnessed vast populations of learners and performers in schools and workplaces across the planet being dramatically affected by the rapidly strengthening twin forces of globalization and human migration. On the one hand, the worldwide spread of Western capitalism is leading to the rapid infiltration of Western technology into far-flung areas wherein they were previously absent, thereby impacting formerly unaffected populations. On the other hand, rising mobility as a result of improved

DOI: 10.4018/978-1-60960-503-2.ch501

transportation links and growing international commerce is leading to increased demographic heterogeneity within hitherto comfortably homogenous societies. The increasing diversity of socio-cultural variables—including race, ethnicity, nationality, language, and religion—among learner and worker populations resulting from the aforementioned phenomena will undoubtedly mediate learning and performance across a wide range of educational and organizational settings (Powell, 1997a; Subramony, 2004).

Mainstream theory and practice in the field of educational technology, however, have not been very successful at evolving and adapting in light of these socioeconomic and demographic changes (Subramony, 2004, 2006). While dominant Western-originated ideas, tools, and procedures—in other words, product and process technologies—related to education, instruction, training, and performance are impacting the lives of more and more non-Western learners both within and outside the geographical boundaries of Western civilization, very little research is being done in our field to document and understand the dynamics of this cultural interchange, specifically in terms of the negotiation between Western and non-Western cultural groups of the sociological “meanings” of using these technologies—that is, what, if anything, are those agents promoting and implementing these technologies doing to make the latter more culturally relevant to the lives of Non-western learners; and how these technologies are being culturally appropriated or rejected by non-Western target populations.

In a modest attempt to steer the prevailing theoretical and practical discourse in our field towards considering questions and issues of the aforementioned kind, the author of this paper enlists the help of data from a particularly interesting and dramatic case involving the introduction of Western educational technologies into a culturally unique non-Western population. Very briefly, the geographical context of this cultural interaction is a vast expanse of Arctic tundra in northern Alaska

where the indigenous Iñupiat (Eskimo) population has, in recent decades, been impacted by unprecedented oil wealth. The area of particular interest to us, in this case, is the resultant provision of an environment that is exceptionally rich in Western technologies within the region’s schools, which, incidentally, happen to be run almost entirely by expatriate educators from the “lower 48” United States. Meanwhile, the majority of learners served by these schools come from traditional Iñupiat families that, until very recently, depended almost entirely upon subsistence hunting, whaling, and gathering for survival.

In this paper we will briefly examine the impact of the Western product and process technologies that are embodied by the Boreal Slope School District (BSSD) schools upon the socio-cultural consciousness of the native Iñupiat Eskimo learners whose educational needs are served by these schools. This documentation involves exploring how the meanings of technology use are being negotiated between the imported Western educators on the one hand and the native Iñupiat learners on the other. There are two distinct aspects to this negotiation, namely: (1) the attempts of the former to reconcile their practices with the values, standards, and expectations of Iñupiat learners; and (2) the efforts of the latter to culturally appropriate the non-indigenous technologies being made available to them. This author believes that professionals working in a range of organizational contexts within our field may be able to gain insight from the remarkably universal nature of the problems and solutions involved in this extreme and instructive situation of socio-cultural tension. As cultural anthropologist Norman Chance explains, “by seeing how events are intimately linked to comparable forces present in other settings (we can) come to appreciate the common themes of historical process along with the uniqueness of cultural difference . . . (since) though differentiated by culture, we are all united by history” (Chance, 1990, p. xvii).

BACKGROUND

This two-part section features a brief discussion of the current state of inattention towards issues of cultural diversity among learners and technology users within the mainstream academic discourse in educational technology, followed by a concise contextual description of the site and case from which data has been drawn to illustrate the key issues discussed in this paper.

Background of Inattention

Back in 1997, Gary Powell—then a faculty member at Wayne State University’s prestigious Instructional Technology Program—was among the first scholars to recognize the neglect of cultural factors by the mainstream discourse within our field. He lamented how matters of cultural, racial, and ethnic diversity among learners were not eliciting the level of attention they deserve in our field’s texts, journals, and conferences—a neglect that persisted despite a growing acknowledgement that key learner characteristics such as prior knowledge, entry behaviors, ability, and motivation, all of which are heavily influenced by the latter’s cultural backgrounds, must be taken into consideration to enhance learning (Powell, 1997a). Seven years later, Subramony (2004) surveyed the current situation and found that not much had changed in the intervening time: Much of the curriculum in leading graduate programs in the field across the nation still did not address the relevance of cultural differences among learners; only three out of 41 chapters in the most recent (2003) *Handbook of Research for Educational Communications and Technology* brought out by the Association for Educational Communications and Technology (AECT) contained any discussion of cultural issues; a mere 2.5% of the more than 500 refereed presentations at the 2003 AECT International Convention tackled this topic; and finally, just 2.9% of the 379 research- and development-related articles published in six, key,

peer-reviewed journals in the field during 2002–2003 featured an explicit discussion of cultural factors in learning or technology use.

Reformist, culturally conscious scholars have attributed the neglect described previously to the historical foundation of traditional curricula within our field in the conservative, Western philosophical canons of positivist science, patriarchy, and Eurocentrism. According to them, this prevailing view of the field (1) distances our research and practice from the multiple values and needs of non-Western sociocultural groups by co-opting its language, analogies, and metaphors from military, industrial, and medical spheres (Jamison, 1992); (2) tends to hold largely media-based and exogenous views of cultural minority groups; and (3) generally sees success as a de-raced phenomenon achieved through meritocracy (Swartz, 2003). Many mainstream scholars in our field thus seem to believe that issues of cultural diversity among learners are already being given more attention than they deserve, that—as noted educational evaluator Reeves (1997) described their feelings—these issues are merely “a passing fad, a byproduct of the current attention to multiculturalism” (p. 27) within North American and European academia.

Reeves (1997) went on to describe how his own perspectives on the field—as those of other evaluation authorities, most of whom are White males steeped in Western philosophy, psychology, and research methodology—have been biased by professional experiences that rarely addressed multicultural or diversity issues. Powell (1997b) also revealed how many middle-class, White scholars and practitioners in our field display ethnocentric attitudes, judge the world by their own cultural values, and have little interest in understanding any cultural differences lying at the heart of their target learners’ lives. Thiagarajan (1988) concurred with Powell (1997b) in noting that mainstream Western scholars commonly ignore minority learners’ cultural reactions to competition, public recognition, negative feedback, authority figures, and gender differences,

instead assuming that their own cultural tradition represents the best or only way. Meanwhile, noted learning scientist Thomas Schwen (personal communication, 2003) bemoaned how educational technologists are often “seduced by the belief that their research and development endeavors are value-free and therefore immune to social and technical criticism.”

Scholars and practitioners in our field are thus finding the faces of their target learners changing faster than their ability to modify their instructional and classroom management strategies, curricular materials, and, most importantly, their mindsets that leave them predisposed to regard diversity at best as “interesting,” and at worst as a “deficit,” and to make erroneous assumptions about cultures other than their own (Powell, 1997b). Such attitudes, in Schwen’s words, serve to restrict social choice, impose pedagogical options, and deprive equal access. As Thomas, Mitchell, and Joseph (2002) go on to describe: “By not directly addressing culture in the design of instruction, many products have been designed that inadequately address the needs of the population for whom the instruction was designed. Unintended consequences of this shortcoming include the production of ineffective instructional products, the under-use of potentially effective products, culturally insensitive products, and products that are deemed overtly culturally offensive by some members of certain populations.” These negative consequences of our field’s neglect of cultural issues are worsened by the pre-existing, well-documented socio-economic and educational challenges faced by many non-Western learners.

Site/Case Background

The case described in this paper, the BSSD, (please note that to protect the privacy of informants/actors and organizations involved, all geographical, institutional, and personal names pertaining to the site and case have been changed) was extensively

studied by this author through successive site visits over a 2-year period. Inquiry methods employed to this end included individual and group interviews, observations, and document analyses. This vast Arctic district is headquartered in Borealis, administrative headquarters of a region of sparsely-peopled, treeless, marshy, mostly-frozen tundra that holds “the largest petroleum deposit ever encountered in North America, with an estimate of 9.6 billion barrels of recoverable oil” (Chance, 1990, p. 153). Borealis has grown into “the focal point of Eskimo adjustment to the modern world, the crossroads of contact with big money, western culture, and industrialization” (Boeri, 1983, p. 193) and the “testing ground where the success of the wedding of modern government, Western technology, and big money with the values Iñupiat place on their heritage and traditional lands will be decided” (Blackman, 1989, p. 32).

Blackman (1989) describes Borealis as a site that “leaves a strong impression on the Outsider. As the northernmost city in the western hemisphere, the largest Eskimo community in North America, oil boomtown, and seat of the largest ‘county’ government in the United States, (Borealis) is the sort of place that attracts modern-day curiosity seekers” (p. 3). What makes Borealis’ character especially unique is the pace at which it has evolved from a pre-agricultural, hunter-gatherer settlement into a modern, technology-intensive socioeconomic hub for the entire northern third of the state of Alaska. As cultural anthropologists Worl and Smythe (1986) explain, Borealis natives currently in their 60s and older experienced, within the span of their lifetimes, “changes from dog-sleds to snowmobiles, from heating homes with blubber to natural gas, and from wearing caribou clothing to denim and polyester. Some witnessed the abandonment of customary practices, such as the (formal wife-swapping arrangements) and the burial of personal property with the dead” (p. 22).

Particularly intriguing to an educational technologist is the unique educational environment that

Borealis' K-12 schools are providing to an equally unique learner population. These schools feature the juxtaposition of a technology-intensive, oil-wealth-fuelled educational system, based on the modern, dominant Western model, with a student body coming from Iñupiat families that deeply and demonstrably cherish their traditional native ways of knowing and being. The BSSD currently runs 10 technology-rich schools spanning the enormous, sparsely populated region. While the relatively large settlement of Borealis—boasting a population of a few thousand souls—is served by separate elementary, middle, and high schools, the seven other significant Boreal Slope settlements, given their small sizes, each have a single, unified K-12 school. Borealis High School (BHS) opened in 1983 at a cost of \$85 million and incessantly expanded and upgraded since then as the flagship institution, the largest and best-equipped school on the Boreal Slope, “the showpiece of them all” (Blackman, 1989, p. 31). In 2004 the total enrollment at BHS was 273 students. The school costs averaged \$21,000 per student per year to run, with the average graduating class comprising around 30 individuals.

Interestingly, as Blackman (1989) explains, while home rule for the Iñupiat has brought a measure of local control over Boreal Slope schools, with the Iñupiat-majority Boreal Slope Borough School Board making decisions on programmatic and budgetary issues, the education of Iñupiat students within the BSSD schools remains largely in the hands of non-Native administrators, teachers, and staff imported from outside the region, mostly from the “lower 48” United States. It is these Western-educated outsiders who get to make most of the immediate administrative and pedagogical decisions that affect the educational experiences of the Iñupiat students. Such cross-cultural control, common across the inhabited world since colonial times, has strengthened as a phenomenon in recent decades thanks to globalization. Those interested in performance technology

issues within corporate settings may be interested in Marken's (2006) recent account of a Fortune 100 company featuring a similar circumstance.

KEY ISSUES

Getting back to the case at hand, it is indeed a recurring feature at schools in Native-populated regions across North America—such as the Far North and Indian reservations further south—that a predominantly indigenous learner population is being served by a predominantly Western educator group. Such circumstances pose unique challenges to both learners and educators. When this author interviewed new BHS teacher Lacy while conducting fieldwork in Borealis, the incongruity of this situation seemed apparent to her from very early on:

In the first week of school, we had that welcome assembly, and that's when it really hit home, because I'd had the classes, that whole day, seeing new faces and trying to get names, but being in that assembly literally gave a very clear picture of kind of what was happening in the community, because we had the superintendent, the principal and the vice-principal, they all spoke at different times up on stage, and we're in this really nice auditorium, and then you've got all the teachers, kind of up and around the auditorium so you can see all the teachers they're standing in the stairs and in the back, so it's like this, and everyone's White, almost everyone has come from the 'lower 48,' the teachers, the superintendent, the principal, kind of the positions of power in terms of the schools are White, and then, I was standing in the back, and you look down through all the students sitting right in the middle, and most of them have this jet-black hair; and it was like, OK now what exactly are we doing here? And it was just very, it was kind of eerie, disconcerting.

Meanwhile, interacting with Native Iñupiat informants in Borealis and reviewing the literature pertaining to the evolution of modern Western-style education in the North American Arctic over the past century or so leads one to an understanding that there existed no such institution similar to a Western “school” within traditional Iñupiaq society. Learning was experiential and organic, with the young learning their social behavior and Arctic survival skills from their family and from the community. The process of education was thus naturalistic and all-encompassing, because, in essence, as a local Iñupiaq elder expressed it, “school was life.” But with the advent of Western-style schooling in the Arctic there was now a dichotomy between education and life, between school and community, a division brought about by the product and process technologies that came along with the Western educational institutions—institutions that were systemically alien to the physical and cultural environment of the Boreal Slope.

Add on to this fact the unique exigencies of Borealis’ Arctic location and the extreme technology richness of its school environments, and the matter becomes even more complicated. One of this author’s primary objectives in studying this case, as mentioned earlier, was to document the impact of the Western product and process technologies embodied by the BSSD schools upon the sociocultural consciousness of the native Iñupiat learners whose educational needs were being served by these schools. It was explained that this documentation involved exploring how the meanings of technology use were being negotiated between the Western educators on the one hand and the Iñupiat learners on the other, with their being two distinct aspects to this negotiation, namely: (1) the attempts of the former to reconcile their practices with the values, standards, and expectations of Iñupiat learners; and (2) the efforts of the latter to culturally appropriate the non-indigenous technologies being made available to them. In the following two sections the reader is presented with a short exploration into these aspects.

ON THE USE OF WESTERN EDUCATIONAL TECHNOLOGIES TO SERVE NON-WESTERN LEARNERS

In an illuminating session at BHS, technology teacher Annabelle permitted this author to observe a 75-minute keyboarding and word processing skills class session she was conducting. Annabelle started the class off by handing her learners hard copies of a sample cover letter for a job application, asking them to copy it into a Microsoft Word file as a “warm-up exercise.” Written by a certain Robert Goldstein of Huntington, WV, the letter was addressed to Frank Westerman, Fire Chief of the Huntington Fire District and expressed its writer’s desire to be considered for a position of firefighter trainee. Annabelle reported having photocopied the letter from a textbook on business communication. The fact that the letter did not contain a single reference to an Arctic or even an Alaskan context—being, instead, set entirely within a “lower 48” milieu—did not appear to cause much concern to Annabelle, nor did she seem to have considered the possibility that this situation could be fixed so easily, that is, just by changing a couple of names and geographical references in the letter before handing it out to the learners.

In the meantime, after the learners—seven Iñupiat and a Filipina—had finished copying Mr. Goldstein’s letter to Mr. Westerman, Annabelle had them move on to do a set of typing exercises using the *All The Right Type* software program, which had been purchased by BHS and made available on the school server. The program presented the learners with a series of sentences in succession to copy, keeping track of their speed and accuracy and providing feedback on these variables. Once again, not a single one of these practice sentences seemed to be related in any way to the learners’ cultural or geographical context, but instead smacked of a traditional “Dick and Jane” paradigm. Examples of sentences the learners faced included “Danny is flying to Denver in January”; “Nora is staying

over in Niagara Falls”; The 6 girls each ate over 6 plums”; “I baked 23 pies, while Jill baked 13”; “24 cows, 14 cats, 24 pigs, 44 horses”; “Manuel picked 114 apples from 4 trees”; and so on. It was rather intriguing for this author to watch the learners dutifully copying these sentences while belonging to a geographical locale in which there existed no trees, cows, pigs, or horses whatsoever, and where the general population, as a rule, did not keep cats as pets, or include pies, plums, or apples as part of their diet.

Meanwhile, when Annabelle—who also taught media classes and oversaw yearbook production—was asked to describe what she did during these classes to make the classroom experiences more responsive to her learners’ native culture, this was what she answered:

(For example) if I taught TV production here, the subject matter for some of the videos may be different than in the ‘Lower 48,’ but certainly the use of technology would be the same ... I think as a teacher, that’s the one thing you want to be really careful of, and I think as any good yearbook teacher ... I try and be a guide and a coach, and I try and teach them journalistic (and design) standards ... but the content, I really try and let the kids decide. And yeah, there will be cultural elements in the yearbook, you know, the big headline when you open page one, is, “Arrigaa,” which is an Iñupiaq word, and that’s the first word in the yearbook this year! So yeah, there is a lot of that ... the theme for the yearbook is “The View from the Boat,” it’s a reference to whalers and whaling, and things work in like that a lot. They ask a lot of times whether senior quotes, do they have to be in English. “No, your senior quote doesn’t have to be in English,” ... and I think we had them submitted in three different languages so far besides English ... so, I think it would be horrible if the yearbook from Borealis High School looked exactly like the one from (a school in the ‘lower 48’ United States)! It would be wrong, and, I don’t think it does!

Readers may note how Annabelle’s response seems, interestingly, to convey the assumption that technology could be used as a vehicle for working with culturally relevant subject matter—in other words, that it was basically the “content” in which cultural elements found their expression. Such a viewpoint would also suggest that, with cultural elements being primarily couched within content and with technology being merely a tool used to deal with the content, there was, thus, not very much in terms of embedded cultural elements within the technologies themselves. Such assumptions would be neatly congruent with mainstream discourses in our field that, as Jamison (1992) describes, define technology as a neutral technical apparatus or technique, and promote Western technology as the ideal catalyst for global progress.

Annabelle meanwhile had provided this author with copies of six previously published BHS yearbooks. Upon analysis, however, very little evidence could be seen of any conscious efforts to include Iñupiaq cultural elements within even the content of these volumes, except that most of the photographs therein showed Iñupiat faces. While some of the yearbooks sported vaguely culture- or location-specific titles—the 1996 volume was titled “Breaking the Ice;” the one from 1997 was “Dancing to the Beat of a Different Drummer;” and the 2004 edition was titled “On the Water’s Edge...” —none of the six yearbooks had a single page devoted to content in the native Iñupiaq language. As for the reporting of any Iñupiaq culture-specific activities, the 2004 yearbook could well be held as a representative exemplar: within its 104 pages, there were exactly three photographs related to whaling, one picture from a sewing class, and, rather inexplicably, one of a skin mask made by a different (Nunamiut) Eskimo group. The rest of the yearbook indeed looked very much like one from anywhere within the “lower 48” United States, with coverage devoted to matters such as sporting activities, academics, fine arts, student government, and Western-style

social events such as a block party and the annual Homecoming ceremony, plus with the usual student portraits. And ironically, these yearbooks displayed production standards equaling those of yearbooks from any affluent suburban U.S. school, featuring profuse illustrations and high-quality paper and binding materials.

This author also visited a 75-minute CAD-CAM class at BHS, taught by shop teacher Liam using an expensive, new *Shopbot* device. The installation comprised of a bank of computers for design work, plus the *Shopbot* machine for doing the actual machining. Learners could design an object on one of the computers using CAD software, and then go over to the *Shopbot* and have it create the object they just designed. Two Iñupiat male learners were working on designing wooden wall plaques the day the class was observed. One of the former was making a plaque that read “The Ahsoak’s Residence—No Trespassing—Guard Dog on Duty,” while the second was making one that read “Mama Susan’s Kitchen.” It was intriguing to watch the two boys manufacture plaques of the kind that, honestly, could be encountered pretty much anywhere in the country. This author asked Liam how might any of this relate to the Iñupiat’s own craft traditions. He replied that he would sometimes find Iñupiat learners picking out from among the standardized design templates those that featured vaguely “native-looking” patterns or elements, for the products they created using the *Shopbot*.

The aforementioned examples have been cited basically to illustrate a strongly felt perception on this author’s part that, while some efforts were certainly being taken to allow the learners to express their cultural elements, the school as a whole remained an essentially Western institution in the way it was structured and run, and in the product and process technologies it employed. Gail, chief of the BSSD’s Department of Bilingual and Multicultural Education (DBME) and a native Iñupiat herself, seemed to agree with this perception:

I mean, look at, when you walk into the school, you feel like you are an outsider in your own community in a building that is Western. So, in the first place, there is that discomfort with just aesthetics, with the environment, as you walk into a building. All the people who are in the school, as the teachers, as the administrators, they are from the ‘lower 48,’ they hardly know much about the kids they are working with ... so, in the first place there is that, well because of the differences in who and what the school is all about, and who and what the community is all about ... because we’ve continued to import curriculum, import all of the text books, import anything we use in the classroom, coupled with the fact that 99.9 per cent of our teachers are not of this area, they are from the ‘lower 48,’ we’ve continued to perpetuate, I think, and strongly believe, the assimilation that occurs ... in the schools, we’ve of course initiated a language program and we’ve done little bits and pieces of integrating culture here and there, but it’s not systemic, it’s not systematic. And so, by virtue of that fact, I believe that we make our children, when they enter the classroom, leave who they are outside; we are mainstreaming them.

Meanwhile, when this author spoke to Isabel, one of the very few Native teachers in the District, about how she, as an Iñupiat educator, might use technology differently—from mainstream approaches—within her classroom, she described her approach thus:

Um, it’s mostly teaching techniques, or how I teach, I teach it, instead of sitting at the board writing down, this is what you do, you know, and then talking, what I do is I sit with them and I rarely say anything because in Iñupiat culture when you are showing somebody how to do something, you don’t, it’s not an oral thing, it’s a very visual thing, you see somebody doing something, and they just follow you. Most of the time we’ll just sit there and I’ll be at a computer, and the kids will be all around me and I’ll say, this is what I’m

trying to do, you know, I tell them to explore, that kind of stuff, it's very visual. I do say it orally, I say it and I write it on the board, but most of my teaching techniques is showing them how to use a computer, what icons mean what ... you know, that kind of awareness is, I had no idea that my teaching techniques were different, I think when I was in grad school it kind of made me aware that I was doing it. [laughing]

Some of the Western teachers that this author spoke with divulged—during informal lunchtime chats in the BHS staff dining room—that they realized how the BSSD schools, and all the product and process technologies therein, represented an inherently Western system. The academic year model, with school during fall and spring and time off in the summer, was based upon the Euro-American agrarian cycle, being originally set up that way so as to permit pupils to help their families on the farm during the warmer growing season and attend school during the lean period between fall harvest and spring sowing. Meanwhile, the nine-to-three school day was based upon the prevalent day-night cycles—and consequent diurnal routines—at much lower latitudes than in the Arctic. This incongruity was not lost upon new BHS teacher Lacy:

...(T)his traditional (Western) kind of schedule, you know, every 90 minutes, and getting here at 9:00, and being out at 3:30, it just seems to go very against the more traditional (Inupiat) way of living in terms of real cyclical—the reason they don't see time the way we do is because of the kind of seasons they have, the constant light and the constant dark, it is very different from the diurnal cycle we know, and I was reading somewhere before I came up here, was that bring your earplugs, because the kids will be out at four in the morning during the summer, playing, and kids literally will, they'll take naps, get up, play, eat something, and then go to sleep again, then wake back up, and then when darkness sets in that just

seems like hibernation time to them, it's just so different – and I don't think life is compartmentalized as much here by the mainstream as it will be down South, you know where you've got your work and your exercise time and your friends and your family and it's all split up in different things, seems like here it is just natural for everything to kind of blend together, so, the education would come naturally, and part of it does, subsistence-wise, from family...

BHS assistant principal Carl also spoke about the incompatibility of Western-style diurnal scheduling in the geographic and cultural contexts of the Boreal Slope:

Up here people, their time clock gets very messed up, because you have to look at the fact that starting beginning of May, the sun's out 24 hours a day. And so, throughout the summertime these kids might sleep from nine a.m. to three p.m. and be up all night long. It's just, you know, there's no record of time really, time isn't necessarily important to them, and so they just sleep when they are tired and participate in activities, subsistence activities, or hunting, or time with family and friends, whenever. And so, as we get into the Fall season, when school starts, we have all these kids that are completely backwards as far as their timeline, and then of course we go into the opposite, where, now, here at the end of October, you know, the sun doesn't come in up now until ten or eleven and it's going down at, you know, five o'clock, and that's going to get shorter and shorter, to the point where, you know, the sun won't be coming up at all. And so then you get the opposite people, sometimes that are sleepy during the day and awake at night and vice versa. It's just, you don't realize how much it affects you until you come and you live it. And it's hard to really understand it being in the 'lower 48,' because, you just get used to it ... and here, it's a little bit different.

Meanwhile, when this author examined the list of Approved Course Offerings for 2004-2005 at BHS, there was little to show that this school was following a curriculum that was different, to any meaningful degree, from high school curricula at any mainstream “lower 48” school. Out of the total of 238 approved courses listed, a mere 7.6%, or 18 courses—two courses in Arctic Science, two in Alaska Studies, two in Subsistence Art, two in Skin Sewing, eight in Iñupiaq Language, and two in Arctic Survival Training—were explicitly related to the physical and cultural environment of the region. When this author pointed this out to BSSD administrators and asked them why the curricula at BSSD schools had to be so similar to curricula at schools elsewhere, the common response was that the district was compelled to adhere to standards formulated externally at state and federal levels, standards imposed by the Alaska Department of Education & Early Development and mandates from Washington, DC such as the No Child Left Behind Act (NCLB). As BHS principal Ryan lamented:

... every time indigenous people in Alaska seem to be making some progress, there's a piece of legislation that comes about with a hammer that can knock them down again ... that's the conflict all the time, because, you know, we have a federal mandate, and then you have a community and a cultural expectation, and no one ever seems to be able to agree on how those two should be integrated.

Focusing particular ire on the controversial and influential NCLB legislation, Ryan described it unflatteringly as a “ball and chain” on the BSSD schools, a “one-size-fits-all kind of thing” that ignored the fact that “every area geographically is different, has different needs,” and thus penalized Iñupiat learners “for being an indigenous people, for being isolated, for not being in a position to be exposed to a lot of the same types of educational situations, just everyday living situations

that are often reflected in the standardized tests.” He claimed that NCLB and other such external mandates had drastically reduced local educators’ powers to make the administrative and pedagogical decisions they judged as being appropriate to the cultural and geographic needs of the learners and communities they served. He specifically mentioned the NCLB’s overarching focus on “reading, writing, and math,” as discouraging local efforts to develop geographically and culturally relevant practices, curricula, and technologies.

ON NON-WESTERN LEARNERS’ CULTURAL APPROPRIATION OF EDUCATIONAL TECHNOLOGIES

During a session at the Borealis Public Library, this author observed 11 Iñupiat teenagers—five males and six females—use a bank of public computing stations. Without exception every one appeared supremely at ease with the computer; most seemed to be in a very cheerful mood indeed. What is more, the same cheerful, comfortable manner—one might even characterize it as “happiness”—was also visible among young technology users in the various school settings this author observed. Each one of them seemed able to touch-type rapidly while keeping their eyes fixed on the screen, and their very sparing use of the mouse suggested that they were also familiar with common keyboard shortcuts. The youngsters, without exception, had multiple windows open on their computers and were switching between windows rapidly as they worked. Most of these windows were of instant messaging conversations; in fact, the only programs that any of the youth could be seen using were instant messengers and Web browsers.

Computing at the public library seemed to be a “social” activity for most of the Iñupiat youngsters this author observed, in the sense that they could be often seen chatting verbally with each other—smiling and laughing a lot during the process—while working on the computer, and also

appeared to be frequently interrupted by friends and acquaintances that came and left as they pleased, the latter often staying for not more than a few minutes. Even the computer users themselves often quit their machines and left the building, only to return a short while later and reoccupy the latter—or whatever machine was available at the time. The most interesting part was how some of the Iñupiat youth using the computers seemed to all be part of the same chat room(s) online and seemed to be communicating with each other via the chat software as well as—by virtue of being in the same room together—verbally.

The interesting social behavior described in the previous paragraphs—using the public library’s computer bank in an intensive, informal, familiar manner; using this setting as a social venue to touch base with friends and acquaintances; chatting with peers via the computer even though the latter might be in the same room at the time; and so on—might be attributable to a relative lack of access to computers and the Internet at home. The learners, by virtue of having plentiful access to these technologies at school, had become used to working with them and were thus led to counteract the fact that they often did not have such access at home by making the public computing facilities—such as the computer bank at the public library—into a veritable home-away-from-home, where they could do the things that boys and girls who had access to technology at home would logically do from the comfort of their own homes.

Moving on to school settings, consider the air of mischievous confidence permeating the following exchange, between Annabelle and Iñupiat learners in her keyboarding/word processing skills class at BHS, after the latter had finished their typing exercises:

Annabelle: [Smiling, inquiringly] OK, so what are we going to do now?

Learner #1: [Smiling, cheerful] Type one paragraph!

Learner #2: [Laughing] Type one sentence!

Learner #3: [Laughing, loudly] Type one word!

[Widespread laughter among learners.]

Annabelle: Um, no, actually we are now going to make our *own* tables, with a heading, a sub-heading, four columns, and ten rows! Remember, you can use data from the Almanac for the tables you make.

Learner #1: Why can’t I make a table in Excel and copy it into Word? It is easier!

Annabelle: That should be OK, but, you know, it is worthwhile to learn how to do it in Word.

Learner #1: But I already know how to do it in Word!

Annabelle: OK, then.

Learner #4: I’d like to do one with seven columns and seven rows, is that OK?

Annabelle: Yes, that is OK.

The utterances made by the learners in the previous conversation would suggest not only a significant confidence and comfort level with technology use in the classroom, but also a certain proactive spirit in terms of selecting tasks to accomplish and, in a larger sense, designing the classroom experience to meet their specific needs. The learners could be seen using the appropriate technical terminology—cell, split, merge, column, row, copy, paste, and so forth—when they referred to specific tasks/problems, or when they asked for help. A similar spirit was also visible in BHS technology teacher Trent’s office productivity tools class; note the following dialogue between Trent and one of the young Iñupiat learners taking the class:

Learner: [To Trent] What are we doing today?

Trent: Today we are learning Microsoft Word.

Learner: Oh, I already know that!

Trent: What do you know?

Learner: See, I know how to make tables. I also know how to write business letters.

Trent: OK, then there'll be somewhat of an overlap.

[Learner groans in mock exasperation.]

Trent: [Laughing] But you know what, that means it will be easier for you!

[Learner giggles as if highly amused.]

The previous two exchanges would also suggest a sure grasp, among the learners involved, of key concepts and principles related to the subject matter being taught. This attribute was also discernible in the following tête-à-tête between Trent and another of his learners:

Trent: What does a jagged red underline mean in Word?

Learner: That's a word spelled wrong!

Trent: But does Word know how to recognize names?

Learner: No.

Trent: So what do you do if you're going to use a particular name or other word often that Word does not recognize?

Learner: You can add it to the custom dictionary.

Trent: And what color is the line that indicates grammar errors?

Learner: Green!

Meanwhile, what was most interesting to this author was the fact that every single learner featured in the previous three conversations was an Iñupiaq female. Girls appreciably outnumbered boys in all the computing classes this author observed at BHS, with Liam's Shopbot class being the sole exception: there were 6 girls versus 1 boy in Annabelle's keyboarding/word processing skills class, 14 versus 3 in her yearbook/newspaper class, and 8 versus 2 in Trent's office productivity tools class. The Iñupiat girls invariably worked quickly—markedly faster than their male counterparts—and quietly, with little chatting or discussions among themselves. They seemed

very conscientious—often asking the teacher for feedback on their work—and deeply engrossed in the tasks at hand, much more so than the boys, and more so even than the occasional Caucasian or Filipina girls spotted in the classes. Most of the Iñupiat girls were done with the exercises/assignments given to them in record time, often taking just a few minutes to finish, and producing work of excellent quality nevertheless. It was particularly fascinating to watch them blaze furiously and accurately through the series of typing exercises within the *All The Right Type* software in order to get to the “reward” computer game offered by the program to learners that successfully completed their assigned exercise modules.

The few Iñupiat boys that were present in the computing classes this author observed put up a comparatively unimpressive performance when assessed against their female counterparts. They seemed less interested in what was going on in class, and less willing to do the work that was required of them. For example, one of the boys in Annabelle's yearbook/newspaper class was not working at all; he was instead busy playing a game on his computer. Another spent the entire class session lounging back in his chair, biting his thumbnail, and staring at his computer screen without doing anything. In Annabelle's keyboarding/word processing skills class, this author noticed the one boy present in the room working much more slowly in comparison with the girls, lounging around for a significant portion of the class period, and generally appearing rather bored and distracted. Meanwhile, the two boys who were signed up for Trent's office productivity tools class did not even show up to class the day the observations were conducted.

This author subsequently asked Isabel—since she was Iñupiat, had been in high school herself not so long ago, was young enough to still be “with it” in terms of current Iñupiat youth culture and behaviors, and was also currently teaching Iñupiat learners at BMS—what she thought about my observations. She nodded in confirmation,

explaining what was seen as being part of a more wide-ranging socio-cultural and gender dynamic among the Iñupiat:

...(T)his is really odd, I've found that women will get an education, it is more socially acceptable for a woman to get an education, than a male, for some reason, I've been thinking about this a lot, [laughing] I think a lot of it is based on, in the past, the men it is a more physical thing ... (among the Iñupiat men) technology like the snow machine is a big deal here, it's a huge deal, it's a social status, I hear kids today, was one kid's parents got a new snow machine, he was teasing another kid's parents because it was an old snow machine, you know, that kind of thing, it's become a social status ... the snow machine is like a huge deal here. Not so much computers, oddly enough, it's really odd, computers are not seen as a social status (among the men), but snow machines are, rifles, you know, things that can kind of border, sit between, straddle those two worlds, hunting, the gathering, and the technological world.

Trent told this author he noticed that the boys in his classes seemed to have very short attention spans for traditional classroom activities. However, in the same breath he noted that the boys seemed to prefer “hands-on activities,” and remarked “however, when they are out hunting or doing subsistence (activities) they show much more inclination to sit still and be patient and persevere!” He also related an interesting story dating from the 1990s. He was supervising his Iñupiat learners as they interacted with the educational game *Oregon Trail*, which involved players making strategic decisions while navigating their way across the North American continent in the footsteps of early Western colonists. Trent described how, when male learners got to the part where they had an opportunity to hunt wildfowl, they would proceed to spend all their time and material resources hunting ducks and geese. They would progressively sell all of their belongings in

order to buy more guns and ammunition so they could do more hunting. They just did not appear to want to move on to the final destination, which was the point of the game, they did not seem to care if their decisions eventually caused them to “die,” they rather would die hunting. Trent said it looked to him like this was not just a reflection of the usual desire among aggressive young boys to shoot things up like in an arcade game, but rather, as he explained, “they are hunters, that was what they wanted to do.” Trent even mentioned how one of the game’s developers came up to the school to visit, and when he saw what the boys were doing he was upset and protested that this was not what the game was supposed to be about at all!

Meanwhile, some technology educators this author met with also spoke about the apparent *superficiality* of the Iñupiat youth’s mastery over computer-based technologies. In their view, while a majority of the latter exhibited a strong penchant for, and remarkable mastery over, the *consumer* level of interaction with technology—electronic communication, online shopping, game playing, and so forth—very few, if any, seemed to exhibit significant technological skills at the *producer* level, such as programming, design, or hardware competencies; in fact, very few expressed even an *interest* in acquiring such proficiencies. As BHS technology teacher Abel revealed:

I look at what's happened with my classes in, you know, I'm providing that opportunity for that upper division, computer repair and networking, but the amount of kids that are in that are not as high as you would expect ... I would love to see programming as one of the things we do but you know, I've just got to develop that base interest first before we can go into it...

In the same breath, however, Abel also explained what he saw as the reason for this reluctance to acquire higher-level technology skills:

I will be honest with you, the biggest applications these students use on the outside would probably be the Office material, being able to work with Word, Excel, PowerPoint, Access, those types of basic job skills get their foot into the door when they get outside. These skills are relevant especially in the Boreal Slope, you look at the (county government), the highest number of jobs are available through (them), and you look at what kind of skills they need ... and they look for those types of things, you know.

This author also asked Jason—the BSSD technology coordinator—and Ryan to share their views in this regard, given the unique insights arising out of their vast experiences and responsibilities related to the district and its learners. Jason’s explanation for the phenomenon was “there are very few role models in the community who are proficient users of technology. Kids don’t see it being used at home, people at home don’t understand it, and therefore don’t appreciate it. Kids struggle therefore to find a place for it in their lives.” Ryan, meanwhile, provided a rich and detailed exposition of what he believed were the environmental factors inhibiting the development of young Iñupiat learners into accomplished technology producers:

I think, that’s what isolation, being in an isolated environment, inhibits ... (if the learners) are in a real technology environment, if you are in Seattle or Portland, there are these facilities right next door, and in their school, and there is partnership with schools, many of them have parents who are engineers and computer programmers and designers and systems engineers, it’s a language right in the home. So, I think that’s the reason, the isolation just doesn’t promote that. Who do we have locally here, occasionally we have a teacher, such a small population, and how deep do you go with it anyway? And then, what’s your model? What’s our model, to show why you want to go really deep? We have your system network,

we have your, some technology that is limitedly supporting our infrastructure. You know, you don’t have a Microsoft or an Intel. (Learners in the big cities of the ‘lower 48’) just have models to look and see. Everybody knows, you know, Portland, Oregon, has an Intel plant, Apple in San Jose, HP plants all over, you know, kids are very in tune with the technology, who the technology leaders are and where they are at. And so, who the technology players are and if you are important you do. In San Jose you do, in Boston. So I think, it’s just that everywhere you look it’s just technology ... And many of the kids here, some of them may want to go outside for a college degree, but many want to return here, specially the Iñupiat population. The majority, even if they go elsewhere to get an education, they see themselves returning and living here in Borealis. And so, you know, to say, I want to be a programmer, or system engineer or, there is a limited need for that here in Borealis, but it’s not a huge demand. Are any of their fathers or mothers any of those things? No. You know, I think, you know, we are typically inspired by much of our, you know, surroundings. You know, they love to dance, they love the whaling, it is huge, get out of school for a couple of weeks in Spring ... Kids are interested in that. I don’t know how at this level how we are going to get them interested and inspire them into being programmers or, you know, systems engineers. There are some Iñupiat kids who see themselves thus, but they don’t see themselves returning to Borealis.

Furthermore, there was also talk of inappropriate use of technology by the Iñupiat youngsters. Jason, for instance, described how he was forced to block the chat protocol on school computers because “the detriments outweighed the benefits;” as he explained, the chat feature “was being misused and abused. Kids were going to porn chat sites and chatting very inappropriately, sharing personal information. The kids were going to meet gentlemen in other states.” BSSD chief

librarian Tammie seconded Jason in this regard; as she described:

...(F)or instance we have the Internet here in the library and, of course, as an educator I would like to think that (the learners are) out there pursuing great thoughts and increasing their educational opportunities on the Internet, but generally speaking when I wander over to see what they're looking at, it's snowmobile sites, Tupac Shakur sites, Britney Spears sites. So if they are not on task for specific assignments, there's a lot of non-educational uses I guess, and so I wish they'd be more excited about learning, just inquiring about things, but I don't see an awful lot of that.

Tammie also mentioned copyright violations—unwitting or otherwise—resulting from learners' use of new media technologies as a potentially serious issue:

We also don't allow Napster-type downloading activities, primarily because of the amount of space on the pipeline that it takes, but also some of those things are just illegal and we cannot encourage that kind of activity. I don't see much awareness or interest among the kids in terms of the ethical-legal issues surrounding technology, copyright issues, plagiarism, I know teachers talk about it, I don't think they have a good grasp of these issues, it's becoming more and more of an issue though, for students that they need to realize that...

EXPLORING THE CULTURAL IMPACT OF WESTERN TECHNOLOGIES ON NON-WESTERN COMMUNITIES

One of the predominant themes that this author has hoped to explicate via this paper is the sense of Borealis as a community wedged between the realms of timeless Iñupiat tradition and of oil-

fuelled modernity; caught—literally—between whale hunting and online shopping, between skin-sewing and instant messaging. Now, while Borealis represents a particularly extreme and instructive case of this phenomenon, it is by no means unique in having to straddle two worlds at once in this day and age. Similar struggles to maintain a balance between indigenous traditions and Westernization—the latter usually occurring under the guise of “globalization,” “modernization,” or “progress”—are now taking place throughout most of the non-Western world, from indigenous communities across the Americas and Oceania, to the oil sheikhdoms in the Arabian Gulf, to the vast emerging economies of India and China, to the established “Asian Tiger” societies in the Far East. Technological catalysts like the information revolution and media convergence are currently playing a particularly powerful role in exacerbating cultural ferment and disjunction of this sort across vast swathes of the planet.

From stakeholder accounts obtained by this author, life seemed particularly challenging for Iñupiat youth, who were being exposed relentlessly to the latest technological and curricular offerings at school, and were yet expected by their community to retain an interest in their traditions. The multiple, competing priorities and constraints that acted upon those caught in such a situation were well expressed by some of the young Iñupiat learners at BHS whom this author spoke with. As Caleb explained, it was not easy when “our elders would like us to learn our traditional knowledge but in school we need to learn other stuff.” Kent added that “some parts are hard to manage, like learning how to do stuff on the computer and also how to put skin on the boat (frame) at the same time, and how to be good at both!” Delia in the meantime talked about how it was hard to balance mutually exclusive activities and expectations into one's schedule: “It's hard to go hunting and camping when you've got school and work to do.” Fabian summed it up eloquently when he described how managing expectations was “real

hard because ... you have to learn one way at school and another way in life.”

Meanwhile, Isabel, speaking from the perspective of a young Iñupiaq adult who had recently grown up facing the same pressures and had survived the additional cultural challenge of getting a higher education in the “lower 48” and then moving back up to Borealis to live and work, declared that while the BSSD schools were embracing technology-mediated learning, she nevertheless thought it went completely against Iñupiaq culture:

Technology in schools is becoming a bigger deal, we have the IAN (Instructional Applications Network) lab, they learn reading, and linguistics, through a computer, the teacher reads out loud to them and they go on a computer. It's becoming more and more accepted to learn from a computer ... but it is totally against our tradition, traditionally you learn from a person, not from a machine. It's barely Iñupiaq. I learned how to cut up a duck, and my uncle sat there, he rarely would say anything, he'd just say “Don't eat this!” [laughing] “you can eat this if you really want to,” “scrape this,” you know, that kind of thing. But that was how I learned it, just watching him do it four or five times and then trying it myself. That's how I learned to cook, I was horrible at it, burned a lot of things, but they let me try it over and over again until I learned it from making mistakes or whatever. But now it's if you press the right button, till you hit the right one, like a rat hitting a, trying to get a treat!

Many of the older Iñupiat this author met in Borealis seemed convinced that the pervasive, seductive, Western technology-based activities were affecting their younger generation's learning processes, and especially taking the latter's time and attention away from learning their traditional activities and native language. Parent and community member Erika declared that, in

her personal opinion, technology was “damaging” to the Iñupiaq youngsters:

I have two (younger) children that I am losing in the oral (Iñupiaq) language, because ... there's too much TV, there's the X-Box, the Nintendo, the PlayStations, and all those games. The games I don't approve of, I don't allow my children to buy and take it home, because I feel it's damaging to them, in terms of their lifestyle, because we Iñupiat, I myself was raised in a very strict world. If you are taught something, you are expected to learn it. And that's how I expected my children to be raised. And this is the reason why I mentioned about my two younger children, that today's technology is damaging. I have to repeatedly say Iñupiaq words to those two, in order for them to understand it. In comparison, my older children, they speak English about 75 per cent of the time, but they understand when I speak to them in Iñupiaq. Whereas the two younger ones, I have to repeatedly tell them before they can finally understand what I am trying to say ... Technology is bad because it will stop the process of the child's learning system, if you are not using it correctly. With a child in the home, it stops the learning process of subsistence lifestyle and oral language. I don't know how else to put it. That's my point of view, that's the way I see it in my home. Some families have a problem because their children are so into all this technology stuff that they don't want to leave their home, because they want to watch TV, they want to play the games. Their parents, their uncles or aunts or whoever wants to take them subsistence hunting, they say no, the game is more important than your subsistence lifestyle. It's getting to that point and there are quite a few families I think, that are like that now.

DBME secretary Hailey, meanwhile, felt that computer-based technologies—specifically games—might be making Iñupiat youth using them more prone to violence:

A lot of crimes are committed by the youth. They have computers, they have video games, and nowadays the video games are getting more and more violent. There is more blood, there is more gore, and some kids demonstrate it, and I have a grandson that I can testify to that, I mean, he gets really, he gets his whole body involved, he is four years old. And, you know, if he is not playing the video game he gets frustrated and that little spark just sets him off and he just starts punching into his sister, you know, and I can see how it affects him. Seeing that, on there, it's very easy. And, you know, he doesn't know what he's doing, I mean, he knows he's throwing the punches and what not, but he doesn't realize that he's grabbing it from that video game and it's implanted in his head that quickly.

Another Iñupiaq parent and community member who believed that modern educational technologies were taking young Iñupiat learners' attention away from their culture was Billie, a staff member in the Heritage Center's education program:

Technology is taking a little bit away from our traditional way of life and I wish they wouldn't emphasize it so much that you need to go to work, that you need to know all this technology. At the schools, that is what it's all about now, technology. I think the schools should emphasize less on technology and more on traditional cultural values, because pretty soon we are going to lose our culture. The more technology there is for the kids to learn, the less of the traditional way of life they will know. You will not have more hunters to hunt for a living.

When I spoke with native community leader and school board member Eva, she also alleged that modern communications technologies were adversely affecting the Iñupiat youth's native language skills, because, as she noted, "you are not communicating with a human being, you are

just communicating with something that doesn't talk back to you." Besides, she pointed out, "the medium of most of these programs is in English . . . so the more dependent you become on technology the more it makes you speak English"—at the expense of speaking Iñupiaq. Another Iñupiaq parent who said she believed technology was distracting her children from traditional native pursuits was IEP secretary Tina, who related how she had been trying to get her daughter involved in beadwork and sewing but the latter was not interested: "She wants to play in the computer, she wants to go and play with these little games that are battery operated, you know, computer games, the Game Boy, yeah." Meanwhile, local community leader Curtis also alleged that the younger Iñupiat's native traditions and language were being affected by computer-based technologies, and blamed the schools for getting them hooked on to the latter:

In many houses across the (region) the kids are going to school, they are getting exposed to computers and technology, they are forced to learn it, they are learning it, they are even getting to like learning it, they are surfing the Internet all day long and playing games, and when they go back home they don't have that there, their elders and parents don't have that exposure to that kind of technology, it is creating a distance between the kids and their elders. Grandma and grandpa's time to talk to you has been taken over by Game Boys and computers. The parents and grandparents are being removed from the child's world. Isolate them, that way you can regulate them easier. The language is slowly disappearing, the values we have on animals and how to treat them are disappearing, and they are being replaced by technology.

When this author asked BHS senior Georgina about all this, she nodded, agreeing that not very many Iñupiat youth of around her age in Borealis liked participating in traditional activities. When asked what she thought might be the reasons for

this, she replied “Because they have their snow machines, they have computers, they have other stuff to do, they want to focus on their school...” When asked further her if she thought technology was distracting the Iñupiat youth in today’s Borealis from their traditions, she agreed, saying “because it is just so much easier to get to know, we have a computer in almost every room or every house now.” She said technology appeared more attractive than traditional activities to modern-day Iñupiat youth “because it’s all around, everywhere, and it’s something new and their parents don’t know it and they want to do something their parents don’t know.” Fabian also agreed that technology was distancing Iñupiat youth from their cultural traditions: “Stuff like technology and computers, it takes a lot of time away from learning traditional activities ... The more people spend time with computers, the less time they spend on subsistence. Some of my friends don’t hunt but ... live an ordinary life.”

Meanwhile, Isabel felt the schools were doing a better job selling technology to the Iñupiat youth than the Iñupiat elders were doing selling their traditions; but then, as she saw it, it was so much easier to sell technology as compared to tradition, because knowledge of technology brought with it the promise of material gain:

The children seem much more sold on technology than on tradition. I think it is way easier to sell technology, when the world is based on technology. It’s really, really easy to say, well, if you know how to use Microsoft Word, you can get a job, you can get money. It’s easier to say that. Trying to explain to a kid why he should learn how to butcher a caribou, I think it’s a lot harder. It takes hours and it smells bad and it’s gross, [laughing] they don’t see it on TV, you know, they don’t see any kind of real need for it. Because you don’t see stuff like that on TV, you don’t have anybody saying that it’s important, and the people that are saying that it’s important just say you have to learn it without explaining why it’s important.

And it’s really tough to do that ... Even if you sat down and learned everything from an elder, it won’t help you get a job, it won’t help you get your new snow machine and new rifles, you know, the elders’ wisdom doesn’t get you money! It might bring you something else, but it’s still, why learn it, when you’re not going to get money, when you’re not going to be paid, when you’re not going to get the stuff that you want. It’s become obsolete, which is horrible, I mean.

Testimonies as provided by Curtis and Isabel suggest that the communicative distance—the so-called generation gap—between Iñupiat youth and their elders has been increasing in modern times, and that technological changes may have been in no small part responsible for hastening this process. Nita, the project manager for the local native Heritage Center, echoed exactly such perceptions, indicating technology and Western education as key causative factors:

I would think it’s kind of getting harder for the kids to relate to their elders, because they are learning a different way, like we still have our elders here, and you respect your elders and family members, especially your grandparents, and that still exists, it’s just the train of thought for the kids I would think when they’re going to school, they’re using just technology, technology, technology, and they have some classes that relate to the culture, the Iñupiaq classes in the school, but having that also, it’s not full-blown Iñupiaq all day long, it’s just for a half hour to an hour a day, and that’s kind of being lost in a way too, where the culture is slowly dying out, because of the way the education is taught it is more of an English, American history, and I don’t see big efforts being pushed for a lot of cultural things to be viewed for classroom papers...

Some of the younger Iñupiat I spoke with seemed to agree that the elders were no longer as important a source of knowledge as they were

in the days when traditional ways of knowing prevailed across the region. “Our elders don’t really know about the Internet or computers,” Caleb declared. Kent concurred, laughing: “Our grandparents don’t know about or use computers.” “They didn’t have computers back then,” Carla explained. “They can tell you all about their traditional things, but not about computers and stuff.” Caleb agreed: “They grew up hunting, no school, and all that kind of stuff.” Besides, this author also gathered from conversations with some of the Iñupiat informants that, from where they stood, it looked very much like the Western technologies were actively trying to replace Iñupiat traditions with alternative ways of living. As Isabel put it, “now we have the world telling us that information and, not only just information but *superior* information comes from technology, from sciences, from computers, you know, this kind of stuff [pointing around her classroom].” Curtis, in the meantime, elaborated on this issue with passion:

The role that technology plays in this culture is very negative, because it’s goal, it’s direction, is that it has to eliminate this culture in order to be the superior culture ... You know, in order for (the Westerners) to be an expert they have to remove someone like me. And once they remove me then they become the expert, with their limited knowledge. Now when you look at Western culture and its technology, that is exactly what it does. What it does is to remove traditional forms to knowledge in order to make room for itself ... Right now the whole school system is, technically speaking, physically removing our language ... And once you take a language away, its total educational structure has just been wiped out. Its knowledge has just been erased ... That’s how you destroy cultures.

Furthermore, Isabel also saw the modern, Western computer-based educational and com-

munications technologies as promoting a capitalist ethos among the Iñupiat:

(The Iñupiat youth) have a society kind of telling you that old things are bad, and mostly they get this through TV, old things are bad, old things are only for documentaries on the History Channel, [laughing] they’re not very exciting, new things are good, new snow machines, new computers, you know, new things are good, lots of them, and so you have capitalism, a very capitalist kind of ethos, and it’s seeping into the culture here. I think technology is a vehicle for capitalism, it’s not sitting there cramming it down our throats, but it is, some of the capitalism is from people coming in from other places, but most of it is through technology, it’s a vehicle, it’s not like technology is bad and it’s like a drug dealer [laughing] sitting there, but it is a vehicle, in several ways, I mean, TV is the obvious, really obvious place, the Internet, you get a lot of stuff on the Internet, I know that some kids who have access to it, they tell their friends that this is cool, [laughing] because everybody in California thinks it’s cool, but it is a way. I mean if you can imagine not having any technology or communication up here, it might just become like a time capsule, but stuff’s being poured in, it’s being poured in at a faster, faster rate...

Meanwhile, talking about how basic cultural values dear to the Iñupiat were being eroded in recent times, Tammie revealed how she sometimes felt modern computer-based technologies, with their emphasis on individual, competitive modes of learning and social action, were at odds with the Iñupiat’s traditional collective, collaborative ethos, and she wondered how that might be affecting the native learners as they worked with these technologies:

The traditional culture is all about sharing and cooperation and collaboration, while the mainstream culture is competition and privacy and patenting, ownership of ideas, I can imagine for

someone who comes from a tradition where everything is collaborative, to get used to the idea that everything is individual, that even information is privately owned. I don't know if they have really internalized that, it's interesting how that might be a real war of cultures there, because they are getting those two different messages definitely, within the community it is still very much that way, it is a community built on traditional principles of sharing an collaboration, I suppose when you're riding two cultures that's one of the things you've got to learn to do, it's you have to sort of figure out when those more traditional values are appropriate and when these other ones should take precedence ... and it's hard for (the Iñupiat youth) to sort of get it to where it meshes in their minds, get their brains around it...

Curtis agreed heartily, claiming that destroying the Iñupiat's culture of cooperation and collective action was part of the Western socio-economic and cultural system's larger plan to isolate, regulate, and culturally assimilate the Iñupiat:

In summertime ... you'll find us way out there on the ice, just enjoying life out there, and when we find each other we don't ask each other what they have in their boats, we go in their and find what we like and eat it. If it's in their boat, it's mine, if it's in my boat, it's theirs; our culture stresses cooperation and collaboration, for example the whale hunt, one man cannot do it, it takes an entire village to bring in one whale, and then the whale is distributed to everybody, shared. With computers, it's all one person to a computer. There's no collaboration anymore. Same thing with Christianity. Only you can save yourself, only you can take yourself to Heaven. There are great similarities between Western technology and Christianity, they both have the same goal; the goal of isolation. Isolate them, that way you can regulate them easier. Western culture has two engines, agents, its technology and its religion, and with the two of these they have managed to bring

about a significant change of mindset here among the Iñupiat. For a lot of the whaling captains we have today, it's the glory in the catch that they're after, which is just so wrong in terms of our culture. It's not "my desire to feed everybody," it's "the credit I'm going to get for catching it." That is a culture-killer. That is what came with the Western ethos, with Western technology; that change of mindset from cooperation to competition.

Taking the discussion regarding traditional cooperative values versus technology-inspired competition further, some of the Iñupiat informants spoke of a new "digital divide" arising among the Iñupiat of Borealis, one that manifested itself in multiple ways. For instance, Nita talked about a technological divide between wealthier and less wealthy individuals, relating how some of the craftspeople she worked with at the Heritage Center felt disadvantaged compared to others because they did not have access to computers and the Internet like the others did; for these people, lack of access was a barrier between themselves and commercial success. She also talked about another dimension of the digital divide, of inter-generational relationship issues provoked by unequal access to and proficiency with modern technologies, describing how "the younger generation for sure has a lot of knowledge of technology, a lot of access to the computers because of the schools, whereas the elders don't have access to that."

DISCUSSION/FUTURE TRENDS

The epic cultural conflict taking place in the Alaskan Arctic—between the hegemonic Western techno-centric, globalizing, commodifying, capitalist-consumerist socio-economic juggernaut with its gigantic ecological footprint (see Bowers, 2000; Bowers, Vasquez, & Roaf, 2000) on the one hand and the diametrically opposite native Iñupiat life-ways on the other—has clearly taken

its toll on Iñupiat communities across the region. As in many other parts of the world, here too, as Bowers et al. (2000) describe, Western science, technology, and ideas of “progress” have been used as the basis of a new ideology that justifies the extinction of the local culture if it fails to adapt to the expanding network of computer-mediated intelligence required by the global economy, as a result of which much local knowledge has been unceremoniously relegated to the junk heap of a past that is seen as being no longer economically useful. Curtis and Isabel—two of the Native informants for this study—hit upon this point when they described how, as they saw it, Western technologies were actively trying to replace Iñupiat traditions with alternative ways of living.

Meanwhile, as Bowers et al. (2000) explain, these ostensibly more “advanced” Western technologies have an ecological footprint that undermines the viability of the earth’s ecosystems; on the other hand, the traditional Iñupiat culture—which, like many other non-Western indigenous cultures, had taken an alternate pathway of development and had demonstrated the capacity to live in a long-term sustainable relationship with its harsh and challenging environment—was actually the one better adapted to its surroundings from an evolutionary standpoint. The new, computer-mediated modes of learning and living—as representative of a Western consumer culture that emphasizes building boundaries between people and nature—has unfortunately accelerated the process of the Iñupiat communities’ alienation from their natural milieu; and over the decades, the resultant losses of local knowledge and patterns of moral reciprocity essential to traditional Iñupiat community life has significantly affected the region’s cultural and ecological well-being (see Bowers et al., 2000).

Consequently, Borealis today is not a very happy place. It is no secret that the small native communities across the Alaskan Arctic currently suffer from some of the nation’s highest rates of alcoholism, drug abuse, domestic violence, and suicide—symptoms of the people’s heightening

sense of isolation, displacement, disorientation, and alienation brought about by the progressive breakdown of their traditional ways of living in the face of a relentless onslaught of foreign socio-economic and cultural influences. Curtis suggested that technological pastimes—along with alcohol and religion—were non-indigenous fixes that the Iñupiat, despairing over the erosion of their traditional culture life-ways, were turning to in their hour of loss:

... (W)e have a very unhappy society. You see a lot of cheerful people up in the front, but when you look in the side you see people never sobering up, and you go to the church and you see them extremists in their churches, you see children hooked on to television and video-games and the Internet. When you go extreme something else, that is not indigenous to you, you are unhappy. You might sing loud, and pray hard, and be a very good Christian, they’re hiding something, they’re trying to substitute something. They are substituting a lost way of life, a teaching mechanism, a self-regulating mechanism, you know, as a society, a culture, we were self-contained, we didn’t need anybody in the world, to feed ourselves and take care of ourselves. That’s what American technology does to our culture. The technology is responsible for this because the people here see a smarter culture than theirs that has taken their land away, their way of life, and regulate what they eat.

So what could the outlook be like for the current and future generations of Iñupiat caught between technology and tradition? To understand this, it might help to ask some of the local Iñupiat community leaders in Borealis to describe what *they* would define as “success,” in terms of the Iñupiat youth’s relationships with Western education and technology. When asked, Curtis mentioned his own children as examples of “successful” young Iñupiat in today’s world:

In my house we have a computer in every room, and all of my kids use them regularly. I have no trouble with that at all; if the world can use it, if they have better access to the world, great. They might be able to learn something out there yet. But when I take them out into the country, they know what to do. They know where the animals are, that they already know. That I have taught them. Any one of my kids can catch ptarmigan without shooting them, without traps. They know how to stop a caribou from running away. Computers and technology just gives them better access to the world. I don't feel access to the world as a threat. Because the values I want them to have are already in them and no one can take that away. On the one hand I have taught them how to live in the Arctic, their home. On the other hand, the world is theirs, too. They can go anyplace and survive, but at the same time they have solid roots here. I think I would call that a successful state of affairs. And that is what I would wish for the other Iñupiat kids as well.

Meanwhile, Erika emphasized true success as being able to go out to the world, get educated in their ways, and return to the Boreal Slope to contribute to the welfare of the local community, a view approximating a “think globally, act locally” type of ethos:

There are a few students who leave the Slope after graduating from high school to get a higher education so they can come back home to their community, and those are the ones that will be pursuing what they see is lacking in the community. If we can get the expectations of the students to fit into the shoes of those students who are going out to receive higher education, that would be a success for us.

One person who did seem to fit this ideal was Isabel, who had made the choice to leave the Slope, obtain a college education, and return home to serve her people as a teacher. But then,

as she explained, not many Iñupiat youth were eager to construct themselves in the identity of a Western-educated schoolteacher, because the latter usually came across to them as the “weird creature” that “came from Michigan, ... popped in and popped out and most of the time didn't stay for more than six months.” Besides, Erika alleged that the Iñupiat youth were discouraged from seeing themselves in the teaching profession due to the Western teachers “looking down upon the Iñupiat.” Isabel explained that the act of “becoming part of the system,” of “going over to the other side” was still “really hard to understand” for the average Iñupiat youngster. As she put it, “it's so far, from ... growing up traditionally, from (their) traditional past, in many ways. There's a huge gap, and who in the world's going to jump that gap? Why in the world should you jump that gap?” going on to add that “only now it's kind of becoming obvious that without that education, you know, you're on welfare!”

Nita, who was one of the Iñupiat who had obtained a higher education and taken up a job that involved using computer-based technologies, ardently emphasized the role of Western education and technology in ensuring the Iñupiat youth's future success:

I've seen how people come from out of town, get all the jobs, and I checked to see why people from out of town are getting jobs and we the Iñupiat people are not, there was just this education part, that you need to have college, you need to have your education to get a good job ... it was like a stumbling block, that education that you needed ... what I always stress to my kids is get your education. That's what you need ... education, even though the education that is available is not related to our culture, we still need it to survive, to pay for your food, to pay for your bills, for your electricity, for your homes, you need a job, and all the jobs that are open need that first step. You need to have at least a high school education, and if you don't have it your name will be at the

bottom of the list and never come up, and you also need to know how to use computers because they all have computers in the workplace, it is hard for employers to train someone new unless they understand you fully, what you want them to do on the computer, and there's always security and data loss issues that you could have if the person doesn't know what they are doing.

Curtis concurred: “(T)hey won’t hire you until you have a minimum of high school education, and then in any place that pays you need a college education. If you don’t have a college education you’re dead, as far as the dollar world is concerned.” The predominant notion of success that was expressed by the Iñupiat community leaders interviewed as part of this study thus featured the twin desires to simultaneously maintain tradition while continuing to enjoy the benefits of modernity. Curtis’s account of how his children were successfully managing to do just this was particularly intriguing, leading this author to wonder if such a state of affairs was common among the local families. But Curtis did not think it was:

The problem is, my kids are lucky and very much an exception. Many other Iñupiat kids do not come from a similar position of strength. Across all the communities in the Boreal Slope, you will find that over sixty per cent of the people cannot find work, there is no work. So they cannot afford things like this ... I am a geologist, my wife is a college graduate, my oldest girl is a college graduate, the second-oldest one on his last year, the next one is starting his second year. We are definitely not the typical Boreal Slope family. When a family has problems with society, or with the law, or being able to take care of themselves, they call this house, they call me, and I tell them what they have to do.

Isabel—who also would be considered as a “success” by the standards of many people, both Iñupiat and Western—concurred with Curtis

in that she admitted her familial circumstances were rather unusual for an Iñupiaq growing up in Arctic Alaska:

In my case, in my family, the teachers’ expectations and the parents’ expectations were the same ... which is really rare, my parents are both, they both have degrees, and Master’s and, they both had really good educations, so our expectations were completely different ... Probably around five per cent (have parents like mine), that’s just a guess, very rarely, and it’s usually somebody who has experience out of here. So it’s not a local, well they’re local but they’ve had experiences in the ‘lower 48’ (United States).

CONCLUSION

The cultural hegemony of the Western school system over the Iñupiaq community could be characterized as forming part of a wider-scale, historic cultural transformation of the Alaskan Arctic by impersonal socioeconomic forces that were larger than—and, for a variety of reasons, only tenuously comprehended by—individual educators and community members themselves. While, on the one hand, it might be possible to characterize the Iñupiat youth and community served by these schools as being helpless victims being buffeted by the inexorable forces of Westernization and globalization as embodied by the Western product and process technologies rapidly and insidiously infiltrating their sociocultural life, on the other hand they could also be recognized as active agents striving against overwhelming odds to create valid cultural forms in response to a barrage of complex social, economic, cultural, and technological stimuli. To this author, this act of “praxis”—referring to Willis’ (1977) expanded construct of praxis, which differs from the classic Marxian view of praxis by encompassing not just the act of work but the whole act of constructing one’s cultural identity in society—appeared to

reflect and be shaped by two sets of contradictory desires on the part of the Iñupiat: (1) to hold onto what was left of their precious traditional culture, and (2) simultaneously to reap the benefits accruing from the adoption of modern Western technological solutions.

In the midst of all this could be perceived a fundamental disjunction between the cultural expectations of the school and the cultural expectations of the local community in terms of the essential issues and goals related to the endeavor of educating the current and future generations of Iñupiat youth, further complicated by a lack of consensus among the Iñupiat themselves on these matters. As Lipka, Mohatt, and the Ciulistet Group (1998) explain in a nutshell, these conflicts have been “exacerbated by the historic context of colonization” of the Alaskan Natives, “the degree of cultural difference between mainstream and (Native) culture, and by issues of cultural continuity” (p. 4). The situation does not seem to be helped by the local community’s astonishing lack of ownership over the schooling of their children—by the fact that the native learners, wracked by pressing “internal” issues related to their besieged culture, were being served almost exclusively by imported Western-trained educators, who could but only offer “external” solutions, the effectiveness of which can often be a foregone conclusion.

The Iñupiat of Arctic Alaska, after enduring decades of shocking assimilationist treatment at the hands of Western missionaries and Bureau of Indian Affairs (BIA) boarding schools, fought hard for and finally won significant political and financial control over the schooling of their children by the late 20th century. Learning how to effectively exercise this control after decades of oppression and alienation is bound to be a slow and painstaking process. It is a process that, as Bowers et al. (2000) advocate, will need to involve efforts to ensure that subsequent generations of Iñupiat are educated to (1) understand the fundamental differences between the dominant Western

culture’s ways of knowing and value system reinforced by computer-based technologies and those characterizing their own indigenous cultural traditions; (2) distinguish between the appropriate and inappropriate uses of the technologies that fill their schools, workplaces, and homes; (3) realize how important aspects of community are transformed or lost when using these technologies as the basis of thought, communication, and problem solving; and (4) use these technologies in ways that recognize the culture gains and losses arising from their integral role within the destructive, culture-transforming cycle of media-controlled communication, consumerism, and identity formation.

KEY TERMS AND DEFINITIONS

Culture: Culture refers to “the sum total of ways of living, including values, beliefs, aesthetic standards, linguistic expression, patterns of thinking, behavioral norms, and styles of communication” (Powell, 1997c, p. 15) developed by a particular group of people.

Diversity: Diversity, as used in this paper, refers specifically to differences based on culture—as defined previously—nationality, race, ethnicity, language, and religion. Additional aspects of diversity that are often considered by educators include age, gender, sexual orientation/preference, ability, geographical location, and socio-economic status.

Educational/Instructional Technology: Educational/instructional technology, as used in this paper, refers to the growing field of research and practice involving the application of interdisciplinary inquiry and emergent technologies towards the solution of instructional and performance problems.

Educational Technology (pl. Educational Technologies): Educational technology, as used in this paper, refers to the growing range of human-engineered tools—both products and processes—employed within educational contexts towards the ultimate goals of promoting and enhancing student learning.

Iñupiaq (pl. Iñupiat): Iñupiaq refers to the Arctic people who make their home in the north and northwest parts of the state of Alaska; the term *Iñupiaqt/Eskimo* is also sometimes used.

Additionally, Iñupiaq is the name given to the native language of the Iñupiat.

Non-Western: Non-Western, as used in this paper, refers to (1) peoples of non-European origin—tracing their roots instead to Asia, Africa, or indigenous populations of the Americas and Oceania; and (2) their diverse heritages of spiritual, intellectual, social, and material culture.

Western: Western, as used in this paper, refers to (1) peoples of European origin and their descendants settled across other continents, notably the Americas and Oceania; and (2) their common heritage of spiritual, intellectual, social, and material culture.

Chapter 5.2

Cross–Cultural Learning Objects (XCLOs)

Andrea L. Edmundson
eWorld Learning, Inc., USA

INTRODUCTION

“Networked virtual organizations outperform competitors by responding more quickly to customers, collaborating better with partners to perform value added activities, and fully standardizing their business processes, data, and IT infrastructure” (Cisco Systems Inc., 2003). Thus, networked and virtual organizations (NVOs) depend heavily on the agility afforded by effective communications, ease of sharing information, and virtual integration of business functions. Such agility however, requires a trained workforce. In keeping with its reliance on technology, NVOs, especially those in the U.S. (Bersin, 2005; Rivera & Paradise, 2006; Sugrue & Rivera, 2005), frequently utilize e-learning as their source of training and education. In e-learning, there is a proliferation

of social and collaborative tools, mobile learning, and dynamic computing (EDUCAUSE Learning Initiative, 2006). These tools, coupled with the global reach of NVOs, will precipitate unprecedented contact between educators and learners from other cultures. Because e-learning is a cultural artifact—embedded with the nuances of the culture that designs it—e-learning will need to be translated, localized, and adapted in profound ways to suit the needs and preferences of learners in other cultures. *Localization* addresses obvious visual and textual differences found in other cultures, such as icons, symbols, gestures, and so forth. However, the deeper ramifications of culture, such as what people value, how they learn, solve problems, and so forth, will require approaches that are more sophisticated. *Reusable learning objects (RLOs)* are “plug and play” chunks of learning materials (content, teaching approaches, and so forth) that allow instructional designers

DOI: 10.4018/978-1-60960-503-2.ch502

to construct and modify e-learning in an easy, efficient, and effective manner that parallels the agility demanded by NVOs in business functions. RLOs are fast becoming the foundation of rapid e-learning development (EDUCAUSE Learning Initiative, 2006). However, *cross-cultural learning objects (XCLOs)* meet the additional challenge of creating e-learning that accommodates the more profound cultural differences of global learners, such as those generated by different values, national cultural dimensions, and even diverse levels of techno-literacy. This article describes XCLOs in more detail and illustrates how they can be used by NVOs to maintain their requisite agile workforce.

BACKGROUND

Technically, a learning object (LO) is a simple unit of instruction designed to achieve a specific learning objective. A variety of learning objects can be designed to achieve the same objective, allowing instructional designers to choose activities based on the demographics of learners, media, environments, and so forth. When one speaks of learning objects today, it is usually in the context of e-learning because LOs are digital and designed to be reusable (reusable learning objects or RLOs), which is accomplished by designing them to meet established standards for a specific data format, such as Sharable Content Object Reference Model (SCORM) and Aviation (all encompassing) Industry Computer-Based Training (CBT) Committee (AICC) (Wikipedia, 2007). A simple definition of an RLO is “[a] self-contained piece of learning material with an associated learning objective, which could be of any size and in a range of media” (Crawley, 2006).

NETg (2003) defines [RLOs] by three components that must be present: the object must have a measurable objective, it must have an activity that exactly matches this objective, and it must have an assessment. Wiley (2000) defines a learning

object as “any digital resource that can be reused to support learning.” Extensive databases, such as the Multimedia Educational Research for Learning and Online Teaching [MERLOT] (MERLOT, 2006), have been created to house these RLOs created by educators and to make them available to other educators.

The extensive coverage of reusable learning objects on Web sites such as <http://www.reusablelearning.org/> (Reusable Learning Project, 2005-2005) and Eduworks (2001-2005) are examples of how RLOs have grown in popularity and sophistication.

Reusable Learning Objects

Reusable learning objects represent an alternative approach to content development. In this approach, content is broken down into chunks. From a pedagogical perspective, each chunk might play a specific role within an instructional design methodology...

- Each chunk must be able to communicate with learning systems using a standardized method that does not depend on the system
- How a learner moves *between* chunks is controlled by the learning system.
- Each chunk must have a description that enables designers to search for and find the right chunk for the right job.

Such chunks are called learning objects. There is no standard for the size (or *granularity*) of a learning object (Eduworks Corporation, 2001-2005).

The primary benefit of using RLOs for rapid e-learning development, as well as for cultural adaptation, is that the needs of different groups of learners can be met by using these “chunks” to adapt existing courses instead of creating new ones for every different group of targeted learners. The major premise, while not entirely proven, is that the cultural characteristics of learners will need to

be “matched” to characteristics of the e-learning courses. The largest producers of e-learning are in Western cultures, but the largest and fastest growing consumer groups are in Eastern cultures (Van Dam & Rogers, 2002). Thus, as e-learning is further globalized, education and training professionals will be challenged to meet the culturally-based needs of these learners. Businesses, higher education, and e-learning producers are rapidly adopting RLOs in the instructional design of e-learning, [but] also, recognizing “[the] issues around re-use of e-content and cultural models of teaching and learning” (Selinger, 2005) and “how culture and IT skills influence development and delivery of e-learning materials” (Benson et al., 2005). Educators acknowledge that “Many objects are culturally-inflected, which is to say that they may not be appropriate at all for diverse learners in remote settings...” (Nash, 2005). They are also recognizing RLOs as cultural artifacts and the inherent socio-cultural differences presented (Berge & Fjuk, n.d.).

Cross-Cultural Learning Objects

However, the term *cultural learning object* (CLO) has already been coined. CLOs are digital representations of art, historical places, and other physical artifacts of the world’s cultural groups. An initial Internet search for *cultural learning objects* illustrates that, for the most part, these are reusable learning objects used in the cultural heritage industries, such as museums (DigiCULT, 2003; Giorgini & Cardinali, 2003). The concept of cultural learning objects came into existence with the proliferation of online museums, digitized art, and the need to move and store these objects for either display or for educational purposes.

Thus, in order to distinguish the CLOs used within the heritage industry from those used to create culturally adapted e-learning, an alternative moniker is needed. The term *cross-cultural* is defined as “...comparing or dealing with two or more different cultures” (Lexico Publishing

Group LLC, 2006), a definition that more aptly describes what instructional designers are trying to accomplish when in adapting e-learning for multiple cultural groups. This author contends that the term *cross-cultural learning objects* (XCLOs) better defines the characteristics of RLOs for globalized e-learning and, in addition, proposes that the e-learning industry adopt the term *cross-cultural learning object* [XCLO] into standard usage. Hence, the term would be distinguished from CLO, already coined by the heritage and museum industry.

MAIN FOCUS

So, how do XCLOs work and how should they be employed?

As a result of classical research and theories in industrial anthropology, Hofstede (1997), Trompenaars and Hampden-Turner (1998), and others, such as Edward T. Hall (1981), identified categories of characteristics across which members of cultures can be compared and contrasted at a national level called *cultural dimensions*. While each researcher categorized these dimensions differently, the concepts are similar: large groups of people within certain national groups (countries) tend to possess similar characteristics that differentiate them from members of other national groups. (For brevity, only segments of Hofstede’s and Trompenaars’ research will be used in this article; however, the reader should further explore the seminal works of Geert Hofstede (1997) Fons Trompenaars and Charles Hampden-Turner (1998), Edward T. Hall (1981), and the other theorists in the reference list).

Based on his research of more than 100,000 individuals in 54 countries, Hofstede created indexes (ratings from low to high) for four categories of characteristics used to describe cultural groups: power distance, individualism, masculinity, and uncertainty avoidance. The *power distance index* (PDI) is “the extent to which the less powerful

members of institutions and organizations expect and accept that power is distributed unequally” (Hofstede, 1997, p. 27). He defined *individualistic* (IDV) societies as those “in which ties between individuals are loose” (1997, p. 51). By contrast, *collectivist* societies are those “in which people from birth onwards are integrated into strong, cohesive *ingroups*, which throughout people’s lifetime continue to protect them in exchange for unquestioned loyalty” (Hofstede, 1997, p. 51). He also defined a dimension called “*masculinity* versus *femininity*” (MAS) in terms of how a culture socializes its members to perform gender roles. In a masculine culture, men are expected to be tough and assertive, while women are perceived as tender and modest. In a feminine culture, men and women are more likely to have similar roles; both are expected to be tender and modest, even if men also express some assertiveness. Lastly, *uncertainty avoidance* (UAI) is “the extent to which the members of the culture feel threatened by uncertain or unknown situations” (Hofstede, 1997, p. 113). Uncertainty avoidance is not risk avoidance; rather, it refers to a pattern of reducing ambiguity.

Not surprisingly, such characteristics are manifested by students and teachers and, consequently, within cultural artifacts (such as e-learning) as well.

Edmundson (2007c) describes two of Hofstede’s four cultural dimensions, *power distance* and *individualism*, as he related them to education:

In nations with a low-power distance index (PDI), teachers and students tend to be perceived as equals. Teachers are not authoritative subject matter experts, but rather are facilitators of student-centered education. In high-PDI nations, teachers are authorities, and students do not question their knowledge (Hofstede, 1997). Students in nations with a high-individualism index (IDV) expect to be treated as equals among peers and faculty, preferring to work as individuals and expecting recognition for individual merit. In contrast,

members of collectivist societies depend on social relationships and may expect differential treatment based upon their social class. Globally, collectivist societies are predominant. (Hofstede, 1997)

Thus, in the scenario above, an American learner (low PDI) would be accustomed to challenging and questioning the instructor; whereas, a learner from India might defer to the instructor’s authority position and not question him or her (high PDI). The presumption is that, to some degree, such differences will affect *learning outcomes* and need to be addressed. *Learning outcomes* were defined by Henderson (1996) as any results that reflect the acquisition of skills and knowledge, such as the effectiveness of instructional techniques, and as students’ perceptions or attitudes. The goal of instructional design is to ensure equitable outcomes for all learners. Most e-learning is designed by Western countries, such as the United States, which have the highest indexes of PDI and IDV among the nations studied; in contrast, Eastern and countries in developing areas tend to have low PDI and IDV indexes, posing challenges in both classrooms and e-learning. *Table 1* summarizes the different cultural dimensions indexes of American and Indian learners as shown by Hofstede (1997).

Classical theorists and researchers in education have long recognized the impact of culture on education (Gardner, 1989; Hall & Hall, 1977; Lave, 1988; Spindler, 1963, 1974, 1987; Vygotsky, 1997). Contemporary researchers and theorists (Downey et al., 2004; Edmundson, 2004; Henderson, 1993, 1996, 2007; Jaju et al., 2002; McLoughlin, 1999, 2000, 2007; Reeves, 1994) are finding that cultural dimensions have an impact on *how* people learn and/or how they *prefer* to learn specifically within *e-learning*. Dunn and Marinetti (2000-2004) were two of the earliest thinkers that recognized learning objects as a way to culturally adapt e-learning:

[Learning] objects are selected that to some extent tailor the experience to the cultural expectations of

Cross-Cultural Learning Objects (XCLOs)

Table 1. Summary of U.S. and Indian indexes for Hofstede's four cultural dimensions

Dimension (range of lowest to highest scores, using all countries)	PDI (lowest-11; highest-104)	IDV (lowest-6 highest-91)	MAS (lowest-5 highest-95)	UAI (lowest-8 highest-112)
USA	40	91	62	46
India	77	48	56	40

the learner... The great advantage of object-based elearning is that once you have identified some of the key [cultural] dimensions for your major cultural areas, you can deliver the same objects to those who share similar traits.

Table 2 proffers an example of how a course developed in the United States (U.S.) might be adapted for learners in India. The suggested uses for XCLOs are highlighted in bold. Note that, while the need for adaptations are presumed, the author recommends several ways in which to determine (a) if any changes are needed and (b) other ways—beyond changes in instructional design—in which to adapt e-learning.

Marinetti & Dunn (2002) illustrated how XCLOs could be used in a course that was originally designed in the U.S. but adapted for Italian learners, based on the cultural dimension, *achievement v. ascription orientation*, a cultural dimension described by Trompenaars and Hampden-Turner (1998) that is similar to Hofstede's PDI.

According to Marinetti and Dunn (2002):

Achievement-oriented cultures judge people according to what they have accomplished. They make limited use of titles and respect to superiors is accorded depending on their knowledge and performance...[whereas] Ascription-oriented cultures attribute status depending on birth, kinship, gender, and age but also connections and educational record. They make extensive use of titles.

Italians have a high “ascription” score whereas the Americans’ score on this dimension is low. If the course were designed in America, for example, it might contain an introductory video of the course designer who, as a corporate professional in workplace performance, tells learners about the value of the course. However, the Italians may not give this professional much credence because he/she is unknown. As a solution, (presuming this proves to be the case), the introductory component of the course could be created as an XCLO. For high-ascription Italians, the introduction may be presented by a well-known, respected and titled authority in Italy.

As illustrated in this article, educational researchers and practitioners are becoming more aware of the need to adapt complex e-learning for use in other cultures: “The digital object should be appropriate culturally, and the meanings that it communicates within a cultural context should reinforce learning objectives,” and “understanding the cultural beliefs and values is critical in developing an instructional strategy that uses learning objects” (Nash, 2005, p. 416). Localization addresses obvious visual and textual differences found in other cultures such as icons, symbols, gestures, and so forth. However, the deeper ramifications of culture, such as what people value, how they learn, solve problems, and so forth, will require approaches that are more sophisticated. Using XCLOs will accomplish that goal.

Table 2. Proposed use of XCLOs, based on assessment of cultural dimensions for the U.S. and India

Course characteristics	Learner characteristics	Potential adaptations to consider	How to measure or evaluate impact/preferences
Use of American English	Taught in schools with British English	• Change words, idioms, colloquialisms • Provide learners with a glossary • Do nothing	Determine learner familiarity with American English and idioms, and other colloquialisms used in the course.
Use of American icons and brand names, such as Harley Davidson motorcycles	Highly educated, work for Americans and are frequently exposed to American culture through mass media, work, colleagues	• Replace with those known to Indian learners • Explain differences • Do nothing	Determine learner familiarity with American icons, pop culture, and other colloquialisms used in the course via focus group
Lacks cooperative activities and group work (except through simulations and post-course discussions)	Prefer cooperative activities and group work	• Use XCLOs ◦ to replace individualistic activities with more cooperative ones ◦ to offer a supplemental cooperative activity just for the Indian learners • Do nothing; learners may accept and/or adapt to individualistic activities	Pilot test the course for equitable learning outcomes; survey participants about reaction to activities provided
Embodies cognitive-constructivist educational paradigm	More accustomed to instructivist-didactic approach to teaching	• Use XCLOs ◦ To create course options based on paradigm to which the learners are accustomed, such as offering written, downloadable handouts of information in place of an interactive activity • Do nothing; learners accept and/or adapt to different paradigm	Pilot test the course for equitable learning outcomes; survey participants about reaction to activities provided

FUTURE TRENDS

As discussed, several trends related to the growth of NVOs and other types of organizations with global reach indicate that the use of XCLOs is imperative. Outsourcing, offshoring, and out-tasking of business functions is growing, creating the need to rapidly train an agile, cross-cultural workforce. E-learning is more frequently the tool of choice for educating the virtual workforce. The design and use of modular learning objects and the logic of reusing content are top areas of focus for corporations, higher education, and e-learning vendors in the U.S. (The eLearning Guild, 2006). In addition, an average of 21% of those organizations wants to increase the global reach of their e-learning content (The eLearning Guild, 2006). Given these trends, reusable XCLOs will become

increasingly popular, collected and developed, and exchanged all over the world. The collection and creation of XCLOs will lead to the creation of new XCLO databases, similar to MERLOT or, alternately, XCLOs will be incorporated into existing databases as a subcategory of RLOs. In addition, the standards for their development – content-wise and technologically – will become more universal. Educational researchers and practitioners have begun to introduce ways in which to adapt e-learning for targeted learners in other cultures, from translation, to localization, to using RLOs. Practical models for adapting e-learning are being developed and tested (Dunn & Marinetti, 2007; Edmundson, 2007a, 2007b; Henderson, 2007; McLoughlin, 2007). However, the first step to integrating XCLOs into e-learning is to differentiate between the cultural learning

objects (CLOs) used in the heritage industries and the cross-cultural learning objects (XCLOs) used in e-learning.

CONCLUSION

NVOs rely on e-learning to maintain an agile, trained workforce globally. However, members of world cultures have different values, perspectives, and even ways of learning. RLOs can address the need for rapid e-learning development. Certain organizations such as MERLOT ("Multimedia educational research for learning and online teaching [MERLOT]," 2006) have built databases of RLOs for educators to use. However, no one has specifically addressed the need to use RLOs for *cultural adaptation*. To the author's knowledge, there is no organized effort to design XCLOs, nor are there any databases that house XCLOs. An Internet search for "cross-cultural learning objects" resulted in ONE hit, an almost unheard of result in today's Web searches: developing and compiling a repository of *cross-cultural learning object* makes sense in the discipline of e-learning, the educational tool of choice for globalized NVOs.

KEY TERMS AND DEFINITIONS

AICC: The Aviation (All Encompassing) Industry CBT (Computer-Based Training) Committee [AICC] is an international association of technology-based training professionals. The AICC develops guidelines for aviation industry [that are being adopted by other industries, as well] in the development, delivery, and evaluation of computer based training, Web-based training and related training technologies (Wikipedia, 2007).

Cross-Cultural [XC]: Comparing or dealing with two or more different cultures (Lexico Publishing Group LLC, 2006).

Cross-Cultural Learning Objects [XCLOs]: Cross-cultural learning objects are reusable learning objects used to adapt e-learning for use by multiple cultures, based on the premise that learners in another culture will learn best by hav-

ing course characteristics and features meet their needs and cultural preferences.

Cultural Artifacts: An instructional design is a cultural artifact. It reflects, often in an inconspicuous or unintentional manner, the values, learning preferences, language, and worldview of the designer (McLoughlin, 1999).

Cultural Dimensions: Cultural dimensions are the mostly psychological dimensions, or value constructs, which can be used to describe a specific culture. These are often used in intercultural communication-/cross-cultural communication-based research. See also Hall (1981), Hofstede (1997), and Trompenaars & Hampden-Turner (1998). (Wikipedia, 2007).

Distance Education or Distance Learning: Distance education, or distance learning, is a field of education that focuses on the pedagogy/andragogy, technology, and instructional systems design that are effectively incorporated in delivering education to students who are not physically “on site” to receive their education. Instead, teachers and students may communicate asynchronously (at times of their own choosing) by exchanging printed or electronic media, or through technology that allows them to communicate in real time (synchronously) (Wikipedia, 2007).

E-Learning: E-learning is a general term used to refer to computer-enhanced learning. It is used interchangeably in so many contexts that it is critical to be clear what one means when one speaks of “e-learning” (Wikipedia, 2007). E-learning is a form of distance learning or distance education; however, the latter two are not neces-

sarily e-learning...they could be correspondence courses, and so forth.

Learning Objects [LO]: A learning object is a reusable unit of instruction for elearning. In order to use it in different contexts, the presentation has to be separated from the content, which calls for specific data formats. SCORM is such a format (Wikipedia, 2007).

Learning Outcomes: Results that reflect the acquisition of skills and knowledge, such as the effectiveness of instructional techniques, and as students’ perceptions or attitudes (Henderson, 1996).

MERLOT: The Multimedia Educational Research for Learning and Online Teaching (MERLOT) was built to house RLOs created by educators and to make them available to other educators (“Multimedia educational research for learning and online teaching [merlot],” 2006).

Reusable Learning Objects [RLO]: Reusable learning objects represent an alternative approach to content development. In this approach, content is broken down into chunks. From a pedagogical perspective, each chunk might play a specific role within an instructional design methodology [and can be interchanged and exchanged, depending on the needs or characteristics of the learners] (Eduworks Corporation, 2001-2005).

SCORM: SCORM stands for Shareable Content Object Reference Model. This is a standard for Web-based e-learning. It defines how the individual instruction elements are combined on a technical level and sets conditions for the software needed for using the content (Wikipedia, 2007).

Chapter 5.3

Technology Integration Practices within a Socioeconomic Context: Implications for Educational Disparities and Teacher Preparation

ABSTRACT

With the call for curricular and instructional reform, educational institutions have embarked on the process to reform their educational practices to aid the lower SES student in their quest to obtain quality education with the integration of technology. The study performed was to examine the socioeconomic disparities of teachers' technology integration in the classroom as it relates to implementing technology interventions to support quality teaching and active student learning. This chapter provides empirical evi-

dence of whether these disparities continue to exist, and their effects on student achievement in the classroom.

INTRODUCTION

The rise and use of educational technology in the 21st century has become one of the dominant issues and challenges facing diverse communities, business and industry, educational arenas and the larger U.S. society as a whole. Amidst the euphoria and craze over the power and the potential of information and communication technology has to transform the way we learn, the ways in

DOI: 10.4018/978-1-60960-503-2.ch503

which we communicate, and the ways in which society functions, there is an increasing debate as to who has access and the consequences of access to full participation in a democratic U.S. society. This debate has particular implication for classroom instruction. Educators concerned about the chronic underachievement of students often fall prey to the allure of technology as a tool for reversing the historical influences of poverty, discrimination, inequity, chronic underachievement, and lack of opportunity because technology has the potential to narrow the achievement gap, if equally distributed or widen the gap if only accessible to selected groups in the educational system (Waxman, Connell, & Gray, 2002; Edyburn, Higgins, & Boone, 2005).

SOURCES OF SOCIOECONOMIC DISPARITIES

Research studies have been devoted to socioeconomic disparity in technology integration and use in education (National Center for Educational Statistics, 2005; U.S. Department of Education, 2005). Becker (2001) found that students from higher income families have been found to use computers in school and in their homes more frequently than students from lower SES families. Students of color from urban schools have also been found to have less access to computers compared to Anglo-suburban students (National Telecommunication and Information Administration, 2006). More recently, lower SES schools are only half as likely to have high speed internet compared to high SES schools (Roblyer, 2006). Consistent with this idea of access are the issues within the digital divide itself. Despite the constraints on school funding in most states, schools have devoted an increasing percentage of their annual budgets to technology. The majority of the efforts of the educational community over the past decade to acquire hardware, software, and Internet access have been successful (Divid-

ing Lines, 2001). However, clear evidence of a digital divide, parallel to historical disparities, continues to distinguish urban schools from their affluent counterparts (Chen & Thielemann, 2001; Guttentag & Eilers, 2004; National Center for Education Statistics, 2004). Historical measures of digital equity have been based on the ratio of the number of computers divided by the number of students. A more recent measure involves determining levels of Internet access. Another dimension of this problem relates to questions about differences in home access to technology, therefore impacting urban student achievement.

A second source of disparity in technology use is how technology is used. Previous studies conducted by Becker (2001) and Finneran (2000) found that low SES schools are more likely to use technology for drill and practice, whereas high SES school uses technology in innovative teaching strategies (Becker, 2001; Finneran, 2000). This idea is consistent with the ideas of curriculum reform and reconceptualization put forth by Pinar (2004). Pinar (2004) suggests that the instruments of computer technology are used to drill and kill students into passing standardized test, not actually being integrated effectively into classroom instruction or pedagogical practice that promote quality teaching and active student learning. He further explains that the current use of computer technology in urban schools generally serve to turn its users (students) into disembodied and alienated subjects. Furthermore, as explained in Becker (2001), high SES students are more likely to use technology for school assignment, use e-mails, and use educational programs.

A third source of disparity in technology use deals with the nature of technology adoption and organizational change. A thorough analysis of major research related to technology and teacher motivation, adoption and usage uncovered important factors that are involved in determining their willingness to use such approaches in the teaching and learning process (Braak, 2001;

Solomon & Wiederhorn, 2000). The literature indicates that teacher's willingness to adopt and implement learning technologies for the teaching and learning process varies, but all share the same denominator—proper internal and external motivation (Braak, 2001; Mooji & Smoot, 2001; Solomon & Wiederhorn, 2000). The top reasons teachers choose to use technology for the teaching and learning process dealt with the notion of continuous training and development, proper technology support from technology personnel, encouragement from school administration, and an organizational structure that supported teachers using technology. While these are the key issues ascertained from the research study, the ideas of change management, technology adoption and innovation, self-efficacy and motivation, support, and the computing experience are relevant to this discussion. The American Council of Education (2003) report noted that the quest to optimize the use of technology in schools could not be fulfilled by the mere supply of more hardware and software. The report suggested that what needs to be addressed first are ways to identify, motivate, and equip teachers with the skills necessary for effective use of educational technologies in their classroom practices.

TEACHERS' PERCEPTIONS AND ATTITUDES TOWARD TECHNOLOGY

Ktoridou, Zarpetea, and Yiangou (2002) studied teachers' attitudes toward technology in the classroom. The study found that most young, novice teachers expressed a willingness to integrate technology in their lessons than more experienced veteran teachers. Moreover, the researchers implied that younger, less experienced teachers are more interested in learning how to use technology since they are more familiar with it, whereas; experienced teachers felt frustrated

by the new technology as it takes too much time to learn and use it. The teachers stated that they had a negative attitude towards technology because of their lack of training, lack of experience, and lack of time to prepare an extensive lesson plan, as well as the inability to acquire computer access. Bauer (2002) adds that a challenge for teachers is how to use technology along with the standards and teachers use the computer to augment regular curricular activity, but not as an integral transformative tool to assist in the teaching and learning process.

The use of technology in the classroom has moved through definable periods involving programming, computer-assisted instruction, problem-solving environments, personal productivity, web-based instruction, and hypermedia. Problems associated with limited opportunities for teacher professional development to learn about new innovations (Loneragan, 2001), as well as limited funds for new hardware and software, often result in the routine use of student learning activities that have been abandoned by high-performing schools (Guttentag & Eilers, 2004). Literacy educators have a responsibility to be aware of these disparities in technology access and education and to work to narrow gaps between the technological haves and have-nots (Bauer, 2002).

METHODS

The data for the present study was drawn from the base year of the Educational Longitudinal Survey of 2002-2004 (ELS: 02). The ELS:02 is a national survey administered by National Center for Educational Statistics to provide an overall picture of the present educational experience of high school students in the U.S. The survey has four sub components completed by students, teachers, parents and school administrators. The design used to collect the data was a two-stage, stratified national probability sample. The

survey included 1,052 public and private school representing about 12,000 students across the country. For the present study the teacher and administrator survey data was used. The total number of teachers that participate in the survey was about 7,322.

The teacher survey provided items used to measure how much training teachers had received in technology use. The items used to measure teacher training were the following: (a) received training in basic computer skills, (b) received training in the use of the Internet, (c) received training in integrating technology in the curriculum, (d) received training in software applications, (e) received training in use of Internet, (f) received training in use of other technology and, (g) received follow-up or advanced training. The outcome measures for these items were dichotomous, yes or no.

The teacher survey also measured Internet and Technology use in Instructions. The item provided on the teacher survey to measure this outcome were the following: (a) how often do you use the computer to create class presentations, (b) how often do you use WWW sites to plan lessons, (c) how often do you access model lesson plans from internet, (d) how often do you do research teaching on the internet, (e) how often do you take professional development courses on the internet, (f) how often do you download instructional software from the internet, (g) how often do you use the computer to give class presentations and, (h) how often do you use the computer to prepare multimedia presentations. The outcome measures for these items were also a four point likert scale, ranging from “never” to “more than once a week.”

Finally, the teacher survey measured how often teachers used technology to communicate between parents, students, and for administrative duties. The item provided on the teacher survey to measure this outcome were the following: (a) how often do you take professional development

courses on the Internet, (b) how often to you use the computer to communicate with colleagues, (c) how often to you use the computer to communicate with parents, (d) how often to you use the computer to communicate with students, (e) how often do you use the computer for administrative records and, (f) how often to you use the computer to post homework and other information. Again, the outcome measures for these items were also a four point likert scale, ranging from “never” to “more than once a week.”

In order to measure the socioeconomics level of the school involved, the administrator survey was used. In this case school administrators were asked the report the percent on students at their school that were eligible for a free lunch program. School percentages were then ranked according to eligibility. The distribution of these percent values were divided into three quartiles, ranging from lowest to high SES schools. The total number of teachers that represent the three SES levels were about 3933 teachers from low SES schools, 2324 from middle SES schools and about 1065 teachers from high SES schools. To determine if an association exist between technology training and use by teachers in the school with different socioeconomic status a Pearson’s chi-square test was used.

RESULTS

Table 1 reports the percent of teachers who received training on technology preparation and the ability to integrating technology in the curriculum they teach. Eighty three percent of the teachers indicated they had received training in basic computer skills. Similarly, almost eighty percent of the teachers indicated they had received training on software applications (78.7%), use of the internet (78.6%) and integrating technology in curriculum (77.0%). Finally, less than fifty percent of the teachers indicated that they had

Table 1.

Teacher Training N= 7322		
	Yes	No
Received training in basic computer skills	83.0%	17.0%
Received training in software applications	78.7%	21.3%
Received training in use of Internet	78.6%	21.4%
Received training in use of other technology	45.7%	54.3%
Received training in integrating technology in curriculum	76.4%	23.6%
Received follow-up or advanced training	43.2%	56.8%

received training on the use of other technology (46.4%) and follow-up or advanced training on technology use (43.2%).

Table 2 reports how often internet and computers are being used by classroom teachers. The most frequent use of the computer by classroom teachers was to create class presentations. About eighty percent of the teachers (80.7%) indicated that used computer to create instructional materials more than several times a week. Seven percent (7.0%) of the teachers indicated they

used computers to prepare multimedia presentations more than once a week. Similarly, about seven percent (6.5%) of the teachers indicated they used the computer to give class presentations and to prepare multimedia presentations more than once a week. The most frequent use of the internet was to use www sites to plan lessons. Forty five percent (44.5%) of the teachers indicated they used a www site more than once a week. The second highest use of the internet was to access model lesson plans. Only sixteen

Table 2.

Internet and Technology Use in Instructions N= 7322				
	Never	Less Than Once a Month	Between one a week and once a month	More than once a week
How often use computer to create class presentations	2.4%	3.3%	13.6%	80.7%
How often use WWW sites to plan lessons	6.3%	16.1%	33.0%	44.5%
How often access model lesson plans from Internet	28.7%	30.8%	25.0%	15.5%
How often research teaching on Internet	25.4%	34.3%	27.4%	12.9%
How often did teachers take professional development courses on Internet.	88.5%	8.5%	2.0%	1.1%
How often was download instructional software from Internet used in the class	59.1%	26.5%	11.9%	2.5%
How often use computer to give	37.1%	33.7%	22.7%	6.5%
How often use computer to prepare multimedia presentations	38.2%	34.1%	20.7%	7.0%

percent (15.5) of the teachers indicated that they used the internet to access model lesson plan more than once a week. Similarly, thirteen percent (12.9%) of the teachers indicated they used the internet more than once a week to research teaching. Finally, less than 10% of the teachers indicated they used the internet more than once a week for the remaining items, download instructional software and take development courses on the internet.

Table 3 reports communication use of the computer and internet by classroom teachers. The most frequent use of the computer in communication was for administrative purposes. Seventy nine percent (78.6%) reported using the computer for administrative purposes more than once a week. The second most frequent use of the computer by teachers was for colleague discussions. Fifty three percent (52.9%) of the teachers indicated that they used the internet for colleague discussions more than once a week. Similarly, almost fifty three percent (52.6%) of the teachers indicated that they used the internet for colleague discussions and to communicate with colleagues more than once a week. Twenty-six percent of the teachers indicated that they used the computer to communicate with students more than once a week. One fifth of the teachers

(20.8%) indicated that they used the computer to post homework/information more than once a week. Finally, less than twenty percent (18.8%) of the teachers indicated that they used the computer to communicate with parents.

Table 4 compares teacher training on computers and technology use across socioeconomic school levels. The results indicated that several differences ($p < .001$) exist in technology training teachers have received in high, median and low SES schools. Teachers from high SES school indicated a larger percent of them had received training in basic computer skills. Eighty four percent (84.1%) of the teachers from high SES school reported receiving training in basic computer skills compared to seventy nine percent (78.6%) of the teachers from low SES school. There was a significant difference ($p < .001$) exist on the percent of teachers that received training on software applications across the three SES environments. In this case teachers from Middle level SES school had the highest percent 85.3%, compared to 80.6% and 80.9% for Low and high SES teachers respectively. When asked if they had received training in the use of the internet there was a significant difference ($p < .001$). Eighty four percent (83.7%) of the teachers from high SES schools reported they had received

garding teachers from low SES school about fifty eight percent (57.9%) of the teachers reported using computers to create class presentations more than once a week. Similar, fifty eight percent of the teachers from middle class schools reported using computers to create class presentations more than once a week. The group that reported using WWW sites to plan lessons the most were teachers from middle SES schools. Nineteen percent of the middle school teachers indicated they used WWW sites more than once a week. Eighteen percent (17.8) of the teachers from High SES schools reported using WWW sites more than once a week. Fifteen percent (14.6%) of the teachers from low SES schools reported using WWW sites more than once a week. When asked how often they accessed model lesson plans from the internet, teachers from low SES schools were less likely to do so. Over fifty percent (52.7%) reported never accessing model lesson plans from the internet. Forty seven percent (47.1%) of the teachers from middle SES schools and forty six percent (46.4%) of the teachers from high SES schools reported never accessing model lesson plans from the internet. Almost fifty percent (47.9%) of the teachers from low SES schools compared to thirty nine percent (38.5%) of the teachers from high SES school reported never doing research teaching on internet. Forty three percent of the teachers from middle SES schools reported never doing research teaching on internet. There was a ten percent decrease in usage of the computer to give when comparing teachers from High and low SES schools. Close to sixty percent (59.7%) of the Low SES teachers and forty nine percent of the teachers from high SES schools reported never used the computer to give. Fifty seven percent (57.3%) of the teachers reported never using the computer to give. There were no other significant differences for the remaining usages of the computer.

Table 6 compares teacher internet and technology use for communication across socioeconomic levels. The results indicated that several differences exist ($p < .001$). There was a significant difference in the using the computer to communicate with colleagues. Fifty-five percent (54.7%) of the teachers from high SES school and forty seventy percent (47.3%) of the teachers from low SES schools reported using computer to communicate w/colleagues more than once a week. Similar, fifty four percent of the teachers from middle SES schools reported using computer to communicate w/colleagues more than once a week. There was a significant difference in the using the computer to communicate with parents. Almost three times as many teachers located at High SES schools reported using the computer to communicate with parents more than once a week compared to teachers in low SES schools. The percentages were 26.7% and 9.4% respectively. Thirteen percent (13.4%) of the middle SES teachers reported using computer to communicate w/parents more than once a week. There was a significant difference in the using the computer to communicate with students. Thirty percent (30.4) teachers from high SES schools compared to twenty five of the teachers from low SES schools reported they used computers to communicate with students more than once a week. Twenty one percent (20.8%) of the teachers from middle SES schools reported using the computers to communicate with students more than once a week. Finally, there was a significant difference in the using the computer to post homework and information. About twenty two percent (21.7%) of the teachers from high SES schools compared to twenty percent (20.4%) of the teachers from Low SES schools used computers to post homework and information. Eighteen percent (18.2%) of the teachers from middle SES schools reported using computers to post homework and information.

The results also indicated several significant differences exist at the .05 level. There was a significant difference in the using the computer for administrative records. Seventy nine percent (78.6%) of the teachers from high SES school and seventy five percent (75.2%) of the teachers from low SES schools reported using computers for administrative records more than once a week. Similar, eighty percent of the teachers from middle SES schools reported using computers for administrative records more than once a week.

DISCUSSION

The use of technology in the classroom has been a main focus in improving student learning outcomes. Technology not only can provide visual learning in the classroom, it also opens the door to improve higher level thinking skills. However, for technology to have its greatest effect there must be equal access and teachers must be well equipped to utilize there potential. The first important finding in the present study relates to

the descriptive results that summarize teacher's training on technology use. The results suggest that majority of the teachers are receiving training on the basic use of technology. This training includes receiving training in basic computer, software applications, training in integrating technology in curriculum and use of Internet. These teachers however were less likely to have received training in the use of other technology and follow-up or advanced training.

The second important finding was the summary of teachers' Internet and Technology Use in Instruction. Teachers were more likely to use the computer to create class presentations. On the other hand these teachers were less likely to use technology for classroom presentations. Furthermore, only a small number of teachers used the internet to receive professional development or to download instructional software from Internet on a consist bases. The most common use of technology for communication purposes was for administrative purposes. Teachers also reported they commonly used computers and the internet to communicate with colleagues on regular bases. Only a small number of teachers reported using computers to communicate with parents and students.

Comparing technology use and training across school environments indicate that socioeconomic status of the school still plays an important role in how well teacher are trained and their ability to use integrate technology in the classroom. In this case teachers from low SES schools are less likely to have received training in basic computer skills and internet use compared to teachers from high SES schools. This leads to less use of technology by teachers from low SES schools to create class presentations. Finally, teachers from low SES schools are less likely to use technology for communication purposes. This includes communication between teacher and student, along with teacher-parent communications.

IMPLEMENTING TECHNOLOGY IN URBAN SCHOOLS

One of the major concerns for urban teachers when integrating educational technology in the classroom is the identification of appropriate principles that help achieve high student learning outcomes. Recent research synthesis efforts by National Center for Education Statistics (2004), the International Society for Technology in Education (2004), and Roblyer (2006) provide principles for appropriate ways to use education technology in urban schools as supported by the education technology research. Research in educational technology has also shown that the effective use of educational technology occurs when the application directly; (a) supports the curriculum objectives being assessed; (b) provides opportunities for student collaboration and project/inquiry based learning; (c) adjusts for student ability and prior experience, and provides feedback to the student and teacher about student performance; (d) is integrated throughout the lesson; (e) provides opportunities for students to design and implement projects that extend the curriculum content being assessed; and (f) is used in environments where the organization leaderships supports technological innovation (National Center for Education Statistics, 2004). Some examples of the strategies that have proved successful in influencing student academic performance include students working in pairs on lessons at the computer assisted instruction through social interactions and teamwork (Brainbridge, Lasley, Sundre, 2004), digital video clips, audio, and graphics to supplement instruction (Boster, Meyer, Roberto & Inge, 2002); mathematics curricula focusing on mathematical analysis of real-world situations supported by computer assisted instructional software program (Koedinger & Anderson, 1999; Cuban, 2001); multimedia creation involving research skills to locate content resources, capability to apply learning to real world situations, organizational

skills, and interest in content (Cradler & Cradler, 1999); software programs that allow students to be aware where they are in the inquiry process and to reflect upon their own and other students' inquiries (White & Frederiksen, 1998); word processing software that utilizes writing prompts; and online feedback among peers who know one another allows learners to feel more comfortable with and adept at critiquing and editing written work (Coley, Cradler, & Engel, 1997).

CONCLUSION

As we look to the future, technology is often viewed as an enticing means of closing the achievement gap. The current literature has implies that innovative approaches used in teaching with technology leaves students with a more effective learning environment that promotes quality teaching and active student learning. Consequently education planners and policy makers must think beyond providing more hardware, software, and connecting schools to the Internet, but instead thinking about keeping urban schools and teachers well-informed and trained in the effective use of technology for educational purposes. One of these investments is meaningless without the other. High-speed connections, complete digital services, and modern computers are basic to every professional workplace and are essential to student learning in the 21st century. However, technology will fail to meet its educational promise if we neglect to equip teachers with the skills they need to understand and use it and transmit this knowledge and skills to the urban learner. Adhering to these procedures, educators will be able to grow as practitioners in the field and use educational technology to support quality teaching and active student learning. The research examined in this discussion provides teachers with a relevant framework to understand the factors that affect the urban learner and the

power of technology in the teaching and learning process can offer the urban learner, thus leading our educational system to fulfill the promise of providing quality teaching and student learning for a more consistent and dynamic educational learning environment that continues to support the ideals and concepts of the great American education system.

Chapter 5.4

Assistive Technology for Individuals with Disabilities

Yukiko Inoue
University of Guam, Guam

INTRODUCTION

Census 2000 figures indicate that more than 19% of the U.S. population aged five and older are people with disabilities (Goddard, 2004). Technology has the great potential for improving the education and quality of life of individuals with special needs. Blackhurst (2005) identifies six distinct types of technology impacting education: (1) *technology of teaching* (instructional approaches designed and applied in very precise ways); (2) *instructional technology* (videotapes and hypermedia); (3) *assistive technology* (AT) (devices designed to help people with disabilities); (4) *medical technology* (devices which provide respiratory assistance through mechanical ventilation); (5) *technology productivity* tools (computer software and hardware); and (6) *information technology* (access to knowledge and resources).

AT (also called “adaptive technology”) can particularly help balance weak areas of learning with strong areas of learning for students with disabilities (Behrmann & Jerome, 2002). There is a growing recognition that an appropriate up-to-date preparation of teachers/tutors and other educational professionals working with students with disabilities has to focus on information and communication technology (ICT), especially on AT (Feyerer, Miesenberger, & Wohlhart, 2002).

Since educational attainment can enhance occupational attainment, individuals with disabilities (mobility impairment, visual impairment, hearing impairment, speech impairment, and learning disabilities) should be encouraged to participate in higher education. AT for students with disabilities increases options for assisting students with a variety of exceptional learning needs, allowing them to accomplish educational goals that they could not accomplish otherwise in the same amount of time or in the same manner (Rapp, 2005).

DOI: 10.4018/978-1-60960-503-2.ch504

BACKGROUND

AT was practically unknown in 1975, the year of landmark legislation establishing equal educational rights for students with disabilities (and personal technology tools for education were in their infancy at that time); in 1997, the Individuals with Disabilities Education Act (IDEA) amendments required AT consideration in every student's Individualized Educational Program (IEP) (Dalton, 2002). IDEA is the nation's special education law, originally enacted in 1975 (Boehner & Castle, 2005): "The Act responded to increased awareness of the need to educate children with disabilities and to judicial decisions requiring states to provide an education for children with disabilities if they provide an education for children without disabilities" (p. 1).

The late 1970s and early 1980s saw the introduction and refinement of the micro-computer; the 1980s also witnessed an increased emphasis on AT and the emergence of technology literature and computer software targeted directly at special education; and major technology advances such as the evolution of the Internet occurred during the 1990s (Blackhurst, 2005).

The first significant law dedicated to AT was the Technology Related Assistance for Individuals with Disabilities Act (TRAID) of 1988 (Public Law 100-407), which established a definition and criteria for those in the field of AT (Campbell, 2004):

The legislation's primary accomplishment was to provide grant funding for states to establish AT resource centers.... Although many regard AT (such as computer software) as high tech, this definition is all encompassing. The law also provides for low-tech devices, such as pencil grips, weighted writing implements, and magnifying glasses.... In 1998, the federal government passed the Assistive Technology Act (ATA) (Public Law 105-394), which reaffirmed the government's commitment to AT. (p. 168)

With the implementation of these federal laws, institutions of higher learning are able to utilize state agencies in the development of technology programs based on a universal design model.

In 2001, the American Library Association Council approved the AT policy that libraries should work with people with disabilities, agencies, organizations, and vendors to integrate AT into their facilities and services to meet the needs of people with a broad range of disabilities, including learning, mobility, sensory, and developmental disabilities (Goddard, 2004).

ASSISTIVE TECHNOLOGY FOR INDIVIDUALS WITH DISABILITIES IN THE INCLUSIVE EDUCATION SYSTEM

Over the past two decades, for instance, the enrollment of students with disabilities and the demands for related services in higher education have greatly increased (Christ & Stodden, 2005). Online programs have worked to make Web sites accessible to deaf and blind users particularly by providing closed-captioned text and textual descriptions of graphics, even though experts have found out that online programs often lack accommodations for students with learning disabilities such as dyslexia and attention-deficit disorder (Carnevale, 2005).

Inclusion and AT Devices

Inclusive education (the practice of keeping special education students in regular classrooms as much as possible and feasible) is part of the regular school system in many European countries, and inclusive teachers should be able to reach the special educational needs of all students (Feyerer, 2002). ICT can facilitate this challenging task, and AT has the enormous potential to improve access to education and employment for disabled individuals. AT also has the potential to ensure

that computing is as *effective* and as *comfortable* as possible for all learners.

AT devices include: books on tape for a student who cannot read; word processors, laptop computers for a student who has a problem with writing; augmentative communication devices for a student who has communication problems; and a large monitor for a visually impaired student. A vast array of application program software is available for instructing students through tutorial, drill-and-practice, and simulation; AT can be combined with instructional programs to develop and improve cognitive, reading, and problem-solving skills (Behrmann & Jerome, 2002).

Students with disabilities often need adaptations made for them so that they can be successful in school. AT can give learners the help that they need by providing “low” technology strategies (switches, writing devices, or software applications), and “high” technology strategies (those that use sophisticated devices or software applications for students with mild and severe disabilities that enable them to access information) so that they can perform tasks that they would otherwise be unable to do (Lewis, 1998). Inclusive teachers should be able to reach the special educational needs of all learners, and AT should be part of inclusive teacher training (Feyerer, 2002).

Current Applications and AT Resources

AT is divided into two categories: (1) any item, piece of equipment or product system, whether acquired commercially-off-the-shelf, modified or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities; and (2) any service that directly assists a university’s teacher education programs to provide future teachers with knowledge of AT and its importance in helping students learn (White, Wepner, & Wetzel, 2003).

The typical AT products or devices for individuals with learning needs are outlined in Table 1. Table 2 describes valuable AT Web sites for students with disabilities.

Challenging Questions, Universal Design, and AT Research

The primary goal of AT is the enhancement of capabilities and the removal of barriers to performance. Five Guiding Principles for Assistive Technology (2004) planning are quite useful: (1) AT can be a barrier; (2) AT may be applicable to all disability groups and in all phases of education and rehabilitation; (3) AT is related to function, not disability; (4) assessment and intervention involve a continuous, dynamic process of systematic problem solving; and (5) AT does not eliminate the need for social and academic skills instruction.

Challenging Questions

Teachers face challenging questions: Are there simple tools that might be incorporated with the student that would provide enough support so that referral to special education would not be necessary? And would these provisions allow the student to remain in the regular education classroom? That is why the perceived usefulness of AT by teachers and their perceptions of ability positively affect students, and their understanding of inclusion, in serving students in inclusive settings; thus various in-service AT training sessions are extremely important.

Technology should be used by individual students who are entitled to special education services if it is needed to access the general education curriculum; recently, there has been a strong commitment on the part of audiologists and educators to improve the acoustic environment for all students through the development of national standards that can be used in the construction and remodeling of schools (Marttila, 2004). Any tech-

Table 1. AT products or devices for individuals with learning needs

Alternative keyboard	It is different from standard keyboards in size, shape, layout, or function. It offers individuals with special needs greater efficiency, control, and comfort.
Captioning	A text transcript of the audio portion of multimedia products, such as video and television, which is synchronized to the visual events taking place on screen.
Digitized speech	Human speech that is recorded onto an integrated circuit chip and which has the ability to be played back.
Electronic pointing devices	It allows the user to control the cursor on the screen using ultrasound, an infrared beam, eye movements, nerve signals, or brains waves.
Joysticks	It may be used as an alternate input device. Joysticks that can be plugged into the computer's mouse port can control the cursor on the screen.
Keyboard additions	A variety of accessories have been designed to make keyboards more accessible.
Onscreen keyboard	These keyboards are software images of a standard or modified keyboard placed on the computer screen by software.
Optical character recognition (OCR)	OCR software works with a scanner to convert images from a printed page into a standard computer file.
Pointing and typing aids	A pointing or typing aid is typically a wand or stick used to strike keys on the keyboard.
Screen reader	A screen reader is a software program that uses synthesized speech to "speak" graphics and text out loud.
Switches and switch software	Switches offer ways to provide input to a computer when a more direct access method, such as a standard keyboard or mouse, is not possible.
Talking word processors (TWP)	TWPs are writing software programs that provide speech feedback as the student writes, echoing each letter as it is typed and each word as the spacebar is pressed.
Touch screens	This is a device placed on the computer monitor (or built into it) that allows direct selection or activation of the computer by a touch of the screen.
A telecommunication device for the deaf (TDD)	TDD is a device with a keyboard that sends and receives typed messages over a telephone line.
Voice recognition	Voice recognition allows the user to speak to the computer instead of using a keyboard or mouse to input data or control computer functions.
Voice synthesizer	Under control of the screen-reader software, voice-synthesizers can vary the rate, pitch, volume, and language of the information.
Word prediction programs	They enable the user to select a desired word from an on-screen list located in the prediction window.

Source: The Family Center on Assistive Services and Technology (n.d.)

nology that is necessary to aid a student in meeting IEP goals and objectives qualifies as an AT, and students who are entitled to special educational services access AT through the IEP process. The purpose of the IEP is to design an individualized education program to ensure that students with disabilities have adequate educational planning to accommodate their unique instructional needs and that these needs are met in appropriate learning environments; IDEA requires that each student's IEP be reviewed at least annually by IEP team members including parents (Copenhaver, 2004).

Universal Design

The Americans with Disabilities Act (ADA) of 1990 requires that AT be provided as an accommodation to students with disabilities, and one way to ensure equal access to all students is to utilize a universal design model (Campbell, 2004). Universal design principles and guidelines for AT, which are defined by the World Wide Web Consortium (W3C) that make it possible for people with disabilities to use electronic resources easily make those resources more accessible to a wide

Table 2. AT Web sites for students with disabilities

Alliance for Technology Access (ATA) (http://www.ataaccess.org/)	This is a national network of 41 technology resource centers which help children/adults with disabilities, parents, teachers, and others to explore computer systems, adaptive devices, and software.
Assistive Technology for People with Mental Retardation (http://thearc.org/faqs/assistqa.html)	This fact sheet describes devices that are used by children/adults with mental retardation and other disabilities to compensate for functional limitations and to enhance learning, independence, mobility, communication, environmental control, and choice.
Center for Electronic Studying (http://ces.uoregon.edu/)	Funded by the U.S. Department of Education, the Center has launched three projects blending portable computer technology with instruction on computer-based study strategies.
Closing The Gap (http://www.closingthegap.com/)	This is an organization that focuses on computer technology for people with special needs through its bi-monthly newspaper, annual international conference, and extensive Web site.
Disability & Technology: A Resource Collection (http://home.nas.net/~galambos/tech.htm)	Most sites will refer to assistive/adaptive devices that are computer-based and/or related to computer access.
DREAMMS for Kids, Inc. (http://www.dreamms.org/)	DREAMMS (Developmental Research for the Effective Advancement of Memory and Motor Skills) is a non-profit parent and professional service agency, which specializes in AT-related research, development, and information dissemination.
EASI – Equal Access to Software and Information – K12 Connection (http://www.rit.edu/~easi/)	The philosophy behind this Information Technology Centre is to ensure that students and professionals with disabilities must have the same access to information and resources as everyone else.
Early Connections – Technology In Early Childhood Education (http://www.netc.org/earlyconnections/)	Connecting technology with the way young children learn: resources and information for educators and care providers.
LD Resources (http://www.ldresources.com/)	This site contains resources for people with learning disabilities, with a focus on the use of AT to help individuals with learning disabilities become successful.
Literacy Instruction Through Technology (LITT) (http://edweb.sdsu.edu/SPED/ProjectLitt/LITT)	This is a research project focusing on the use of technology to improve the reading skills of students with learning disabilities. Project LITT is located at San Diego State University.
Speaking to Write (http://www.edc.org/spk2wrt/)	This is a federally-funded project which explores the use of speech recognition technology by secondary students with disabilities.
Tools for Understanding (http://www.ups.edu/community/tofu/)	This site is for educators who teach mathematics and are interested in integrating common technologies into their daily instruction.

Source: TheFamily Village School (2006)

variety of devices, such as handhelds (Goddard, 2004). Universal instructional design is “the design of instructional materials and activities that make the learning goals achievable by individuals with wide differences in their abilities to see, hear, speak, move, read, write, understand English, attend, organize, engage, and remember (Burgstahler, cited in Campbell, 2004, p. 167). Colleges should not restrict the use of AT to those students being serviced by disability service providers (Campbell, 2004): “Often there are individuals who benefit from AT that do not have disabilities or have disabilities and have not registered with

service providers. Universal design makes room for users of all abilities” (p. 172).

AT Research

Hetzroni and Shrieber (2004) investigated the use of a word processor for enhancing the academic outcomes of students with writing disabilities in high school. Their research indicated the clear difference between handwritten and computer phases. In paper-and-pencil phases, students produced more spelling mistakes, more reading errors, and lower quality of organization and

structure in comparison with the phases in which a computer equipped with a word processor was used (the word processor could be considered a writing tool for those students who have writing difficulties where compensation for disabilities becomes more appropriate).

According to Sharpe, Johnson, Izzo, and Murray's (2005) research, students with disabilities ($N = 139$) identified the following AT products or devices that they were generally satisfied with: scanner (35%), talking books (20%), portable note taking (17%), text help software (15%), optical character recognition (14%), specialized tape recorders (12%), voice recognition (12%), mouse/switch options (10%), adapted workstation (10%), word prediction software (9%), talking dictionary (8%), screen readers (6%), adapted keyboard (6%), screen magnification-software (5%), real-time captioning (5%), screen magnification-devices (4%), pointer (4%), talking calculators (3%), Braille note takers (3%), assistive listening devices (3%), speaker phones (3%), video captioning (3%), hearing aides (1%), and augmentative communication (1%).

FUTURE TRENDS

Currently, AT is used primarily as an equalizer—a compensatory tool—and on occasion applied *universally*. As institutions of higher learning become more willing to develop a universal design approach to educating, the need to provide separate accommodations for those individuals with disabilities will diminish (Campbell, 2004). One of the principles with respect to AT that can be applied universally, it is important to develop a *technology curriculum* that is based on universal design principles (to improve skill areas, such as reading, writing, organization, note-taking, and using the Internet particularly); doing so definitely sets the educational foundation for all learners within the classroom environment (Copenhaver, 2004).

Colleges and universities could develop an interdepartmental curricula and students from each target audience could attend and learn how interdependent they are in serving the AT needs of students and adults, and, according to Osborn (2006), this would insure that participating students: (1) gain an awareness of AT services and devices, (2) understand the principles of universal design, and (3) know about federal and state laws that impact rights to AT devices and services. In the near future, knowledge of AT may become a requirement for licensing.

Telematic multi-disciplinary AT is essentially ICT or e-learning (video conferencing and the Internet, for example) and offers to many the solution to common obstacles associated with attending educational courses, such as classroom and lecture availability, and lack of adequate transportation. Traditional higher education will increasingly adopt greater components of e-learning. As Turner-Smith and Devlin (2005) maintain, e-learning has enormous potential for use as a component of AT education; AT will be increasingly recognized as an umbrella term for any device or system that allows individuals to perform a task they would otherwise be unable to do, and that increases the ease and safety with which the task can be performed.

CONCLUSION

Currently there are over 20,000 items classified as "AT devices," for all disabilities, all ages, and all levels of functioning; AT can help individuals *talk, write, move, see, read, and hear* for themselves (Center for Innovations in Special Education, 2002). The devices range from low-tech supports (large pencils for writing, and calculators for building math skills) to high-tech supports (specialized software, and voice-output communication devices). Since each student's technology needs are unique, the support necessary for implementing technology requires a variety of

types of AT awareness training for teachers and other educational professionals. Such awareness training could be provided as a staff in-service training under the institution's comprehensive system of personal development plan under IDEA (Copenhaver, 2004).

In the final analysis, a major challenge is to move decisions about technology applications to the point where they reflect a state of the science; such technology applications must be studied continuously in objective ways so that educators can make informed decisions about their AT selection to best meet the needs of individuals with learning disabilities (Blackhurst, 2005).

KEY TERMS AND DEFINITIONS

Adaptive Technology: The use of hardware and software to assist individuals who have difficulty accessing information systems using conventional methods. It often refers to assistive technology.

Early Intervention Services: A program of activities and services, including assistive technology, required by the Individuals with Disabilities Education Act for children from birth through age two.

Learning Disabilities: Conditions that cause people to understand and process information more slowly than average. These individuals may require information to be presented in multiple formats before they completely understand it.

Multisensory Learning: An instructional approach that combines auditory, visual, and tactile elements into a learning task. Tracing sandpaper numbers while saying a number fact aloud would be a multisensory learning activity.

Prereferral Process: A procedure in which special and regular education teachers develop trial strategies to help a student showing difficulty in learning remain in the regular classroom.

Special Education: Specially-designed instruction to meet the unique needs of a student with disabilities including but not limited to instruction conducted in the classroom.

Universal Design: Designing programs, services, tools, and facilities so that they are usable, without additional modification, by the widest range of users possible, taking into account a variety of abilities and disabilities.

Chapter 5.5

Cognitive–Adaptive Instructional Systems for Special Needs Learners

Bruce J. Diamond

William Paterson University, USA

Gregory M. Shreve

Kent State University, USA

ABSTRACT

This chapter provides a perspective on the problems, challenges, and unique opportunities faced by instructors and designers of information technology in helping students who are differently-abled learn more effectively in online environments. The proposed solution is provided in the form of a cognitive-adaptive instructional system. This system provides menu-driven adaptive options or online assessments that evaluate a student's cognitive and sensory needs. These needs are translated into cognitive-sensory profiles, which are linked to compensatory and remedial actions. These actions render content automatically and dynamically in ways that provide adaptations that compensate for a student's special-needs while complementing their strengths.

DOI: 10.4018/978-1-60960-503-2.ch505

CHAPTER OBJECTIVES

This chapter should help the reader:

- Better understand the nature and extent of the problems faced by special needs learners
- Better understand the interrelationships between cognitive and sensory impairments and their potential impact on participation in online learning communities
- Understand the importance of integrating adaptive instructional capabilities into online instructional models
- Understand the key technical concepts underlying the cognitive-adaptive instructional system and identify potential applications

INTRODUCTION

Recent decades have seen significant advances in the design and implementation of hardware and software for delivering online and computer-assisted instruction. Educational applications of information technology are increasingly integrated into a diverse array of devices, from personal digital assistants and cell phones, to laptop and desktop computers. They are deployed in a dizzying variety of forms, ranging from broadband distance learning to CD-based instruction and digital textbooks. Information technology is increasingly the primary instructional vehicle for a number of application areas including basic skills training in companies, educational telemedicine, military training, and, of course, the delivery of K-12 and college curricula.

At the same time that this technological infrastructure is developing, our understanding of the pedagogy of online and computer-assisted instruction is rapidly increasing. As a result, more and more individuals participate successfully in innovative learning environments that are partially or wholly computer-based and increasingly delivered online. As we learn more about how students learn online, we can develop increasingly sophisticated and effective instructional models to inform and guide more effective instructional information system design. One population at risk in this new digital learning environment is students who have inherited or acquired cognitive and sensory impairments. These impairments may interfere with a student's ability to access and learn subject matter in both traditional and in digital information rich environments. These special needs students will challenge our ability to translate educational and cognitive remediation theory into practice and into the design of more intelligent online educational technology systems.

Therefore, the goal of this chapter is to provide a context and rationale for the need to develop and use adaptive instructional systems in order to help students, especially those with learning

disabilities (LDs) or deficiencies in basic skills or academic achievement, to learn more effectively. In order to achieve the goal of providing effective online instruction to diverse user populations, a cognitive-adaptive instructional system that uses adaptive hypermedia is proposed. The ways in which this system can be used to accommodate a diverse range of cognitive and sensory impairments and skill deficiencies will be described. In explaining how this system can be implemented, new Web-based information technologies will be discussed. In addition, examples of online applications of adaptive models will be provided in order to demonstrate that such a practice-based system can help meet the learning needs of special students.

BACKGROUND

Special needs individuals at risk in digital learning environments are of all ages and at all developmental stages. They become cognitively "differently-abled" due to the effects of aging, accidents (e.g., traumatic brain injury), disease, or specific developmental or inherited neurological conditions. Many of these individuals are often left behind in traditional classroom environments. The failure to provide for their information processing and learning needs in online and other digital environments will only widen an educational and social participation gap that already threatens their full inclusion in 21st century life. If we do not address the problems and special needs of such differently-abled users, we will help promote the development of a generation of digitally disenfranchised individuals who are not able to participate equitably in technology-mediated educational, cultural, social, and economic communities. The effectiveness with which issues relating to the accessibility and utility of digital environments by the differently-abled are addressed will critically impact the role that information technology will play for these populations now and in the future.

Instructional models and information architectures for learners with special needs must provide mechanisms that dynamically adapt the information delivery interface as well as the organization and presentation of instructional content to the learner's unique cognitive-sensory impairment profile. Such "cognitive-adaptive" instructional information systems have the potential to optimize information delivery for such users and maximize the efficacy of instruction to the greatest extent possible. A significant issue in online instructional modeling for special needs populations will be creating adaptive online instructional systems that integrate clinical and educational evaluations of a learner's cognitive and sensory impairments with instructional heuristics. These heuristics will then drive specific adaptive and "compensatory" information system behaviors at the human computer-interface.

Learning Disabilities in Context

Cognitive-adaptive instructional systems must be understood against the background of an increasing use of digital resources for educational purposes and an increasing population of special needs learners with low academic achievement, basic skill deficiencies, and learning disabilities associated to cognitive impairment. The impact of digital information delivered via the Internet to all students is dramatic. Ninety seven percent of 12- to 18-year-olds use the Internet, with 61% reporting the Internet "very" or "extremely" important as an information source compared with 60% for books and 58% for newspapers (UCLA, 2002). Moreover, "having access to the Internet and its rich resources...is having a positive impact on student achievement" (eSchool News, 2003).

However, the number of students diagnosed or classified with specific learning disabilities has also increased by 34% since 1990-91 (OSEP, 2001). Learning disabilities can occur in one or more areas of language development, reading, memory, mathematics, reasoning, and problem

solving. Impairments contribute to lower levels of school achievement than would be expected based on intelligence. The prevalence of LDs in the United States is estimated to be up to 6% of the school children aged 6-18 (Lewitt & Baker, 1996), translating into approximately six million children. Given that 11 million children and adults have learning disabilities, it is one of our most prevalent developmental disabilities (Reiff & Gerber, 1994). Overall, learning disabilities cost the nation an estimated \$50 billion in the 1999-2000 school year alone (Chambers, Parrish, & Harr, 2000). Fifty one percent of students receiving special education services in public schools have learning disabilities (OSEP, 2001), and almost one in three college freshmen with disabilities report a learning disability (Henderson, 1995). The National Institute of Child Health and Human Development (NICHD) longitudinal studies indicate that of children who are reading-disabled in the third grade, 74% remain reading disabled at the end of high school. In other words, learning disabilities can impact performance in and out of the classroom throughout a person's lifetime.

Educational models for dealing with special-needs students are sometimes driven by instructional, diagnostic, and assessment techniques that emphasize deficits rather than the creative abilities and resources special needs learners already possess. Talents and abilities are simply not recognized. The interventional efficacy of deficit-oriented techniques is low (Coles, 1987; Poplin, 1988a, 1988b). As early as 1983, Gardner widened our view of intelligence to include the idea of "multiple intelligences" (e.g., linguistic, logico-mathematical, musical-rhythmic, visual-spatial, bodily-kinesthetic, interpersonal, and intra-personal). Among students with learning disabilities, four areas of multiple intelligence strength have emerged: conceptual writing, divergent thinking, computer aptitude, and musical ability. In divergent thinking skills, LD students are at least as able as students with no learning disabilities (NLD), as measured by the test

of divergent thinking and the test of divergent feeling. In some cases, LD students have scored higher than their NLD counterparts on measures of figural and verbal creativity, such as the Torrance test of creativity and the alternative uses test (Tarver, Ellsworth, & Rounds, 1980). Stone, Poplin, Johnson, and Simpson (1992), reported no difference between elementary school LD and NLD students with LD students actually scoring higher than NLD students on many of these measures.

These areas of multiple intelligence strength, especially computer aptitude, create a promising foundation for educational intervention models for special needs learners using computer-assisted and online technology. On tests of computer aptitude that do not require complex linguistic skills, such as the computer aptitude, literacy, and interest profile (Poplin, Drew, & Gable, 1984), Hearne, Poplin, Schoneman, and O'Shaughnessy (1988) reported that students with LD had computer "aptitudes" equivalent to those of their non-disabled counterparts with no gender differences noted. This is relevant to cognitive-adaptive systems, as it suggests that having learning disabilities due to cognitive-sensory impairments will not necessarily preclude a student from using and benefiting from instructional systems. However, as computer systems are increasingly used in online learning environments, more complex cognitive operations and skills will be needed in order to effectively use these learning tools.

Cognitive Impairments, Learning Styles, and Instructional Technology

The development of adaptive instructional systems can be especially challenging in certain populations (i.e., older people) because they are less likely to have computer experience (Czaja & Sharit, 1998) and may lack the knowledge and skills required for interacting with computer search engines (Morrell, Mayhorn, & Bennett, 2000). Acquired neurological injuries, developmental

conditions, or declines in memory and reasoning skills due to aging can all adversely impact online information-seeking (Park, 1999) and digital library searching (Rousseau, Jamieson, Rogers, et al., 1998), resulting in less efficient search strategies (Mead, Spaulding, Sit, et al., 1997). Czaja, Sharit, Ownby, Roth, and Nair (2001) reported relationships between search and retrieval performance in older participants and cognitive abilities (e.g., processing speed, memory, and verbal speed). Westerman, Davies, and Glendon (1995) reported that older participants were slower than their younger counterparts in retrieving information (perhaps attributable to difficulty in recalling previous links and page information). Moreover, participants with low spatial ability also took longer in retrieving information. These challenges are not restricted to the elderly. Younger people (e.g., college students) with a variety of learning disabilities can exhibit similar impairments in information processing, working memory, and attention (Henderson, 1995). Glisky and Schachter (1988) demonstrated that by using self-paced and vanishing cue techniques even individuals with profound memory impairments could learn how to use computer-based systems (although they might not remember the specific learning episode afterwards).

The areas of memory, attention, executive function, information processing, and higher-order thinking skills are emphasized in the cognitive-adaptive approach because these cognitive domains involve skills that mediate student success in school-related tasks that require information manipulation and processing. In other words, these skills are used in reading and textbook comprehension, attending to class lectures, writing and thinking effectively, and using instructional and information technology tools. Thus, effective approaches for modeling user behavior in impaired individuals should involve educational and clinical assessments of these cognitive domains and result in compensatory actions whose effectiveness can

be demonstrated empirically to have an effect on the performance of learning behaviors.

Helping Special Needs Students Learn: Meeting the Challenge

The challenge is that the cognitive impairments that impede students' academic progress in the classroom can also impede their ability to effectively use more complex information technology tools and resources. However, as previously stated, we can build on some of the demonstrated strengths in computer use exhibited by special learners, but we must also be cognizant of the challenges. For example, school-aged children with mild to moderate learning disabilities exhibit impairments in working memory compared to children of average ability. Impairment is more severe with increases in task and content complexity (Bayliss, Jarrold, Baddeley, & Leigh, 2005). The generalized working memory deficit in LD students has been attributed to storage constraints in the executive system (Swanson, 1993). Inefficient decoding and word recognition skills during the reading process can also reduce attention and memory resources, with comprehension impeded by poor verbal recall (Stothard, 1994). Problems in speed of processing, processing verbal and visual-spatial material, organizing information, and multi-tasking can have a devastating impact on functioning both in and out of the classroom, but especially in the use of complex information displays and user interfaces.

TOWARDS THE SOLUTION

If special needs learners are going to be able to use information systems in educational contexts, including digital libraries, learning object repositories, and widespread educational technology delivery systems such as Blackboard, WebCT and Vista, we must develop systems that are adaptive enough to respond to specific learning disabilities.

Educational materials and information delivery systems are generally not designed to meet these special needs. If an instructional application for learners with cognitive impairments and sensory impairments is properly designed, it should be able to quickly and effectively provide personalized information display and educational content packaging. This information would be reflective of the learner's cognitive strengths as well as their impairment profile so that the learning environment can fully or partially compensate for deficiencies in cognition through dynamic system adaptation of content and display. The following sections provide a more technological discussion of current information technologies that will be used to design and build a more flexible and adaptive instructional system.

Accessibility and Adaptive Systems: Current Technologies

The impetus underlying the development of cognitive-adaptive instructional systems is that implementation of compensatory information delivery techniques will enhance educational outcomes for learning-disabled users. Recent developments in the core Web protocols and data formats including the extensible markup language (XML), cascading stylesheets (CSS), extensible stylesheet language (XSL), scalable vector graphics (SVG), and the synchronized multimedia integration language (SMIL) have provided a technological infrastructure capable of supporting innovative new information delivery systems for learning disabled populations with cognitive impairment.

Many of these protocols (XML, SVG, SMIL) are "markup languages." A markup language is a way of using simple text-embedded codes to describe the structure and semantics of documents. XML, for instance, provides a generic mechanism for describing the content of almost any kind of document, while SVG is oriented toward describing, creating, and controlling the appearance of

online graphics. SMIL allows for the integration of multimedia properties with XML and SVG documents. Documents containing markup codes can also be attached to “stylesheet languages” (CSS, XSL) that provide instructions that tell computers how to handle and display the contents of a marked-up document. A basic objective of markup languages is the separation of content from display. A document’s content may be described just one time using XML, but then presented in multiple different presentation formats simply by assigning new stylesheets to it. In addition to greater flexibility in the presentation and display of documents, a new level of interactivity and dynamism can be added to digital documents through the use of the “document object model”(DOM). The DOM is an Internet browser technology that allows for the attachment of server and client-side scripts (small programs) to documents. For example, the DOM allows an instructional designer to assign a script creating a popup message to a section of a document. The message would appear whenever a mouse is moved or clicked over the section. The combination of scripts and DOM can dynamically access and update the content and structure of HTML (hypertext markup language) and XHTML (extensible hypertext markup language) and XML documents. The new World Wide Web Consortium (W3C) XML-Events specification makes the online document interface even more dynamic, providing for the association of specific DOM document behaviors with XML-based markup languages and content, thereby separating document content from scripting.

These technologies for separating content from on-screen behavior, presentation, and display can be used to specify how to render underlying content markup for multiple information appliances and multiple user groups “on the fly.” The modality specifications (which information appliance) and presentation specifications (organization and appearance) for the document are provided at the moment the document is invoked. The document perceived by the user at the human-computer

interface is “rendered” dynamically in real time. This on the fly capability is particularly critical in the development of adaptive online systems since it allows for the dynamic tailoring of Web content to individual needs.

Many of the new protocols also include so-called accessibility features. For instance, the newest CSS specification includes several accessibility features such as dynamically generated content, aural stylesheets, and access to alternative representations of content that could be used to great effect with differently-abled populations. One interesting example of how current online technology helps address users with special needs is the W3C recommendation XHTML+Voice Profile that combines the VoiceXML markup language with XHTML and XML-Events to allow voice output from Web pages and voice reaction to page events. If these technologies are used in combination with cognitive adaptive models, they offer the instructor the capability to alter content, presentation, and pedagogy in flexible ways that respond to individual student needs, strengths and weaknesses. Taken together, it seems clear that the foundation for more accessible and adaptive systems has been established.

A Global Perspective

In fact, there are a number of initiatives that have tried to address the issues of online information accessibility for those with cognitive and sensory impairments. For instance, in addressing the needs of those with sensory impairments the CAPS (Communication and Access to Information for Persons with Special Needs) project of the European Union’s Directorate for Telecommunications, Information Industries and Innovation focused on visual (reading) impairment by providing broader access to digitally distributed documents, especially newspapers, books, and public information. The follow-up HARMONY (Horizontal Action for the Harmonization of Accessible Structured Documents) project tried to improve the quantity

and quality of documents accessible to the reading impaired by focusing on standardization issues, for example, population needs and compensatory actions that could or should be taken by information systems.

The Federal Government of the United States is also increasingly committed to improving the accessibility of information technology and Web-based information (i.e., Section 508 guidelines from the Architectural and Transportation Barriers Compliance Board of the U.S. Federal Government). In addition, the World Wide Web Consortium has launched a large-scale Web Accessibility Initiative (WAI), and there have been numerous calls for information system and software design to subscribe to “universal design” principles—the notion that design methods can be developed and applied so as to make “products, communications, and the built environment” more usable by more people (Aslaksen, 1997). The W3C recognizes accessibility barriers for the deaf, the blind and those with physical disabilities, and argues that “people with cognitive or neurological disabilities may have difficulty interpreting Web pages that lack a consistent navigation structure or that lack visual signposts” (Chisholm, Vanderheiden, & Jacobs, 2001).

This is an implicit recognition that the next step in online document design and online instructional modeling is to deal with the more “invisible” cognitive impairments associated with learning disabilities. Over the last decade, the hypertext markup language-based World Wide Web has become the nation’s premiere educational resource. However, using simple HTML documents as educational tools poses serious accessibility problems, particularly if documents need to be displayed using alternate modalities (Flammia, 1997). The mere digitization of documents does not ensure their accessibility or utility. Solving accessibility problems can involve difficulties in any number of areas including extracting content from format (a necessary first step in alternative presentation) and exerting finer more dynamic

control over non-textual content (audio, video, images). New technologies, such as XML and XSL, provide more opportunity for overcoming these obstacles to accessible design than simple HTML can offer.

While the European initiatives have focused on visual processing impairments, they emphasized two important issues with broader implications for cognitive-adaptive design: (1) the increasing “digitization” of information previously delivered in document form (including Braille for the vision impaired) has created online accessibility problems, and (2) the need to develop standard protocols and formats for representing and displaying digitized information.

Developing and Implementing Cognitive-Adaptive Instructional Systems

The great potential of cognitive-adaptive systems derives from the integration of advances in applied cognitive and clinical neuroscience with recent developments in online information technology. What design considerations need to be addressed in order to combine these two areas of research to benefit special need populations?

We argue that information can be made more accessible if several conditions are satisfied in the information delivery system: (1) educational content is separated from presentation and display information and stored as “user neutral” learning objects in an object library, (2) there are methods for acquiring and protocols for representing relevant cognitive impairment data in XML-based cognitive user profiles, (3) there are standard protocols for attaching cognitive user profiles to sets of adaptive and compensatory actions that systems should make when rendering educational content at the human-computer interface, and (4) appropriate online technologies exist for implementing the adaptive actions implied by the profiles.

Design Elements of a Cognitive-Adaptive Instructional System

The recent appearance of World Wide Web Consortium standard core protocols like XML and XSL makes a learning-adaptive Web increasingly possible by satisfying the previously mentioned fourth condition. It remains only to satisfy the first three conditions. The first design element of a cognitive-adaptive system involves the creation of learning objects via decomposition and metadata description. Learning objects have several unique characteristics: (1) they are atomic and self-contained, decomposed from objects of greater complexity, (2) they are reusable “in multiple contexts for multiple purposes,” (3) they can be recombined to create larger, more complex structures including lessons, courses and curricula, and (4) they are described with metadata about their educational function, physical characteristics, semantic content, and other relevant properties (Chitwood, 2005). Once created, learning objects are stored in an object library (OL) as a set of elementary resources capable of dynamic recombination with other objects under the influence of the rules of an instructional model.

Some objects may already be atomic, with little or no internal structure and may not be decomposable into smaller information units. In these cases, it is sufficient to describe the resource, for example, a particular image, with metadata and store in the object library. Many other existing instructional objects, on the other hand, are information containers, with both a complex semantic structure and a complex internal “document” organization. That is, they are structurally and semantically decomposable. An example of educational content that would have to be decomposed for use in a cognitive-adaptive system might be an online biology lesson whose organizational structure would consist of headings, paragraphs, figures, tables, and graphics, and whose content would have to be decomposed into special vocabulary or terminology, concepts, concept relations, proper

names, and a myriad of other semantic properties and relationships.

Even as the educational materials are stripped of formatting information to become as user and culture-neutral as possible for display purposes (Cannataro, Cuzzocrea, Mastroianni et al., 2002), they are enriched with both educational metadata and content description metadata. Educationally relevant metadata can be provided by an object schema such as the IEEE LTSC 1484.12 Learning Object Metadata (LOM) protocol. This metadata specification provides a rich set of descriptors for describing the core characteristics of the resource (identifier, title, author, description) as well as a wide range of other characteristics from rights management through educational uses, to technical information. The LOM specification also provides a rich annotation mechanism to allow users of the library to add commentary to the resource record as well as a relationship mechanism that allows any given LOM-described resource to be linked to other resources (Shreve & Zeng, 2003).

Content Description

Content description of the objects in an object library can be accomplished with metadata derived from existing or custom domain-specific semantic markup languages. The domain specific markup languages chosen to describe content elements in a cognitive-adaptive system would be dependent, once again, on the pragmatics of object library use, that is, what the library’s user communities expect to do with the resources and what functions they expect the resources to serve. The tag names, attributes, and document type descriptions or schema provided by a markup language directly reflect a domain-specific semantics and pragmatics. Markup languages are the single most important way that an explicit semantics can be applied directly to natural language and multimedia resources (Shreve & Zeng, 2003). Cognitive-adaptive systems will undoubtedly leverage many existing semantic (content) markup

languages, depending on the field of the educational materials to be delivered (for instance, MathML the mathematics markup language or GML (geography markup language). Markup languages to represent the user profiles and other elements of the cognitive-adaptive system will have to be borrowed or customized.

User Profiles: Determining Individual Learning Needs

Assuming an object library is successfully created, the next step in designing a cognitive-adaptive system would involve acquiring and storing user models or profiles. Current research in adaptive hypermedia systems (De Bra, 1999), user modeling (Brusilovsky, 1994; Fink, Kobsa, & Schreck, 1997; Hothi & Hall, 1998), and Web accessibility (Velasco & Mohamad, 2002) has provided useful guidance in designing systems to make instructional content more accessible to learning disabled students. This research emphasizes the importance of coupling user profiles with adaptive information system design. Current adaptive approaches typically modify navigation support and document content for individuals or target populations based on a user model most often developed empirically by observing patterns of use and browsing behavior (De Bra, Brusilovsky & Houben, 1999; Wu, de Kort, & De Bra, 2001). However, because this approach implicitly presumes that cognition is within normal limits, it cannot account for and differentiate user behaviors that are due to cognitive impairment, as opposed to simple preference or idiosyncratic work style.

We propose an approach based on specifying a set of empirically-derived “best practice” adaptations (a *prescription*, if you will), offered by cognitive and educational remediation experts after evaluating the results of educational and neuropsychological assessments. This prescription can (and should) be later refined with a customization wizard and modified with data gained from

the empirical observation of the actual behavior of cognitively impaired user-learners.

It is not uncommon for sensory impairments to be dealt with by information system actions based on user profiles. For instance, “visual profiles” for low-vision computer users meet the need to account for visual impairments of acuity, contrast sensitivity, color perception, and field of view when designing human-computer interfaces (Jacko, Rosa, Scott, et al., 2000). Although existing systems can use profiles to alter elements of the user interface including site navigation, organization, and content to support visually impaired users, more flexibility, and innovation is needed in order to remediate less visible cognitive impairments. Few if any studies have focused on building systems that integrate more complete and complex cognitive impairment user profiles with online information systems.

Successful cognitive-adaptive systems are dependent on robust user profiles to generate the parameters for determining the specific compensatory modifications to be made at the computer-human interface, for example, the architecture of the presentation or display, as well as to control the re-packaging of educational content delivered in digital documents. Cognitive user profiles could be based on combinations of online and in-person clinical and educational assessments of learners diagnosed with cognitive impairments and specific learning disabilities. The assessments, consisting of neurocognitive and educational screens, will measure, among other capacities, memory, executive function, and cognitive information processing. The assessments could also include measures of mood, anxiety, computer aptitude, and creative or divergent thinking.

Automated User Profile Development

A significant issue in the design of adaptive systems is determining exactly what remedial or compensatory actions to take for a given set of impairments and how to derive the actions and

their representations in a practical, automatic manner. Initial test systems will have to rely heavily on standard educational and clinical empirical research with prototypes in the hope of gathering data that can be used to establish principles that would enable systems to do online assessment, generate user profiles, and then automatically generate action models.

User profile acquisition could be accomplished by the development of a modeling wizard to acquire additional user cognitive/sensory impairment data from online dialogs and/or browser modeling and represent it in a machine-usable XML-based metadata format. The wizard could elicit educational and clinical profile information to supplement the data collected in off-line assessments. The wizard would also process the data in off-line assessments and convert it to XML data. The profiles generated by the wizard provide a basis for determining optimal adaptive information delivery and display. The wizard might also include some “exemplars” of differently presented or formatted online information to gauge user reactions and preferences. An important research objective will be to determine the optimal requirements and content for a cognitive profile wizard including the correct mixture of cognitive-sensory assessment and exemplar presentation.

The results of neurocognitive and educational assessments would be stored in an XML-based user profile, using, where possible, data elements derived from the clinical document architecture (CDA) (Health Level Seven, 2002). In cases where appropriate data elements do not exist, they would be developed as subsets or extensions to the CDA. In any case, an ongoing area of research in cognitive-adaptive systems will be working with the neurocognitive and educational assessment community to develop a markup language to represent the relevant data.

The representation and storage of user profiles are well discussed in the literature (Fink, Kobsa, & Schreck, 1996; Kules, 2000; Velasco & Mohamad, 2002) and a variety of approaches are offered. We

adopt the broad model described by Velasco and Mohamed, who suggest storing user profiles as XML schema, with the exception that we specify CDA conformance. The authors also suggest merging user information with device information in a single schema that follows, where possible, the guidelines for device profiles.¹

Action Models and Compensatory Action Heuristics

Once a user profile is generated from an assessment battery, it remains to specify the set of adaptive compensatory actions the system should take for specific configurations of impairment or skill deficiency. The pairing of neurocognitive assessments with information system action is a complex scenario referred to as a cognitive-adaptive “action model” and characterizes the relationship between cognitive impairment and remedial or compensatory system actions (Diamond, Shreve, & Johnston, 2001).

The heuristics of the cognitive-adaptive action model are represented as rules. In the database they are stored as XML statements that express the relationship between configurations of educational assessments and compensatory action in general production rule form: **IF***this-educational-result***THEN***this-adaptive-action*. The head of the rule is an XML-expressed cognitive impairment pattern and the tail is a set of actions also expressed in XML, including attachment to XML-Event behaviors, CSS, XSL and other stylesheet rendering technologies. The use of production rules for this purpose is an adaptation model as described by Cannataro and his colleagues (2002).

The action recommendations in the action models are linked to specific adaptive system actions via the adaptive control language (ACL), (i.e., the set of conventions that express the production rules). The heuristics underlying the action models are stored in cognitive adaptation (CA) and sensory adaptation (SA) databases that contain action instructions describing generic system

actions and adaptations addressing impairments in a variety of cognitive/sensory domains. These adaptations provide instructions for how learning objects are to be expressed, organized, configured, formatted, and manipulated for the benefit of a specific class of user impairments or disabilities. There are also instructions that inform the system how to react to particular events in the document/user interface.

The ACL connects the results of the cognitive profiles generated by the user profile wizard to the adaptive heuristics of the CA/SA databases and to the set of educational objects (resources) to be displayed. The heuristics are expressed by the ACL at the system level by XSL (eXtensible Stylesheet Language) transformations of XML-based object/action representations derived from the CA/SA databases as modified by the profile wizard. The ACL produces system responses such as reorganization of the user interface; changes in rate of presentation of visual materials; dynamic selection, presentation, and linking of content; alteration in the configuration and organization of “information units;” and so on.

Taken together, the ACL specifies the relationship between cognitive, sensory or functional impairment and remedial or compensatory system actions (Diamond, Shreve, Bonilla, et al., 2003; Diamond et al., 2001). To the extent that users with similar impairments may require similar adaptations, it should be possible to group adaptive rules into categories reflective of clusters of recommended actions for particular user groups, creating what Brusilovsky has called user stereotypes (1996). To this point there has been little attempt in the user modeling community to address automated mechanisms for deriving adaptation models appropriate for complex cognitive and sensory impairment conditions. Other approaches that could be applied include deriving stereotypes (Rich, 1979) and inferring dynamic modeling rules from the data using acquisition heuristics as discussed by Ardissono and his colleagues (Ardissono, Console, & Torre, 1999).

Compensatory Actions, Cognition, and Educational Applications

Individuals with short-term memory impairments, for instance, could be expected to experience difficulty in memory of previously-visited links or for the content of dropdown menus and their submenus. A CA-stored instruction for such cases would spell out the “performance implications” of this class of impairment and detail the general system steps that could be taken, such as alternative presentations for links or dropdown menu information.

In order to help improve learning and accessibility, the relationships between impairments and the ability to use an information system need to be delineated. Diamond et al. (2003) demonstrated that there are important relationships between the severity and nature of cognitive impairments and the ability to use information technology. The most important finding in their study was that while all participants learned how to use a telerehabilitation system (referred to as the VRC or Virtual Rehabilitation Center), the rate of learning or the number of “trials to acquisition”

Figure 1. Schematic of an adaptive system

varied among participants with traumatic brain injuries. Individuals who needed more trials to acquisition were more impaired in visuo-spatial construction, reasoning-similarities and language repetition. Interestingly, 50% of those individuals who required fewer trials to acquisition and 75% of those who required more trials to acquisition exhibited impairments in memory. Thus, memory impairments were pervasive, but memory alone did not account for all of the differences in learning and accessibility.

The relationship between identified areas of cognitive impairment and performance on the VRC may be due to the implicitly normative information architecture of the VRC and other internet and computer-based systems that require impaired users with deficits in working memory and executive function (e.g., reasoning and organization) to process and store visual and auditory information (i.e., text, graphics, embedded or streaming audio and video) using displays that are ill-suited to them. Overall, the authors found that impairment in cognitive domains reflecting visual-spatial integration, memory, language processing, and executive-type functions inhibited learning efficiency and accessibility. The work underscored the need to link system design intended for differently-abled populations to individualized adaptations and compensatory actions.

Recent research has supported the contention that adaptations informed by clinical and educational assessments can be effective in improving task performance. Diamond, DeLuca et al. (2000) showed that using special software individualized processing speeds could be computed and used to help older adults achieve levels of performance accuracy that did not significantly differ from that of younger adults. These results demonstrated that a cognitive neuroscience-derived software tool could be used to help suggest efficacious compensatory actions that enhanced the ability of seniors with moderate cognitive and sensory impairments due to age, to process information more efficiently. Similar optimal processing

speeds could be integrated into computer-based learning systems so that information could be presented to student users in ways that enhance their processing and performance accuracy.

The REY-organizational and extended memory (R-OEM) protocol (Diamond, DeLuca, & Kelley, 1997) used an “executive prosthetic” (i.e., a cognitive assistive technique) that helped individuals with learning and executive impairments learn and recall complex visual information. This assistive technique helped enhance performance. It did so, by first guiding the decomposition of text, images, and graphics into simpler, more atomic elements, and then providing organizational structures or schemas for re-organizing the graphic and textual information in new ways that more effectively tap explicit and implicit memory. Generally, the decomposition of complex objects or behaviors, with the subsequent reintegration and synthesis of the parts into a whole, increases instructional effectiveness in treatment subjects and predicts the magnitude of treatment outcomes for higher-order cognitive functions (Swanson, 1999). In clinical tests, the R-OEM generated alternative displays of information that allowed amnesiacs to retain information over a 30-minute delay, a performance comparable to that of non-amnesiacs (Diamond et al., 1997).

In a cognitive-adaptive information system, analogues of R-OEM-based techniques could be used to implement a stylesheet-based “executive function” facilitator that displays complex text and images dynamically by building them up from simpler graphic and textual elements. These decomposed learning objects, stored as XML data, could then be rendered by an XSL stylesheet to produce a synchronized multimedia integration language (SMIL) document where relative positioning, and attributes and tags such as *begin* and *<sequence>*, as well as SMIL events (begin event, end event) could be manipulated to dynamically construct more complex presentations according to the results of the protocol. SMIL presentations, essentially dynamically constructed multimedia

presentations, could dynamically present information in the manner prescribed by an R-OEM-type informed representation schema.

Another example of adaptive, computer-based techniques derived from cognitive and clinical neuroscience work are the auditory threshold serial addition test (ATSAT), visual threshold serial addition test (VTSAT) and the dual task (DT) protocol (Diamond et. al., 1997; Diamond, DeLuca, et al., 2000). These protocols quantify processing speed while controlling accuracy and they have been implemented with clinical populations (stroke, traumatic brain injury, chronic fatigue syndrome, and multiple sclerosis). These programs measure speed and accuracy and determine the optimum speeds at which both visual and auditory information can be presented while maintaining a given level of performance accuracy. Dual task software is used to measure a subject's ability to process simultaneous streams of information presented in both the visual and auditory modes. Taken together, these programs assesses the impact of the single and dual processing of information streams on working memory, sustained attention, accuracy of performing arithmetic operations, and on reaction time. These techniques could be used to enhance a user's processing speed and accuracy by incrementally altering the computed optimum speeds and stimulus parameters of, for instance, the presentation of text online or the speed at which voice or video information is displayed. In other words, information could be both visually and aurally presented at individualized and optimized speeds of presentation, thus enhancing processing efficiency. The dynamic adaptation of a display, including speed/duration of text, graphic, or auditory information display could be controlled by using XSL stylesheets to generate multimedia SMIL documents and then controlling the value of the SMIL *duration* attribute for individual page elements to control how long they appear on the screen.

Adaptive action models based on semantic activation techniques also arise out of research

in the fields of neuropsychology and behavioral neurology (i.e., prosopagnosia and visual agnosia, or the inability to recognize familiar faces and objects, respectively). Diamond and his colleagues describe another adaptive approach using the semantic activation protocol (SAP) protocol, where faces or objects drawn from similar semantic categories helped enhance and activate aware memory in a prosopagnosic patient (Diamond, Valentine, Mayes, & Sandel, 1994). In this research, it was shown that clustering faces/objects according to semantic categories induced a sense of familiarity and recognition. Similar types of semantic activation techniques could be used in educational systems to optimize learning and memory.

For example, a cognitive-adaptive information system could enhance memory for images and objects by visually clustering or navigationally linking information stored in XML-based semantic network representations or content schema. Using XSL stylesheet-generated SMIL documents, items could be dynamically clustered in visual regions of a presentation using the SMIL <layout>, <root-layout> and <region> tags. Similarly, semantic categories (semantic information would have to be stored in the content schema) could be used to organize links between dynamically created displays to capitalize on semantic similarity.

Perceptual priming protocols can also play a role in cognitive-adaptive systems. These protocols are based on the observation that information (words or images) that have been previously experienced can exert an effect on subsequent behavior or physiology (Diamond et al., 1994). Thus, while the specific learning episode may not be remembered, information can still be encoded and subsequently alter performance (i.e., perceptual fluency) (Johnston, Dark, & Jacoby, 1985). Improvement in performance as a result of prior exposure can be measured by reaction time protocols that indicate changes in saliency of learning (i.e., faster reaction time with learning) or faster relearning of material. In a cognitive-

adaptive system, a priming reaction time (PRT) protocol could be used to measure the saliency of implicit and explicit learning as well as the speed of making perceptual-semantic decisions by determining if RT decreases or information processing speed increases following instruction. The results could be used to create XSL-generated “priming pages” for important content elements, which over repeated presentation and display could assist special needs learners in representing and storing information.

There are also modality-based processing differences between individuals that have an important bearing on the design of adaptive systems for the cognitively impaired learner. Some individuals display faster visual versus auditory processing speed and some display reverse patterns (Diamond et al., 2000). A cognitive-adaptive system could provide modality-specific options. Similar content could be presented as text, as image, or as speech using the relevant multimedia SMIL tags and attributes. For instance, using the SMIL <parallel> tag, parallel text and voice streams could be simultaneously presented in a document and selection between modalities could be offered to the user.

An Online Educational Scenario

Clearly, a variety of tools and technologies are currently available for use in online instructional communities. These technologies, implemented in a cognitive-adaptive instructional system, can significantly enhance the responsiveness and adaptability of online learning environments to special needs students. Systems could allow instructors to provide dynamic control over most aspects of an online display, including: (a) speed and duration of information unit presentation; (b) organizational structure or layout of the page; (c) placement and clustering of visual or typographic elements; (d) sequence of presentation of visual elements; (e) adaptive navigation and linking to other content/displays; (f) graphic or typographic features: size,

color, font, and so on; (g) modality: text, image, voice, and (h) dynamic selection of page elements from underlying content. The system could also alter the rate at which information is presented; select memory and executive prosthetics; and alter the manner in which content and learning objects are to be expressed, organized, configured, formatted, and manipulated. The following is an example of an online scenario:

A student who is taking an online course in biology has had a mild brain injury. The current topic is the concept of *action potential* (AP). This topic includes information involving a variety of constituent concepts described in text (e.g., ion movements, resting potential, electrophysiological and concentration gradients, threshold of excitation, depolarization, hyper-polarization, and channels/gates), numerical and statistical information (tables, calculations), and visual material (images, movies, animations). The events that constitute the AP process occur in a specified sequence, and the event is usually described in narrative and then illustrated schematically in the typical textbook or Webpage. This static and normative presentation might not be the optimal display for a brain-injured student.

However, if the AP lesson document is first decomposed and described using an XML-based markup language, it would be possible to gain control of the appearance and presentation of the material in the lesson down to the level of individual words, sentences, paragraphs, illustrations, text, images, tables, and animations. This enhanced level of control could be used to optimize the individual learning experience if then connected to individual user profile information. The user profile information would allow: (a) for system presentation adaptations that would dynamically organize the visual and textual material in the lesson in ways that would compensate for executive dysfunction (i.e., deconstructing information into simpler units); (b) compensate for visual-conceptual integration deficits (i.e., simpler arrangement and sequencing of information via

alternative schematics or custom animations); (c) alter the modality of textual presentation in order to compensate for reading disorders (i.e., use auditory-based text); (d) alter the rate of information presentation (visual and auditory) in order to compensate for slower processing (often observed in individuals with learning disabilities and brain injury) or ; (e) provide linkages to specially designed learning objects with built-in memory cues (i.e., clustering of semantically-related objects) to compensate for deficiencies in working memory. Overall, control over these elements would provide a range of compensatory and remedial actions to help improve the educational performance of students with special needs.

CONCLUSION

Adaptive information systems provide an opportunity to broaden the participation of certain classes of differently-abled populations in learning environments that depend heavily on information technology, such as Web-based and distance learning. The challenges in developing instructional models for online adaptive systems serving special needs learners with cognitive and sensory impairments are considerable. The instructional models must deal not only with the diverse learning problems such users confront in “traditional” classroom environments, but also with the new challenges presented by online instruction. Adaptive systems must integrate new online technologies in ways that provide unique opportunities to enhance individual instruction and learning through the use of highly personalized pedagogical models.

Adaptive online instructional systems achieve the goal of personalizing the content and delivery of information to the needs of individual learners by integrating educational and clinical evaluations of a user’s cognitive and sensory impairments with instructional heuristics. The combination of specialized heuristics and clinical assessment

data drives specific adaptive “compensatory” information system behaviors at the human computer-interface. Such adaptive interfaces act dynamically to modify information architecture and display in ways that address higher level cognitive processing deficiencies as well as altering formatting and presentation in order to address sensory-based needs. Using adaptive information systems to deliver educational content and services can make online learning environments and communities more accessible to individuals with inherited or acquired learning problems.

The implementation of an adaptive approach to instructional modeling offers a number of additional advantages. It affords both instructor and students a great deal of flexibility. The approach is practical and cost-effective from a technology standpoint. That is, the system can be implemented on any information system that implements the core World Wide Web (W3C) data formats and protocols. Because content is not rigidly linked to format, once heuristics and cognitive user profiles are developed, instructional content of all types can be automatically and dynamically adapted to an individual user’s special needs.

Overall, the cognitive-adaptive approach we have described enhances and expands our understanding of how computer-assisted and online instructional systems can be more effectively designed for special needs learners. As such, it makes a new contribution to an important area of online instructional modeling for special populations. Cutting-edge, cross-disciplinary work will help inform the development of instructional models that enable cognitively impaired learners to acquire, remember, and manipulate information more effectively. Such systems will broaden the participation of this underrepresented group in education and in knowledge-based communities. In this age of global communication, educators have an obligation to equip as many individuals as possible with the tools that will allow them to participate in the educational, social, and political fabric of contemporary societies. By integrating adaptive instructional system concepts into the broader area

of online instructional modeling, we can help empower differently-abled individuals to more fully use information technology and participate in an increasingly global educational community.

FUTURE RESEARCH

Future research must address a number of multi-disciplinary issues involving clinical research with special populations, accessible information system design, and models of online instruction for special needs learners. Scholars in cognitive neuroscience, neuropsychology, and online and special education need to conduct empirical research focusing on information technology usage and the human-computer interface. The research should detail how cognitive and sensory deficits associated with a variety of inherited and acquired neurological and learning disorders might be mitigated by adapting the organization, navigation, and display of digital information in specific ways. Clinical insights into the mechanisms, course, and impact of learning and sensory deficits are needed in order to develop more effective remedial and compensatory strategies for employment in adaptive information systems. Research should especially be directed at developing more valid, reliable, and economical online assessments of cognitive and sensory deficits that are accompanied by appropriate age, education and culturally-adjusted norms. These assessments must be represented in a markup language format that can be integrated with rule-based instructional heuristics that act to guide a system's adaptive responses. Adaptive system designers need to communicate more effectively with brain and behavior scientists and educational and rehabilitation specialists in order to translate research advances from diverse fields into effective heuristic algorithms that would satisfy a wide array of special user needs. Software application researchers must continue to develop standard software mechanisms, using available Web-based protocols and markup languages such as XML and XSL, to integrate clinical findings and

assessments, compensatory heuristics, and adaptive system action. Application research needs to focus on the goal of incorporating "universal access" principles that will help foster greater inclusiveness and system accessibility for special needs user by allowing for the creation of localized, personalized information system interaction and display. Finally, empirically based, randomized placebo controlled (RPC) trials need to be developed and executed in ecologically valid environments in order to evaluate the efficacy of adaptive models and identify areas of future research and development.

Chapter 5.6

Animated Computer Education Games for Students with ADHD: Evaluating Their Development and Effectiveness as Instructional Tools

Kim B. Dielmann

University of Central Arkansas, USA

Julie Meaux

University of Central Arkansas, USA

ABSTRACT

Children and adolescents with Attention Deficit Hyperactivity Disorder (ADHD) have difficulty maintaining attention, controlling their activity level, and they typically demonstrate poor interpersonal relationships skills. Because of their challenges, educational performance tends to suffer. Paradoxically, when seated in front of a videogame or computer program they enjoy, the performance of individuals with ADHD becomes similar to non-ADHD peers. The purpose of this chapter is to present a conceptual framework for understanding the factors that affect the outcome of individuals with ADHD, and to demonstrate how instructional design models can be used to guide the design and implementation of animated computer education games as instructional tools

for this population. Specifically, the FIDGE model and Gagné's Nine Events of Instruction are evaluated for their contributions to understanding the unique technological needs of the ADHD learner.

INTRODUCTION

Current estimates indicate Attention Deficit Hyperactivity Disorder (ADHD) affects 4% to 12% of U.S. children (Froehlich et al., 2007). Longitudinal studies suggest children who are diagnosed with ADHD continue to have difficulties with organization, time management, impulsive thoughts and actions, stress management, emotional regulation, interpersonal relationships, and academic skills such as reading, studying, and test taking as adolescents and as young adults (Barkley, Fischer, Smallish, and Fletcher, 2006). Children and adolescents with ADHD often struggle in

DOI: 10.4018/978-1-60960-503-2.ch506

traditional classrooms. Many fidget and have difficulty remaining in their seats, thus causing disruption to the classroom as well as to the child's own education. Even when children with ADHD are able to sit quietly, they often require multiple repetition in order to retain information they hear. Most teachers cannot pause to emphasize each individual fact to a child with ADHD while the rest of the class has grasped the material and moved on. As a result, adolescents with ADHD are more likely to drop out of high school and fail to complete college compared to their non-ADHD counterparts. Lower educational achievement often leads to underemployment, poor social adjustment, and decreased overall quality of life. To address these problems, a more engaging and personalized education format is necessary for children and adolescents with ADHD.

According to DuPaul and Stoner (2003), students with ADHD are educated more effectively if multiple mediators (peers, computers, and parents) are involved. They also recommend the intervention strategies be individualized particularly since the ADHD population is heterogeneous. According to the Centers for Disease Control and Prevention (September 2, 2005), 56% of all children ages four to 17 years diagnosed with ADHD were taking stimulant medications. Though medication is the most widely used treatment for ADHD, a combination of self-monitoring and self-reinforcement may have longer lasting effects. Barkley, Copeland, and Savage (1980) found this combination improved task-related attention, academic accuracy, and peer interactions. DuPaul, Rutherford and Hosterman (2008) suggested the use of self-monitoring and self-reinforcement particularly at the secondary level because there are fewer opportunities for this age group for token reinforcement, contingency contracting, or response cost.

Technological advances and the increased availability of technological resources afford most schools the ability to incorporate different types of instructional technology into the classroom. For students with ADHD, educational tools that

involve computerized technology offer a wider range of options for learning. The benefits of computerized presentation of information include the use of multiple senses, the breakdown of material into smaller pieces, provision of immediate feedback, and the limitation of unnecessary, distracting features (DuPaul & Weyandt, 2006). According to several studies, children and adolescents with ADHD are more attentive to computerized programs or interventions than to traditional instruction methods (Shalev, Tasal & Mevorach, 2007; Farrace-Di Zinno et al., 2001; Carroll & Bain, 1994). They also seem to respond better to interactive instruction than when they serve in more passive roles as listeners or viewers (Shaw & Lewis, 2005; Klingberg et al., 2005). Shaw, Grayson & Lewis (2005) found students with ADHD performed better and were more engaged by information presented in a game format than by regular computerized instruction. In addition, Farrace-Di Zinno et al. (2001) observed how students with ADHD were more similar to their peers without ADHD with regard to the amount of motor movement and distractibility during computer video game play.

According to Fister (1999), computer games can be used for primary learning of different subjects rather than just for review and reinforcement. Ota and DuPaul (2002) evaluated the effects of a game-based math software program on the performance of ADHD students. They found increased math performance, decreased off-task and disruptive behavior, and increased active engagement in the computer-based instruction compared to the traditional classroom lesson. Mautone, DuPaul, and Jitendra (2005) found similar math improvements in ADHD students. Oral reading fluency has also been the target of research using computer-assisted technology with ADHD students. Clarfield and Stoner (2005) found improvements in oral reading fluency and subsequent engagement in the activity when a computer-assisted reading program was used. While data suggest students with ADHD may

benefit from the use of computerized educational tools, it is important to understand what and how to appropriately integrate gaming technology into the classroom to improve learning outcomes for these students. In addition, it is imperative educators evaluate the appropriateness of such technology for use with all students. In this chapter, a conceptual framework for understanding the intervening factors that affect outcomes for people with ADHD will be discussed along with models to help educators design and evaluate the quality of computerized games for education purposes.

THE “GAME GENERATION”

Prensky (2001a) describes the most recent generation of children who integrate videogames into their daily activities as the “game generation.” He also coined the term “Digital Natives” to describe this generation’s approach to learning. Digital Natives routinely manage large amounts of information at one time, find alternative ways to acquire knowledge, and seek solutions through different means previously unavailable. Prensky (2001b) compared the digital natives to previous generations, who he named “Digital Immigrants”. The primary differences between the groups lie in how they approach learning. Digital natives prefer to multi-task. They prefer to “leap around” as they learn rather than sequentially process information (Prensky, 2001c). According to Prensky (2001c), children of this game generation “have been adjusting or programming their brains to the speed, interactivity, and other factors in the games” (pp.3). This generation of learners has also been referred to as “Generation M” for the group between the ages of 8-18 years who have never known a time without media (Rideout, Roberts, & Foehr, 2005). Other labels given to this generation of learners include “Generation I” to represent the influence of the internet in their lives or “Generation Z” to denote the generation following Generation Y (Schmidt & Hawkins,

2008). Despite their nomenclature, the generation of learners today is vastly different from previous generations. Prensky developed ten cognitive traits (Table 1) to describe the differences between children of the game generation and children of previous generations.

Twitch speed refers to the fast speed at which the game generation wants information presented. Classroom lectures and independent seatwork that occur at a slower pace can be frustrating and boring to this group who are accustomed to rapid presentation of information. Parallel processing refers to the randomness of responding, such as surfing the internet or completing game challenges in no specific order. The historic rules of reading textbooks and conducting research follow a sequential order and require systematic approaches. The game generation of children can become inattentive and disruptions may result. Graphic representations stimulate the game generation, while reading text may provide little inspiration for learning. The game generation wants to be connected at all times and they often feel as if they are a part of a community of gamers rather than lone players. This sense of interconnectivity can also stimulate negative behavior, such as cheating in school, because of the diffu-

Table 1 Differences in cognitive traits between children of the game generation and more traditional learners (Prensky, 2001a).

Game Generation	Traditional
Twitch speed	Conventional speed
Parallel processing	Linear processing
Graphics First	Text First
Random access	Step-by-Step
Connected	Stand alone
Active	Passive
Play	Work
Payoff	Patience
Fantasy	Reality
Technology as friendly	Technology as foe

sion of responsibility that accompanies. They are active participants who can impose change on their environments, and can become easily frustrated when placed in an environment where they have no control. Within the game environment, they experience immediate payoff, and many of these activities are fantasy-based. They do not simply use technology as a tool—they are immersed in it as an extension of themselves. Educators who are born of generations past (Digital Immigrants) have to engage the game generation with a different set of tools than what they learned in school (Prensky, 2001a).

Students with ADHD have always used cognitive traits similar to those described by Prensky. Yet, their approaches were viewed as disruptive to the learning environment. Twitch speed was considered hyperactivity and impulsivity. Parallel processing was viewed as disorganization. Connectedness was seen as attention-seeking. Play was considered inattention. Children with ADHD needed more from the learning environment than was available. Now, the needs of the game generation may actually be consistent with the needs of children with ADHD.

Caution has been stressed to adults who are interested in using gaming technology to teach children. There have been negative effects associated with video game use reported in the research. Increased aggression has long been associated with the degree of violence in the game (Gentile & Anderson, 2003; Gentile, Lynch, Linder & Walsh, 2004; Porter & Starcevic, 2007). Gentile et al. (2004) found children who play violent video games are more prone to increased aggression, confrontation with teachers, fights with peers, and decreased academic achievement. However, in a meta-analysis of the effects of violent video-game playing, Ferguson (2007) found no evidence to link playing violent video games with increases in aggression. Additionally, Ferguson et al. (2008) found that when family violence was controlled for, there was no correlational or causal effect of violent video games on aggression. The authors

concluded that aggressive personality types and exposure to family violence were greater predictors of violence than simply exposure to violent video games.

The largest concern associated with video game play seems to be the addictive properties associated with it. Chan and Rabinowitz (2006) found a positive correlation between the amounts of time spent playing video games daily and the number of ADHD symptoms present. Furthermore, Bioulac, Arfi, and Bouvard (2008) found increased addictive tendencies for video games in ADHD children compared to their non-ADHD peers. Results suggest children who play video games for extended periods of time may be prone to more complications and more ADHD symptomology than those who play them less frequently.

Several positive effects from video game play have also been noted. Okagaki and Frensch (1994) found positive effects associated with repeated play of the game Tetris™. Adolescents involved in the study enhanced their visual-spatial and visual reasoning skills through playing the game. They suggested game playing may actually influence performance IQ scores. Ferguson (2007) confirmed these findings and concluded that playing violent video games can actually increase visuo-spatial cognition. Other positive effects include increased problem-solving, increased motivation, and accelerated learning (eg., de Freitas & Levene, 2004; Garris, Ahlers & Driskell, 2002; Gee, 2003; Hays, 2005).

These benefits could level the playing field for children and adolescents with ADHD. Educators who use gaming technology can more easily accommodate many different types of learners. Games can adjust to the skills and needs of their players, allowing the same product or software to meet the needs of all students. However, before educators adopt the “one size fits all” policy for educational games, they need to understand the specific learning styles associated with the ADHD learner.

ADHD LEARNERS AND EDUCATIONAL GAMES

Mediating Factors that Challenge the ADHD Learner

Students with ADHD have difficulty because their core symptoms of inattention, impulsivity, and hyperactivity affect their ability to manage daily life. ADHD affects the person at three interacting levels: (a) body functions, (b) activities, and (c) participation in society. The impact of ADHD on these three interacting levels is also moderated by environmental and personal factors. A conceptual framework (Figure 1) adapted from the International Classification of Functioning, Disability, and Health (ICF) developed by the World Health Organization identifies how symptoms of ADHD can impede school, social, and home functioning (Ustun, 2007).

The ICF framework provides the basis for understanding the learning and behavioral needs of the students with ADHD.

Intervening Factors:

- **Personal factors** are features of life that are not a part of ADHD but can impact other levels of function. Some personal factors are not amenable to change such as gender, race, social background, familial factors, comorbidity, severity of symptoms, and predominant learning styles. Other personal factors such as knowledge of the disorder and medication use can be affected by intervention. While stimulant medications are effective in decreasing the primary symptoms of ADHD, few adolescents take them routinely (Marcus, Wan, Kemner, & Olfson, 2005). Since games are adaptable to the needs of the individual students, they can be implemented as educational interventions regardless of personal factors. An estimated 30% of students with ADHD have reading or math disabilities (Capano, Minden, Chen, Schachar, & Ickowicz, 2008; Faraone, Biederman, Monuteaux, & Seidman, 2001). Learning becomes more challenging for this large minority of students. Games can be presented in high text formats (where users

Figure 1. Conceptual framework for ADHD students adapted from the International Classification of Functioning, Disability, and Health Conceptual Model (Ustun, 2006)

must read a substantial amount to complete) and low text formats (where users navigate more through pictures and limited reading) thereby reducing the need for assistance by special educators with reading and comprehension of the material.

- **Environmental factors** consist of physical, social, and attitudinal factors in which people live and conduct their lives (Ustun, 2007). A major focus of ADHD management for young children is modification of the classroom environment in order to improve behavior and performance. Research indicates that during videogame play, hyperactivity and impulsivity decrease for students with ADHD while attention and learning increase (Farrace-Di Zinno et al., 2001). Providing opportunities for integrating videogame technology into the learning environment is a simple way to address the behavioral and academic needs of these students.

Outcome Factors:

- **Body functions** are defined as physiological and psychological functions, and they include the core symptoms of ADHD—inattention, hyperactivity, and impulsivity (American Psychological Association, 2000). Neuroimaging studies indicate differences in the size and activation of the prefrontal cortex during cognitive processing tasks in individuals with ADHD compared to those without ADHD (Epstein et al., 2007; Konrad, Neufang, Hanisch, Fink, & Herpertz-Dahlmann, 2006). Secondary impairments of ADHD, such as verbal and nonverbal working memory, emotional regulation, and behavioral reconstitution (Barkley, 1997), are also considered body functions according to ICF coding. Behavioral reconstitution is the ability to shape behavior or learn new behavior patterns based on cues provided by models in the environment, and it allows

individuals to learn vicariously. According to Barkley (1997), individuals with ADHD have difficulty with behavioral reconstitution. They frequently have to experience the consequences of their own behavior in order to shape new behavior patterns. Videogames can allow the player to become the character in the game; therefore, the player serves as his or her own model for behavior change. Bandura in his social learning theory (1971) emphasizes people can learn by observing a model. Seeing the self successfully perform a skill provides information about how to best perform that skill, strengthens self-efficacy, and reinforces learning.

- **Activities** are defined as the execution of tasks or actions. General activities of daily living are included in this category, such as learning and applying knowledge, general tasks and demands, communication, mobility, self-care, and interpersonal relationships. Symptoms of ADHD are known to cause inconsistency and persistent problems in adaptive functioning for general activities of daily living. Research indicates the symptoms of ADHD significantly impact academic performance and learning. Frazier, Youngstrom, Glutting, and Watkins (2007) conducted a meta-analysis that included 72 studies of academic achievement in children and adolescents with ADHD and found moderate to large discrepancies between achievement scores of those with and without ADHD. Adolescents with ADHD have persistent problems with adaptive communication skills (Clark, Prior, & Kinsella, 2002) as well as difficulties with interpersonal relationships and social situations (Barkley, 2006; Maedgen & Carlson, 2000). Computer technology and virtual reality can be used to create social situations and model interpersonal relationships in order to shape behavior and reinforce learning.

- **Participation** is defined as involvement in life situations, which include education, employment, and community activities. Typically, compared to their peers without ADHD, adolescents with ADHD experience more difficulty moving through and succeeding in educational programs, obtaining and retaining work, and even being involved in community, social, and civic life (Spencer, Biederman, & Mick, 2007). Games that simulate real-world situations could teach these students how to participate by providing them with immediate feedback about their actions without having to expose them to potentially harmful situations.

Students with ADHD need educational opportunities that are purposeful yet fun and engaging. The advancements in gaming technology, as they relate to the instructional environment, are promising. However, the quality, format, and purpose of technological mediums vary widely and it is important to evaluate and select the most appropriate medium for the desired learning outcomes.

EDUCATIONAL GAMES VS. EDUCATIONAL SIMULATIONS

Research differentiates between educational games and educational simulations. According to Price (1990), the purpose of an educational video game is to teach and provide practice. A simulation, on the other hand, has been described as something that mirrors real life and requires the player to act (Tessmer, Jonassen, & Caverly, 1989, p. 89). According to Gredler (1996), games are typically linear, requiring correct responses before advancing to the next level. Simulations are non-linear, allowing for flexibility in movement within the modules based on decisions made previously. Prensky (2001a) expanded on Gredler's interpretation of games and simulations by sug-

gesting games are viewed as fun, have specific goals, provide structure through rules, and include a competitive component that assumes the player will either win or lose. Using this interpretation, Prensky suggested that simulations can also be games if they are designed as such. He went as far as to say simulations "simulate" reality, which could be boring to the player. By adding game-like components to the simulation (components that are unrealistic), players may enjoy playing and at the same time be able to generalize the skill to an aspect of real life (Prensky, 2001a). Educators must be mindful of these differences when introducing an educational game or simulation into the lesson. A game may be fun with limited learning associated with it. A simulation may have the potential for learning, but it may not be fun. Prensky suggests the best situation may be to give the player real choices, but to "include enough humorous or even outrageous possibilities" to make it fun (Prensky, 2001a). The goal is to keep even the most inattentive and distractible players interested and motivated to continue.

VIDEOGAME PERFORMANCE OF CHILDREN WITH AND WITHOUT ADHD

Research has found mixed results regarding videogame performance of children with ADHD compared to their non-ADHD peers. Continuous Performance Tests (CPT) are typically used to evaluate speed of responding, sustained attention level, motor movements, and executive functioning in individuals with ADHD. These computer-based assessments require individuals to respond to a correct target sequence and refrain from responding to an incorrect target sequence or distractor. People with ADHD are more restless, inattentive, and talkative than their typically developing peers when completing CPTs (Barkley, Grodzinsky, & DuPaul, 1992). In addition, children find them aversive (Smith,

Barkley, & Shapiro, 2007). These assessments lack the criteria suggested by Prensky that would engage and motivate the individual during the task. Tannock (1997) conducted an assessment of motor movement in boys with ADHD using the Pacman™ videogame; a two-dimensional, repetitive, restricted player-interface game with a non-variable background, and also found a pattern of restlessness, inattention, and talkativeness compared to boys without ADHD. To paraphrase Prensky, these tasks are not fun and are not based on real-life experiences.

Farrace-Di Zinno et al. (2001) and Lawrence et al. (2002) designed their studies for children with ADHD around an interactive adventure videogame (Crash Bandicoot™, 1996), which requires response inhibition, motor control involving visiospatial skills, and eye-hand coordination skills. The videogame requires the player to negotiate hazards along a jungle path while viewing the journey from the character's perspective. The game depends on the player's ability to move quickly under some circumstances and to refrain from responding when certain hazards are presented. Rolling wheels, killer skunks, snapping plants, and the risk of falling off cliffs are some of the challenges the player faces during the adventure. The player must apply the rules in order to get from the beginning of the path to the end. These tasks mirror real-life skills, but include fun and unrealistic components. Unlike earlier studies involving CPT and Pacman™, the researchers found children with ADHD were more similar to children without ADHD during the interactive adventure videogame. They attributed the variability in results to the differences in the videogame presented to the children. The adventure videogame provided the player with immediate visual and auditory feedback and the responses were self-paced. Children could slow down or speed up the action depending on their individual needs. CPTs and games like Pacman™ are not so adaptable.

EVALUATING INSTRUCTIONAL GAMES AND SIMULATIONS

Instructional development has been the term most used to describe the activities of educators. With the increased need to integrate educational games into the instructional environment, educators are taking on more instructional design responsibilities. Design models help educators understand how to create and evaluate the quality of a game or simulation. Educators can use the design models to understand the needs of ADHD students as well as those of the game generation. One useful design is the FIDGE model (Akilli & Cagiltay, 2006).

FIDGE stands for "Fuzzified Instructional Design Development of Game-like Environments." Ironically, the word *fidge*, or in more current vernacular, *fidget*, means "to move restlessly" or "a condition of restlessness manifested by nervous movements" (American Heritage College Dictionary, 2000). The model was designed to address the eagerness and physical tension associated with the game player. The model is non-linear and includes consideration and evaluation of several components: (a) participants; (b) game-player experience; (c) socio-cultural environment; (d) dynamic elements of the game; (e) change; (f) management; (g) technology; and (h) use. An example of the application of the FIDGE model for educators would be the design of a computer game to teach a concept to elementary students using a simple PowerPoint application.

- **Participants** are the users of the game and the experts involved in the development and evaluation of it. The ADHD learner and peers who are members of the game generation are similar, but the added challenge of potential learning disabilities could create a unique set of challenges for educators in the presentation of curricula. One way educators can ensure the needs of the ADHD learner and other subpopulations of learners

Figure 2. The eight components of evaluation for computer games or simulations. (Akilli & Cagiltay, 2006) recommend educators evaluate the needs of their learners and the presentation of the game to ensure there is a match before introducing the game to the players

are included in the curricula is to develop focus groups. Educators may not understand the unique digital needs of the learners, but the learners know what appeals to them. By creating focus groups to help educators choose educational games or simulation material, educators may better understand the needs of the learners. In the example of creating a computer game for teaching the Bill of Rights, educators would first select a heterogeneous group of students from their classes to serve as the focus group. This group would discuss their needs in regards to the learning environment. Such discussions may include what the group identifies as interesting or boring. The responses may differ significantly for the ADHD learner group compared to the non-ADHD counterparts.

- **Game-player experience requires** the need to consider the differences in styles of

learning and skill levels of players. Providing multi-sensory experiences can support a diverse group of learners. de Freitas (2004) found that games and simulations can significantly support differentiated learning. When selecting game-like environments for learning, educators need to ensure the quality of the game or simulation is adaptable to all learning styles represented. The use of PowerPoint does not limit the multi-sensory experiences available. Sound, visual cues and touch if a Smart board or touch screen computer is used will add to the learning experience for these students.

- **Socio-cultural environment** involves an understanding of the environment in which the game will be played, the change in relevance from year to year, and the transfer of skills from one activity to another. Educators are creating games that are important to the

current student population, but they do not want to have to re-create these instructional tools from year to year. When developing your PowerPoint presentation, you may need to find links, sounds, or graphics that can transition from one group to the next. It's probably not a good idea to choose current trends as examples.

- **Dynamic elements of the game** include challenge, fantasy, and creativity. Research indicates a similar abnormal brain pattern in creative individuals (Herrmann, 1981; Torrance, 1984) and individuals with ADHD (Hynd, Hern, Voeller & Marshall, 1991). In fact, Shaw (1992) found ADHD children use a magnitude of imagery in problem-solving similar to creative individuals. By including dynamic elements in the games, educators can stimulate not only the attentional needs, but also the creativity needs of the ADHD learner. Integrating video clips, puzzles, or competition into the presentation can enhance the learners' interest in it.
